tcex09 - Calculating a Dew Point with POLY3 1297

tcex11 - Oxidation of Cu2S with an H2O/O2 Gas Mixture 1297

tcex12 - Tabulation of Thermodynamic Data for Reactions 1297

tcex22 - Calculating an Adiabatic Flame Temperature 1298

tcex23 - Calculating a Paraequilibrium and the T0 Temperature in a Low Alloyed Steel 1298

tcex28 - Pitting Resistance Equivalence (PRE) for a Duplex Stainless Steel 1298

tcex29 - Calculating the Speciation of a Gas 1299

tcex32 - Calculating Oxide Layers on Steel 1299

tcex41 - Calculating a Solubility Product 1300

tcex49 - Quasichemical Model Using GES1300

Ternary Phase Diagram Examples 1301

tcex03 - Calculating an Isothermal Section 1301

tcex05 - Calculating a Vertical Section in the Al-Cu-Si System 1301

tcex14 - Variations in Solidification of an Al-Mg-Si Alloy 1301

tcex17 - The Pseudo-binary System - CaO-SiO2 1302

tcex19a and tcex19b - Mapping of Univariant Equilibria with the Liquid in Al-Cu-Si 1302

tcex21 - Calculating a Ternary Isotherm in Fe-Cr-Ni 1303

tcex33 - An Fe-Cr-C Isopleth 1303

tcex37 - Calculating an Isothermal Section 1303

tcex42 - Paraequilibrium Calculation - Formation of Para-pearlite - Isopleth 1303

tcex43 - Paraequilibrium Calculation - Formation of Para-pearlite - Isothermal 1304

Multicomponent Phase Diagram Examples 1305

tcex06 - An Isopleth in Low Alloyed Fe-Mn-Si-Cr-Ni-C Steel 1305

tcex10 - Preventing Cr2O3 Clogging in a Continuous Casting Process 1305

tcex23 - Calculating a Paraequilibrium and the T0 Temperature in a Low Alloyed Steel 1306

tcex27 - Calculating Chemical Vapor Depositions (CVD) 1306

Thermodynamic and Related Quantities Examples 1307

tcex02 - Plotting Thermodynamic Functions 1307

tcex13 - Calculating the Binary Al-Ti Phase Diagram and its G Curve 1307

tcex14 - Variations in Solidification of an Al-Mg-Si Alloy 1307

tcex18 - A3 Temperature of a Steel 1308

tcex22 - Calculating an Adiabatic Flame Temperature 1308

tcex26 - The As-Ga Phase Diagram: Plotting the Partial Pressures of a Gas Species 1309

tcex34 - The Al-Zn Phase Diagram and its G Curve 1309

tcex39 - Calculating Reversible Carnot Cycles of a Heat Engine 1309

Single Equilibrium Calculation Examples 1311

tcex07 - Single Equilibria in Low Alloyed Fe-Mn-Si-Cr-Ni-C Steel 1311

tcex18 - A3 Temperature of a Steel 1311

tcex20 - Adiabatic Decompression in a Geological System 1312

Potential Diagram Example 1313

tcex35 - Calculating a Potential Diagram 1313

Scheil-Gulliver Examples 1314

tcex15 - Simulating the Solidification of a Cr-Ni Alloy 1314

tcex30a and 30b - Scheil Calculation for an Al-4Mg-2Si-2Cu Alloy 1314

tcex48 - Scheil Solidification with C Back Diffusion 1314

tcex54 - Scheil Solidification of an Al-2.1Cu-1Si Alloy including Back Diffusion 1315

tcex57 - Scheil Solidification with Solute Trapping 1315

Chemical Ordering Example 1316

tcex16 - Second Order Transition of the Al-Fe System 1316

Gibbs Energy System (GES) Examples 1317

tcex31 - Using GES to Calculate CVM 1317

tcex38 - Calculating the Morral “Rose” .. 1317

tcex39 - Calculating Reversible Carnot Cycles of a Heat Engine 1318

tcex49 - Quasichemical Model Using GES 1318

tcex52 - Changing the Excess Models for Interaction Parameters in a Solution Phase 1319

Introduction

The days of poring over handbooks in search of materials data that may be incomplete or non-existent are over. Thermo-Calc Software develops computational tools used to predict and understand materials properties, allowing you to generate computational materials data without costly, time-consuming experiments or estimations based on the limited data available.

Thermo-Calc can be used to fill the gaps in material property data and make predictions of material behavior throughout the materials life cycle. With Thermo-Calc, you can make better decisions about your products and improve your material processing conditions with accurate, reliable materials data.

Thermo-Calc Software

Thermo-Calc Software develops computational tools used to predict and understand materials properties, allowing you to generate computational materials data without costly, time-consuming experiments or estimations based on the limited data available.

Thermo-Calc can be used to fill the gaps in material property data and make predictions of material behavior throughout the materials life cycle. With Thermo-Calc, you can make better decisions about your products and improve your material processing conditions with accurate, reliable materials data.

The Thermo-Calc software (also referred to as the *Thermo-Calc program* or *the software* to distinguish it from the company name) is used to perform thermodynamic calculations. It can calculate complex homogeneous and heterogeneous phase equilibria, and then plot the results as property diagrams and phase diagrams.

The software fully supports stoichiometric and non-ideal solution models and databases. These models and databases can be used to make calculations on a large variety of materials such as steels, nickel, aluminum, magnesium, titanium and titanium aluminide-based alloys, high entropy alloys, copper, noble metal alloys, metal oxide solutions, zirconium, molybdenum, niobium, permanent magnetic materials, ultra-high temperature materials, molten salts, ceramics, solders, polymers, subcritical aqueous solutions, supercritical electrolyte solutions, non-ideal gases, and hydrothermal fluids or organic substances. The calculations take into account a wide range of temperature, pressure, and compositions conditions.

Add-on Modules

The Thermo-Calc program also includes Add-on Modules:

The Diffusion Module (DICTRA) is used to simulate diffusion controlled transformations in multicomponent systems.

The Precipitation Module (TC-PRISMA) is used to simulate diffusion controlled multi-particle precipitation process in multicomponent and multiphase alloy systems.

The Process Metallurgy Module is used to set up calculations for steel and slag used in steel making.

There are also specialized Property Models available with the Nickel Model Library, Noble Metal Alloys Model Library, Steel Model Library, and Titanium Model Library.

The Additive Manufacturing (AM) Module is used to better understand the laser powder bed fusion (LPBF) process by predicting the temperature distribution and melt pool geometry as a function of process parameters.

Databases

There are over 40 high quality kinetic, properties and thermodynamic databases for use in our software. Each database is developed for a specific materials system or application, and all databases are developed using the proven CALPHAD methodology.

The quality of the predictions in Thermo-Calc is strongly dependent on the quality of the databases because they provide the data for the calculations. This makes the databases as important, if not more so, than the software itself.

Thermo-Calc Software has long experience in the field of database generation using the proven CALPHAD methodology. We employ a highly qualified team of people working on database development internally and through international collaboration projects. With our kinetic, properties, and thermodynamics databases, you can rest assured that you are working with the most advanced CALPHAD databases available.

Learn More

There are several resources available on our website to help you learn how to use Thermo-Calc and other Add-on Modules. Go to the Getting Started Guides page and choose one of the guides that provides new users an introduction to setting up simple calculations in Graphical Mode. The information there is also in this help documentation.

Discover more or refresh your skills with an Advanced Lecture Series on Fundamentals of Thermodynamics, created by Professor John Ågren, one of the original developers of Thermo-Calc.

Go to our website to review the databases available. The online help contains all the content including technical information and examples.

About the Thermo-Calc Add-on Modules

Thermo-Calc Software offers several Add-on Modules that allow users to extend the functionality of the software in your area of specialization. All Add-on Modules are built into the Thermo-Calc platform, so there is no need for additional installation. This also creates a unified workflow and allows data to move seamlessly between the modules.

Additive Manufacturing (AM) Module

The Additive Manufacturing (AM) Module (also referred to as the AM Module) is an Add-on Module to Thermo-Calc and it is available in Graphical Mode as the AM Calculator. The aim of the Additive Manufacturing Module is to better understand the laser powder bed fusion (LPBF) process by predicting the temperature distribution and melt pool geometry as a function of process parameters and using material properties from the Thermo-Calc thermodynamic and properties databases. You can also simulate the powder bed fusion-electron beam (PBF-EB) process, commonly called Electron Beam Melting (EBM), using the electron beam heat source. Special focus is to have a unified treatment of alloy-dependent material properties and process parameters when solving the multiphysics problem of a moving heat source that melts and solidifies metal powder. The multiphysics simulation involves thermal conduction, fluid flow, evaporation-, radiation-, and convective-heat loss.

The Module can simulate the transition from conduction- to keyhole-mode. With experimental melt pool data you can calibrate the heat source. The calibrated heat source can be used to predict additional process conditions and/or to construct printability (aka process) maps. It can also predict composition changes caused by evaporation during additive manufacturing.

Furthermore, once you have the temperature distribution, for instance as a function of time and space, you can also use this information for other Thermo-Calc Add-on-Module simulations such as with the Diffusion Module (DICTRA) or the Precipitation Module (TC-PRISMA), or for input to other external finite element programs.

Diffusion Module (DICTRA)

The Diffusion Module (DICTRA) is an Add-on Module to Thermo-Calc. It is used for simulation of diffusion controlled transformations in multicomponent systems. The simulation calculations are both time- and space-dependent. The Diffusion Module (DICTRA) is available in both Graphical Mode (as the *Diffusion Calculator*) and Console Mode (as the *DICTRA module*).

The Diffusion Module (DICTRA), which is often just referred to as DICTRA, is ideally suited to solve diffusion simulations that include a moving boundary (*Stefan problems*). The multicomponent diffusion equations in the various regions of a material are solved under the assumption that thermodynamic equilibrium holds locally at all phase interfaces. Simulations are one-dimensional and three different geometries can be performed: planar, cylindrical, and spherical.

Examples of cases that have been simulated using the Diffusion Module (DICTRA) include:

- Microsegregation during solidification
- Homogenization of alloys
- Growth/dissolution of carbides, nitrides and intermetallic phases
- Coarsening of precipitate phases
- Interdiffusion in compounds, e.g. coating systems
- Austenite to ferrite transformations in steel
- Carburization, nitriding and carbonitriding of high-temperature alloys and steels
- Post weld heat treatment
- Sintering of cemented-carbides

Precipitation Module (TC-PRISMA)

The Precipitation Module, or TC-PRISMA, is an Add-on Module to Thermo-Calc and it is available in Graphical Mode as the *Precipitation Calculator*.

The Module treats concurrent nucleation, growth/dissolution and coarsening under arbitrary heat treatment conditions in multi-component and multi-phase systems using Langer-Schwartz theory and the Kampmann-Wagner numerical approach. It is a general computational tool for simulating kinetics of diffusion controlled multi-particle precipitation processes in multicomponent and multiphase alloy systems.

You can use the Precipitation Module for:

- Concurrent nucleation, growth/dissolution and coarsening of precipitates
- Normal grain growth and Zener pinning
- Temporal evolution of particle size distribution
- Average particle radius and number density
- Volume fraction and composition of precipitate

- Nucleation rate and coarsening rate
- Time-Temperature-Precipitation (TTP) diagrams
- Continuous-Cooling-Transformation (CCT) diagrams
- Estimation of multi-component interfacial energy
- Estimation of yield stress using the Yield Strength Property Model

Process Metallurgy Module

The Process Metallurgy Module is an Add-on Module to Thermo-Calc and it is available in Graphical Mode as the *Process Metallurgy Calculator*. The Add-on Module is designed to model reactions that occur in metallurgical processes. Although primarily used in steelmaking and steel refining processes—such as basic oxygen furnaces, electric arc furnaces, ladle furnace metallurgy, and so forth—applications are not limited to steelmaking.

There are two main branches of calculations possible: **Equilibrium** and **Process simulation**. Equilibrium calculations do not consider any kinetics, the process simulation includes reaction kinetics.

In general, for both types, the main difference compared to using a standard Equilibrium Calculator is that it is easy to handle the different materials present in a metallurgical process. The materials used in the process can be pre-defined, saved and used for the equilibrium calculations. Metallic materials can be defined in element weight percent, oxide materials in weight percent of oxide components, the gas phase in volume percent of gas components and its amount can be defined in normal cubic meters, and so forth. In principle this can be done in a standard Equilibrium Calculator. However, it is much easier when using the Process Metallurgy Calculator as this is designed for this specific purpose.

When using the **Equilibrium** branch of calculations, both isothermal and adiabatic calculations are possible. Adiabatic calculations assume no heat and mass exchange with the environment during the equilibrium reaction, meaning that the temperature changes as a result of exothermal or endothermal reactions taking place.

For a **Process simulation** branch of calculation, the reaction kinetics of the process are considered. This is done by dividing the system into zones. Typically one would have one steel zone containing liquid metal and a slag zone containing liquid oxide (slag). The kinetic model assumes that only a fraction of the steel zone reacts with a fraction of the slag zone per time step. This reacting fraction of the whole system is termed the reaction zone (in literature it has become known as Effective Equilibrium Reaction Zone or EERZ).

You can use the Process Metallurgy Module to calculate the following:

- The equilibrium between custom-defined steels, slags, and gasses.
- The equilibrium between other metallic and non-metallic phases.
- Desulfurization, dephosphorization, and decarburization.
- Any partition coefficient, for example the partitioning of sulfur between the liquid steel and slag phase.
- Slag characteristics, such as slag basicity or sulfur capacity.
- The fraction of liquid and solid in the slag.
- The temperature change in an adiabatic process.
- Kinetics of the reaction between phases. Typically this is the reaction between a liquid metal and slag phase, but it could also be the reaction between a solid oxide and slag (simulation of refractory wear) or between a solid metal and liquid metal (simulation of dissolution of alloy), etc.

Material Specific Property Model Libraries

There are specialized Property Models available for those working with specific materials such as steel, nickel, and titanium. The libraries, also sometimes referred to Add-on Modules, are available with the Property Model Calculator and the applicable database licenses.

- The *Nickel Model Library* includes the following models specially designed for those working with nickel alloys: Antiphase Boundary Energy, Coarsening, Equilibrium with Freeze-in Temperature, Solvus for Ordered Phase, and Strain-Age Cracking.
- The *Noble Metal Alloys Model Library* includes the Optical Properties Property Model.
- The *Steel Model Library* includes the following models for those working in the steel industry: Bainite, CCT Diagram, Critical Transformation Temperatures, Ferrite, Martensite Fractions, Martensite Temperatures, Martensitic Steel Strength, Pearlite, and TTT Diagram.
- The *Titanium Model Library* includes the following models specially designed for those working with titanium alloys: Alloy Strength and Martensite Temperatures.

Learn More

Go to the Add-On Modules page on our website for more information about license requirements. These requirements are also mentioned throughout the documentation as well as additional details about the Add-on Modules.

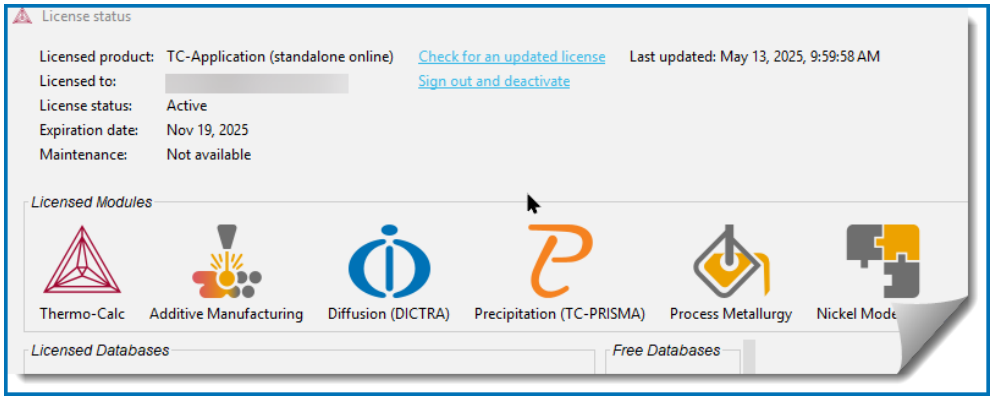
Displaying Thermo-Calc License Information

You can start (and install) the software without a valid Thermo-Calc license but you cannot do any calculations. To show information about the available and installed licenses, from the main menu select **Help → Show License Info**.

There are two **license activation types** available with Thermo-Calc 2026b: One using a *license file* that is installed on your computer (this also includes the different network installation types using Sentinel License Management Software), and the new type where *user credentials* (user name and password) are entered after installation and when you first open (launch) Thermo-Calc.

User Credentials Activations

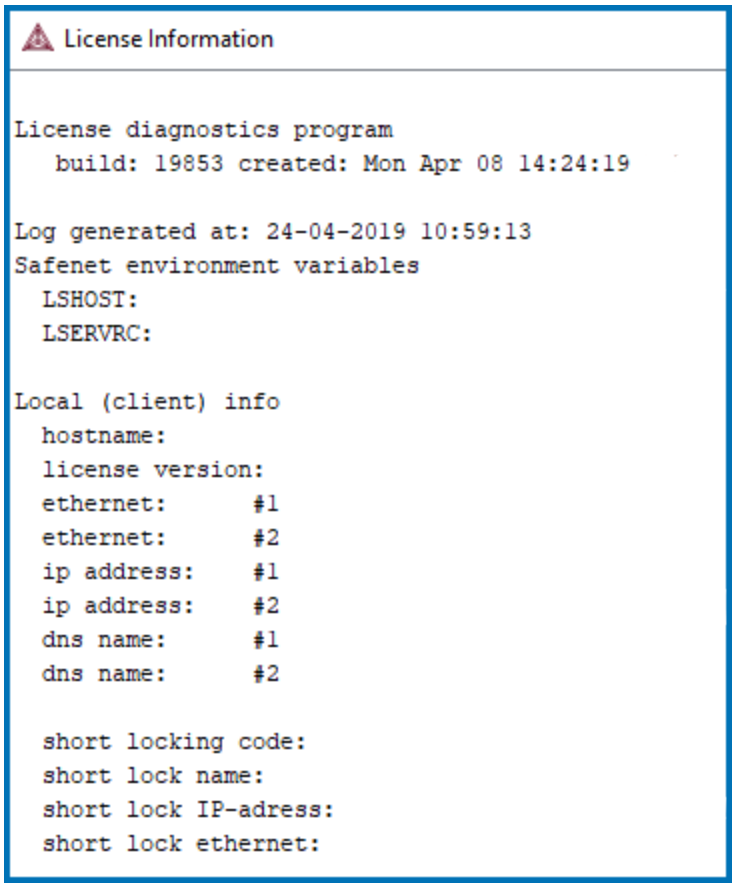
Below is an example of part of a **License Information** window for a Standalone installation using the **User credentials** activation type. The details are unique for each installation.



About User Credentials License Activations

License File Activations

Below is an example of part of a **License Information** window for a network installation using the **license file** activation type. It only shows the fields you would expect to see as the details are unique for each installation.



Getting License Information for License File Activations Using Thermo-Calc

Network Licenses

For a *network* license, under each license type with instances checked out, there is a list of who checked out each license.

In Graphical Mode, an instance is checked out when an Equilibrium Calculator activity is created, and checked back in when that Equilibrium Calculator is removed. For the Add-on Diffusion (DICTRA), Precipitation (TC-PRISMA), and/or Additive Manufacturing Modules this also applies to the Diffusion Calculator, Precipitation Calculator, AM Calculator, and Process Metallurgy Calculator, respectively.

In Console Mode, an instance is checked out when you enter the POLY module and is checked back in when you exit the POLY module.

- The **Features** column is a list of the specific software, databases and API licenses purchases.
- The **Version** is an internal version number for the feature.
- The **number of licenses** column is how many instances of each license type available to be checked out simultaneously.
- The **in use** column shows how many license instances are checked out.

Console Mode License Restrictions

- If you start Thermo-Calc without a valid Thermo-Calc license you cannot leave the SYS module.
- If all the licenses are checked out for a network client installation of Thermo-Calc, you may not be able to enter the POLY or DICTRA modules until a license is available.
- To enter the DICTRA and the DIC_PARROT modules, you need a valid Diffusion Module (DICTRA) license key.
- If you enter and use either the DIC_PARROT module or the PARROT module, then you cannot enter the other module in the same session. You must close down Thermo-Calc and launch the program again to enter the other data optimization module.

Network Computer License Restriction

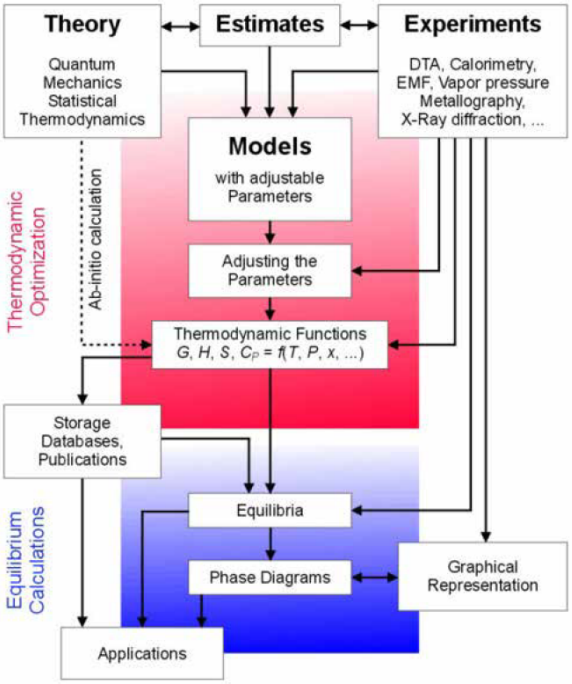
If you have a network computer installation of Thermo-Calc, then you may not be able to do any calculations even if you have access to a valid network license file. This is because others who are part of your network installation may have checked out all allowed instances of the software.

If you are running a network installation of Thermo-Calc, you can see how many instances of the client licenses are currently checked out and how many of them are left. You can also see which client computers have checked out the licenses.

The CALPHAD Method and the Thermo-Calc Databases

To make a calculation with Thermo-Calc, it is necessary to select a database from which the thermodynamic data are obtained. These databases are developed using the CALPHAD (CALculation of Phase Diagrams) approach, which describes both the thermodynamics and phase equilibria of a system as a function of chemistry and temperature in a self-consistent framework. This approach enables the prediction of properties of multicomponent systems based on data obtained from the critical assessment of binary and ternary subsystems. These assessments are combined to construct a multicomponent database.

CALPHAD is a phase-based approach, whereby the thermodynamic properties of each phase are described through the Gibbs free energy, G, which is a function of the chemical composition, temperature, and pressure of a material. The Gibbs free energy is evaluated through a critical assessment of all experimental and theoretical information available on phase equilibria and thermochemical properties in a system. Additionally, physical and chemical properties of the system such as crystallography, type of bonding, order-disorder transitions and magnetic properties are also considered.



Building a CALPHAD Database

More information specific to Thermo-Calc is contained in the *Database Manager User Guide*. Search the Thermo-Calc online help starting with the topic Thermodynamic and Kinetic/Mobility Databases.

The following is a basic overview about how the thermodynamic data contained within a CALPHAD database is collected and assessed. Within the CALPHAD methodology, for a given thermodynamic system with elements A and B, there exists a number of thermodynamically distinct regions or so-called phases. The materials science professionals who compile the information in these databases use their experience to assign a model for the Gibbs energy to each of these phases. The mathematical function used to model the Gibbs energy is a polynomial in composition and temperature. Depending on the structure of each phase, various terms appear in the polynomial function and these terms are related to thermochemical properties of the system, e.g., formation enthalpy, configurational entropy, heat capacity, etc.

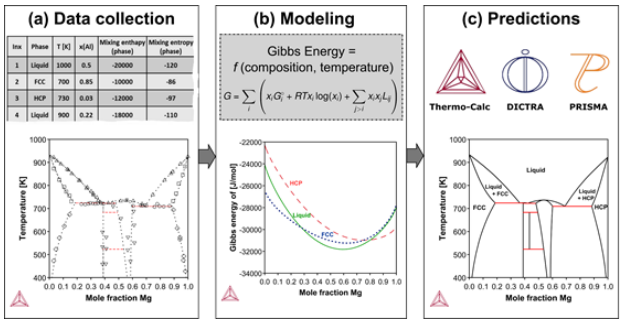
After assigning the models to these phases, the experts fit the free parameters of the model to the experimental data. At different stages of the assessment, this process requires extensive human judgment, often because the free parameters of all phases should be consistent with each other. In other words, the modeling task is a multi-objective optimization with constraints. Once the parameters for all phases are fitted to the experimental data, the optimized Gibbs energy models are collected in a text file (a so-called TDB file) with a format readable by the Thermo-Calc calculation engine. These are the database files included with any Thermo-Calc software installation.

The standard CALPHAD modeling steps are data collection, modeling, and prediction:

a. *Data collection*: The first step is to collect data for materials systems and phases. The data is primarily from experimental and high-fidelity simulation calculations.

b. *Modeling*: A materials scientist expert in the CALPHAD method then defines a hypothesis space for the mathematical expression of the model, a process in which they rely on experience and intuition. Using a trial-and-error approach, they then assess several of the hypothetical expressions by fitting its free parameters to the data until one is found that satisfactorily describes the target system.

c. *Predictions*: Finally, the models are loaded into the Thermo-Calc software to calculate thermodynamic properties of the systems of interest.



Accuracy and Validation

The accuracy of the calculations using Thermo-Calc depends on the quality and completeness of the database used. In the case of the solution databases, generally the more binary, ternary and high order systems that have been assessed, the more wide-ranging the composition space will be and the more accurate the predictions. This information, along with examples of validation of the databases, are available on our website. Every effort is made to validate the databases as broadly as possible. However, since the CALPHAD approach allows for predictions to be made for multicomponent systems of any composition, critical calculations should always be verified by experimental data.

Learn More

CALPHAD is originally an abbreviation for *CALculation of PHAse Diagrams*, but was later expanded to refer to *computer coupling of phase diagrams and thermochemistry*. More about the CALPHAD methodology, including some of its history, is available on the Thermo-Calc Software website.

Discover more or refresh your skills with an Advanced Lecture Series on Fundamentals of Thermodynamics, created by Professor John Ågren, one of the original developers of Thermo-Calc.

For more learning resources about CALPHAD and our databases, visit the video tutorials on our website or our YouTube playlist.

Also see an historical Thermo-Calc Software scientific bibliography on our website.

About the Database Examples

The *Validation and Calculation Examples Collection* that is available for many databases demonstrates both the *validity* of the database itself as well as demonstrates some of its *calculation* capabilities when combined with Thermo-Calc software and its Add-on Modules and features. For each database, the type and number of available examples varies. In some cases an example can belong to both a validation and calculation type.

Validation vs Calculation Examples

Validation examples include experimental data in the plot or diagram to show how close to the predicted data sets the Thermo-Calc calculations are. It is applicable to the most recent version of the software and relevant database(s) unless otherwise specified.

Calculation examples are generally intended to simply demonstrate a use case of the database. This might be showing a binary or ternary system calculated in a phase diagram, or demonstrate how the database and relevant software features would be applied to a heat treatment application, process metallurgy, soldering process, and so forth.

Where relevant, references related to each example set are included at the end of the individual topic. You can also find additional references specific to the database itself when using the database within Thermo-Calc.

Learn More

Database Technical Information and Examples: Included in the help is all the information about the databases. There are also separate *Technical Information* and *Validation and Calculation Examples Collection* PDFs for the **current version** of the database available for download from the Thermo-Calc website. There are many other resources and examples also available.

If you are interested in sharing your own examples using Thermo-Calc products in unique or surprising ways, or if you want to share your results from a peer reviewed paper, send an email to info@thermocalc.com.

Graphical Mode vs Console Mode

Thermo-Calc and the Diffusion Module (DICTRA) are available in both modes. All other products are available only in Graphical Mode. Learn more about these differences, especially if you find yourself working in both modes.

Graphical Mode *37*

Console Mode *37*

Graphical Mode vs Console Mode

There are two interfaces available in Thermo-Calc: *Graphical Mode* with a graphical user interface (GUI) and *Console Mode*, which uses a command line interface. Thermo-Calc and the Diffusion Module (DICTRA) are available in both modes, and all other Add-on Modules are only available in Graphical Mode.

If you are a new user, Graphical Mode is a good way to learn how to work with Thermo-Calc. Depending on what you want to simulate, in some advanced use cases Console Mode can have additional functionality but until you are comfortable with the concepts, it is recommended you start in Graphical Mode.

General Terminology

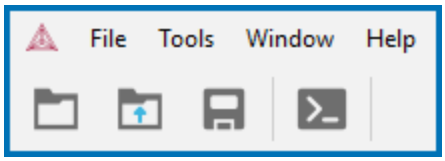
In Graphical Mode calculations are set up, carried out, and visualized as part of a *project*. The steps in the project are performed with *activities*. There are templates and Quick Start Assistants available to guide you through the process of defining the project. See Getting Started Links, Templates, and the Property Navigator.

In Console Mode you work with *modules*, which are managed using commands typed at a prompt. Some modules, called *response-driven modules*, ask you a series of questions that typically take you through the process of defining your system, setting calculation conditions, performing calculations and plotting the results.

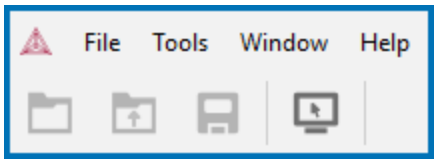
Switching Between Modes

The first time you open Thermo-Calc, it defaults to Graphical Mode. For any future instance it defaults to the last mode used.

Along the top of the GUI is the Graphical Mode Toolbar where you switch between modes.



In Console Mode, except for the **Switch to Graphical Mode** button, the toolbar is not used.



See Menu, Toolbar, and Keyboard Shortcuts for information about the **Tools**, **Window**, and **Help** menus, which are available in both modes.

File Extensions

The file extensions are different based on the mode you are in. In Console Mode the extensions are also based on whether you are working with Thermo-Calc or the Diffusion Module (DICTRA).

In Graphical Mode, the Thermo-Calc project files have the extension *.`tcu`. This includes the examples for the Add-on Modules.

In Console Mode, Thermo-Calc macro files have a *.`TCM` extension and the Diffusion Module (DICTRA) file extension is *.`DCM`. In addition to macro files in Console Mode the are also *Log* files and *Workspace* files, which also differ.

Modes Run Simultaneously

The two modes can be run simultaneously, but there is no communication between them. What you do in Graphical Mode does not affect the state of the Console Mode session and vice versa. One exception is the plot settings.

Global Settings: Graphical and Console Mode Plotting

Data Optimization and Thermodynamic / Kinetic Assessments

Although many calculations can be done in either mode, data optimization (i.e. PARROT) and thermodynamic or kinetic assessments (i.e. custom database development) are only available in Console Mode or using an SDK such as TC-Python.

Graphical Mode Activities vs Console Mode Modules

Although many calculations can be done in either Graphical Mode (GM) or Console Mode (CM), only data optimization and thermodynamic or kinetic assessments are available in Console Mode. Conversely, Calculators are only available in Graphical Mode as indicated in the table.

About the Activity Nodes (Graphical Mode) and Console Mode Modules

Graphical Mode (GM) versus Console Mode (CM)

GM Activity	*CM module (Short Name)*	*Primary Functions*
AM Calculator	–	Run additive manufacturing (AM) simulations using the Add-on Additive Manufacturing (AM) Module. In addition, probe data generated from an AM calculation can be used with the Diffusion Calculator and/or Precipitation Calculator. Additional licenses are required for full access to this Add-on Module and/or the extended use of the probe data.
Binary Calculator	BIN	Calculate binary phase diagrams. Access to specific databases designed for BIN, such as TCBIN, is required.
System Definer	DATA	Select appropriate databases, define chemical systems and retrieve the data required for calculations.
Diffusion Calculator	DICTRA	Run simulations of diffusion controlled transformations in Thermo-Calc using the Diffusion Module (DICTRA). An additional license is required for full access to this Add-on Module.
–	DIC_PARROT	This is to do data optimization for the Diffusion Module (DICTRA) and Precipitation Module (TC-PRISMA). It allows you to assess experimental data and use such data to optimize calculations. An additional license is required for full access to this Add-on Module.
–	ED_EXP	Part of the PARROT submodule, use it to edit experimental data points to make reliable optimizations.
This is the calculation engine	GIBBS or GES	Handles thermodynamic models and quantities. Generally you do not need to use this, but you can get information about models, and list, add or amend the thermodynamic parameters in use.

GM Activity	*CM module (Short Name)*	*Primary Functions*
–	PARROT	Used for data optimization to assess experimental data and use the data to optimize calculations.
Precipitation Calculator	–	Set the conditions for, and perform, a precipitation calculation using the Precipitation Module (TC-PRISMA). An additional license is required for full access to this Add-on Module.
Property Model Calculator	–	Predict and optimize material properties based on their chemical composition and temperature. There are preconfigured **General Models** available for all users and specialized material specific models such as **Nickel Models**, **Noble Metal Alloys Models**, **Steel Models**, and **Titanium Models** available with additional licenses.
Equilibrium Calculator	POLY	Equilibrium calculation command module. Specify conditions and make calculations.
Material to Material Calculator	–	To calculate materials transitioning from one into the other.
Plot Renderer	POST	This is a submodule to POLY and is for post-processing and plotting of calculation results. Modify property and phase diagrams, add labels, change the diagram colors and so forth.
Ternary Calculator	POTENTIAL	Calculate and plot gas potential diagrams in a ternary system. The potential of two gas species are used as the diagram axes.
Aqueous Calculator	POURBAIX	Calculate and plot pH-Eh diagrams (Pourbaix diagrams) and property diagrams for heterogeneous interaction systems involving aqueous solutions. For Console Mode, you can only calculate Pourbaix diagrams. Graphical Mode allows for all types of aqueous calculations. It is recommended for best results to use the Aqueous Calculation template in Graphical Mode.
Process Metallurgy Calculator	–	Use this to model with the Process Metallurgy Module and for reactions that occur in metallurgical processes. Although primarily used in steelmaking and steel refining processes (such as basic oxygen furnaces, electric arc furnaces, ladle furnace metallurgy and so forth), applications are not limited to steelmaking. An additional license is required for full access to this Add-on Module.

GM Activity	*CM module (Short Name)*	*Primary Functions*
–	REACTOR	Simulate chemical reaction processes in several feed-forward steady-state stages or in several dynamic stages.
Scheil Calculator	SCHEIL	Simulate and plot Scheil-Gulliver solidification processes with no diffusion in the solid phases and with/without consideration of back diffusion of interstitial components (such as C, N, O, S).
–	SYS	Interact with the operating system and change environmental settings. Create and execute macro files.
–	TAB	Tabulate properties of chemical reactions and substances (stoichiometric or solution phases).
Ternary Calculator	TERN	Calculate ternary phase diagrams.

Graphical Mode vs Console Mode: Calculation Types

When you are using Thermo-Calc and the Add-on Modules, you generally first set up a system, select the databases to use, and then define various parameters related to the simulation you want to conduct. Once this is set up you decide what *Calculation Type* to perform, choose a *Plot type* (or a table for single equilibrium, for example) to use and then eventually get a result.

How Thermo-Calc handles the calculation behind the scenes is the same whether you use Graphical Mode (GM) or Console Mode (CM). However, there are differences with the workflow and for historical reasons some calculation types are named differently based on whether you are in one mode or another.

Calculation Types in Graphical Mode and Graphical Mode vs Console Mode: Calculation Types

In addition, the plot types (diagrams) you choose to output the information are also different based on whether you are in GM or CM. These plot types are often based on the type of calculation being done, where in some cases you can only do it in one mode and not the other. For example, precipitation calculations are only available with the Precipitation Calculator, GM only, but you can do diffusion calculations in both modes.

Comparison of Calculation Types in Graphical Mode vs Console Mode

The table lists in alphabetical order most of the calculation types that you will want to perform. The first column is primarily based on the calculation types you can select when working in GM and when using the various calculators as indicated in the second column. The third column is the module or command in CM that you would use to perform the same, or similar, type of calculation.

Calculation Type	Graphical (GM)	Console (CM)	Definition
Activity curves	Binary Calculator	BINARY module	To calculate at a constant temperature over the whole composition range.
Aqueous solutions, Pourbaix diagram	Aqueous Calculator	Pourbaix Diagram module, POLY module	A Pourbaix diagram is a kind of phase diagram that shows the stability boundaries for a metal-aqueous interaction system. The phase boundaries are shown as a function of pH (acidity) and Eh (standard hydrogen electronic potential).
Batch	Property Model Calculator, AM Calculator	not available	With the Property Model Calculator, it allows for high throughput calculations and reads data from a file, such as a spreadsheet, rather than, for example, having a fixed grid or random values. Results from these batch calculations can then be compared to experimental values (as long as this data is included). For the AM Calculator it is available with the Additive Manufacturing (AM) Module and a Steady-state simulation. It is to include power and scan speed data, which is read from a file such as a spreadsheet. You can optionally include experimental melt pool width and depth (if there is data), and compare this to the calculated results.
Diffusion simulation	Diffusion Calculator	DICTRA monitor	Detailed simulation of diffusion controlled reactions in multicomponent systems.
Equilibrium calculations	Equilibrium Calculator	POLY3 module	An equilibrium defines the amount(s) and composition(s) of one or several phases that have the minimum Gibbs energy at a given temperature and pressure. A prerequisite for a successful equilibrium calculation is that the number of degrees of freedom according to Gibb's phase rule must be zero. This means that the right number of independent conditions must be set in order to successfully be able to calculate an equilibrium.
Equilibrium simulation[1]	Process Metallurgy Calculator	not available	Isothermal and adiabatic calculations are available. Equilibrium simulations do not consider any kinetics.

Calculation Type	Graphical (GM)	Console (CM)	Definition
Evaporation with Steady-state simulation[2]	AM Calculator	not available	Use this Additive Manufacturing (AM) Module simulation type to compute composition changes due to evaporation using a steady-state solution.
Gibbs energy curves	Binary Calculator	BINARY module	To calculate at a constant temperature over the whole composition range.
Grid	Property Model Calculator, Equilibrium Calculator, Process Metallurgy Calculator, AM Calculator	not available	With the Equilibrium Calculator, it computes the equilibrium of each grid point in a two-dimensional grid. With the Property Model Calculator and Process Metallurgy Calculator, it evaluates two axis variables of the selected quantities in the specified range and number of steps. For the AM Calculator it is available with the Additive Manufacturing (AM) Module and a Steady-state simulation. It evaluates two axis variables of power and scanning speeds in the specified range and number of steps.
Heat source calibration	AM Calculator	not available	This is available for the Additive Manufacturing (AM) Module for Steady-state simulations, and used to import parameters for a range of experimental melt pool data then store the calibrated heat source for further use.
Isothermal	See below for Isothermal and non-isothermal	POLY3, DICTRA monitor	Isothermal calculations in general can be done in all Console Mode modules, for example an Isothermal diffusion in DICTRA monitor and an isothermal calculation in POLY3 using the STEP command.
Isothermal and non-isothermal	Precipitation Calculator	See above for Isothermal	You can calculate nucleation, growth/dissolution and coarsening of particles size classes under these conditions: isothermic (precipitation simulation at constant temperature) or non-isothermic (precipitation simulation with user-defined temperature profile).

Calculation Type	Graphical (GM)	Console (CM)	Definition
Isothermal section	Ternary Calculator	TERNARY module	To calculate the ternary system for the whole composition range at a constant temperature.
Liquidus projection	Ternary Calculator	TERNARY module	The projection liquid surface and the monovariant lines are calculated over the given temperature range.
Min/Max	Property Model Calculator	not available	Evaluates the Property Model(s) for all variations of the selected quantities at the given limits.
Monovariant lines	Ternary Calculator	TERNARY module	To calculate the variation of the liquid compositions with temperature.
One Axis	Property Model Calculator, Equilibrium Calculator, Material to Material Calculator, Process Metallurgy Calculator, Aqueous Calculator	POLY3 module	To vary a quantity on the X-axis.
Paraequilibrium	not available	POLY3 module	A paraequilibrium is a partial equilibrium where one interstitial component, such as carbon (C) and nitrogen (N), in a multicomponent alloy can diffuse much faster than the other components (the substitutional elements, including the matrix element and alloying elements).

Calculation Type	*Graphical (GM)*	*Console (CM)*	*Definition*
Phase diagram	Equilibrium Calculator, Binary Calculator, Material to Material Calculator, Ternary Calculator, Aqueous Calculator	POLY3 module, *MAP* command, BINARY module, and TERNARY module The Material to Material Calculator is not available in Console Mode	A phase diagram is mapped within a specific space constructed by two (or more) independent mapping variables. These are mostly temperature and composition, but can be many other, such as temperature and pressure, activity of oxygen and activity of sulfur, and so forth.
Phase fractions	Binary Calculator	BINARY module	To calculate as a function of temperature at a constant composition.
Process simulation[1]	Process Metallurgy Calculator	not available	Compared to the Equilibrium simulation, it includes the reaction kinetics.
Property diagrams	One Axis: available with Equilibrium Calculator, Material to Material Calculator, Property Model Calculator	POLY3 module, *STEP* command	A property diagram is calculated by stepping one of the conditions that were defined for the equilibrium calculation and plotting some other property against this variable. For example stepping through temperature and plotting equilibrium composition of a certain phase, or stepping through composition and plotting equilibrium phase fractions, and so forth.

Calculation Type	Graphical (GM)	Console (CM)	Definition
Potential diagrams	not available	Potential Diagram module and POLY3 module	A potential diagram uses the activities of two major species in the gaseous mixture phase as mapping variables. For example, use this for a metal-oxide/sulphide-gas interaction system to calculate a diagram based on a specific temperature and pressure .
Scheil calculations	Scheil Calculator	Scheil module	Simulate a non-equilibrium transformation or partial-equilibrium transformation, also called a Scheil-Gulliver solidification.
Single equilibrium	Property Model Calculator (Equilibrium model), Equilibrium Calculator, Material to Material Calculator	POLY3 module	To calculate a single equilibrium. The results from this calculation are displayed as follows: • Graphical Mode: In the Visualizations window for a Table Renderer or in the Event Log window (for the Property Model Calculator) • Console Mode: With the LIST_EQUILIBRIUM command.
Single (no axes)	Property Model Calculator Process Metallurgy Calculator, Aqueous Calculator	POLY3 module	To calculate a single point. The results from this calculation are displayed as follows: • Graphical Mode: In the Visualizations window for a Table Renderer or in the Event Log window. • Console Mode: With the LIST_EQUILIBRIUM command.
Steady-state simulation[2]	AM Calculator	not available	Use this Additive Manufacturing (AM) Module simulation type to predict melt pool geometry and cooling rates around the melt pool.
Tabulation reaction	not available	TAB module	To tabulate thermodynamic functions of any type of substance, stoichiometric phase or solution phase, or reaction.

Calculation Type	Graphical (GM)	Console (CM)	Definition
T0 temperature simulations	This is available as the T-Zero Temperature Property Model using the Property Model Calculator	POLY3 module	The T0-temperature is the temperature at which two phases have the same Gibbs energy for a certain composition for a certain alloy composition.
Transient simulation[2]	AM Calculator	not available	Using the Additive Manufacturing (AM) Module, perform full-scale transient simulations in a 3D rectangular build part and have the possibility to specify a scanning strategy comprising multiple tracks and multiple layers.
Transient with heat source from Steady-state simulation[2]	AM Calculator	not available	Use this Additive Manufacturing (AM) Module simulation type to determine the effect of fluid flow due to Marangoni convection in the melt pool without solving for Navier-Stokes equations in the full-scale 3D domain.
TTT and CCT	Precipitation Calculator	not available	The TTT (Time-Temperature-Transformation) and CCT (Continuous Cooling Transformation) diagram can be simulated for one or more particles.
Uncertainty	Property Model Calculator, Process Metallurgy Calculator	not available	Evaluates the Property Model(s) where the values of the quantities are sampled from Gaussian distributions.

[1] Process Metallurgy Module simulation types are described in About the Process Metallurgy Module.

[2]AM simulation types are described in more detail in Additive Manufacturing Simulation Types.

About the File Types and Formats

The file formats (and the file extensions / suffixes) are based on whether you are working in Graphical or Console Mode, and in Console Mode, whether you are working with Thermo-Calc and/or the Diffusion Module (DICTRA).

Graphical Mode

In Graphical Mode you work with one file type, a *project* file, which has a `*.tcu` file extension. This is applicable to Thermo-Calc and all the Add-on Modules and Property Model Libraries.

Console Mode

In Thermo-Calc Console Mode there are file *types*—**macro** (including log files) and **workspace**—and *extensions* —`*.TCM`, `*.POLY3`, `*.GES5`, `*.PAR`, `*.POP`, and `*.EXP`.

A reminder that Linux and macOS are case sensitive; when applicable ensure you enter file extensions with capital letters.

Workspace files are not currently available with GES6.

Working with the Console Mode File Types

About the Technical Content

There are different options to access the information about the software and databases.

Installed Examples, Manuals, and Materials Folders

There are several ways to access installed folders that include examples, a PDF with all software documentation content, plus materials data.

Many resources are available from our website. On the Support → Documentation page you can download the current and archived PDF documentation and examples, or navigate to the TC-Python and TC-Toolbox for MATLAB® help and diagnostics tools. For current technical information and examples collections for the databases, you can access these by database starting on the Products → Databases page.

Installed Items Location Overview

Item	*Main Menu*	*My Project*	*System Definer or Material to Material Calculator*	*Windows Start Menu*	*On your Computer*
Manuals Folder (*Thermo-Calc Software Documentation Set* PDF)	x	-	-	x	x
Software Development Kits (SDKs) (TC-Python, TC-Toolbox for MATLAB®, TQ-Interface)[1]	-	-	-	-	x
Examples (project and macro files)[1]	x	x	-	x	x
Materials[2]	-	-	x	x	x

Item	*Main Menu*	*My Project*	*System Definer or Material to Material Calculator*	*Windows Start Menu*	*On your Computer*
Property Models[3]	-	-	-	-	x
Process Metallurgy Materials[4]	-	-	-	-	x

[1] The SDK folder is installed during installation and available when you have a license for the applicable SDK. There are also differences based on the API as to where examples are installed.

[2] The Material Properties libraries for the Additive Manufacturing (AM) Module are handled by the software.

[3] The Property Models folder is installed with the program based on OS. Go to **Tools > Options > Model directory** to confirm the file path.

[4] The Process Metallurgy Module user-defined material compositions are saved from the Process Metallurgy Calculator and managed from the **Options** tab.

From the Main Menu

Once your Thermo-Calc software is installed you can open the Examples and PDF documentation set (*Manuals Folder*) from the main menu:

- To open the Manuals folder select **Help → Manuals Folder**. Note for Linux openSUSE users: This link is not functional. To access the folder, navigate to the default location based on your installation type.
- To open the Examples based on whether you are in Console Mode or Graphical Mode, select **File → Examples Files** or **Help → Examples Files**.

The first time you open an Additive Manufacturing (AM) Module example after a new Windows installation of Thermo-Calc, it copies various files that can take some time to download. Then the example itself can take further time to open where it seems that the program is frozen. After the first instance, the other examples should not take as long to load.

My Project Configuration Window

When in Graphical Mode, click the **My Project** node. In the **Configuration** window under **Getting Started**, click **Example Files**.

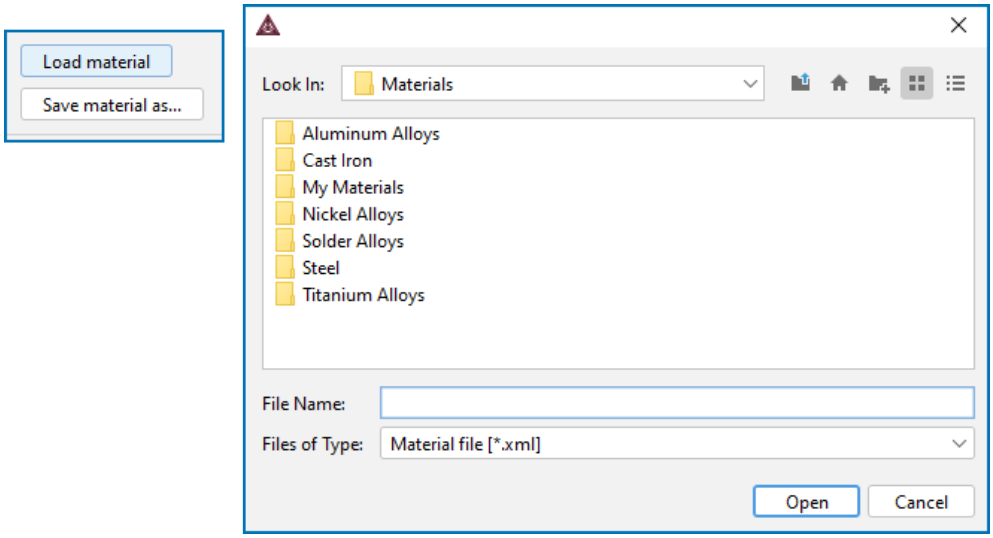
Installed Materials Folder

When you are working with the System Definer or Material to Material Calculator you can open the default **Materials** folder included with your installation.

At the bottom of the window under **Material**, click **Load material** to navigate to a material file.

There is a separate folder for materials saved using the Process Metallurgy Calculator. See Installation Default Directory: Process Metallurgy Materials.

For the Additive Manufacturing (AM) Module, the Material Properties library is managed by the software.



The default directory where these material files are stored is based on operating system:

<table>
<tr><th>Operating System</th><th>Materials Installation Directory</th></tr>
<tr><td>Windows</td><td>The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements.

<i>Single user (Local, Non-Admin Installation)</i>

<code>C:\Users\<<i>username</i>>\AppData\Local\Programs\Thermo-Calc\2026b\Materials</code>

 The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click View > Show > Hidden Items. For more control, you can also make changes to more than one folder via the Folder Options > View > Advanced Settings window then select Show hidden files, folders, and drives. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.

<i>All Users (Admin)</i>

<code>C:\Users\<username>\Documents\Thermo-Calc\2026b\Materials</code></td></tr>
<tr><td>Linux</td><td>On Linux all user files are installed where the program is installed. If installed as root the default is:

<code>/opt/Thermo-Calc/2026b/Materials</code></td></tr>
<tr><td>macOS</td><td><code>/Users/Shared/Thermo-Calc/2026b/Materials</code></td></tr>
</table>

Start Menu (Windows Only)

On Windows, once Thermo-Calc is installed, you can locate the Examples and Materials folders, plus all the Manuals. Go to the Start menu and in the search field enter **Thermo-Calc**. A list of the installed versions is provided or click the **Apps** or other tabs to browse search results.

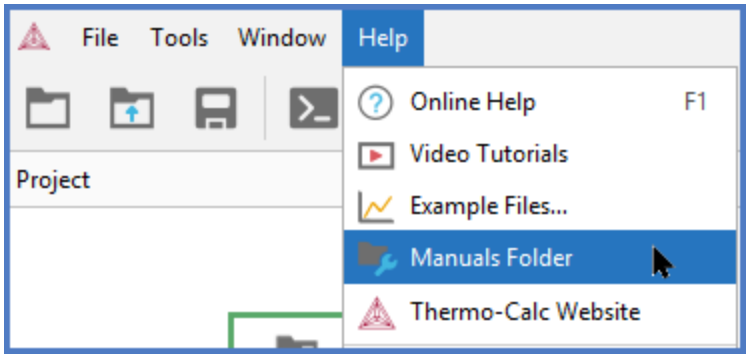
On Your Computer (All Operating Systems)

The PDF, example files, and materials xml files are included with your installation in a folder location based on the operating system. See these topics in the installation guide for details:

- Installation Default Directory: Windows
- Installation Default Directory: macOS
- Installation Default Directory: Linux

About the Manuals Folder

Once Thermo-Calc is installed, the *Thermo-Calc Software Documentation Set* PDF is available and found via the **Help** → **Manuals Folder** location.



Learn More

The *Thermo-Calc Software Documentation Set* PDF is a complement to the Thermo-Calc help (installed and web versions). It is recommended you search the help (press F1), especially if you are looking for specific database-related content.

Database Technical Information and Examples: Included in the help is all the information about the databases. There are also separate *Technical Information* and *Validation and Calculation Examples Collection* PDFs for the **current version** of the database available for download from the Thermo-Calc website. There are many other resources and examples also available.

What is in the Thermo-Calc Software Documentation Set PDF?

The summary of the sections below generally pertain to the help structure, with a few exceptions due to the different format and how one works with a PDF vs HTML.

The *Thermo-Calc Software Documentation Set* PDF (also referred to as the *Documentation Set*) has almost all of the same content as the help (installed and web versions). The PDF, with over 3500 pages, contains all the software content for the standard (base) Thermo-Calc software

plus for the Add-on Modules that require additional licenses, e.g. Additive Manufacturing (AM), Diffusion (DICTRA), Precipitation (TC-PRISMA), Process Metallurgy, and the specialized Property Model Libraries (Steel, Nickel, etc.). It also includes the full TQ-Interface SDK Programmer's Guide, and much more.

In general, you can get started with an overview in the **Introduction** that outlines some of the differences between Console Mode and Graphical Mode. Then the content is grouped by mode (Graphical vs Console) and by Add-on Module and Specialized Material Property Libraries. There is full information about the TQ-Interface but limited information for TC-Python and TC-Toolbox for MATLAB®. It also has a **General Reference** section and full **Installation** instructions.

Thermo-Calc Graphical Mode

Review some **Key Concepts and Features** then learn about the Thermo-Calc base license features in **Calculations in Graphical Mode** and **Visualizations in Graphical Mode**. There are descriptions for all the installed base examples listed in **Thermo-Calc Graphical Mode Examples**.

Other Graphical Mode examples and Calculator details are grouped by Add-on products.

For example, you will find details about Calculators and examples available with the specific add-on or advanced products such as the Additive Manufacturing (AM) Module (AM Calculator), Diffusion Module (DICTRA) (Diffusion Calculator), Precipitation Module (TC-PRISMA) (Precipitation Calculator), Process Metallurgy Module (Process Metallurgy Calculator), and all the Add-on Material Specific Property Model Libraries (i.e. Steel, Nickel, etc.), which use the Property Model Calculator and require additional databases.

All of the Graphical Mode examples are summarized in the *Graphical Mode Examples Guide*. The information is spread out in this PDF but it is available as a standalone guide on our website (direct link to the current version).

Thermo-Calc Console Mode

There are details about the functionality and features available with the Console Mode version of Thermo-Calc as well as brief descriptions for all the installed Console Mode examples. There is also Console Mode only advanced content available for the following:

- The PARROT module optimization content is described in the *Data Optimization User Guide*.
- If you develop your own custom databases, this is described in the *Database Manager User Guide*. There is some other related documentation found under **General Reference**.
- If you use the old DATAPLOT functionality for plotting, this is included in the *DATAPLOT User Guide*.

Due to PDF size and because this is classic Console Mode, the *Thermo-Calc Console Mode Example Macros* PDF is only available on the website (direct link to the current version) and not included in the *Documentation Set* PDF or in the help. The macro example files themselves continue to be included in the installation.

General Reference

This is content that spans some of the general topics applicable to multiple applications within Thermo-Calc, i.e. it might be for both Console Mode and Graphical Mode, or needed for a specific database calculation in Thermo-Calc (i.e. model information, variables, and functions for thermophysical and elastic properties).

- **Global Settings**: In the **Options** window you can globally set general settings for Graphical Mode as well as default settings for any new activities for both Graphical Mode and Console Mode.
- **Parameters, Functions, and Variables**: Information applicable to both Console Mode and Graphical Mode with respect to understanding the format these are to be written in for Thermo-Calc to use the parameter, function, or variable. However, many of the sections are specific to Console Mode where the explicit use of these terms is more often used.
- **Thermophysical Properties Data**: This includes the model descriptions and data parameters you would need in combination with a database that has the relevant thermophysical property.
- **Elastic Properties Variables**: This includes the model descriptions and data parameters you would need in combination with a database that has the relevant elastic properties.

- **Database Files and Database Checker**: Information about the database initialization file, differences between Thermo-Calc encrypted and user-defined unencrypted databases, about cached database files, and more. Some content is more specific to those developing their own databases, other information is intended for advanced users, for example, the Database Checker information is a supplement to the *Database Manager User Guide*.

Installation

All installation instructions are included. Individual PDF guides and are found in other locations (i.e. the Download Center and website). The information has all installation instructions for all platforms (Windows, macOS, and Linux) and license types as well as instructions for the SDKs TC-Python and TC-Toolbox for MATLAB®.

The stand-alone *Quick Install Guides* (Windows and macOS) plus the full installation guide are available in PDF format on the **Documentation** page of our website.

Specialized Material Property Model Libraries

For each of the following libraries, the content includes details about each Property Model, the configuration settings, plus information about the installed Graphical Mode examples. The Property Model Calculator is used for all of these and this is described in the general Thermo-Calc content.

- Nickel Model Library
- Noble Metal Alloys Model Library
- Steel Model Library
- Titanium Model Library

Add-on Modules

Thermo-Calc Software offers several Add-on Modules that allow users to extend the functionality of the software in your area of specialization. All Add-on Modules are built into the Thermo-Calc platform, so there is no need for additional installation. This also creates a

unified workflow and allows data to move seamlessly between the modules.

Additive Manufacturing (AM) Module

The Additive Manufacturing (AM) Module is an Add-on Module in Thermo-Calc that is primarily designed for modeling the powder bed fusion process in additive manufacturing.

Special focus has been to have a unified treatment of alloy dependent material properties and process parameters when solving the multiphysics problem of a moving heat source that melts and solidifies metal powder. The multiphysics simulation involves thermal conduction, fluid flow, evaporation-, radiation- and convective- heat loss. The Module is available in Graphical Mode.

The content provides a theory overview and details about the AM Calculator, plus details about the installed Graphical Mode examples.

This product is unique and a highly specialized product. It is interconnected to Thermo-Calc features such as the Scheil Calculator, Diffusion Calculator, and Precipitation Calculator, information that is linked throughout the PDF.

There is a standalone user guide available with this information via the website for this product (direct link to the current version).

Diffusion Module (DICTRA)

The Diffusion Module (DICTRA) is an Add-on Module to Thermo-Calc that makes modeling multicomponent diffusion-controlled transformations simple and accessible. It is based on the numerical solution of the multicomponent diffusion equations and the CALPHAD approach. This Add-on Module is available in both Graphical Mode and Console Mode.

The *Graphical Mode* content provides some specific theory, the *Quick Start Guide*, and details about the Diffusion Calculator plus information about the Graphical Mode examples.

The classic *Console Mode* content has the *Quick Start Guide*, plus more details related to the unique commands found in the *Command Reference*. This is a supplement to the main Thermo-Calc Console Mode content.

Graphical Mode and Console Mode both continue to have standalone quick start guides. These are included in this PDF but can also be found on the Documentation page of our website.

Due to PDF size and because it is classic Console Mode, the *Diffusion Module (DICTRA) Console Mode Example Macros* PDF is only available on the website (direct link to the current version) and not included in this PDF or in the help. The macro example files themselves continue to be included in the installation.

Precipitation Module (TC-PRISMA)

The Precipitation Module (TC-PRISMA) is an Add-on Module that treats concurrent nucleation, growth/dissolution, and coarsening under arbitrary heat treatment conditions in multicomponent and multiphase systems using Langer-Schwartz theory and the Kampmann-Wagner numerical approach. The Module extends the functionality available in Thermo-Calc by allowing you to make calculations related to the precipitation of your materials. It is available in Graphical Mode.

The content provides a theory overview and details about the Precipitation Calculator, plus details about the installed Graphical Mode examples.

Process Metallurgy Module

The Process Metallurgy Module is an Add-on Module within Thermo-Calc that makes it easy to set up calculations for steel and slag. The Module also includes a kinetic model that allows the simulation of the evolution of the steel and slag composition and also the inclusion amount and composition as a function of time based on the actual steelmaking process, including alloy or slag additions, blowing of gases into the steel, heating by electric arc, and so on.

The Module is primarily designed for application to steelmaking and steel refining processes including converters, such as basic oxygen furnaces, electric arc furnaces, ladle furnace metallurgy, and more. The Module can also be applied to other metallurgical processes. It is available in Graphical Mode.

The content provides details about the product, the workflow and the Process Metallurgy Calculator, plus details about the installed Graphical Mode examples.

Software Development Kits (SDKs)

The Software Development Kits (SDKs) are available for users who wish to use the power and flexibility of Thermo-Calc in their own application programs. SDKs are add-on features that allow users to call Thermo-Calc functions and access the thermodynamic and mobility databases directly from within your own software codes or other software programs.

Each SDK incorporates an application programming interface (API), an embedded and web help system, a PDF programmer's guide, and a collection of examples to help users get started.

Only the full content for the **TQ-Interface** is included in the *Documentation Set* and Help. General information and basic example information for the other SDKs is described in Introduction to TC-Python API and About TC-Toolbox for MATLAB®.

For the following SDKs, the help is available in HTML and PDF formats. Full access is available via our website. For **TC-Python** go to the TC-Python Help page. For **TC-Toolbox for MATLAB®** go to the TC-Toolbox for MATLAB Help page.

About the Examples

To learn more about how to use the software you can open and run the example *project* (Graphical Mode) and *macro* (Console Mode) files.

Graphical Mode Examples

Graphical Mode examples are available for all products. The *project* files are in the format of *.tcu.

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Console Mode Examples

Console Mode examples are available for Thermo-Calc and the Diffusion Module (DICTRA). The *macro* files are in the format of *.TCM and *.DCM, respectively.

There are other file types when you are working in Console Mode. See Working with the Console Mode File Types or About the DICTRA File Formats.

Examples by Product

This topic includes links to the available product examples based on availability in Graphical or Console Mode.

Thermo-Calc Examples

A description of the Thermo-Calc examples, and how to access them, is based on whether you are using Graphical Mode or Console Mode.

- Thermo-Calc Examples Collection
- Console Mode Examples

Aqueous Solutions and Pourbaix Diagrams

A description of these examples, which are available for both Graphical Mode and Console Mode, is included in the Thermo-Calc documentation. However, it is recommended that the Graphical Mode version is used. See Aqueous and Pourbaix Diagram Examples Summary for details.

Additive Manufacturing (AM) Module Examples

A description of examples using the AM Calculator, which is only available in Graphical Mode, is included in the Thermo-Calc documentation. See Additive Manufacturing (AM) Module Examples Collection.

Diffusion Module (DICTRA) Examples

A description of Diffusion Module (DICTRA) examples, which are available for both Graphical Mode and Console Mode, is included in the Thermo-Calc documentation.

- For Graphical Mode, see Diffusion Module (DICTRA) Graphical Mode Examples Collection
- For Console Mode see Opening the Setup, Run, and Plot Macro Files where there are links to descriptions of all the examples.

Precipitation Module (TC-PRISMA)

A description of examples using the Precipitation Calculator, which is only available in Graphical Mode, is included in both the Thermo-Calc and Precipitation Module (TC-PRISMA) documentation. See Precipitation Module (TC-PRISMA) Examples Collection.

Process Metallurgy Module Examples

A description of examples using the Process Metallurgy Calculator, which is only available in Graphical Mode, is included in the Thermo-Calc documentation. See Process Metallurgy Module Examples Collection.

Property Models including Material Specific Model Library Examples

A description of examples using the Property Model Calculator, which is only available in Graphical Mode, is included in the Thermo-Calc documentation.

- Thermo-Calc General Property Models Examples Collection
- Nickel Model Library Examples Collection
- Noble Metal Alloys Model Library Examples Collection
- Steel Model Library Examples Collection
- Titanium Model Library Examples Collection

TC-Python Examples

There are examples for TC-Python available after installing the SDK. A brief description of the TC-Python SDK examples, and how to access these, is in About the TC-Python Installed Examples.

TQ-Interface Examples

There are examples for the TQ-Interface available as described in Installed Examples, Manuals, and Materials Folders. See Installing the TQ-Interface and Examples for brief descriptions.

TC-Toolbox for MATLAB® Examples

There are included examples with all TC-Toolbox installations. These are generally the same as the examples included with TC-Python although with a different suffix (`matex`) and prefix (*`.m` or *`.mlx`) in the file name. Not all examples included with TC-Python are available for this SDK.

See Installation Default Directory: TC-Toolbox Examples and Diagnostic Script to learn where these are located. Also see About TC-Toolbox for MATLAB®.

Database Examples

Database Technical Information and Examples: Included in the help is all the information about the databases. There are also separate *Technical Information* and *Validation and Calculation Examples Collection* PDFs for the **current version** of the database available for download from the Thermo-Calc website. There are many other resources and examples also available.

Graphical Mode Examples Listed by Product

This topic includes links to the descriptions for the installed examples available in the software for each product.

About the Examples

Category	*Example Number*
The Thermo-Calc collection includes binary and ternary system examples, Scheil, the Equilibrium Calculator, Material to Material Calculator, plus more. Thermo-Calc Examples Collection	T_01 to T_22
General Property Models Library	General Models: PM_G_ 01 to PM_G_20
Additive Manufacturing (AM) Module Examples Collection	AM_01 to AM_16
Diffusion Module (DICTRA) Graphical Mode Examples Collection	D_01, D_02, D_03 (the Quick Start Guide Examples) D_04 to D_10
Nickel Model Library Examples Collection	Nickel Property Models: PM_NI_01 to PM_Ni_04
Noble Metal Alloys Model Library Examples Collection	Noble Metals Property Models: PM_Noble_01
Precipitation Module (TC-PRISMA) Examples Collection	P_01 to P_18
Process Metallurgy Module Examples Collection	PMET_01 to PMET_08
Steel Model Library Examples Collection	Steel Property Models: PM_Fe_01 to PM_Fe_12
Titanium Model Library Examples Collection	Titanium Property Models: PM_Ti_01 to PM_Ti_03

Console Mode Examples

There are many examples to examine and to help you learn Thermo-Calc in Console Mode (CM). Some of the examples in the table below are included with specific sections, whereas some of the general examples are included (repeated) in more than one section.

Opening Console Mode Macro Files

Thermo-Calc and DICTRA Console Mode Example Macros PDF

All the Thermo-Calc Console Mode macro files and the outputs are also combined into one file that you can search and read. This is available as a PDF on our website. For the current version of the PDF, navigate to *Current Documentation > Examples > Thermo-Calc Console Mode*. A direct link to the PDF is here. The PDF is also found in the Archive and saved by release version.

All the DICTRA Console Mode macro files and the outputs are also combined into one file that you can search and read. This is available as a PDF on our website. For the current version of the PDF, navigate to *Current Documentation > Examples > Diffusion Module (DICTRA) Console Mode*. A direct link to the PDF is here. The PDF is also found in the Archive and saved by release version.

Thermo-Calc CM Examples

Each topic has a brief description of the example and includes some or all of the commands used in the macros.

As of Thermo-Calc 2026a, the Aqueous Calculator is available in Graphical Mode. Both the Calculator and the Aqueous Calculation template allows for efficient setup of advanced aqueous calculations compared to the Console Mode POURBAIX module. Two Graphical Mode examples, T_21: Pourbaix Diagrams of Fe with the Aqueous Calculator and T_22: Aqueous pH of Solutions, are included with your installation and it is recommended to use Graphical Mode for aqueous calculations.

Topic	*TCEX Examples Included*
Binary Phase Diagram Examples	1, 4, 13, 16, 17, 26, 31, 34, 50
Property Diagram Examples	2, 8, 9, 11, 12, 22, 23, 28, 29, 32, 41, 49, 50
Ternary Phase Diagram Examples	3, 5, 14, 17, 19A, 19B, 21, 33, 37, 42, 43
Multicomponent Phase Diagram Examples	6, 10, 23, 27
Thermodynamic and Related Quantities Examples	2, 13, 14, 18, 22, 26, 34, 39, 51
Single Equilibrium Calculation Examples	7, 18, 20
Potential Diagram Example	35
Scheil-Gulliver Examples	15, 30A, 30B, 48, 54, 57
Chemical Ordering Example	16
Gibbs Energy System (GES) Examples	31, 38, 39, 49, 52
T0 Temperature Example	23
Paraequilibrium Examples	23, 42, 43
Functions and Variables Examples	44
PARROT and EDIT_EXPERIMENT Examples	36A (consists of various parts).
Pourbaix Diagram Examples	40, 40A, B, C, and E, 53 Aqueous and Pourbaix Diagram Examples Summary
Tabulate Reaction (TAB) Example	12
REACTOR Module Example	24
Thermophysical Properties Examples	55 - Viscosity 56 - Surface Tension 58 and 59 - Molar Volume

Topic	*TCEX Examples Included*
	60 - Electrical Resistivity and Thermal Conductivity
Application Examples	9 - Dew Point 10 - Continuous casting, preventing Cr_2O_3 clogging 11 - Gas oxidation of Cu_2S 20 - Adiabatic decompression in Geological system 24 - Silicon arc furnace 27 - Chemical Vapour Deposition 28 - Materials design of a stainless steel 29 - Gas speciation 41 - Solubility product 44 - Proof strength calculated from empirical functions

Opening Console Mode Macro Files

The macro files (with the extension *.TCM) include comments, which you can either run in Thermo-Calc or open and read in a text editor.

Options To Open Macro Files

You can open the macro files (*.TCM or *.DCM files) in different ways.

- From the main menu,
- Using a command,
- By dragging and dropping the file into the Console window, or
- Navigate to the file location on your computer and double-click to open it. If you already have Thermo-Calc open, the macro opens in a new tab. Otherwise a new instance of Thermo-Calc is launched.

  If you are using the advanced pipe or redirect option (Technical Note: Pipe or Redirect Output Data from Console Mode) then a new instance of Thermo-Calc is always started.

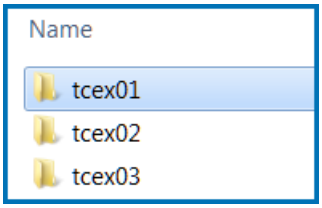
- You can also read the commands listed in the macro file using a text editor.

If you only open and read the macro file in a text editor, you do not see the output that Thermo-Calc gives in response to the commands stored in the macro file.

Opening a Macro from the Main Menu

To open a Thermo-Calc example macro file:

1. Open Thermo-Calc.
2. Confirm you are in Console Mode. If not, click the **Switch to Console Mode** button.
3. From the main menu, select **File →** or **Help → Examples Files**. The Console Mode folder opens.
4. Open the **Thermo-Calc** folder to see the available examples contained in separate folders.



For the Diffusion Module (DICTRA) examples (*.DCM macro files), open the **Diffusion Module - DICTRA** folder.

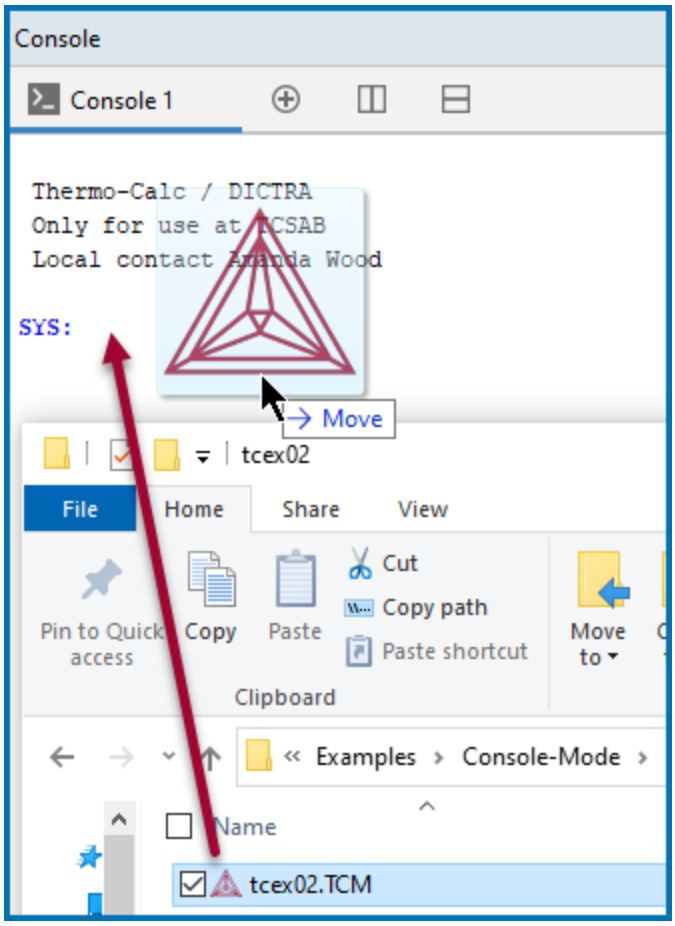
5. In the folder, double-click the *.TCM file or click **Open**.
6. Follow the prompts in the Console window i.e. keep pressing <Enter> to run the macro and produce a plot in the **Console Results** window.

Opening a Macro Using a Command

At the SYS prompt, type MACRO_FILE_OPEN and press <Enter>. In the file dialogue window that opens, navigate to and select the macro file to open.

Dragging and Dropping a Macro File into the Console Window

For example, on your computer, navigate to the examples folder. Drag the file from its location into the Thermo-Calc Console window. When you release (drop) the file, the macro starts running. Follow the prompts in the Console window i.e. keep pressing <Enter> to run the macro and produce a plot in the **Console Results** window.



```

   ... the command in full is GOTO_MODULE
 THERMODYNAMIC DATABASE module
```

Drag and drop files into the Console window to open or run a macro, for example. File types that can be opened this way are macro files (*.TCM and *.DCM), database files (*.TDB), and workspace files (*.POLY3, *.GES5,*.PAR, and *.DIC). Note that *.DCM and *.DIC file extensions are applicable to the Diffusion Module (DICTRA).

Help Resources: Installed and Web Versions

The technical content is available in HTML format as an Online Help system that you can access from two locations. Both versions are viewed in your browser.

Local vs Web Help

Go to these locations to access the same content:

- **Locally Installed Help**: When in Thermo-Calc, press F1 to open the current version of the help in a local browser. You can also click **Online Help** from the **My Project** page to open the file. Then search or navigate to the applicable folder to browse the contents. This does not not require an Internet connection.
- **Web Help**: Go to the Documentation page to link to the most recent version of the web help. Then search or navigate to a relevant folder to browse the contents.

Between releases there may be minor updates to the web version compared to the installed version. All updates made to the web version are included in the next installed release version.

There are several resources available on our website to help you learn how to use Thermo-Calc and other Add-on Modules. Go to the Getting Started Guides page and choose one of the guides that provides new users an introduction to setting up simple calculations in Graphical Mode. The information there is also in this help documentation.

Discover more or refresh your skills with an Advanced Lecture Series on Fundamentals of Thermodynamics, created by Professor John Ågren, one of the original developers of Thermo-Calc.

Opening the Web Version of the Help

A web version **specific to only the most recent release version** is available at the following link (copy this):

https://help.thermocalc.com/2026b/content/intro/help-home.htm

Opening the Installed Help: No Internet Needed

There are several ways to access online help in a browser. The content opens in a browser but uses local content so you do not need an Internet connection except for links to external websites.

First open Thermo-Calc, then choose one of these options to go to the local browser version of the help:

- Press <F1> on the keyboard.
- Select **Help** → **Online Help**.
- On the **My Project Configuration** window, click **Online Help**.
- At the bottom of any **Configuration** window, click **Help**.

Opening the Console Mode Help

Console Mode is for Thermo-Calc and the Diffusion Module (DICTRA).

The installed or web versions of the help are recommended. The Console Mode help is not maintained other than adding new commands.

In Console Mode at the command line prompt, you can access help in these ways:

- For a list of all the available commands in the current module, at the prompt type a question mark (`?`) and press <Enter>.
- For a description of a specific command, type `Help` followed by the name of the command. You can only get online help about a command related to the current

module you are in.

- For general system information type `Information`. Specify the subject or type `?` and the available subjects are listed. This subject list is specific to the current module.

Typographical Conventions

The following typographical conventions are used throughout the documentation, both online and in the PDF documents.

Text

Convention	*Definition*
Forward arrow →	The forward arrow symbol → instructs you to select a series of menu items in a specific order. For example, **Tools → Options** is equivalent to: From the **Tools** menu, select **Options**.
Boldface font	A **boldface** font indicates that the given word(s) are shown that way on a toolbar button or as a menu selection. For example, if you are told to select a menu item in a particular order, such as **File → Save Project**, or to click **Save**.
Italic font	An *italic* font in the body of the text indicates the introduction of important terminology. Expect to find an explanation in the same paragraph or elsewhere in the guide.
COMMAND	For features in Thermo-Calc that use Console Mode (i.e. the command line), this font and all capital letters indicates that this is a Console Mode COMMAND. Examples of how you can use a command are written with code font. For example: Use DEFINE_ELEMENTS followed by a list of the elements that you want in your system. (To list the elements that are available in your current database, use LIST_DATABASE and choose `Elements`).
HELP	Text in blue and underline and a page number is a link to another topic in the current or referenced guide. Command names are often also topics. Clicking the link takes you to more detail about a particular command or subject in the PDF or documentation set.
<Enter>	Text with <angle brackets> indicates a keyboard entry. Usually to press <Enter> (or Return) or to use a series of keys such as <Ctrl + S>.
`code`	A `code` font shows a programming code or code example. It is also used for file names or paths to help distinguish it from other text. e.g. For Windows users, the documents, materials, examples and other folders that sometimes require additional licenses are first installed in `C:\Users\Public\Public Documents\Thermo-Calc\<version>`.

Convention	*Definition*
click vs press	In general, you *click* with the mouse to perform an action on the screen (e.g. click **Save**) and you *press* keys on a keyboard to enter a set of commands (e.g. press Ctrl+S). When working in Console Mode, you can use keyboard shortcuts. Sometimes a window opens where you have the option to **Save**, **Cancel** or **Open** a file, for example. In these cases the instructions might say *click* Save, whereas you would need to *press* the applicable keys to perform the action.

Icons

Convention	*Definition*
Important	Provides important information. It is recommended that you read the text or follow the link.
License Required	This indicates that additional licenses are required for the feature, database, or example.
Note	The information can be of use to you. It is recommended that you read the text or follow the link to more information.
Time	Indicates that something you are going to do will take some time, usually related to running an example.
Tip	This is general information that can be of use but is not required knowledge.

Convention	*Definition*
Learn More	Learn more at the link, which may be to our website or another source of general information.
See More	Go to the link or guide to see more general information about the topic being discussed.
Training	Indicates there may be training opportunities available, usually related to a specific feature.
Link to more information	Click the link to more information in the content.
Examples	Go to the example collection to learn more.
Console Mode	This note relates specifically to something in Console Mode.
Video	Indicates there is a video tutorial on our website, usually in relation to an example.
Graphical Mode	This note relates specifically to something in Graphical Mode.
Diffusion Module (DICTRA)	This indicates that the information relates to the Add-on Diffusion Module (DICTRA).
Precipitation Module (TC-PRISMA)	This indicates that the information relates to the Add-on Precipitation Module (TC-PRISMA).
Process Metallurgy Module	This indicates that the information relates to the Add-on Process Metallurgy Module.

Convention	*Definition*
Property Models	This indicates that the information relates to the Property Models. This includes all material specific libraries, i.e. Steel Model Library, Nickel Model Library, etc. as well as the general Models included with all installations.
Additive Manufacturing (AM) Module	This indicates that the information relates to the Add-on Additive Manufacturing (AM) Module.

Key Concepts and Features

Learning how to work in Graphical Mode is an important first step to navigate the software and to confidently and correctly set up your simulation and then understand the results.

The Graphical Mode Desktop Layout

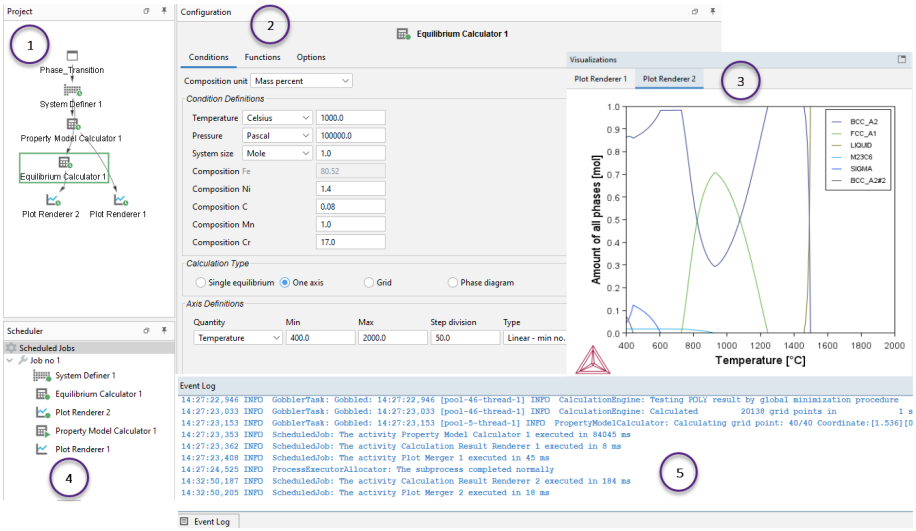
Open Thermo-Calc to view the default graphical user interface (GUI) layout for Graphical Mode. The windows are:

1. **Project**: Create, make changes, and navigate between the activities that make up a project. Click the **My Project** node to access the Quick Start assistants, a variety of templates to create projects for all the calculator types, and several other resource links.
2. **Configuration**: Shows the settings that can be configured for the currently selected activity node, i.e. when you click the **Equilibrium Calculator**, the **Configuration** window has the settings for this node.
3. **Visualizations**: Shows the results of a calculation, either plotted as a diagram or displayed in table format. For some types of calculations, there are also previews of settings shown in this window. In this example, there is only a Plot Renderer *tab* in the Visualizations window.

   Previews in the **Visualizations** window are applicable to some of the Add-on Modules, i.e. for the Diffusion Calculator, Precipitation Calculator, and AM Calculator. The information is detailed in the relevant sections of the documentation.

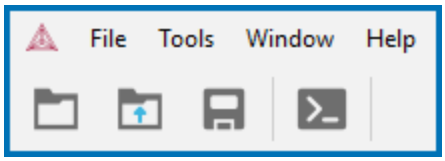
4. **Scheduler**: Displays information about jobs, such as calculations, that are being performed or are scheduled to be performed. You can cancel scheduled jobs and if a job has failed, then you can view information about the error.
5. **Event Log**: By default this window is closed but it displays during calculation processes. You can always open it to view progress of calculations and to troubleshoot.

   In this example, the **Visualizations** window also has a **Plot Renderer** tab. You can also have a **Table Renderer** tab and when working with calculations that have specialized settings, these tabs are also included and match the names of the nodes in the **Project** window.



Organizing the Windows on the Desktop and Getting Started Links, Templates, and the Property Navigator

Menu, Toolbar, and Keyboard Shortcuts



The **File** menu and toolbar are reserved for Graphical Mode but in Console Mode the **Tools**, **Window**, and **Help** menus have the same options.

For Mac users, the **Tools** menu has only one item. The global **Options** window is opened by selecting **Thermo-Calc** *<version>* → **Preferences** or press <⌘> on the keyboard.

In Console Mode you use commands to access the other options, for example see Main Menu Commands.

Graphical Mode Menu and Toolbar Options

Button or Icon	*Action*	*Description*	*Action (s)*
	New Project	Create a new project. Also see Creating a Project from a Template.	• Click the **New** button on the toolbar • Select **File → New Project** • Windows: Press <Ctrl+N> • Mac: Press < ⌘ + N>
	Open Project	Open an existing project. See Opening Project Files.	• Click the **Open** button on the toolbar • Select **File → Open Project** • Windows: Press <Ctrl+O>.

Button or Icon	*Action*	*Description*	*Action (s)*
			• Mac: Press < ⌘ + O>
--	Open Recent Project	Open a recent project. See Opening Project Files.	Select **File → Open Recent Project** and choose from the list of projects or click **Clear Recent Projects** to reset the list. Up to the last 10 projects are listed and numbered in the order at which last opened.
	Save	Save a project. See Saving Project Files.	• Click the **Save** button on the toolbar • Select **File → Save Project** • Windows: Press <Ctrl+S>. • Mac: Press < ⌘ + S>
	Save Project As	Save an existing project with a new name. See Saving Project Files.	• Select **File → Save Project As** • Windows: Press <Ctrl+Shift+S> • Mac: Press < ⇧⌘ + S>
	Switch to Console Mode	This button is available when working in Graphical Mode. Click to switch to Console Mode and the command prompt.	Click the button to exit Graphical Mode and open Console Mode.
	Switch to Graphical Mode	This button is available when working in Console Mode. Click to switch to Graphical Mode and work with the GUI version.	Click the button to exit Console Mode and open Graphical Mode.
	Append Project	Combine two projects into one project file. See Appending Project Files.	• Select **File → Append Project** • Windows: Press <Ctrl+Shift+O>

Button or Icon	*Action*	*Description*	*Action (s)*
			• Mac: < ⇧⌘+O>
	Exit	Exit the program.	• In the upper right-corner of the program, click the X. • Windows: Select **File → Exit** or press <Ctrl+Q> on the keyboard. • Mac: **Thermo-Calc** *<version>* **→ Quit** or press <⌘+Q> on the keyboard.
	Options	Change the global defaults for a variety of settings.	To open the **Options** window: • Windows: Select **Tools →** **Options**. • Mac: Select **Thermo-Calc** *<version>* **→ Preferences** or **Settings** or press <⌘> on the keyboard.
	Database Checker	Open the **Database Checker**, a program to check that the syntax of Thermo-Calc database files is correct. This is for advanced users who develop and manage databases. See About the Database Checker.	Select **Tools → Database Checker**
--	Window menu	Highlight a specific window on the GUI	From the **Window** menu, select an option to refocus on that specific window.
	Help	Open the help system where you can browse or search all the Thermo-Calc documentation.	First open Thermo-Calc, then choose one of these options to go to the local browser version of the help: • Press <F1> on the keyboard. • Select **Help →** **Online Help**. • On the **My Project**

Button or Icon	*Action*	*Description*	*Action (s)*
		This does not require an Internet connection. The content is stored locally.	window, click **Online Help** **Online Help**. • At the bottom of any **Configuration** window, click **Help**.
	Video Tutorials	Open a link to the Thermo-Calc website where a variety of video tutorials are available.	• Select **Help → Video Tutorials** • On the **My Project Configuration** window, click **Video Tutorials**.
	Examples Files	Open the examples folder based on whether you are in Console Mode or Graphical Mode. Also see Opening Example Project Files in Thermo-Calc.	• Select **File → Examples Files**. • Select **Help → Examples Files**. • On the **My Project Configuration** window, click **Example Calculation**.
	Manuals Folder	Open the folder on your computer that has the PDF documentation and guides. Also see About the Manuals Folder.	Select **Help → Manuals Folder**
	Show License Info	Open the License Information window. Also see Displaying Thermo-Calc License Information and First Steps of Installation	Select **Help → Show License Info**
	Check for update	Check for updates to the software. Also see Updating the Software for Interim Releases.	Select **Help → Check for Updates**

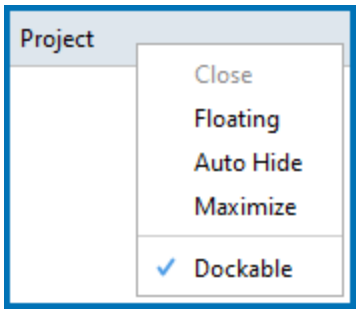
Button or Icon	*Action*	*Description*	*Action (s)*
	Request Support	Open a link to the Support on the Thermo-Calc website. There are instructions about how to submit your question.	Select **Help → Request Support**
	New in Thermo-Calc 2026b	Each release this pop up window includes details about the new and improved features and databases, with links to content on the website.	Select **Help → New in Thermo-Calc <version>**
	About	Includes the version number of the installed software and information about third party software licenses.	Select **Help → About**
	Notes	Open a **Notes - My Project** window to add notes to your project file.	At the bottom center of the **Configuration** window, click the Notes ( ) button. Once a note is added, hover your mouse over the button and it is then called **Read and edit notes**.

Organizing the Windows on the Desktop

The windows on the Thermo-Calc desktop can be fixed or free floating. By default, most windows are fixed and open. Using a combination of menu (right-click the window bar) and buttons (top right corner of a window), you can organize the windows as needed for your workflow.

Menu to Float, Auto Hide, Maximize or Dock the Window

Right-click the top of a window to select from the options to float, auto hide, maximize, or dock it. You can also left-click on the top bar of a window to float (i.e. detach) and move a window or to dock it again using the guides on the screen.



Reset the Desktop Layout

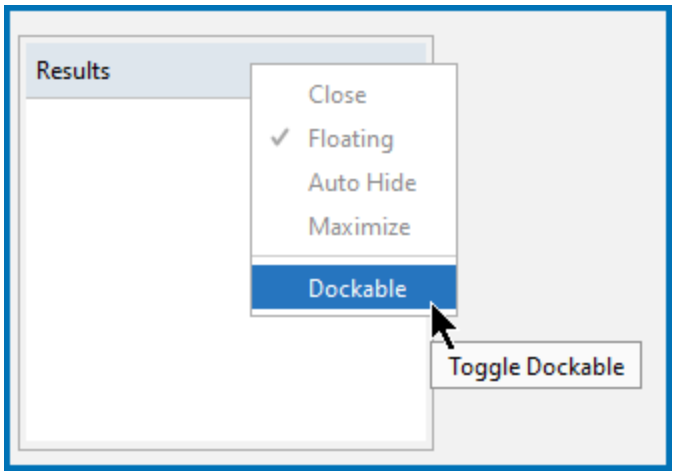
At any time to return to the standard desktop layout, from the main menu, select **Window → Reset Windows**.

Make a Window Dockable or "Permanently" Floating

By default windows are dockable, i.e. you can move the windows around using the outline guides and adjust the layout location for each window on one monitor. When a window is NOT dockable the window can be moved around it is just does not become part of the layout, it stays floating all the time (i.e. it is "permanently" floating).

When **Dockable** is turned off (i.e. not selected) the other options are not available and there are no buttons at the top right corner of the window. However, you can reset the desktop layout to return it to the default location.

Right-click the top of a window to select **Dockable** to turn this option on and off.



Auto Hide (Minimize) a Window

When a window is fixed it can also be set to auto hide. Auto-hiding means that the window is minimized and placed as a tab either along the top or bottom or side of Thermo-Calc. A free-floating window is shown on top of the other windows and can be moved outside the frame of Thermo-Calc. when you select another window.

- Right-click the top of a window to select **Auto Hide** to turn this on and off.
- Click the pin and unpin buttons to **Toggle auto-hide** on and off. The buttons are on the top-right of a window.
- Click the minimize button to **Hide active auto-hide window**. The window automatically minimizes if another window is selected. This button is available on the top right of a window that is already set to auto-hide.

The **Event Log** window is set by default to auto-hide.

Maximize or Restore a Window

- Double-click the top bar of a window (i.e. Project, Configuration, Visualizations, etc.) to maximize the window pane across the whole monitor. This hides the other windows. To restore the configuration (and the hidden windows) double-click the top bar of the window a second time.

> This can be useful for small screens, or if you are working on a large screen and want to compare two configurations side-by-side.

- Right-click the top of a window to select **Maximize**. To restore the window to its previous state and location, right-click the bar of the window again and select **Restore**.

Float or Fix a Window

There are several ways to float and fix a window back to its most recent location in the layout.

- Right-click the top of a window to select **Floating** and turn this on and off.
- Left-click on the top bar of a window to float (i.e. detach) and move a window or to dock it again using the guides on the screen.
- Click the **Toggle floating** button to float the window.
- Click the **Toggle floating** button to turn off floating and dock the window automatically to its last location.

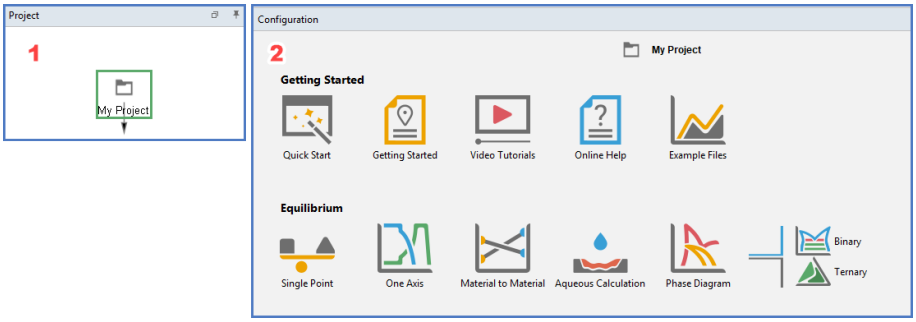
Getting Started Links, Templates, and the Property Navigator

When you first open Thermo-Calc, the **My Project Configuration** window has a variety of links and templates available to get you started. From here, click any template button to add the relevant nodes to a Project tree.

Adding Templates to the Project Window

1. In the **Project** window, click the **My Project** node.

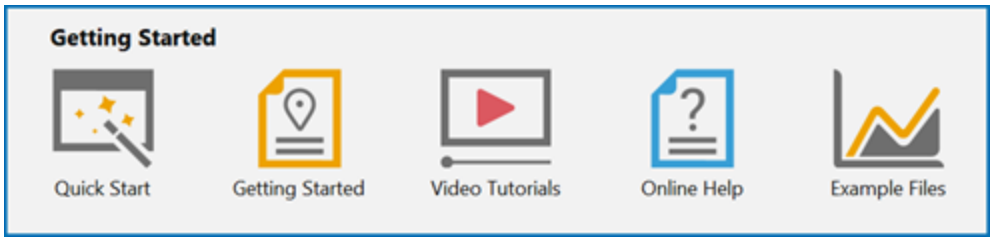
2. The templates (plus additional links under **Getting Started**) are available to click in the **My Project Configuration** window.



You can also right-click the **My Project** node and select a template from the **Create New Activity → Use Template** list. However, the **Use Template** list does not include the **Quick Start** or **Property Navigator** as these are guided step-by-step assistants and not templates.

Getting Started Links Including the Quick Start Assistant

Even before you understand how to work with Thermo-Calc projects or use the available templates, there are some links of interest available under **Getting Started**.



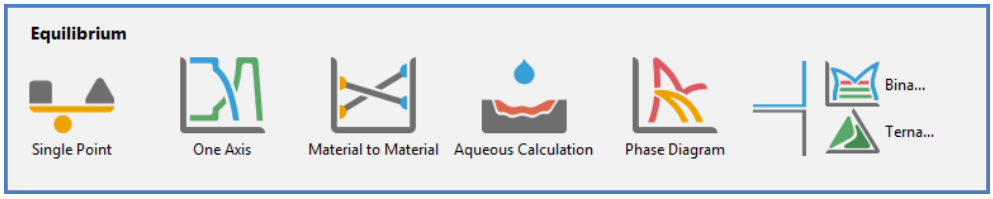
- Click Getting Started to go to the *Getting Started Guides* on the website.
- Click Video Tutorials to go to the Video Tutorials on the website.
- Click **Online Help** to open the installed help locally in a browser (or press F1).
- Click **Example Files** to open the Graphical Mode folder containing the installed example files.

In addition to the links above, click **Quick Start** to open the assistant, which helps you set up a basic project and run calculations in Graphical Mode. You can set up, calculate, and visualize any of the following:

- Single point equilibrium
- One axis equilibrium
- Phase diagram
- Scheil solidification simulation

Creating a Project with the Quick Start Assistant

Equilibrium Templates



Under **Equilibrium**, click a template to create a project and add the applicable nodes to the **Project** window.

- **Single Point**: To calculate a single point equilibrium. The project consists of a System Definer, Equilibrium Calculator, and a Table Renderer.
- **One Axis**: To calculate a one axis diagram. The project consists of a System Definer, Equilibrium Calculator, and a Plot Renderer.
- **Material to Material**: To examine how materials transition into one another. The project consists of a System Definer, Material to Material Calculator, and a Plot Renderer.
- **Aqueous Calculation**: To calculate aqueous properties. The project consists of a tailored System Definer, Aqueous Calculator, and Plot Renderer.
- **Phase Diagram**: To calculate a phase diagram. The project consists of a System Definer, Equilibrium Calculator, and a Plot Renderer.
- **Binary**: To perform a binary calculation. The project consists of a Binary Calculator and a Plot Renderer.
- **Ternary**: To perform a ternary calculation. The project consists of a System Definer, Ternary Calculator, and a Plot Renderer.

Non-Equilibrum Templates

Under **Non-Equilibrium**, click a template to create a project and add the applicable nodes to the **Project** window.

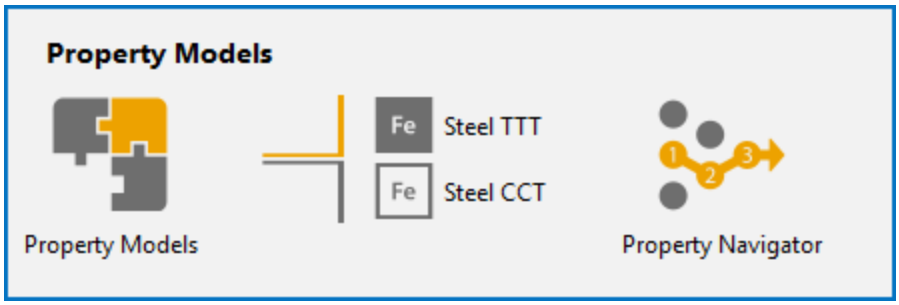
- **Scheil Solidification**: To perform a Scheil calculation. The project consists of a System Definer, Scheil Calculator, and a Plot Renderer.
- **Homogenization**: To perform a Scheil solidification calculation followed by kinetic homogenization simulation of segregated composition profile. The project consists of a System Definer, a Scheil Calculator, a Diffusion Calculator, and two Plot Renderers.
- **Diffusion**: To calculate general diffusion simulations. The project consists of a System

Definer, Diffusion Calculator, and a Plot Renderer.

- **Precipitation**: To simulate the evolution of particle size distributions. The project consists of a System Definer, Precipitation Calculator and a Plot Renderer.

To run full calculations with the **Homogenization**, **Diffusion**, and **Precipitation** templates require additional licenses although you can run these in demo mode with up to three (3) components. See Diffusion Module Available Graphical Mode Features and Available Options.

Property Models Templates and Property Navigator



Under **Property Models**, click a template to create a project and add the applicable nodes to the **Project** window. Also click **Property Navigator** to be guided through several options before the nodes are added to the **Project** window.

- **Property Models**: To choose from a variety of Property Models available on a Property Model Calculator. The project consists of a System Definer, Property Model Calculator, Plot Renderer, and a Table Renderer.
- **Steel TTT**: To use the **TTT Diagram** Property Model as part of the Steel Model Library and add all the activities for a Time-Temperature-Transformation (TTT) diagram calculation. The project consists of a System Definer, Property Model Calculator, and a Plot Renderer. See Steel Library TTT Diagram Template.
- **Steel CCT**: To use the **CCT Diagram** Property Model as part of the Steel Model Library and add all the activities for a Continuous-Cooling-Transformation (CCT) diagram calculation. The project consists of a System Definer, Property Model Calculator, and a Plot Renderer. See Steel Library CCT Diagram Template.

- **Property Navigator**: Use this to help guide you through the choices of *Material Category and Process Selection*, *Property Selection*, and *System Definition and Model Configuration*. After making your selections, a System Definer, Property Model Calculator, and a Plot Renderer and/or Table Renderer are added with the applicable settings preselected on these nodes. See Creating a Project with the Property Navigator.

> To run full calculations with the **Steel TTT** and **Steel CCT** templates (as part of the Steel Model Library) requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases.

Applications Templates

Under **Applications**, click a template to create a project and add the applicable nodes to the **Project** window.

- **Process Metallurgy**: To allow for calculation and efficient setup of advanced calculations involving slag, metal, and gas. See Process Metallurgy Template.
- **Additive Manufacturing** and **With Material Library**: These templates are to work with additive manufacturing. The Additive Manufacturing (AM) Module is used to better understand the laser powder bed fusion (LPBF) process by predicting the temperature distribution and melt pool geometry as a function of process parameters. See Additive Manufacturing Templates.

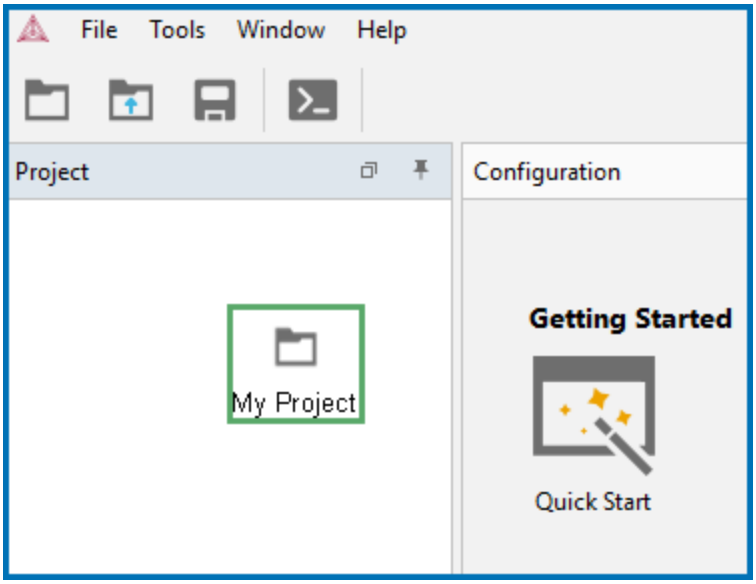
To run full calculations with the **Process Metallurgy** template requires both a valid Maintenance and Support Subscription (M&SS) and a license for the TCS Metal Oxide Solutions Database (TCOX8 or newer).

To run full calculations with the **Additive Manufacturing** and **With Material Library** templates require a license for the Additive Manufacturing (AM) Module.

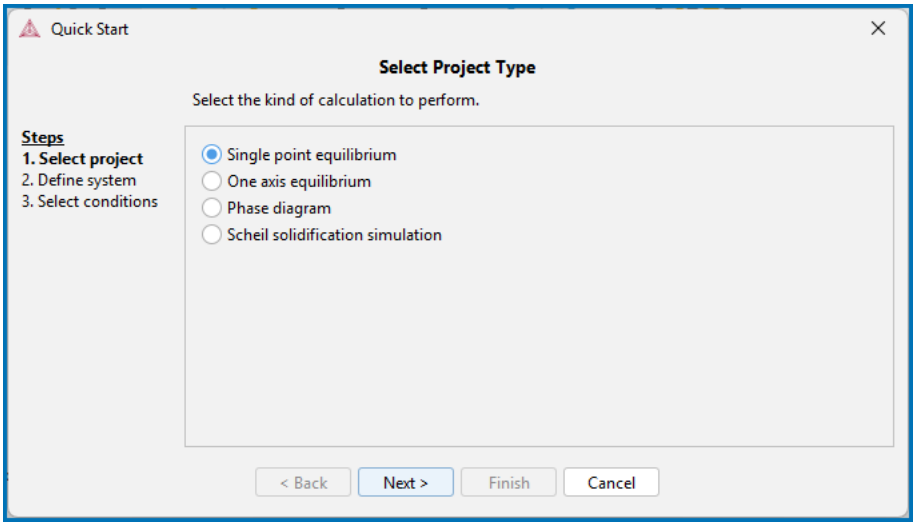
Creating a Project with the Quick Start Assistant

This topic walks you through the basic steps to set up, perform, and visualize a calculation using the Quick Start assistant. For Property Models, see Creating a Project with the Property Navigator.

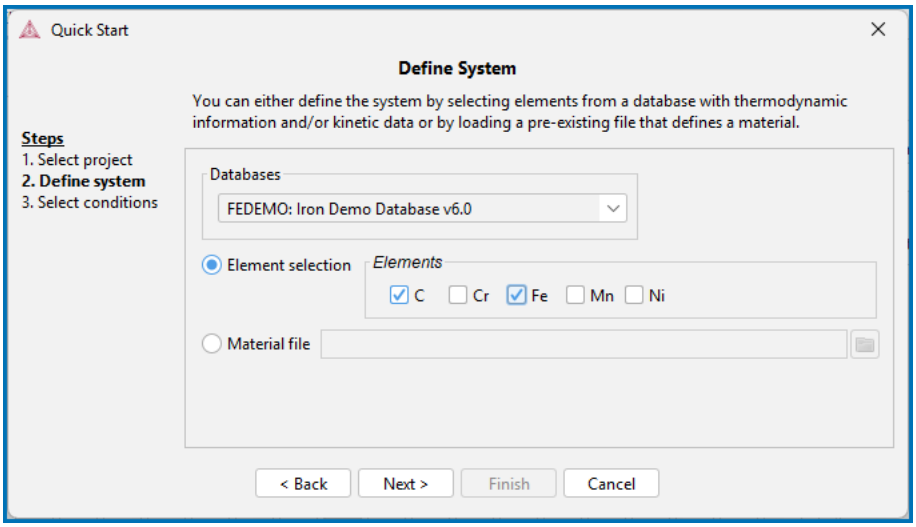
1. In the **Configuration** window click **Quick Start**. If you cannot see the **Quick Start** button, first click **My Project** in the **Project** window.



2. In the **Select Project Type** window click to select the type of calculation to perform. **Single point equilibrium**, **One axis equilibrium**, **Phase diagram**, or **Scheil solidification simulation** (a Classic Scheil simulation). Click **Next**.

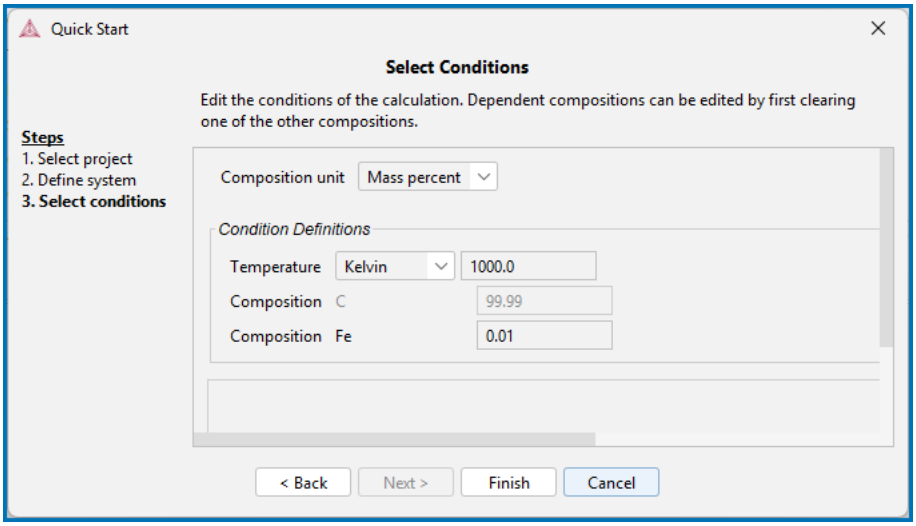


3. In the **Define Systems** window, choose an available **Database**.



4. Click to select **Elements** checkboxes to include as system components. To add elements from an existing material file, click the **Material file** button to enter the file path to a material file or then click the **Select Material File** button (to the right of the field) to navigate to a file on the computer.
5. Click **Next**. The **Select Conditions** window has different options depending on the project type and the elements selected.

   In this example, using a **Single Point Equilibrium**, choose the **Composition unit** from the list and under *Condition Definitions* specify the values of the state variables in the system.

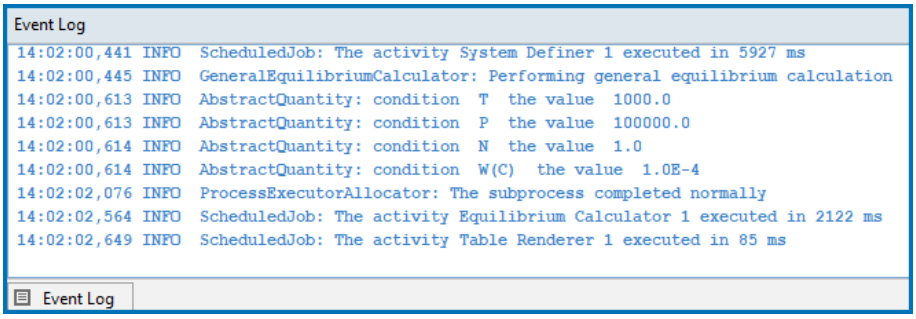


For **One axis equilibrium** or **Phase diagram** projects, specify the **Axis Definitions** of the stepping or mapping operation. Choose minimum and maximum values for the variable (s) (select **Linear – min no. of steps**, **Linear – max step size**, or **Logarithmic –scale factors**) and whether it is **Normal** or **Separate phases**.

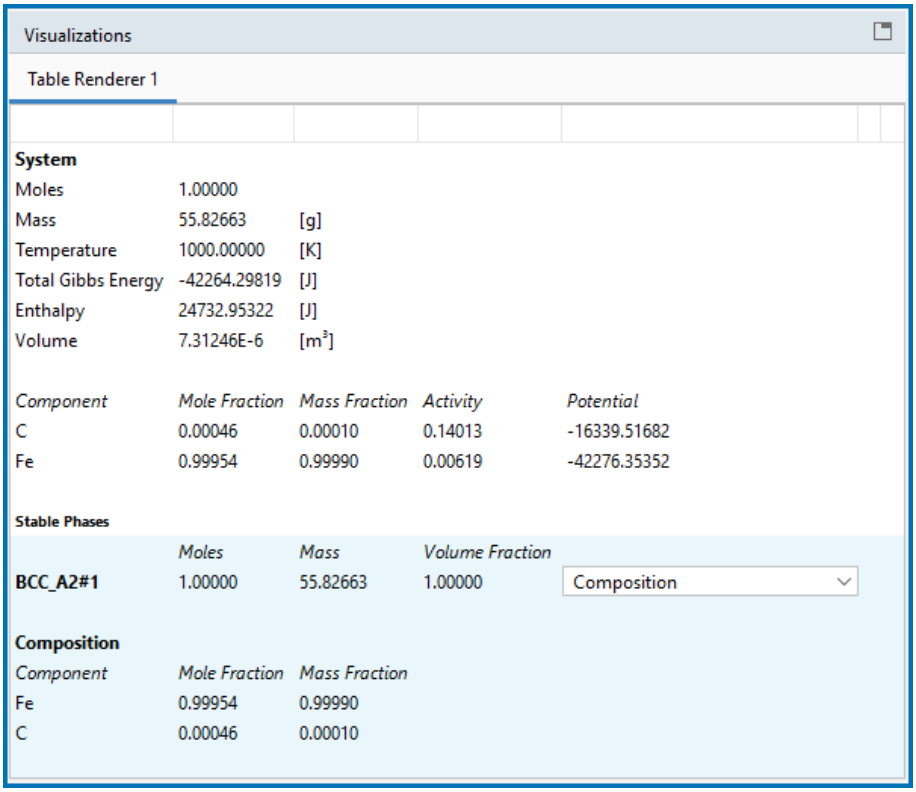
For a **Scheil solidification simulation** project, and where applicable, select **Fast diffuser**.

After using this Quick Start assistant to do a Classic Scheil calculation (or with fast diffuser components), a Scheil Calculator is added to the Project window. At this point you can review Scheil-Gulliver Solidification Calculations for details about all the options using the Scheil Calculator, i.e. back diffusion and solute trapping.

6. Click **Finish**. Click to expand the **Event Log** window to see information about the progress of the calculation.



The diagram is plotted in a **Plot Renderer** tab in the **Visualizations** window. If you have calculated a single-point equilibrium, then a **Table Renderer** tab shows information about the equilibrium.



7. To save the project, click **Save** on the main toolbar. To save a diagram or table, right-click the diagram or table and select **Save As**.

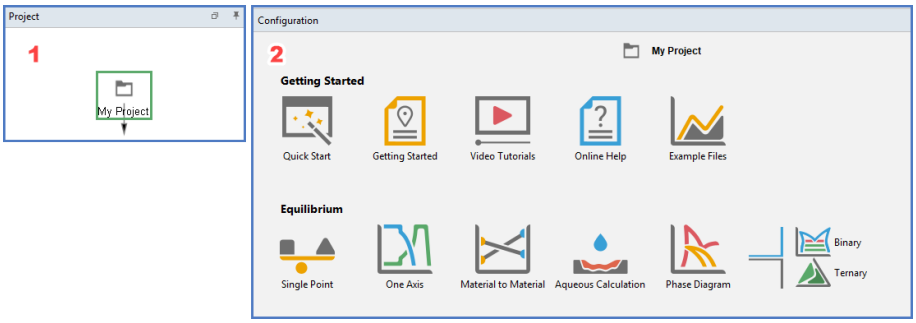
Creating a Project from a Template

Use a *Template* to create all the activities for a certain type of calculation.

Getting Started Links, Templates, and the Property Navigator

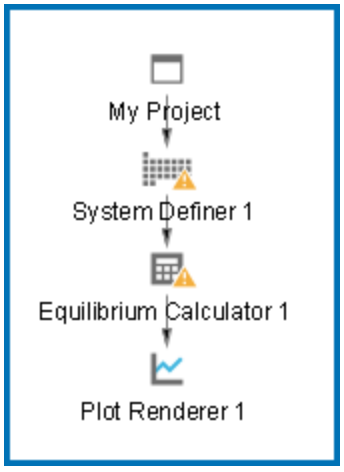
1. In the **Project** window, click the **My Project** node.

2. The templates (plus additional links under **Getting Started**) are available to click in the **My Project Configuration** window.



When you click a template, an activity tree is added to the **Project** window. You can then configure and perform the activities or the project.

For example, if under **Equilibrium** you click **One Axis**, a tree is added to the **My Project** node with **System Definer**, **Equilibrium Calculator**, and **Plot Renderer** nodes.



You can also add templates by right-clicking the **My Project** node and choosing an option from the **Create New Activity → Use Template** menu.

Creating a Project with the Property Navigator

The **Property Navigator** (the *Navigator*) is a step-by-step series of choices that helps you quickly configure Property Model calculations based on the desired scope (alloy system and processing route) and quantity of interest. The Property Navigator identifies suitable Property Models and databases and automatically configures the calculation and plotting set up by adding all the relevant nodes with settings to the **Project** window. This removes the need for manual model selection, and reduces dependency on inspecting plots or tables to identify available properties. Simulations can still be reviewed and fine-tuned manually after setup is finished.

Learn More

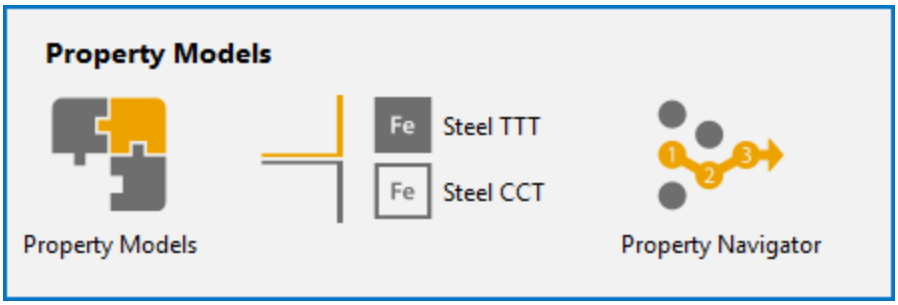
The associated properties for the Steel Library Property Models—**Bainite**, **Ferrite**, **Pearlite**, **CCT Diagram**, and **TTT Diagram**—are not available with the Property Navigator. For **CCT Diagram** and **TTT Diagram**, you can specifically use the dedicated **Steel CCT** and **Steel TTT** templates instead. For **Bainite**, **Ferrite**, and **Pearlite**, these are simplified TTT calculations, so you can also use the **Steel TTT** template to start.

Property Model abbreviations next to each property help guide you to understand what you are choosing. See Property Model Abbreviations and About the Temperature Options for Property Models for useful details.

For the **Property Navigator**, *Material Category* and *Process Selection* categories for the **Steel**, **Nickel**, **Noble Metal Alloys**, and **Titanium**, are available to select even without the required database licenses. However, you will not be able to run the final simulation without the correct licenses.

Setting Up a Property Model Project with the Property Navigator

1. In the **My Project > Configuration** window under **Property Models** click **Property Navigator**.



2. In the **Material Category and Process Selection** window from the *Material Category* list choose **General**, **Steel**, **Nickel**, **Noble Metal Alloys**, or **Titanium**.

> **Steel**, **Nickel**, **Noble Metal Alloys**, and **Titanium** are available to choose even if you do not have the necessary database licenses. You can still continue with the selections, where a demo database is automatically selected and all the nodes with preselected settings added to the **Project** tree. However, the **Perform** button is ultimately not available and the calculation cannot be run without the necessary database.

3. Based on the *Material Category* selection and license, choose a *Processing Route*: **Casting, Welding and AM**, **Annealing, Quench and Temper**, **Annealing with Freeze-in Temperature**, **Isothermal Treatment**, or **Heating or Cooling**. The availability of each process category depends on the available models in a given Materials category.

4. On the **Property Selection** window, click to select the applicable checkboxes under each category to choose the properties to calculate.

   The properties for each *Material Category* and *Processing Route* combination are listed in these topics:

- General Models: Property Selection Options
- Steel Models: Property Selection Options
- Nickel Models: Property Selection Options
- Noble Metal Alloys Models: Property Selection Options
- Titanium Models: Property Selection Options

5. Click **Next**. On the **Project** window (in the background), the Navigator adds a **System Definer** and **Property Model Calculator**. The **System Definition and Model Configuration** window opens.

6. On the **System Definition and Model Configuration** window, continue to choose the settings for each category: *Database*, *Elements*, *Composition and Units*, plus other grouped categories, such as *Temperature and Time Settings* and *Numerical Model Settings*.

   Only the most important settings are included on the **System Definition and Model Configuration** window. There are often more advanced settings available via the **Property Model Calculator Configuration** window that you can use to fine-tune for each Property Model.

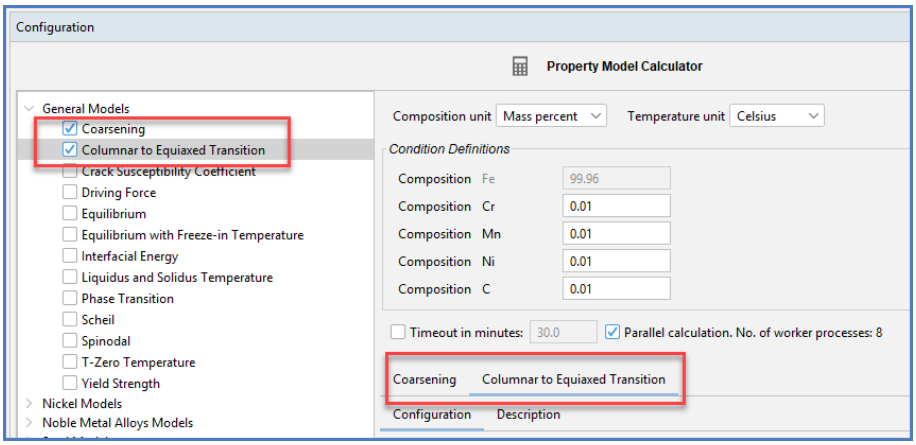
   See About Database Selections to learn more about the *Database* defaults. For additional guidance when there are multiple model properties combined, see About Event Log Warnings for Grouped Property Model Settings.

   If you are not sure about what to enter or choose for a particular setting, you can skip it here and fine-tune it later on the **System Definer** or **Property Model Calculator**. In addition, a more extensive choice of properties to calculate can be seen when inspecting the **Plot Renderer**. Some models have overlapping properties and some properties require more user input.

7. Click **Finish**. Then depending on your choices, a **Table Renderer** (e.g. for single point calculations) and/or **Plot Renderer** node is added to the **Project**.

8. In the **Project** window, click the **System Definer** to review the database selection as needed.

9. Click the **Property Model Calculator** node to examine the settings added for each Property Model. On the **Configuration** window there are separate tabs corresponding to each of these models where you can review all the available settings, some of which are now preset by the Navigator, and some that you may want to further define for your calculation.



10. Click **My Project** node and then **Perform Tree** to see what results are output to the **Visualizations** window. If the results are not quite what you expected, click the **Table Renderer** and/or **Plot Renderer** nodes to examine the Navigator's preset choices. Remember you can also right-click the **Property Model Calculator** to add additional Plots or Tables.

11. Continue to work with this project to fine tune your simulation. Alternatively, click **New Project** and start over with the **Property Navigator**.

About Database Selections

For **General** models, you choose the database or databases to use. The Navigator defaults to the relevant database package available based on license and the properties selected. When a licensed database is not available, it defaults to a relevant demo database (i.e. FEDEMO, NIDEMO, etc.). The database selection can be changed on this window or at the end on the **System Definer** when the Navigator adds all the nodes to the **Project** window. If the selection defaults to a demo database, then this also means that only up to three (3) elements can be used in the simulation.

For the Material Specific Model Libraries—**Steel**, **Nickel**, **Noble Metal Alloys**, and **Titanium**—the applicable and most recent database version is preselected for you. After using the Navigator, the database version can be changed as required on the **System Definer** node in the **Project** window.

In order for these material specific models to run, the correct databases need to be used. If you choose a material where you do not have the licensed database, a demo database is preselected but later the calculation cannot be run. The **General** models are more flexible with respect to database choices.

For any *Material Category* and *Property Selection* combination, a mobility database is preselected when it is needed for the calculation. For example, in the **Nickel** Model Library when using the **Coarsening-Ni** model or with the **General** model, **Columnar to Equiaxed Transition**.

About Event Log Warnings for Grouped Property Model Settings

A benefit to using the Navigator to initially set up your calculation is that when properties are chosen from different models, these settings are grouped together, for example *Temperature and Time Settings* or *Numerical Model Settings*. When you are on the **System Definition and Model Configuration** window the available settings are then set for all the models. However, if you choose different models that use different inputs then there is a warning provided in the **Event Log** window after you click **Finish**. For example, if a range for an **Evaluation temperature** is selected, but there is no such temperature to be set, there is a warning listed in the Event Log.

General Models: Property Selection Options

When you are setting up your system on the **Property Navigator** (see Creating a Project with the Property Navigator) for a **General** *Material Category*, you have also chosen a *Processing Route*:

- **Casting, Welding, and AM**
- **Annealing, Quench, and Temper**
- **Annealing with Freeze-in Temperature**
- **Isothermal Treatment**
- **Heating or Cooling**

Then on the **Property Selection** window, the following properties can be selected.

Learn More

Only the most important settings are included on the **System Definition and Model Configuration** window. There are often more advanced settings available via the **Property Model Calculator Configuration** window that you can use to fine-tune for each Property Model.

Property Model abbreviations next to each property help guide you to understand what you are choosing. See Property Model Abbreviations and About the Temperature Options for Property Models for useful details.

The associated properties for the Steel Library Property Models—**Bainite**, **Ferrite**, **Pearlite**, **CCT Diagram**, and **TTT Diagram**—are not available with the Property Navigator. For **CCT Diagram** and **TTT Diagram**, you can specifically use the dedicated **Steel CCT** and **Steel TTT** templates instead. For **Bainite**, **Ferrite**, and **Pearlite**, these are simplified TTT calculations, so you can also use the **Steel TTT** template to start.

Property Model abbreviations next to each property help guide you to understand what you are choosing. See Property Model Abbreviations and About the Temperature Options for Property Models for useful details.

Annealing, Quench, and Temper

Annealing, Quench, and Temper

Titanium Models: Property Selection Options

When you are setting up your system on the **Property Navigator** (see Creating a Project with the Property Navigator) for a **Titanium** *Material Category*, you have also chosen a *Processing Route*:

- **Annealing, Quench, and Temper**
- **Annealing with Freeze-in Temperature**

Then on the **Property Selection** window, the following properties can be selected.

Learn More

For the **Property Navigator**, *Material Category* and *Process Selection* categories for the **Steel**, **Nickel**, **Noble Metal Alloys**, and **Titanium**, are available to select even without the required database licenses. However, you will not be able to run the final simulation without the correct licenses.

Only the most important settings are included on the **System Definition and Model Configuration** window. There are often more advanced settings available via the **Property Model Calculator Configuration** window that you can use to fine-tune for each Property Model.

Property Model abbreviations next to each property help guide you to understand what you are choosing. See Property Model Abbreviations and About the Temperature Options for Property Models for useful details.

About the Activity Nodes

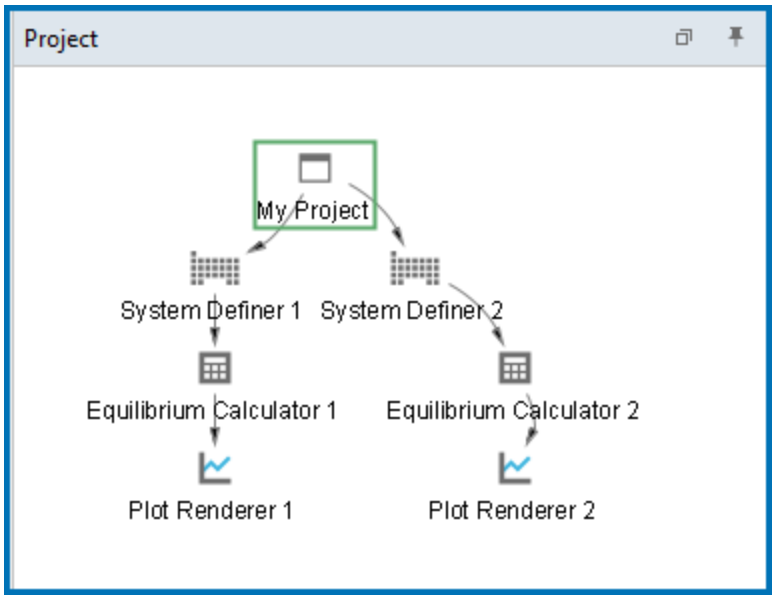
In a *project*, a set of linked activities is called a *tree*. A result calculated within a tree is fed as input into the next *activity* in the tree. Consequently, if you have an Equilibrium Calculator with another Equilibrium Calculator as its *successor*, the successor takes the calculation results of the *predecessor* as the starting values for its calculation. When working with activities in the Project window these are also referred to as *nodes* (or *activity nodes*) in the tree structure.

Graphical Mode Activities vs Console Mode Modules

Example of the Project Tree Structure

The example below shows a *My Project* node with two trees. In each tree, settings and calculation results are propagated downward until the calculation and the visualization of the results are completed in the *Plot Renderer* nodes.

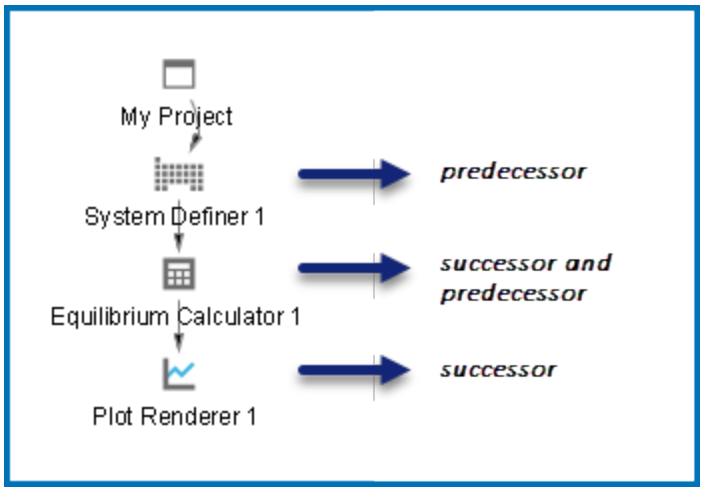
The system definitions, settings, and calculation results of the two trees are independent of each other in this example.



There are several resources available on our website to help you learn how to use Thermo-Calc and other Add-on Modules. Go to the Getting Started Guides page and choose one of the guides that provides new users an introduction to setting up simple calculations in Graphical Mode. The information there is also in this help documentation.

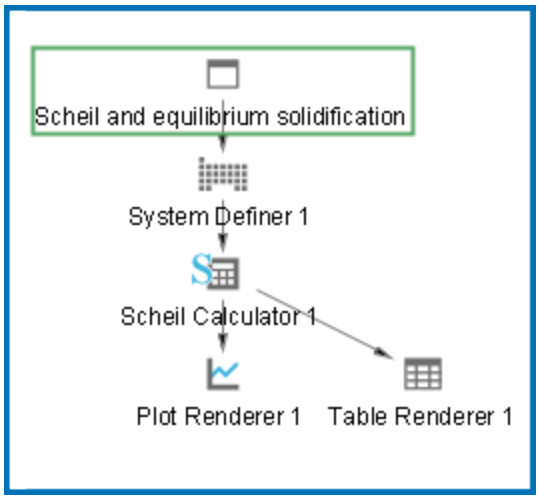
Activity Successor and Predecessor Nodes

An activity node located below another activity node in a tree is referred to as that activity's *successor*. An activity located above another activity is called that activity's *predecessor*. A predecessor is performed before the predecessor's successors and its result is fed forward to any successor activities. See the Activity Node Descriptions table below.



For example, to calculate and display a phase diagram, create a branch with three linked activities: A **System Definer** activity linked to an **Equilibrium Calculator** activity, which in turn is connected to a **Plot Renderer** activity.

You can determine the available successors by right-clicking a node in the **Project** window to browse what is available from the menu and follow the arrows connecting the nodes. The example below shows that **Scheil Calculator 1** is a predecessor to the successors, **Plot Renderer 1** and **Table Render 1**.



Creating Activities and Successors and Cloning Activities and Trees

Activity Node Descriptions

The table below is a brief description of the activity types you work with in the **Project** window. When working with activities these are referred to as *nodes* in this documentation.

These are the project activity nodes available in Graphical Mode. Some of these require additional licenses for full feature availability. Listed in alphabetical order.

Activity Type	*Description*
AM Calculator	Using the Additive Manufacturing (AM) Module this activity is used in conjunction with either the Scheil Calculator or a Material Library to define the necessary settings to better understand the laser powder bed fusion (LPBF) process by predicting the temperature distribution and melt pool geometry as a function of process parameters. There is also connectivity with the Diffusion Calculator and Precipitation Calculator to include probe data with a Thermal Profile calculation. In DEMO mode you can view the settings and experiment with some things, but no calculations can be run.
Aqueous Calculator	An **Aqueous Calculator** allows you to set the conditions for, and perform, an aqueous calculation. This calculator is a specialized Equilibrium Calculator and is set up to help you quickly define and run aqueous or Pourbaix calculations in Graphical Mode.

Activity Type	*Description*
	When the Aqueous Calculator is added to your project using the template, this allows for efficient setup of advanced aqueous calculations. For optimal results, the latest version (TCAQ4) of the TCS Aqueous Solutions Database (TCAQ) is recommended as it is designed specifically for this. Although other versions (TCAQ 3.1 and older) and the free PAQ2 database can be used, there are limitations and additional requirements to conduct more complex simulations.
Binary Calculator	Use it for some calculations involving two components only. It is like a combination of System Definer and Equilibrium Calculator activities with adaptations to simplify the configuration of calculations on binary systems. To perform this activity, you need a database designed for the Binary Calculator, such as the TCBIN database.
Diffusion Calculator	Using the Diffusion Module (DICTRA), this activity is where you set the geometry, add one or more regions, enter grids and phases in the regions, and then enter compositions of phases. You can also use this in DEMO mode with up to three components. There is also connectivity to the Scheil Calculator and to other Add-on Modules such as the Additive Manufacturing (AM) Module.
Equilibrium Calculator	Set thermodynamic conditions and define axis variables when a series of equilibrium calculations are to be performed in one or more dimensions.
Experimental File Reader	Read experimental data files (*.EXP). This type of file contains information specifying a plotted diagram, written in the DATAPLOT graphical language.
Material to Material Calculator	This activity calculates materials transitioning from one into the other.
Plot Renderer	Determine the layout of non-text based output.
Precipitation Calculator	Set the conditions for, and perform, a precipitation calculation using the Precipitation Module (TC-PRISMA). You can also use this in DEMO mode with up to three components. There is also specialized connectivity to the Yield Strength Property Model and to other Add-on Modules such as the Additive Manufacturing (AM) Module.

Activity Type	*Description*
Process Metallurgy Calculator	This calculator allows for efficient setup of advanced calculations involving slag, metal, and gas. Define the composition of a steel and slag system using material groups: one each for steel, slag, and gas.
Property Model Calculator	Choose one or more **General Models** to predict and optimize material properties. You can evaluate models simultaneously over a range of compositions and cross plot the results. You can then conduct an uncertainty analysis and plot the results as either a histogram or as a probability plot. With additional licenses, there are material specific libraries, i.e. **Steel Models**, **Nickel Models**, etc.
Scheil Calculator	Perform Scheil-Gulliver calculations (also known as Scheil calculations). A default Scheil calculation is used to estimate the solidification range of an alloy assuming that i) the liquid phase is homogeneous at all times and ii) the diffusivity is zero in the solid. However, it is possible to disregard the second assumption for selected components. The Scheil Calculator is also used with other specialized Add-on Modules such as the Diffusion Module (DICTRA) and Additive Manufacturing (AM) Module.
System Definer	Define a certain thermodynamic system, including choosing the databases, and then read it from file into memory.
Table Renderer	Use this activity for text-based output.
Ternary Calculator	Use it for some calculations involving three components. It is like a combination of System Definer and Equilibrium Calculator activities with adaptations to simplify the configuration of calculations on ternary systems. To get a reliable result you need a database that fully assesses binary and ternary systems.

Activity Node Workflow

You can set up a tree in the **Project** window (starting with the **My Project** node) and then perform all the activities at once, or create and perform one activity at a time.

A Typical Workflow Example

The typical workflow is to:

1. *Define a System*: Add a System Definer activity (in the **Project** window) where you select a database and the elements to have as system components (in the **Configuration** window).

   To the **My Project** node, you can alternatively add and define one of these activity nodes: AM Calculator, Binary Calculator, Ternary Calculator, Process Metallurgy Calculator, or Experimental File Reader.

2. *Set up and run a calculation*: Add an Equilibrium Calculator activity (a successor to the **System Definer**), where calculation conditions are set (temperature, pressure, etc.). This is where axis variables are set to create a property or phase diagram. These settings are also made in the **Configuration** window.

   You can also add several other calculators to the System Definer:

   - Material to Material Calculator
   - Scheil Calculator
   - Property Model Calculator
   - Diffusion Calculator
   - Precipitation Calculator
   - The AM Calculator is also available and can either be added directly to the **My Project** node or as a successor to the Scheil Calculator. It depends how you work with this Add-on Module.
   - The Aqueous Calculator is also available but it is more convenient to add the template in this case.

It is recommended to add the **Aqueous Calculation** template that ensures all nodes (i.e. **System Definer**, **Aqueous Calculator**, and **Plot Renderer**) have the necessary default predefined settings to more easily conduct aqueous simulations.

3. *Preview some settings*: For some specialized calculations (i.e. with the Add-on Modules), you can preview the settings in the **Visualizations** window. For example, for the Diffusion Calculator (Composition Profiles and Thermal Profiles), for the Precipitation Calculator (Thermal Profiles), and with the AM Calculator a variety of settings are previewed during the set up.

4. *Visualize the results*: Add either a Plot Renderer or a Table Renderer activity in the **Project** window. When calculated, this creates a plot or table in the **Visualizations** window. The results are shown in a **Plot Renderer** or a **Table Renderer** tab.

You need to **Perform** a Plot Renderer or a Table Renderer activity to visualize the calculation results from an Equilibrium Calculator.

Learn More

You can also use the templates to add all the necessary activity nodes based on your simulation needs. See Creating a Project from a Template and for Property Models, a useful workflow is to use the Property Navigator. See Creating a Project with the Property Navigator.

Getting Started Links, Templates, and the Property Navigator and About the Activity Nodes

Additional licenses are required for some of the listed features.

Creating Activities and Successors

You can create a new activity in these ways:

- In the **Project** window, right-click an activity and choose **Create New Activity** (**My Project** node only) or **Create New Successor** (all other nodes).
- Select the activity you want to create from the submenu.
- At the bottom of the **Configuration** window, click **Create New Activity** or **Create New Successor** and select the activity to create.
- Use the available templates, the **Quick Start** assistant, or the **Property Navigator**: Click the **My Project** node and select templates from the **Configuration** window to quickly add a set of activity nodes to the tree.

About the Activity Nodes and Cloning Activities and Trees

Activity Node Predecessors and Successors

The activity nodes listed in the table are in alphabetical order not in order of selection from the various menus. Additional licenses are also required to access full functionality for any Add-on Modules.

Activity	*Possible Predecessors*	*Possible Successors*
My Project	None; this is the first node of the tree structure. You can add activities using the Quick Start assistants or templates. Getting Started Links, Templates, and the Property Navigator	AM Calculator, Binary Calculator, Experimental File Reader, Process Metallurgy Calculator, System Definer, Ternary Calculator. Also choose templates from this level.
AM Calculator	My Project, Scheil Calculator	Diffusion Calculator, Plot Renderer, Precipitation Calculator

Activity	*Possible Predecessors*	*Possible Successors*
		When a Diffusion Calculator or Precipitation Calculator is added, a full set of nodes, including a System Definer and Plot Renderer, are added as a template to the top My Project node. The Diffusion Calculator or Precipitation Calculator is linked to the AM Calculator.
Aqueous Calculator	System Definer (it is recommended to use the Aqueous Calculation template).	Plot Renderer, Table Renderer
Binary Calculator	My Project	Plot Renderer
Diffusion Calculator	AM Calculator, System Definer	Plot Renderer, Table Renderer
Equilibrium Calculator	Equilibrium Calculator, System Definer	Equilibrium Calculator, Plot Renderer, Table Renderer
Experimental File Reader	My Project	Plot Renderer
Material to Material Calculator	System Definer	Plot Renderer, Table Renderer
Plot Renderer	AM Calculator, Binary Calculator, Diffusion Calculator, Equilibrium Calculator, Experimental File Reader, Material to Material Calculator, Precipitation Calculator, Process Metallurgy Calculator, Property Model Calculator, Scheil Calculator, Ternary Calculator	None
Precipitation Calculator	AM Calculator, System Definer	Plot Renderer, Table Renderer
Process Metallurgy Calculator	My Project	Plot Renderer, Table Renderer

Activity	*Possible Predecessors*	*Possible Successors*
Property Model Calculator	System Definer Creating a Project with the Property Navigator	Plot Renderer, Table Renderer
Scheil Calculator	System Definer	AM Calculator, Diffusion Calculator, Plot Renderer, Table Renderer
System Definer	My Project, System Definer	Aqueous Calculator, Diffusion Calculator, Equilibrium Calculator, Material to Material Calculator, Precipitation Calculator, Property Model Calculator, Scheil Calculator
Table Renderer	Aqueous Calculator, Binary Calculator, Diffusion Calculator, Equilibrium Calculator, Material to Material Calculator, Precipitation Calculator, Process Metallurgy Calculator, Property Model Calculator, Scheil Calculator	None
Ternary Calculator	My Project	Plot Renderer

Cloning Activities and Trees

As described in Creating Activities and Successors, you can clone a single activity or the selected activity and all the activities that come after it (successors). The predecessor of the selected activity also is the predecessor of the clone.

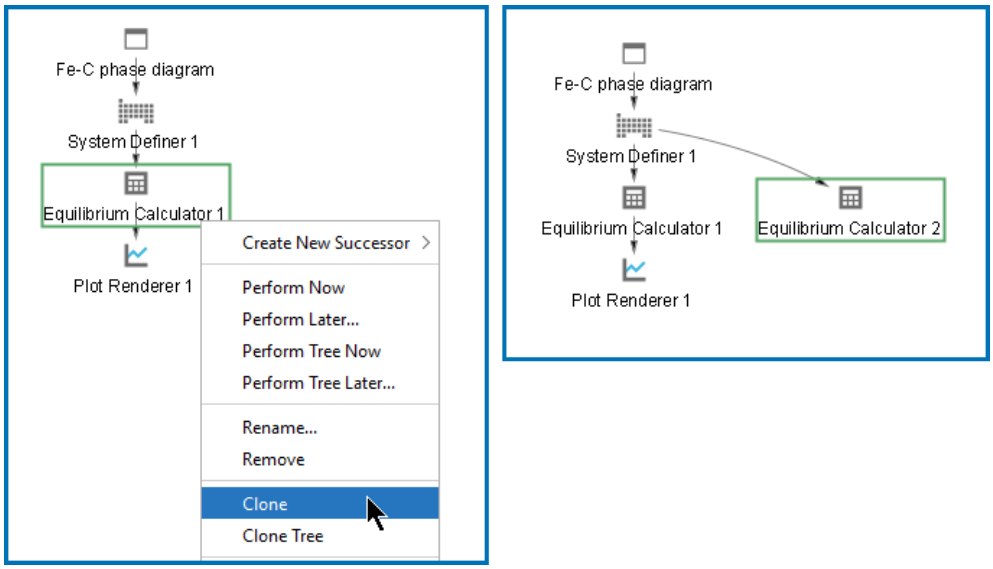
Cloned activities are configured exactly like the activities that they were cloned from, and any results of calculations or plots are also cloned. To clone a selected activity, right-click the activity and select **Clone**.

Example of Cloning an Activity Node

For example, if you clone the Equilibrium Calculator in this project the result is an **Equilibrium Calculator 2** created as a successor to **System Definer 1**.

The following applies to clones.

- The new Equilibrium Calculator has the same settings for conditions, functions, and options as its Equilibrium Calculator 1 clone.
- If the Equilibrium Calculator is already performed, then the calculation results are cloned.
- If the activity is a Plot Renderer or a Table Renderer, then the plot or table is cloned.
- If you want to clone all the successor activities that follow a selected activity, then right-click and select **Clone Tree** instead.



Cloning an Equilibrium Calculator activity node.

About Equilibrium Calculator Clones and Successors

If you create an Equilibrium Calculator as a successor to another Equilibrium Calculator, then the successor inherits all the settings for conditions, functions and options from its predecessor. In this respect, it is similar to a clone.

The Equilibrium Calculator successor is different from a clone in that it does not inherit any calculated results and it is a successor to the Equilibrium Calculator instead of a successor to its predecessor.

The calculated result from an Equilibrium Calculator that is the predecessor to another Equilibrium Calculator is the starting value for the latter's calculation. On the other hand, the clone of an Equilibrium Calculator does not receive any data as input from the Equilibrium Calculator that it is cloned from.

Moving or Grouping Nodes and Using the Grid

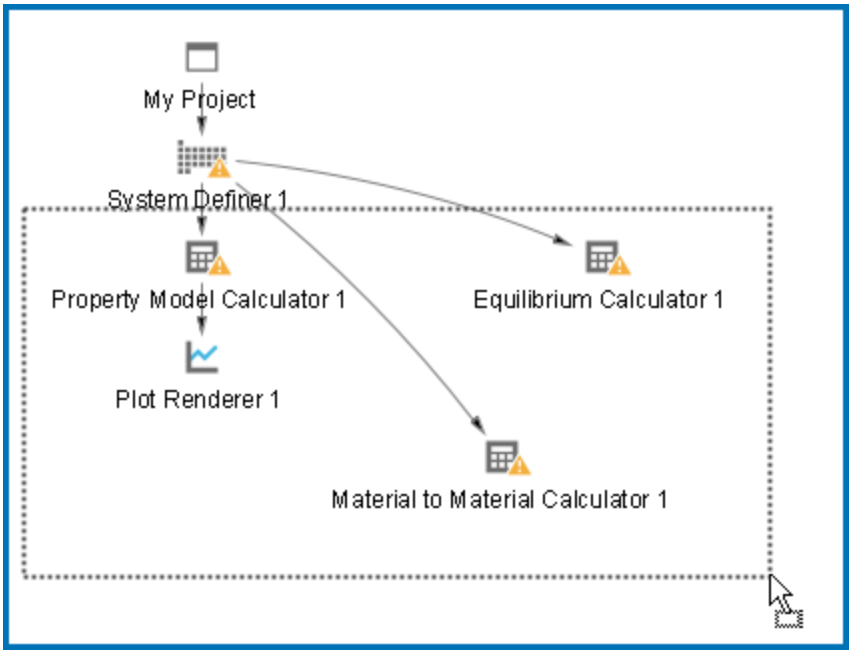
In the **Project** window, you can work with the activity nodes in various ways.

Select and Move Individual Nodes

- Click an activity node to select it.
- To move activities, click and hold the activity node and move the cursor.

Select Several Nodes at a Time

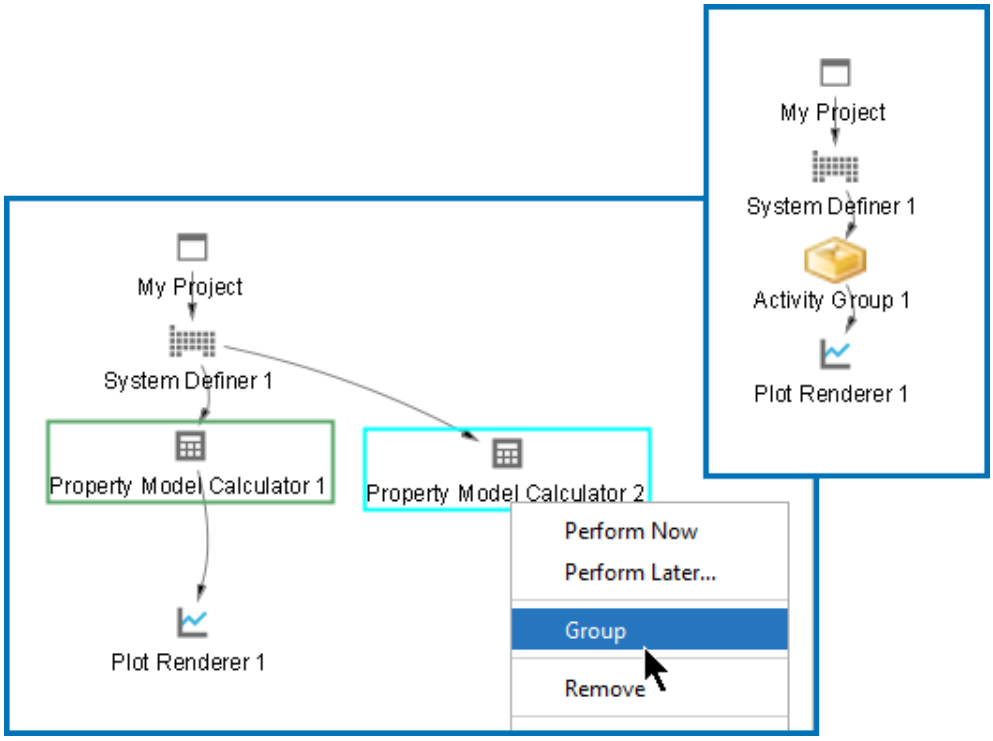
- To select several activity nodes, hold down <Ctrl> while clicking on each node you want to select.
- Click and hold the mouse button and draw a square around the activity nodes to select. Both the name and the icon that represents an activity must be within the square.



Group Activity Nodes

You can group activity nodes together on the **Project** window. This also creates separate tabs on the **Configuration** window so you can more easily edit the settings for each one. It is important to have logical groupings of nodes because the calculation relies on this connectivity.

In the **Project** window, control + click to select each node, then right-click and select **Group**. An **Activity Group** node is created (you can rename it) and on the **Configuration** window there are two tabs created, named for each of the group nodes. For example, Property Model Calculator 1 and Property Model Calculator 2. The order of the tabs is based on the order of when you select each node.



Apply Auto Layout

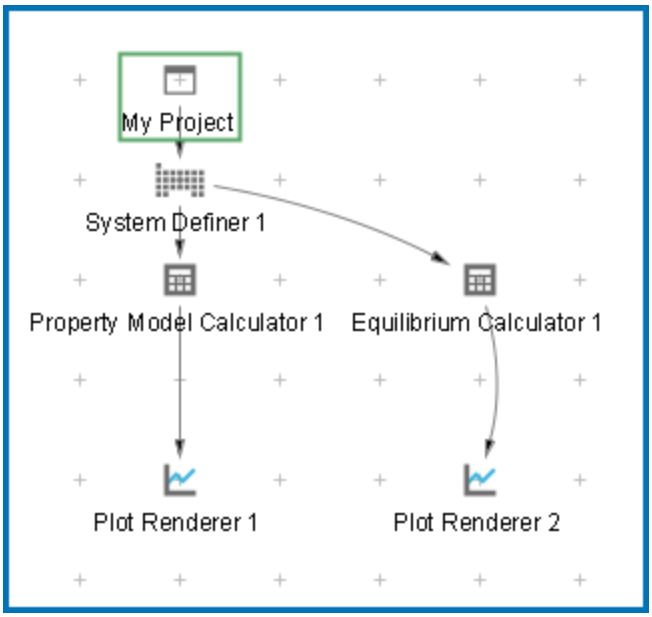
In the **Project** window, right-click anywhere and choose **Apply Auto Layout** from the menu. The nodes and the tree default to the center of the Project window.

Show Grid and Snap to Grid

To show a grid of light grey cross-hairs overlaid on a project, click **Show Grid** in the toolbar. Click the button again to turn the grid off. Or right-click in the **Project** window and select **Show Grid**.

Click **Snap to Grid** in the toolbar or right-click in the **Project** window and select **Snap to Grid** to automatically position each activity in the Project window at a cross-hairs point in the grid.

The Project window with the grid turned on and activity nodes moved from the default location. These nodes are snapped to the grid.



Node or Window Status Markers

Status markers indicate whether an activity is ready to be performed, is being performed, or has been performed. The markers are overlaid on the activity nodes in the **Project** window. The status markers are displayed on a **System Definer** node.

About the Activity Nodes

Project Window Status Markers

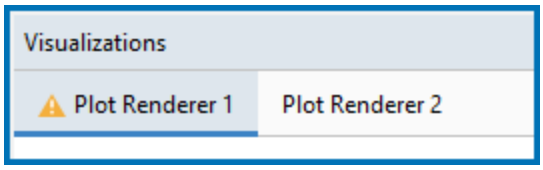
Status	*Description*
	No status marker means the activity is ready to be performed (i.e. it has not been performed).
	A yellow circle with an exclamation mark means there is an error or the activity needs to be run again. For example, the necessary configurations for the activity may not be set or other prerequisites are not met.
	A green circle with a right-facing arrow means the activity is being performed.
	A pink circle with a clock face means the activity is currently scheduled to be performed or in the process of being performed.
	For the Diffusion Calculator and Precipitation Calculator, you can pause a calculation. A blue circle with a the pause symbol indicates this state.
	A green circle with a check mark means the activity has finished its calculation, i.e. it is performed.

Scheduler Window Status Markers

Status	*Description*
	No status marker means the activity (the job) is scheduled to be performed (the job has not started).
	A yellow circle with an exclamation mark means there an error happened during the activity job.
	A green circle with a right-facing arrow means the activity (the job) is being performed.
	A green circle with a check mark means the activity (the job) performed successfully.

Visualizations Window Status Marker

If you have plotted a diagram and then modify something in the tree that the Plot Renderer is associated with, then a notification —an exclamation mark enclosed in a yellow triangle—is shown in the **Visualizations** window for the applicable tab. The tab names match the node names in the **Project** window (i.e. if a node is renamed, the tab is renamed to match).



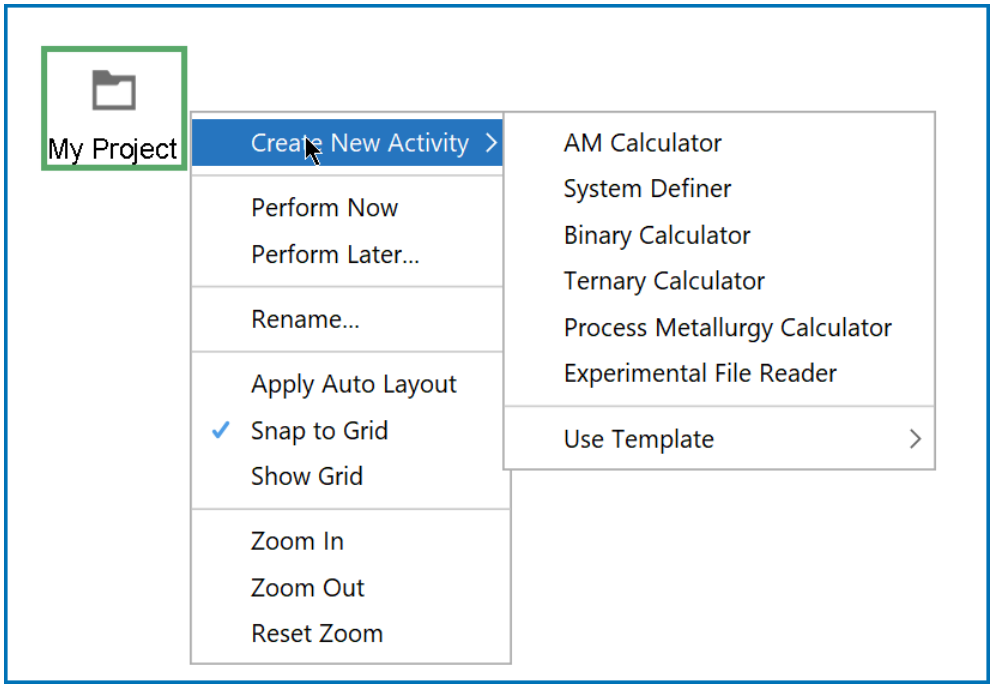
My Project and Activity Menus

When working in the Project window you can right-click nodes to open menus with the available options for the activity nodes. For example, click the **My Project** node to open the menus. Most nodes in the tree have a common menu with differences due to placement in the tree and the activity type.

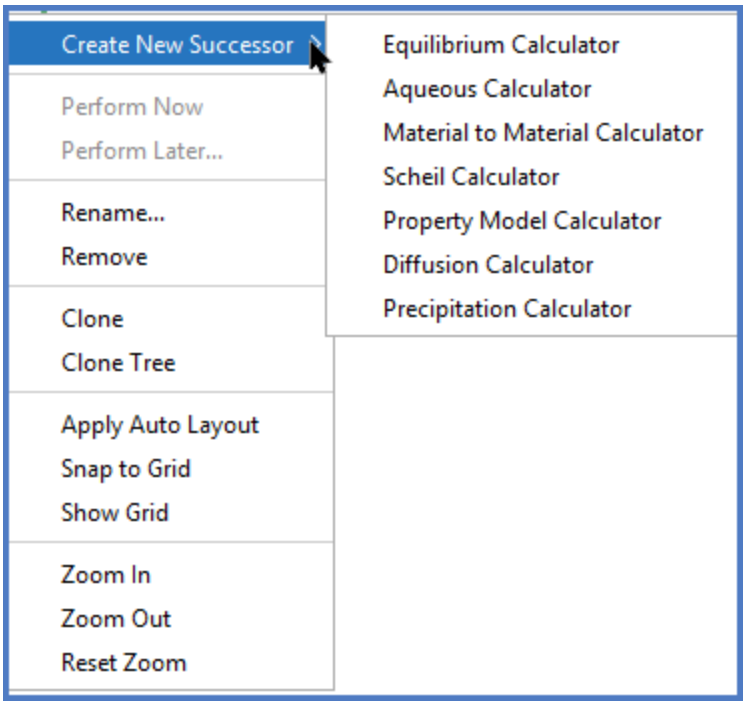
About the Activity Nodes

Menus

My Project Node



Activity Node General



Menu Options for Activity Nodes

Option	*Description*	*Action (s)*
Create New Activity	Add AM Calculator, System Definer, Binary Calculator, Ternary Calculator, Process Metallurgy Calculator, and Experimental File Reader nodes.	Right-click **My Project** and from the **Create New Activity** menu choose an option. Creating Activities and Successors
Create New Activity → Use Template	Choose from the available templates or add predefined nodes.	Right-click **My Project** and from the **Create New Activity → Use Templates** menu choose an option. The templates are also available on the **Configuration** window, which you can access by clicking the **My Project** node, or from the **Window** menu. Creating a Project from a Template

Option	*Description*	*Action (s)*
		For Quick Start Assistants, these are available from the My Project window. Creating a Project with the Quick Start Assistant and Creating a Project with the Property Navigator
Create New Successor	Add a successor to the selected node.	Right-click the **System Definer**, any **Calculator** node or the **Experimental File Reader**. Then from the **Create New Successor** menu choose an option. Creating Activities and Successors
Add a Predecessor	Add a predecessor to the selected node.	Right-click a node to add a predecessor to it (when available).
Perform Now or Perform Later	Perform a calculation or create a plot or table immediately, or schedule it for a time in the future.	Right-click any node. Using the Scheduler
Perform Tree Now or Perform Tree Later	Perform a calculation for the whole project immediately, or schedule it for a time in the future.	Right-click the System Definer or any Calculator node. Using the Scheduler
Rename	Change the name of the node.	Right-click any node.
Remove	Delete the selected node from the tree.	Right-click any node except My Project.
Clone	Duplicate the selected node and add it to the same tree.	Right-click any node except My Project. Cloning Activities and Trees
Clone Tree	Duplicate a tree and add it to My Project.	Right-click any node except My Project.
Apply Auto Layout	Apply an automatic layout to the nodes in the tree.	Right-click any node.
Snap to Grid	Snap a node to align it with the grid.	Right-click any node.

Option	*Description*	*Action (s)*
		Moving or Grouping Nodes and Using the Grid
Show Grid	Turn the grid on or off in the Project window.	Right-click any node.
Zoom In, Zoom Out, Reset Zoom	Zoom in and out of the Project window or reset the zoom to the default.	Right-click any node.

Performing Projects, Trees, and Activities

You can trigger the performance of an activity (also called a *job*) and all the activities below it in the same tree in either the **Project** or **Configuration** window. In the Project window you can also perform a single activity without performing its successors or perform the whole project (all the activity trees).

In the **Configuration** window, click **Perform Tree** to perform the currently selected activity and all the activities below it. If there are no activities below the selected activity, then the button says **Perform** instead.

All activities that must be completed as prerequisites are automatically performed first. For example, if you click **Perform Tree** for a Plot Renderer, then the predecessors, Equilibrium Calculator and System Definer, are automatically performed before the Plot Renderer.

In the **Project** window, you can do any of the following:

- Perform an activity: Right-click the activity and select **Perform Now**. Or select **Perform Later** to schedule a time to perform the activity.
- Perform an activity and all activities below it in the tree: Right-click any node in the tree and select **Perform Tree Now**. Or select **Perform Tree Later** and schedule a time for all activities in the tree to be performed.
- Perform a project: Right-click **My Project** and select **Perform Now**. Or select **Perform Later** to schedule a time to perform all project activities in the tree.

If there is an error during the performance of an activity, icons display status markers, which are described in Node or Window Status Markers.

Opening Old Project Files in the Original Version of Thermo-Calc *164*

Opening Project Files

Opening a project file in the same software version in which it was saved, with or without results, is straight forward and there are several methods to open a file.

- For standard instructions to open a project file with or without results, see Opening Project Files in the Same Version of Thermo-Calc. There are checkbox controls for plot themes and opening with or without results that are also described.
- To open a recent project file, see Opening Recent Project Files.
- Also take note of what happens when Opening Project Files Including Results and with Different GES Versions.

Learn More

Starting with Thermo-Calc version 2022b, all older project files including results generated and saved in Thermo-Calc versions 2015a to 2022a, can only be opened with results in the original software version. You can still open a project file without results and then re-perform the calculation. However, this can require a review and update to the settings and configurations, especially if there is a wide gap between versions.

See the Saving Project Files topic for useful details about saving a project file to include calculated results.

For old project files being opened in a different software version, see the topic Converting Project Files to a Newer Version of Thermo-Calc, where you can also learn about regenerating the results and the automatic creation of backup files in these instances.

Opening Project Files in the Same Version of Thermo-Calc

To Open a Project File from Thermo-Calc

1. To open a project file with or without results in the same version of the software in which it was created, choose a method below:
   - On the toolbar, click the **Open** button.
   - From the main menu, select **File → Open Project**.
   - Press <Ctrl+O> (Windows) or < ⌘ + O> (macOS).
2. On the **Open File** window review the checkboxes that control global plot themes and results:
   - By default the **Apply plot theme from Tools/Options** checkbox is selected and depends on whether the global setting checkbox is also selected on the **Options** window, which applies a predefined or custom theme globally to the project file. Click to deselect the checkbox to keep the original plot design in your project file. For more information about the settings, see About Project Files and Plot Themes for additional details.
   - For macOS users, **Tools/Options** refers to the **Options** window, which is accessed differently. Select **Thermo-Calc** *<version>* **→ Preferences** or press <⌘> on the keyboard.
   - By default the **Open project with results if present** checkbox is selected. Click to deselect the checkbox if you want to exclude results for a file saved in the same version of the software.
3. If you are opening an older project file with results (in which case the file is converted), you are prompted by a secondary window that includes related version information and options to continue or not. **Even if the checkbox is selected, old project files still cannot be opened with results**. See Converting Project Files to a Newer Version of Thermo-Calc.
4. When you are ready, navigate to the file on your computer and click **Open**.

To Open a Project File from a File Location on the Computer

Navigate to the project file on your computer then choose between these methods:

- In an open instance of Thermo-Calc, drag and drop it into the **Project** window. This replaces any other project already open.
- Double-click to open it. This launches a new instance of Thermo-Calc.

The checkbox controls **Open project with results if present** and **Apply plot theme from Tools/Options** are not available when dragging and dropping or double-clicking to open.

For macOS users, **Tools/Options** is the same as the **Preferences** menu that accesses the **Options** window.

For old projects with results, and if you are dragging and dropping or double-clicking to open, you are also prompted to decide what to do next. See Converting Project Files to a Newer Version of Thermo-Calc.

Opening Recent Project Files

Select **File → Open Recent Project** and choose from the list of projects. Up to the last 10 projects are listed and numbered in the order in which they were last opened. You can click **Clear Recent Projects** to reset the list.

About Project Files and Plot Themes

When opening project files, a predefined or custom plot theme can be automatically applied to all plots. There are two checkboxes that control this, one is a global setting and one is a local setting applied to a specific file as it is opened.

If you double-click or drag and drop to open a project file it automatically uses the global settings in Thermo-Calc (which may or may not be to apply a theme). This means you may inadvertently apply a theme to your plots without realizing it.

On the **Open File** window, the **Apply plot theme from Tools/Options** checkbox is selected by default and applies a theme locally to the specific project file being opened. Click to clear the checkbox to allow the specific file to keep existing plot settings.

If this checkbox is selected or cleared it only applies to the specific project file being opened, i.e. the global settings **Apply the selected theme to opened file [.tcu]** checkbox on the **Tools → Options** window does not change.

For macOS users, **Tools/Options** is the same as the **Preferences** menu that accesses the **Options** window.

See Global Plot Settings: About Plot Themes for the details about how the checkbox interacts with its counterpart.

If you have a project file with calculated results and local settings applied to plots i.e. applied from the **Visualizations** window to a specific plot via the **Plot Properties** settings window, then click to clear the local setting as you open the file using **Apply plot theme from Tools/Options** checkbox. Otherwise the default global settings are applied to all plots and you would need to individually change these settings back to your original design. Alternatively, experiment with applying a predefined theme, e.g. **Publication**, as this could be sufficient for your final output.

Opening Project Files Including Results and with Different GES Versions

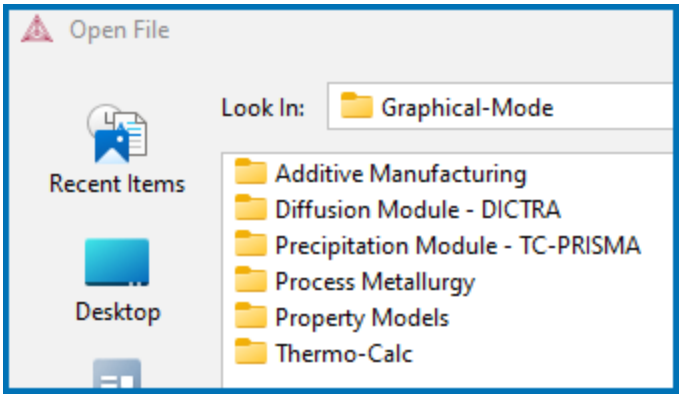
When projects with calculated results created with a different Gibbs Energy System (GES) version than selected from the **Options** window, the results are discarded as these are not 100% compatible.

GES6 (**Version 6** is the default, but some may be using GES5 (**Version 5**). See Global General Settings for more information.

Opening Example Project Files in Thermo-Calc

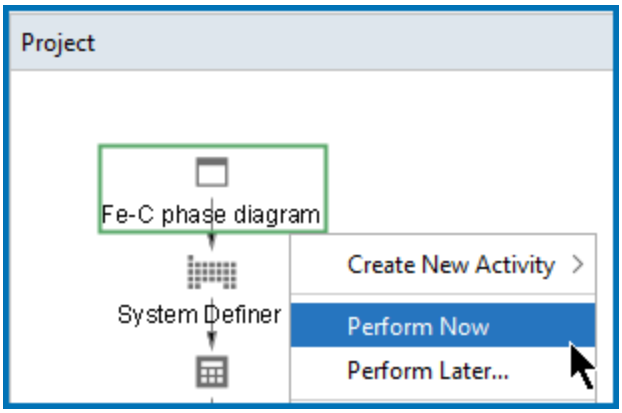
To open an example project file:

1. Open Thermo-Calc.
2. Confirm you are in Graphical Mode. If not, click the **Switch to Graphical Mode** button.
3. There are these ways to open the folders and files:
   - From the main menu select **File** → **Examples Files**
   - From the main menu select **Help** → **Examples Files**.
   - Click the **My Project** node and on the **Configuration** window, click the **Example Calculation** button.
4. The examples are divided into folders. Navigate to the folder and project file you want and double-click to open.



5. The Graphical Mode examples are stored without calculated results so you will want to run the example calculation and generate a plot or table. To do this, click the first node in the tree at the top of the **Project** window. Then right-click and select **Perform Now**.

Some examples require additional licenses in order for the calculation to run.



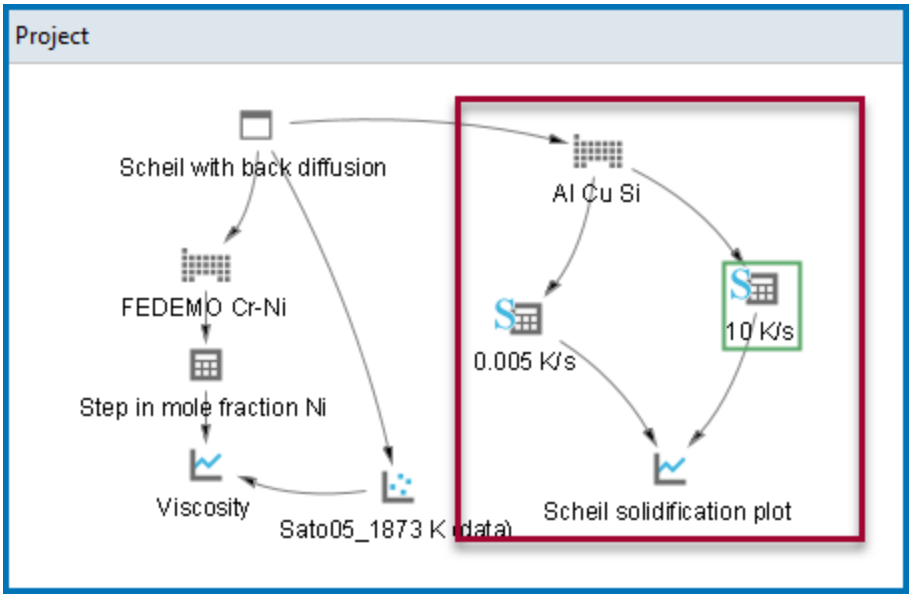
Additional licenses may be required to run calculations with the examples. The individual example descriptions detail this information.

Appending Project Files

You can only have one project file open at a time in any one instance of Thermo-Calc. However, you can *append* the nodes from additional project files to the topmost **My Project** node in the **Project** window.

To append a project file into the Project tree:

1. Chose an option:
   - From the main menu, select **File** → **Append Project** .
   - Press <Ctrl+Shift+O> (Windows) or < ⇧⌘O> (macOS).
2. Then in the **Append file** window, navigate to the project file and click **Open**.
3. The nodes are appended to the top node. Drag the nodes to separate and arrange within the Project window.



Saving and Printing the Output in Graphical Mode and *Saving Tabulated Data* for the Table Renderer

Saving Project Files

In Graphical Mode, Thermo-Calc uses a *project file* format with a `.tcu` suffix. A project file always includes project activities and the configurations. You can also include calculated results, although there are factors and limitations that need to be considered as described below and also detailed in Opening Project Files and Converting Project Files to a Newer Version of Thermo-Calc.

Save Methods

In general, to save your project file, you can choose between the following methods:

- On the toolbar click the **Save** button.
- Press CTRL + S (Windows) or ⌘ + S (macOS).
- From the menu, select **File → Save Project**.
- When you want to give an existing project a new name, OR when saving with results, select **File → Save Project As** . See Including Calculated Results with Project Files and Saving a Project File with Results.

If you are working in a file that includes results, any method to save the project file continues to include the calculated results. However, if this is the first time results are being included, there are additional important factors to consider.

If you are working in Console Mode there are other file formats used for both Thermo-Calc and the Diffusion Module (DICTRA). See Working with the Console Mode File Types.

Including Calculated Results with Project Files

Starting with Thermo-Calc version 2022b, saved calculated results are only accessible in the same version of Thermo-Calc in which it is originally created. For example, if you have a project file with saved results from version 2020a, the results are only immediately available in 2020a. You can regenerate results in a different version of the software but that can require adjustments to the configuration if new functionality or changes impact the particular project set up, especially if there is a wide gap between release versions.

When including calculated results in the project file there are these factors to consider: Future compatibility, file size, and plot design and themes.

- **Future compatibility**: If you want to use this project file over time, in future versions of Thermo-Calc, it will require recalculation after opening. It also depends on the difference in versions; the project can require reconfiguration of the settings and other fine tuning. However, if you are going to work in the same version of the software for a short term project, for example, saving the file with results eliminates the need for re-calculating results when the file is re-opened. This is particularly advantageous when a simulation takes several hours to complete such as when working with the Add-on Diffusion (DICTRA), Precipitation (TC-PRISMA), and/or Additive Manufacturing Modules.
- **File size**: When results are included, the size of the file increases. This is especially true when working with the Add-on Diffusion (DICTRA), Precipitation (TC-PRISMA), and/or Additive Manufacturing Modules.
- **Plot design and themes**: When you save your results, the plot design may have local or global designs or themes applied, which are also saved as part of the calculated results. There are considerations related to this when you open the project file again, especially in future versions of the software. See Opening Project Files for more information.

Saving a Project File with Results

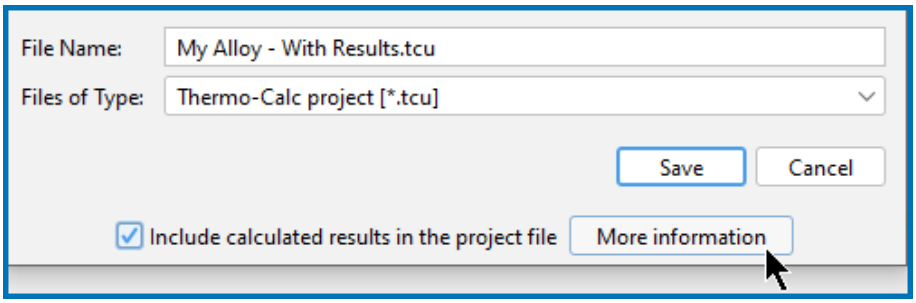
1. First, determine if saving results is efficient for your particular project based on future compatibility, file size, and plot design and theme factors. To save calculated results with the project file, choose an option:

- From the menu, chose **File** → **Save Project As** or,
- Press CTRL + Shift + S (Windows) or ⇧+⌘ + S (macOS).

2. On the **Save** window, select the **Include calculated results in the project file** checkbox.

> The checkbox is not available (it is greyed out) if no results have yet been calculated. In this case, go back to your project, click **Perform Tree** (or any other action to generate results) and then save the project file as above.

3. Click **More information** to learn about the activity nodes with calculated results that are included / saved in the project file.



4. Enter a meaningful **File Name**. It can be useful to include the version of the software in the file name, especially if the file is converted in a future version of the software.
5. Navigate to the location where you want to save your project file and then click **Save**.

Converting Project Files to a Newer Version of Thermo-Calc

Converting Project Files to a Newer Version of Thermo-Calc

This topic discusses the various considerations related to opening old project files, with or without results, in a different version of Thermo-Calc, i.e. converting a project file. In both types of conversion (with or without results), a backup file is automatically created and can be useful during the review or regeneration of results for a converted file.

Saving Project Files and Opening Project Files

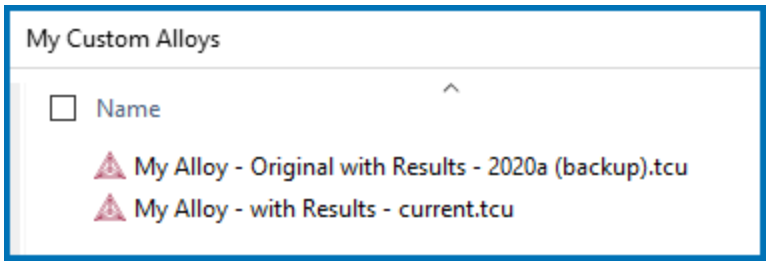
About Backup Files

When you first open a project file in a newer version of Thermo-Calc, a backup file is automatically created. The backup file has (backup) added to the end of the file name, e.g. *My Alloy (backup).tcu*. This is applicable whether the file has included results or not.

If a file including the name (backup) is also converted, then another (backup) is added to the file name, e.g. *My Alloy (backup)(backup).tcu*.

As soon as the original project file containing results is converted, it overwrites any previously saved results. This is where the backup file can be useful.

Since the version of the software used for the original project file is not always known, you can use the information provided in the **Old project file with results** window to rename the backup file with key information once the file is converted. See Converting Old Project Files - Original with Saved Results for information about this window.



An example of the backup file created (in the same folder) when an old project file is opened in a newer version of Thermo-Calc, i.e. converted. It is recommended that users rename the file in a meaningful way in order to include a software version number and to indicate if it contains saved results.

Converting Old Project Files - No Results Saved

When opening an old project file without results, the procedure is the same as described in Opening Project Files. The main difference is that a backup file is automatically created. There can also be potential differences in setup configuration that need to be addressed.

After opening the file in the new version of Thermo-Calc, also open the **Event Log** to see if there are any messages. Try also to perform the simulation and check the results against the original or expected output, then continue as normal.

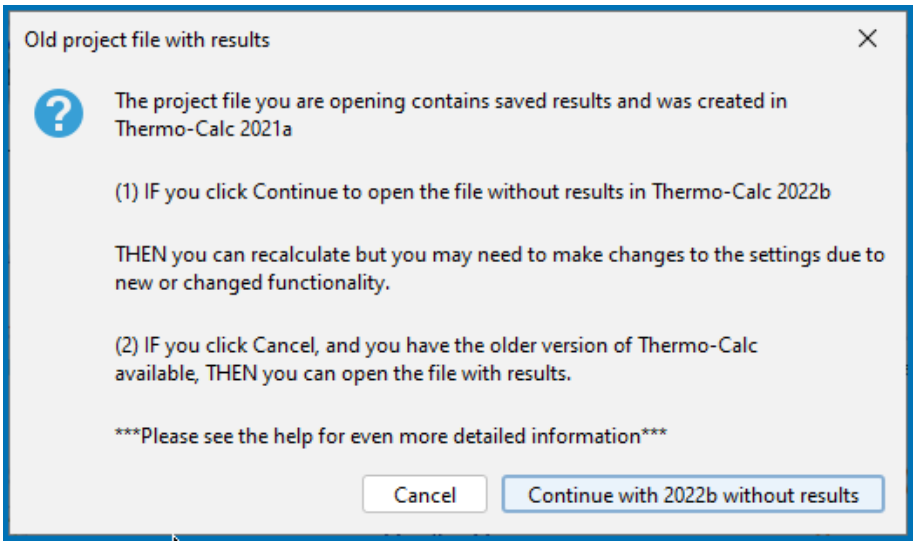
Converting Old Project Files - Original with Saved Results

Starting with Thermo-Calc version 2022b, all older project files including results generated and saved in Thermo-Calc versions 2015a to 2022a, can only be opened with results in the original software version. You can still open a project file without results and then re-perform the calculation. However, this can require a review and update to the settings and configurations, especially if there is a wide gap between versions.

To Open and Convert a Project File with Results

1. Follow the instructions as described in Opening Project Files.
2. At the point of opening the old project file including results, the **Old project file with results** window displays. This also occurs when the **Open project with results if present** checkbox is selected because no results can be included.

The window provides information about the original Thermo-Calc version in which the results were calculated as well as the version of the software in which you are opening the project file.



3. Click **Continue** to open and convert the file to the version of the software indicated. A backup file is automatically created, which includes the old results. Click **Cancel** to exit without converting the file.
    a. If you click **Continue**, then it is recommended that you first review the setup and then regenerate the results. Review the **Event Log** to see if there are any messages.
    b. If you click **Cancel**, or want to use the backup file to compare results between versions, then open the old or backup file in the original version of the software.

Regenerating the Results for a Converted File

As part of the project file conversion, all previous results are overwritten and the file is opened without results. However, the project structure and settings are maintained.

When the versions of the software are not far apart, then re-performing a simulation is likely to have no or few errors recorded in the Event Log.

However, to regenerate and compare results in a newer version of Thermo-Calc also depends on the original project set up and whether new or improved functionality in Thermo-Calc impacts the recalculation. Another consideration includes the availability of a newer version of a database than was used in the original calculation. In other words, there are various factors that can change the new or regenerated results compared to the original.

Opening Old Project Files in the Original Version of Thermo-Calc

There are various reasons for wanting to open an old project file in its original version of the software. For example, if you are:

- Regenerating the results in a newer version of the software and there are errors in the **Event Log** or unexplained differences.
- Reviewing or comparing the original configuration settings to update the settings.
- Comparing results from the older version of the software to the converted version of the results.

Different versions of Thermo-Calc can be installed at the same time on your computer and have project files opened alongside each other to facilitate such comparisons.

If you are having problems with opening an old project file, or are unable to access an installed version of the software that you know your organization has a license for, complete this Request Support form on our website to get help. Be sure to include all relevant details such as your organization number.

Calculation Types in Graphical Mode

A variety of Plot Types are available based on the Calculator and, in most cases, *Calculation Type* selected. Also see Graphical Mode vs Console Mode: Calculation Types.

Link to the Sections		
AM CalculatorAqueous Calculator	Binary Calculator	Diffusion Calculator
Equilibrium Calculator	Material to Material Calculator	Precipitation Calculator
Process Metallurgy Calculator	Property Model Calculator	Scheil Calculator
Ternary Calculator		

AM Calculator

The AM Calculator is available with the Additive Manufacturing (AM) Module. It is used to predict the temperature distribution and melt pool geometry as a function of process parameters. There are these simulation types: **Steady-state**, **Transient**, **Transient with heat source from Steady-state**, and **Evaporation with Steady-state**.

For **Steady-state** simulations, you can also choose to run different *Calculation Types*:

- **Single point**: The standard steady-state calculation for a single set of processing parameters. This is available with all heat sources.
- **Heat Source Calibration**: To calibrate a heat source based on the imported or entered experimental data instead of performing a single point calculation. This is available with **Gaussian**, **Double ellipsoidal**, or **Conical** heat sources.
- **Batch**: To include power and scan speed data, which is read from a file such as a spreadsheet. You can optionally include experimental melt pool width and depth (if there is data), and compare this to the calculated results using a **Parity plot** on the Plot Renderer. Other plots are also available. This is available with all heat sources.
- **Grid**: To evaluate two axis variables of power and scanning speeds in the specified range and number of steps. This is available with all heat sources.

Aqueous Calculator

The following calculation types are available for an Aqueous Calculator activity node:

- **Single equilibrium** (no axes): To calculate a single point. The results from this calculation are displayed in the **Event Log**.
- **One Axis**: To vary a quantity on the X-axis. This is useful for stepping in pH and Eh for aqueous calculations.
- **Phase diagram**: To calculate in a defined multicomponent heterogeneous system, from one or more initial equilibria. A phase diagram is usually mapped within a specific space that is constructed by two (or more) defined independent mapping axis-variables. This is how to produce a Pourbaix diagram with the Aqueous Calculator.

Binary Calculator

The following calculation types are available for a Binary Calculator activity node:

- **Phase diagram**: To calculate in a defined multicomponent heterogeneous system, from one or more initial equilibria. A phase diagram is usually mapped within a specific space that is constructed by two (or more) defined independent mapping axis-variables.
- **Gibbs energy curves**: To calculate at a constant temperature over the whole composition range.
- **Activity curves**: To calculate at a constant temperature over the whole composition range.
- **Phase fractions**: To calculate as a function of temperature at a constant composition.

Diffusion Calculator

Diffusion calculations are done with the to have detailed simulation of diffusion controlled reactions in multicomponent systems. There are no calculation types you need to choose when setting up your simulation.

Equilibrium Calculator

The following calculation types are available for an activity node:

- **Single equilibrium** (no axes): To calculate a single point. The results from this calculation are displayed in the **Event Log**.
- **One Axis**: To vary a quantity on the X-axis.
- **Grid**: Computes the equilibrium of each grid point in a two-dimensional grid.
- **Phase diagram**: To calculate in a defined multicomponent heterogeneous system, from one or more initial equilibria. A phase diagram is usually mapped within a specific space that is constructed by two (or more) defined independent mapping axis-variables.

Material to Material Calculator

The following calculation types are available for a activity node:

- **Single equilibrium** (no axes): To calculate a single point. The results from this calculation are displayed in the **Visualizations** window if a Table Renderer is used.
- **One Axis**: To vary a quantity on the *X*-axis; the fraction of one of the materials or temperature.
- **Phase diagram**: To calculate a section in a multicomponent system between two materials, transitioning from one into the other. The phase diagram is mapped within a specific space that is constructed by the two mapping axis-variables; the fraction of one of the materials and temperature.

See Plot Types for Plot Renderer choices related to the **One Axis** *Calculation Type*.

Precipitation Calculator

The following calculation types are available for a activity node:

- **Isothermal**: Precipitation simulation at constant temperature.
- **Non-isothermal**: Precipitation simulation with user-defined temperature profile.
- **TTT Diagram**: Time-Temperature-Transformation diagram calculation.
- **CCT Diagram**: Continuous Cooling Transformation diagram calculation.

Process Metallurgy Calculator

The following calculation types are available for a activity node when doing an **Equilibrium** simulation.

- **Single**: To calculate a single point. The results from this calculation can be displayed in the **Visualizations** window using a **Table Renderer**.
- **One Axis**: To vary a quantity on the *X*-axis.
- **Grid**: Evaluates two axis variables of the selected quantities in the specified range and number of steps.
- **Uncertainty**: Evaluates calculations where the values of the quantities are sampled from Gaussian distributions. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The result is visualized as a histogram or normal probability plot by adding a Plot Render activity.

Property Model Calculator

The following calculation types are available for a activity node:

- **Single** to calculate a single point. Any model can use this calculation type and no additional settings are required. The results from this calculation are displayed in the **Event Log** or if a **Table Renderer** is used, in the **Visualizations** window.
- **One Axis**: To vary a quantity on the *X*-axis.
- **Grid**: Evaluates two axis variables of the selected quantities in the specified range and number of steps.
- **Min/Max**: Evaluates the Property Model(s) for all variations of the selected quantities at the given limits. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The total minimum and maximum of the model(s) results are shown in the **Event** log.
- **Uncertainty**: Evaluates the Property Model(s) where the values of the quantities are sampled from Gaussian distributions. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The result is visualized as a histogram or normal probability plot by adding a Plot Renderer activity.

- **Batch**: Use this to allow for high throughput calculations and read data from a file, such as a spreadsheet, rather than, for example, having a fixed grid or random values. Results from these batch calculations can then be compared to experimental values (as long as this data is included), using a **Cross plot** on the Plot Renderer.

Scheil Calculator

When using a activity node there are no calculation types you need to choose when setting up your simulation.

Ternary Calculator

The following calculation types are available for a activity node:

- **Isothermal section**: To calculate the ternary system for the whole composition range.
- **Monovariant lines**: To calculate the variation of the liquid compositions with temperature.
- **Liquidus projection**: The projection liquid surface and the monovariant lines are calculated over the given temperature range.

Working with Batch Calculations

When defining a **Batch** calculation for a Property Model Calculator, you choose to load (import) a configuration data file that contains predefined data. The *Batch Control* settings, which are described in this section, are found on the Property Model Calculator **Configuration** window. See Configuration Window Settings.

Batch calculations are also available with the Additive Manufacturing (AM) Module and described separately.

What Can Be Included with the Data File?

The columns that can be included in the data file are:

- Element compositions and the associated unit
- Temperature unit

Specific temperatures i.e. *evaluation temperature* are entered as a **Parameter**.

- Experimental data and a key word
- Parameters (as long as these are both available and selected for a Property Model)
- An identifier (ID) for each row of data

Only these types of data are read / used in calculations. It is important that the data file contents are correctly entered in order for the calculation to perform smoothly. The software runs a validation of the data file prior to allowing you to perform a calculation. Warnings related to this validation display on the Property Model Calculator. You can also skip this data file validation for composition or parameter inconsistencies. See below for details.

Batch Controls

For the settings in this section, it is recommended you read the Data File Rules, Data File Requirements, and Skip Validation of Data File sections prior to importing the data file.

In the **Data file** field, either enter a file path or click the load data file button ( ) to navigate to a data file such as an Excel spreadsheet (with `*.xls` or `*.xlsx` extensions) or a `*.csv` file. You can also use other programs (e.g. Google Sheets) to enter data and export to a CSV format that can be read by the software.

Click **Open** to import the data. In the **Data file** field you can see the file path to the selected file. The next time you click the load data file button ( ) the program remembers the last location from where the file is opened.

Choose the delimiter—**Comma** (`,`), **Colon** (`:`), **Equals sign** (`=`), **Semicolon** (`;`), or **Tab**—that matches the delimiter in the data file and click the **Reload** ( ) button.

The data is imported and displays on the Property Model Calculator:

- The data are used for the applicable fields that must match what already exists as a Property Model parameter (e.g. critical radius, grain size, etc.) as well as the composition, temperature, and units that you want to run the calculation for. Also, if the dependent element composition is not included in the data file, the batch calculation then sets the dependent element to be the same as defined in the user interface.
- The calculation runs once for every row of data included in the file.

When the data file is imported into Thermo-Calc, there is also a **Row** column autogenerated by Thermo-Calc.

Select the **Set zero amount to value (in mole-/mass-fraction)** to enter a small value for the mole/mass-fraction in cases where a Property Model has problems calculating zero amounts of elements.

Select the **Skip validation of data file** checkbox to allow a calculation to perform using the data file even when certain criteria are not met.

When selected, the validation of the data file is skipped:

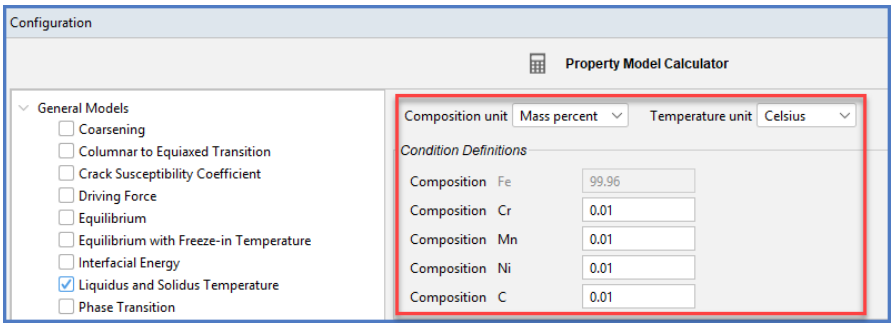
- If the **Composition** (elements) do not match the system composition entered on the GUI in the System Definer or Property Model Calculator.
- If one or more **Parameters** are not correctly entered, not selected for the specific Property Model, or are unavailable with the selected Property Model, then these are ignored in the calculation.

If there are any data file validation error(s), a tooltip on the **Perform** button lists and describes these.

Data File Rules

General Rules

- No abbreviations are allowed.
- All header text must be in English, i.e. no translations into other languages will be read correctly by the data file.
- For the settings on the Property Model Calculator (at the top, **Composition unit** and **Temperature unit**, and then under *Condition Definitions*, **Composition**) when there is nothing specified in the data file, the default is taken from the GUI and used in the calculation. Also, if the dependent element composition is not included in the data file, the batch calculation then sets the dependent element to be the same as defined in the user interface.

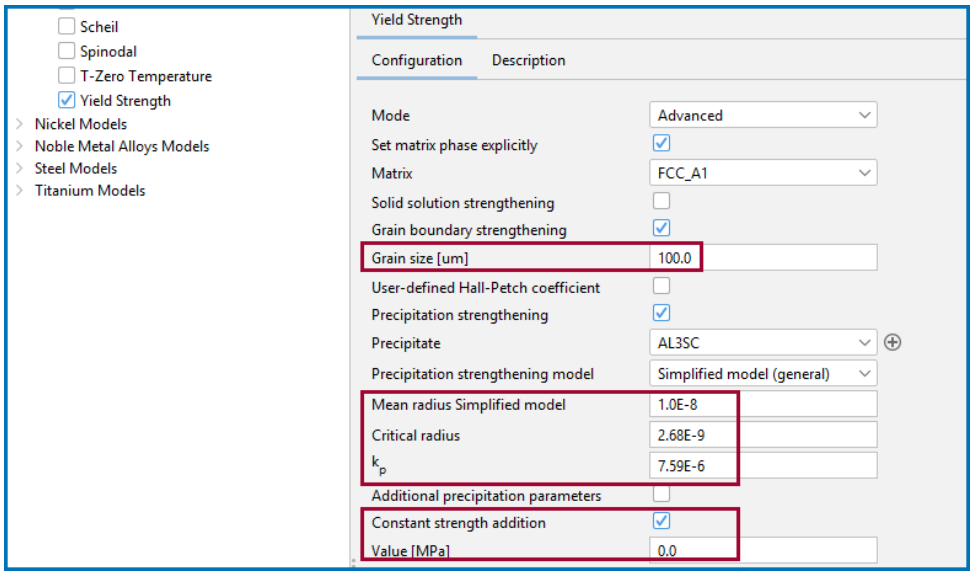


Parameter, Parameter Name, and Parameter Value Rules

> Only numeric parameters available on the **Configuration** tab for the selected Property Model can be included in the calculation.

The column entries for the Parameter + *<parameter name>* plus the row entries for the *<parameter value>* must adhere to these rules. The validation checks for inconsistencies, which could be the result of any of the following criteria not being met.

- When including **Parameters** in the data file, these must be existing Property Model parameters and the applicable Property Model must be selected on the GUI.
- The *<parameter name>* is case sensitive and must be entered exactly as you see on the GUI, no abbreviations are allowed.
- The *<parameter value>* must be numeric or it is not included in the calculation.



An example of the Yield Strength Property Model numeric parameters available for the Batch calculations. These are available on the Property Model Calculator Configuration tab after selecting Yield Strength under General Models. The parameter name must be entered in the data file exactly as you see on the GUI. No parameters from other calculators are accepted.

Data File Requirements

Only the columns described here are read / used in the calculation. It is important to enter the information exactly as described. It is recommended that the data file is cleaned up before importing / loading it and performing calculations. All header text must also be written in English, i.e. no translations into other languages will be read correctly by the data file.

In the table below, `code font` indicates something entered into the data file (or it is an example) and any *<text in italic with angle brackets>* is a generic name for an entry.

Column Heading Description	*Column Heading Requirements and Options*	*Row Cell Requirements and Options*
Composition Each element of the composition is in a separate heading column using the *<element short name>* e.g. Fe, C, Mn, Si, etc.	Enter an *<element short name>*. It is not case sensitive. For example: `Fe`. It is not case sensitive, so alternatives in this example are `fe` or `FE`.	Valid format and entries of the *<composition value>*: • A number for the composition e.g. `0.1`, `8.7`, `1.00E-05`, etc. • Text entry `Bal` to define the balanced element. • Empty cells are read as zero (`0`) amounts.
Composition unit	Enter the text `Composition unit`. No abbreviations allowed but it is not case sensitive. For example, it is acceptable to enter `composition unit` or `Composition Unit`, or `COMPOSITION UNIT`, etc.	Valid format and entries of the *<composition unit>*: • `mass_pct` • `mass_frac` • `mole_pct` • `mole_frac`
Temperature unit	Enter the text `Temperature unit`. No abbreviations allowed but it is not case sensitive. For example, it is acceptable to enter `temperature unit` or `Temperature`	Valid format and entries – • `C` • `F` • `K`

Column Heading Description	*Column Heading Requirements and Options*	*Row Cell Requirements and Options*
	`Unit`, or `TEMPERATURE UNIT`, etc.	Specific temperatures i.e. *evaluation temperature* are entered as a **Parameter**. See below.
Parameters with numerical values only. The heading column is defined with `Param` in front of a Property Model *<parameter name>*	`Param` + *<parameter name>* For example: `Param Critical radius` The *<parameter name>* has requirements– • It is case sensitive based on the available and selected Property Model parameter • It must be an existing Property Model parameter and be included with any selected Property Model • No abbreviations	Valid format and entries – The *<parameter value>* must be numeric or it is not included in the calculation. An example of an accepted Property Model parameter is for the **Yield Strength** model where *Grain size* and *Critical radius* are accepted (these have fields for numerical entries) but you cannot use *Matrix* or *Precipitate* as these are text choices from a drop down list. There are several temperature parameters based on the Property Model. As with all parameters, enter what you see on the Configuration tab, i.e. `Param Evaluation temperature`, or `Param Annealing temperature`, etc. About the Temperature Options for Property Models
Experimental value. The heading column is defined with `Exp` followed by any *<keyword>*.	`Exp` + *<keyword>* where the *<keyword>* is defined by the user. For example: `Exp Ms`.The keyword is not case sensitive so alternatives are `MS` or `ms`.	Valid format and entries – • Each *<experimental value>* must be numeric
Identifier (i.e. an alloy name). The heading column is defined as `Id`	Enter the text `Id`. It is not case sensitive so alternatives are `id` or `ID`.	Valid format and entries – • An *<identifier>* can be any text or number defined by the user.

Data File Example and Column Definitions

	A	B	C	D	E	F	G	H	I
1	Id	Fe	C	Cr	Exp Ms C	Exp Ms	Composition unit	Temperature unit	Param Critical radius
2	2	Bal	0.000928	0.0149	529.85	803	mole_frac	K	2.88E-09
3	3	Bal	0.000928	0.0449	489.85	763	mole_frac	K	3.88E-09
4	4	Bal	0.000324	0.0422	499.85	773	mole_frac	K	4.88E-09

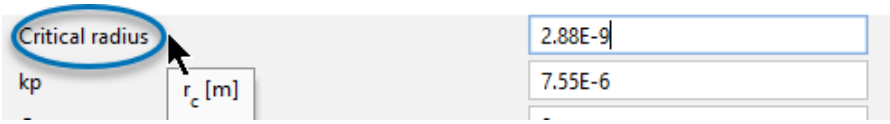
This is an example of data entered into an Excel spreadsheet. When this is imported into Thermo-Calc, an additional "Row" column is automatically added and is a way for you to locate any errors in the data file that are identified as needing correction or adjustment to allow the program to read the file.

- A1 to A4 is the **Identifier** column and rows. The heading text is `Id` and then in the entries in rows A2 to A4 can be text or numbers, for example it might be an alloy name or another user-defined *<identifier>*.

> When the data file is imported into Thermo-Calc, there is also a **Row** column autogenerated by Thermo-Calc.

- B1 to B4 is the **Composition** column and rows for the element `Fe`. In this example, `Bal` indicates that the balance of the composition will be calculated for this column after the *<composition values>* for `C` and `Cr` are entered.
- C1 to C4 and D1 to D4 are the **Composition** columns each for `C` and `Cr` with the specific *<composition values>*, e.g. `0.000928` for `C` and `0.0149` for `Cr` in row 2.
- E1 to E4 and F1 to F4 are the **Experimental Value** columns and rows. The header starts with `Exp` and then user-defined *<keywords>* are added, e.g. `Ms C` and `Ms`. Then specific *<experimental values>* are entered, e.g. `529.85` for `Ms C` and `803` for `Ms` in row 2.
- G1 and H1 are the headings for the **Composition unit** and **Temperature unit** columns. No abbreviations allowed but it is NOT case sensitive. Then the rows G2 to G4 and H2 to H4 include an accepted text value e.g. `mole_frac` for the composition unit and `K` for the temperature unit.
- I1 is the **Parameter** heading where you need to enter `Param` followed by the parameter name `Critical radius`, which has numeric values entered in rows I2 to I4. The *<parameter name>* matches that on the GUI and is an available and selected

Property Model parameter.



Skip Validation of Data File

Select the **Skip validation of data file** checkbox to allow a calculation to perform using the data file even when certain criteria are not met.

When selected, the validation of the data file is skipped:

- If the **Composition** (elements) do not match the system composition entered on the GUI in the System Definer or Property Model Calculator.
- If one or more **Parameters** are not correctly entered, not selected for the specific Property Model, or are unavailable with the selected Property Model, then these are ignored in the calculation.

> If there are any data file validation error(s), a tooltip on the **Perform** button lists and describes these.

Skipping Composition Validation

If the **Composition** (elements) do not match the system composition entered on the GUI in the System Definer or Property Model Calculator then the default system composition is used for any missing elements after you select the **Skip validation of data file** checkbox.

This can occur when there are more elements included in the data file but not entered on the GUI, and then these are excluded from the calculation. For example, you might have too many or too few elements included in the data file compared to the composition entered on the System Definer, which is then further viewed under *Condition Definitions* on the Property Model Calculator **Configuration** window.

When configuring the System Definer, it is recommended you select the composition to match the composition in the data file. However, if this is not possible you can use this checkbox to override any differences of the composition included in the data file and use the GUI default.

Skipping Parameter Validation

If one or more **Parameters** are not correctly entered, not selected for the specific Property Model, or are unavailable with the selected Property Model, then these are ignored in the calculation after you select the **Skip validation of data file** checkbox.

For example, if a data file is uploaded and you are unable to perform the calculation, it means that one of the following criteria are not met for the `Param` columns and related to the *<parameter name>*.

- The parameter name is misspelled (does not match) the one on the GUI
- The parameter is not available with the selected Property Model.
- The parameter is not available with any Property Model.

It is best practice to use a data file that only includes available Property Model parameters. However, if this is not possible then use this checkbox to override the validation. Alternatives to skipping this validation, include removing the prefix `Param` from the data file (or delete this column), and confirming that the parameter you want to calculate is available and selected for the Property Model.

Plotting Experimental Data Against Simulation Results

You can plot experimental values loaded to the Property Model Calculator using the **Cross plot***Plot type* available on the Plot Renderer. There are also additional options for this *Calculation Type*. See Plot Types for a list and also Plot Type: Cross Plot and Statistical.

About the Uncertainty Calculations

The **Uncertainty** calculation in Thermo-Calc uses the values (the mean) entered for quantities under the *Condition Definitions* section as the starting point to estimate, within a certain probability, the true variation of the quantity. Uncertainty calculations are available with the **Property Model Calculator** and the **Process Metallurgy Calculator**.

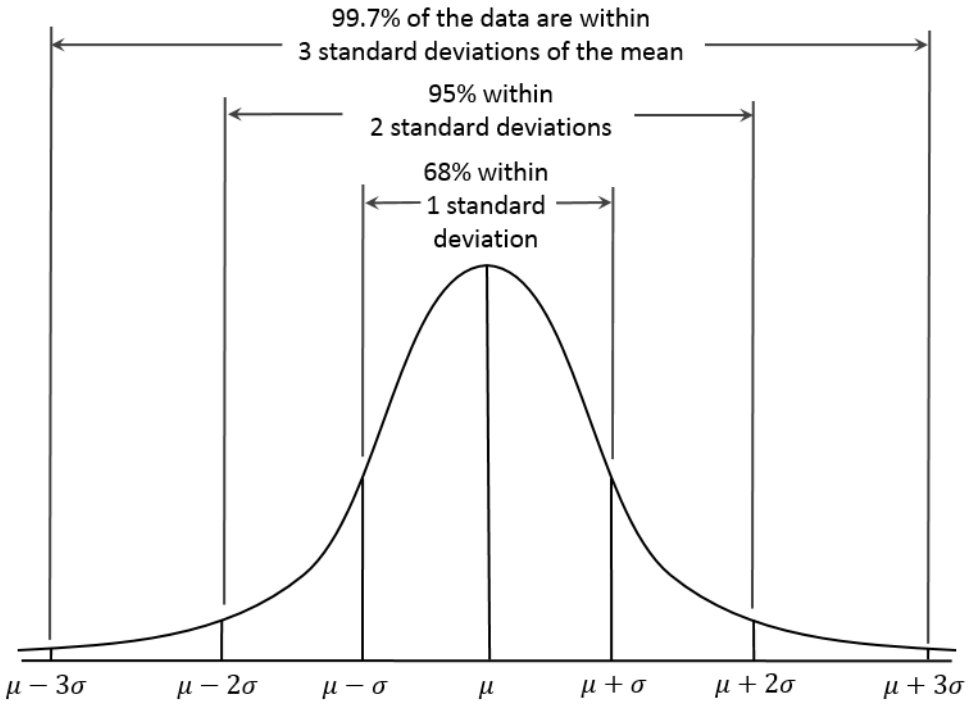
- Gaussian Distribution, the 3-Sigma Rule
- Condition Definitions and Sampling Settings
- Sampling Parameter Settings
- Histogram Plot
- Normal Probability Plot

Gaussian Distribution, the 3-Sigma Rule

An example of a Gaussian distribution is shown. The example uses the Phase Transition Property Model Settings and an **Uncertainty** *Calculation Type* to describe how the sampling of data is performed. The example PM_G_01: Phase Transition predicts the transition temperature to the unwanted brittle Sigma phase and shows how the temperature is influenced by changes to a steel alloy's composition.

- The *mean* is at the peak of the curve (labeled μ).
- The *standard deviation* (σ) is a plus and minus range, ±1σ, ±2σ or ±3σ, of the variance from the mean.

Image by Dan Kernler: https://en.wikipedia.org/wiki/Normal_distribution#/media/File:Empirical_Rule.PNG.

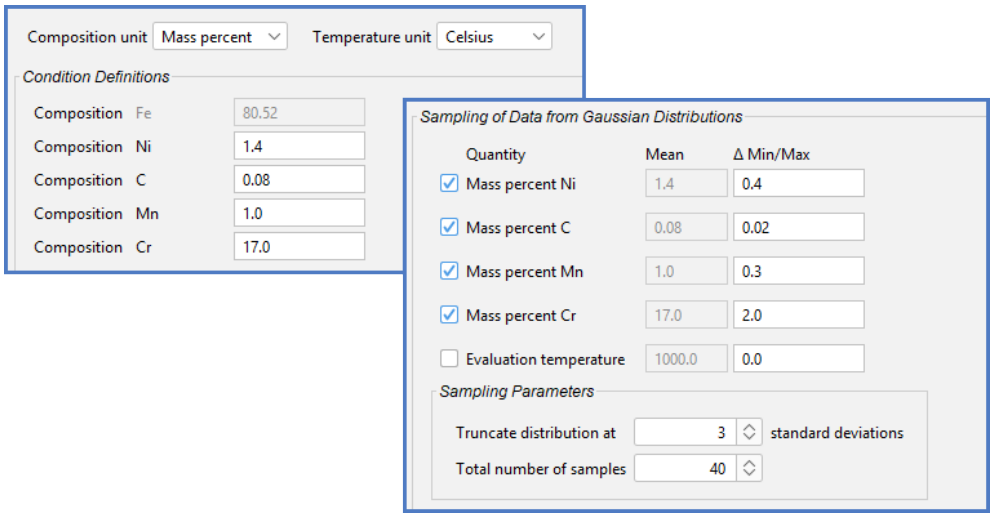


As long as the number of events (the sample size) is very large, then the Gaussian distribution function can be used to describe physical events. A Gaussian distribution is assumed to describe how each quantity varies in an uncertainty calculation, as shown next.

Condition Definitions and Sampling Settings

In Thermo-Calc, the mean of the quantity's distribution is defined in the *Condition Definitions* section. The **Mean** is then used in the *Sampling of Data from Gaussian Distributions* section as the starting point for how much you want to deviate from this value.

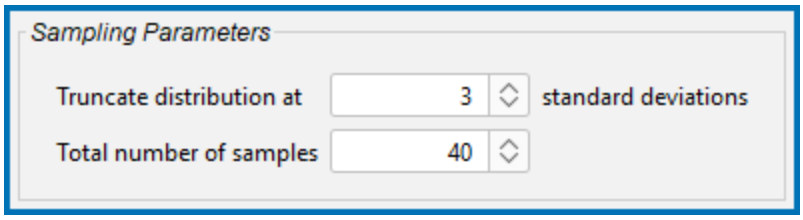
The mean defined under *Condition Definitions* is used during the sampling.



The values entered in the Δ **Min/Max** fields are the resulting width of the distribution corresponding to the 95% confidence interval (approximately μ ± 2σ) shown in *Gaussian distribution, the 3-sigma rule*.This confidence interval means that approximately 95% of the sampled values fall within these limits, as shown next.

Sampling Parameter Settings

The default value for truncating the distribution is set at **3 standard deviations** in the *Sampling Parameters* section. This is also where you set the **Total number of samples**. The default is 200. In order to maintain a Gaussian distribution for the varied quantities, this number should not be too low.

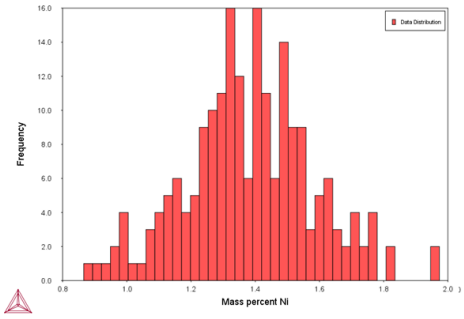


You can experiment by varying the conditions and the number of samples to see the distribution results smooth out as is to be expected based on the Central Limit Theorem, as shown in the histogram plot. You can also plot the results as a normal probability.

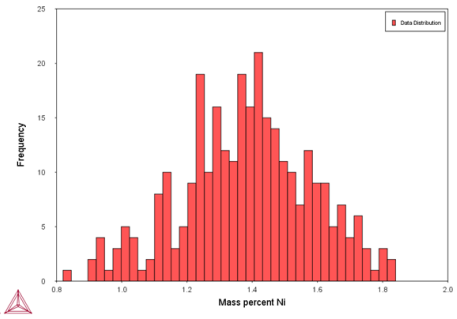
Histogram Plot

This series of histogram plots shows the uncertainty calculations sampling data from Gaussian distributions. On the **Plot Renderer** the variable is set to measure the **Composition** of **Ni**. It compares the Ni composition where the total sample size is increased. In the example, the initial sample size uses the default, 200, and then the sample size is increased to 300, 400, 600, 800, and 1000, showing how the plot follows the Gauss distribution.

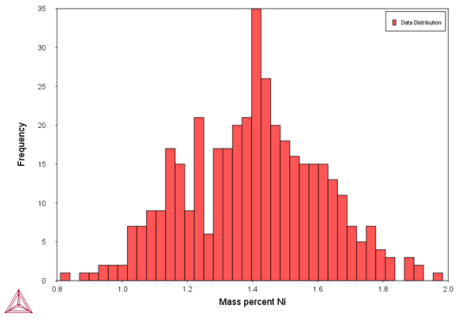
Total samples = 200



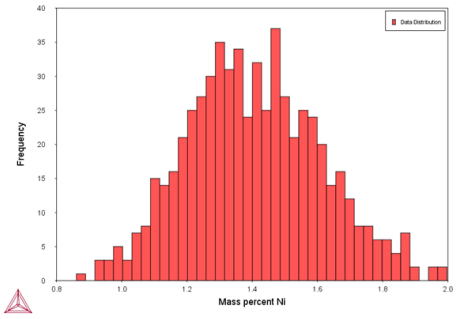
Total samples = 300



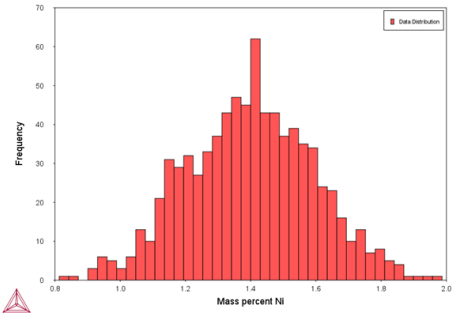
Total samples = 400



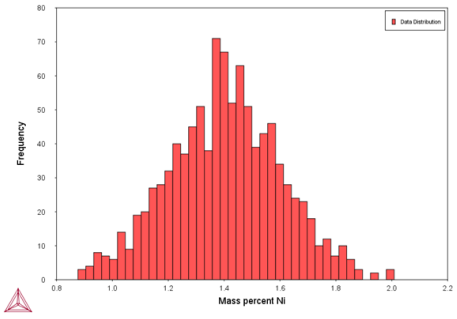
Total samples = 600



Total samples = 800

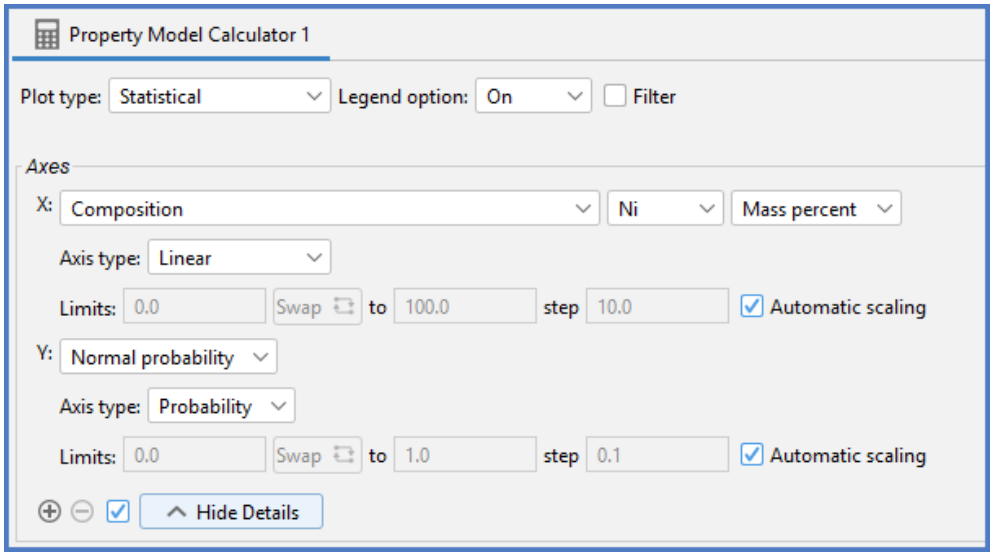


Total samples = 1000



Normal Probability Plot

You can also plot the results as a **Normal probability**. Continuing with this example, for the Property Model Calculator the *X* variable is plotted as **Composition** and the *Y* variable is plotted as the **Normal probability**.



This is a normal probability plot example of the uncertainty calculations sampling data from Gaussian distributions. It compares the relaxed condition where the total sample size is 200. The sampled data (blue line) closely follows the ideal normal distribution (red line). Deviations are naturally larger at the tails (≈1%Ni and ≈2%Ni) since the number of samples are fewer there compared to the center of the distribution.

Plot Types

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and, in most cases, *Calculation Type* selected.

The *Mode* plot types are related to groups of settings made available (or hidden) on the Plot Renderer, rather than a particular plot output type such as contour, cross plot, or heat map, for example.

The sections below list the *Plot types* available with the various Calculator and *Calculation Type* combinations.

- By Calculator
- By Plot Type
- By Calculation Type

Learn More

Calculation Types in Graphical Mode

There are a variety of combinations of Calculator and *Calculation Type* that offer different Plot Types. These are described in separate topics:

- Plot Type: Cross Plot and Statistical
- Plot Type: Heat Map, Contour, and 3D
- Plot Type: Parallel Coordinates

- Plot Type: Flexible Mode and Grouped Mode
- Plot Type: CCT Mode
- Plot Type: TTT Mode
- Plot Type: Simple Mode and Advanced Mode

If you also have a license for the Additive Manufacturing Module, there are additional plots available and described elsewhere, i.e. see About the AM Plot Types.

The following require additional licenses: Aqueous Calculator, Diffusion Calculator, Process Metallurgy Calculator, CCT Mode, and TTT Mode.

About Scheil Solidification Simulations

The Scheil Calculator is a calculator within Thermo-Calc that allows users to easily set up and perform Scheil solidification simulations, which are non-equilibrium transformations or partial-equilibrium transformations that result in an estimation of the solidification range of an alloy. The calculator is included in all Thermo-Calc installations. Users can also make Scheil solidification simulations using the Property Model Calculator, which offers the benefit of additional calculation types, such as Uncertainty, Min/Max, and Batch.

The Scheil options are briefly described here with links to configuration details available in the settings sections.

Scheil-Gulliver Solidification Calculations

In Graphical Mode, you use the Scheil Calculator activity node to simulate the various models available in Thermo-Calc or with the Add-on Modules or additional databases.

Thermo-Calc is often used to perform equilibrium calculations, but some non-equilibrium transformations or partial-equilibrium transformations can also be simulated.

A well-known example of a non-equilibrium calculation is the *Scheil-Gulliver solidification simulation*. In Thermo-Calc, the available Scheil-Gulliver solidification simulations are *classic* Scheil, Scheil with *back diffusion* in the primary phase, or Scheil with *solute trapping*. There are also configuration options available with *fast diffusers* for the classic and back diffusion models. Also learn about Homogenization, Segregation Profiles, and the Diffusion Module.

Classic Scheil Simulation

This is a Scheil simulation based on the well-known *Scheil-Gulliver* model. If this model is used without "fast diffusers" it is *Classic Scheil* simulation with the following assumptions:

- Diffusion in the liquid phase is assumed to be very fast, that is, infinitely fast.
- Diffusion in the solid phases is so slow that it can be ignored, that is, diffusion is assumed to be zero.
- The liquid/solid interface is in thermodynamic equilibrium.

In this Classic Scheil simulation the temperature is decreased step-by-step. When the temperature drops below the liquidus temperature the equilibrium amount and composition of solid and liquid phase is calculated. The solid phase is removed from the system and only the amount and composition of the liquid phase is used for the next calculation step at a lower temperature. Again, the equilibrium amount and composition of solid and liquid phase is calculated and again the solid phase is removed from the system for the next step. This procedure is repeated until the last liquid disappears.

This calculation procedure is equivalent to assuming that there is no diffusion in the solid phase and infinitely fast diffusion of all elements in the liquid phase. It has been shown to be a good approximation of the solidification of most alloys such as Ni-superalloys, Cu alloys, Al alloys, Mg alloys, and others. However, in materials with interstitial elements, such as carbon,

ignoring diffusion in the solid causes discrepancies with experimental results. Interstitial elements have much faster diffusion rates. The assumption of no diffusion in the solid phase during solidification is thus not correct at most industrial or lab-scale solidification rates.

For this reason, a variant of the Scheil simulation was developed and implemented in Thermo-Calc, where one or more elements can be defined as *fast diffusers*. See Other Options: Fast Diffusers and Scheil Simulations.

Scheil Simulation with Back Diffusion in Primary Phase

The *Scheil simulation with back diffusion in primary phase* kinetic model quantitatively takes into account the real back diffusion of all elements in the primary solid phase (typically the FCC or BCC phase). This model requires the use of both a thermodynamic and mobility database. The calculation also requires the cooling rate to be specified; a fast cooling rate allows for less time for back diffusion and the simulation result is similar to the classic Scheil-Gulliver solidification simulation. A very slow cooling rate allows for almost complete back diffusion, the solidification simulation is then close to an equilibrium calculation. It also requires that the size of the solidification domain is specified. In most cases this domain size corresponds to the secondary arm spacing, as this is where typically the liquid is trapped during solidification.

The secondary arm spacing also depends on the cooling rate. For this reason, a simple empirical relation between cooling rate and secondary arm spacing is predefined in Thermo-Calc.

For the *Scheil simulation with back diffusion in primary phase* model the following assumptions are made.

- Diffusion of all elements in the liquid phase is infinitely fast.
- Diffusion of all elements in the primary solid phase are quantitatively calculated using mobility data, a cooling rate and a domain size (typically this is the secondary arm spacing).
- The liquid/solid interface is in thermodynamic equilibrium.

Also see Other Options: Fast Diffusers and Scheil Simulations.

Scheil with Solute Trapping

The *Scheil with solute trapping* model simulates deviation from local equilibrium for the primary phase. It is useful for high solidification speeds, such as those seen in additive manufacturing applications.

For equilibrium- and classical Scheil-type solidification simulations thermodynamic equilibrium is established at the solid-liquid interface. This means that solutes are partitioned between the solid and liquid phases according to solidus and liquidus lines of the phase diagram. The assumption of thermodynamic equilibrium at the solid-liquid interface however, is invalid for very fast solidification rates, as encountered for example during additive manufacturing. The faster the solidification rate, the less the partitioning at the interface, which can be perceived as that solutes in the liquid are trapped in the advancing solid phase, hence the term *solute trapping*.

The *Scheil with solute trapping* model calculates the solute partitioning between liquid and primary solid that deviates from thermodynamic equilibrium due to solidification speed.

The following assumptions are made:

- Only one primary solid phase forms dendrite, NOT necessarily the first solid phase.
- Solute trapping in primary solid phase only. Other solid phases have equilibrium compositions following Scheil model.
- Dynamic liquidus for primary solid phases is dependent on solute trapping and solidification speed.
- Amounts of solid phases are dependent on solute trapping and solidification.

More theory details are in About Scheil with Solute Trapping.

Other Options: Fast Diffusers and Scheil Simulations

If a *Classic Scheil* or *Scheil simulation with back diffusion in primary phase* model is selected plus one or more *Fast diffuser* checkboxes selected, then Thermo-Calc takes into account the concept of the *fast diffuser*. Typically, C is defined as a fast diffuser, but also other elements such as N, O, or others can also be defined.

Fast diffuser does not quite define this since diffusion is not actually simulated. It is simply assumed that the “fast diffusers” distribute throughout the solid and liquid phase according to thermodynamic equilibrium. This corresponds to *infinitely fast diffusion* for the selected elements.

For a *Classic Scheil* model with the compositions defined with *Fast diffuser* the following assumptions are made.

- Diffusion of all elements in the liquid phase is infinitely fast.
- Diffusion of all elements in the solid phases, except the ones defined as “fast diffusers”, is zero.
- Diffusion of the elements defined as “fast diffusers” is infinitely fast in the solid phase.
- The liquid/solid interface is in thermodynamic equilibrium.

For a *Scheil simulation with back diffusion in primary phase* model with the compositions defined with *Fast diffuser* the following assumptions are made.

- Diffusion of all elements in the liquid phase is infinitely fast.
- Diffusion of all elements in the primary solid phase are quantitatively calculated using mobility data, a cooling rate and a domain size (typically this is the secondary arm spacing).
- Diffusion of the elements defined as “fast diffusers” is infinitely fast in the solid phase.
- The liquid/solid interface is in thermodynamic equilibrium.

The Classic Scheil simulation and Classic Scheil simulation with fast diffuser models can be considered *thermodynamic* models. There are clear limitations as a certain amount of back diffusion always takes place in the solid phase at real solidification.

You can also use the more sophisticated *Scheil simulation with back diffusion in primary phase* kinetic model. Adding the fast diffuser option to this can be useful, for example for interstitials like C in steels where these then equilibrate in all phases and not just the primary phase.

Homogenization, Segregation Profiles, and the Diffusion Module

Scheil calculations can be used in diffusion simulations with the Diffusion Module (DICTRA).

Homogenization is a process were you want to get rid of the composition segregation from solidification with a homogenization heat treatment. This composition segregation can be simulated with Scheil. Then with the Diffusion Module (DICTRA), you input the secondary dendrite arm spacing to get the right diffusion distances. With composition profile from file the idea is that you should be able to input for example a measured composition profile (from EDS/WDS, micro-probe etc). This could also be a segregation profile but also composition profiles over a weld, substrate/coating, diffusion couple, and so forth.

Summary

The available Scheil-Gulliver solidification simulations are *classic* Scheil, Scheil with *back diffusion* in the primary phase, or Scheil with *solute trapping*. There are also configuration options available with *fast diffusers* for the classic and back diffusion models.

There is also connectivity to the Diffusion Module (DICTRA) and *homogenization* where you collect data from a Scheil solidification calculation, which is then used as part of the kinetic homogenization simulation of segregated composition profiles.

Scheil in Graphical Mode vs Console Mode

The Scheil with back diffusion feature is only available for systems with diffusion data, i.e. this model requires the use of a mobility database.

In Thermo-Calc, the Scheil calculation allows the calculation of:

- The solidification range of an alloy.
- Depression of the solidus temperature due to segregation.
- Composition of the last liquid to disappear in segregation pockets.
- Phases formed on final solidification in segregation pockets.
- The composition gradient in the primary solid phase(s) (segregation profile).
- Solute trapping to simulate deviation from local equilibrium for the primary phase
- Kinetic homogenization simulation of segregated composition profile (diffusion calculations)

Read more on our website about applications for Sustainability. The webpage highlights several examples demonstrating how Thermo-Calc has been applied to address key sustainability challenges.

About Scheil with Solute Trapping

The *Scheil with solute trapping* model simulates deviation from local equilibrium for the primary phase. It is useful for high solidification speeds, such as those seen in additive manufacturing applications.

For equilibrium- and classical Scheil-type solidification simulations thermodynamic equilibrium is established at the solid-liquid interface. This means that solutes are partitioned between the solid and liquid phases according to solidus and liquidus lines of the phase diagram. The assumption of thermodynamic equilibrium at the solid-liquid interface however, is invalid for very fast solidification rates, as encountered for example during additive manufacturing. The faster the solidification rate, the less the partitioning at the interface, which can be perceived as that solutes in the liquid are trapped in the advancing solid phase, hence the term *solute trapping*.

The *Scheil with solute trapping* model calculates the solute partitioning between liquid and primary solid that deviates from thermodynamic equilibrium due to solidification speed.

The following assumptions are made:

- Only one primary solid phase forms dendrite, NOT necessarily the first solid phase.
- Solute trapping in primary solid phase only. Other solid phases have equilibrium compositions following Scheil model.
- Dynamic liquidus for primary solid phases is dependent on solute trapping and solidification speed.
- Amounts of solid phases are dependent on solute trapping and solidification.

Background Theory

The model is based on Aziz [1982Azi; 1988Azi] and Hillert [1999Hil], and extends to multicomponent systems. The motion of liquid/solid interface is regarded as two concurrent processes, trans-interface diffusion (solute transport across the interface leading to solute partitioning) and migration (liquid to solid transformation without changing composition).

Aziz and Hillert used slightly different formulations to describe the trans-interface diffusion. Aziz [1982Azi; 1988Azi] formulated the expression in terms of chemical reaction theory, describing the diffusion of the i th solute element (the dependent element being labeled as n in a n-component system) with respect to chemical potential gradient and interface velocity v as:

[*Eq. 1*] $$\left(X_i^L - X_i^S\right)\frac{v}{v_i^D} = X_i^S X_n^L\left(1-\psi_i^e\right) \quad (i=1,2,\ldots,n-1)$$

Where X_i^s and X_i^L are compositions (mole fractions) of primary solid and liquid at the interface, respectively. v_i^D is the diffusion velocity defined as:

[*Eq. 2*] $$v_i^D = \frac{D_i}{\lambda}$$

Where D_i is the trans-interface diffusivity and λ is the interface thickness. In the software, λ is treated as a constant of 1×10^{-9} m.

In Eq. 1 ψ_i^e is an activation term for diffusion:

[*Eq. 3*] $$\psi_i^e = exp\left[-\frac{\Delta\tilde{\mu}_i}{RT}\right]$$

Where $\Delta\tilde{\mu}_i$ is the diffusion potential difference:

[*Eq. 4*] $$\Delta\tilde{\mu}_i = \left(\mu_i^S - \mu_n^S\right) - \left(\mu_i^L - \mu_n^L\right)$$

Where $\mu_i^{\S}$ and μ_i^L are chemical potentials of i th element in the primary solid and liquid at the interface.

Hillert [1999Hil], on the other hand, formulated the expression based on diffusion theory as:

[*Eq. 5*] $$\left(X_i^L - X_i^S\right)\frac{v}{v_i^D} = -K_i\Delta\tilde{\mu}_i$$

Where:

[*Eq. 6*] $$K_i = \frac{X_n^L X_i^S}{RT}\exp\left(-\frac{\Delta\tilde{\mu}_i}{RT}\right)$$

For migration process, the formulation relates the free energy change, or driving force that is opposite to free energy change, to the interface velocity. The overall free energy change (termed as *driving energy*), including both trans-interface diffusion and migration processes, is defined as:

[*Eq. 7*] $$\Delta G^{DE} = \sum_{i=1}^{n} X_i^S\left[\mu_i^S - \mu_i^L\right]$$

The free energy change for migration process (termed as *migration energy*) is:

[*Eq. 8*] $$\Delta G^{ME} = \sum_{i=1}^{n} X_i^L\left[\mu_i^S - \mu_i^L\right]$$

The interface velocity is then related to the free energy change as:

[*Eq. 9*] $$v = v_0 \left[1 - \exp\left(\frac{\Delta G^E}{RT}\right)\right]$$

Where:

- ΔG^e can be either ΔG^{DE} or ΔG^{ME} defined in Eq. 7 and Eq. 8.
- v_0 is the maximum velocity limit when the free energy change becomes infinitely negative.

Additionally, the mass conservation within the interface is assumed:

[*Eq. 10*] $$\frac{X_i^0 - X_i^L}{X_i^S - X_i^L} = \frac{X_j^0 - X_j^L}{X_j^S - X_j^L} \quad (i \neq j, i, j = 1, 2, \ldots n-1)$$

Where X_i^0 is the far-field liquid composition.

Eq. 1 (for Aziz model) or Eq. 5 (for Hillert model), together with Eq. 9 and Eq. 10 are then used to calculate the solute partitioning at the interface between primary solid and liquid for multicomponent systems. Likewise, if replacing X_i^L with the initial alloying compositions, Eq. 1 (Eq. 5) and Eq. 9 are used to calculate the dynamic liquidus of the primary solid phase.

Solute trapping also reduces the volume fraction of other solid precipitates. The reduction factor is estimated by employing the effect of the solute trapping on the heat of fusion, which can be manifested by the liquid + primary solid phase boundaries in the phase diagrams by [1998Hil]:

[*Eq. 11*] $$\sum_{i=1}^{n} X_i^S \left(H_i^S - H_i^L\right) = -\frac{T}{dT} \sum_{i=1}^{n-1} \sum_{j=1}^{n-1} \left(X_i^S - X_i^L\right) g_{ji}^L dX_j^L$$

Where all values are determined at phase boundaries. g_{ij}^L is the second partial derivative of Gibbs free energy of liquid phase with respect to mole fraction. The left side of Eq. 11 is the enthalpy change when one (1) mole of primary solid with composition X_i^S is melted into a reservoir of liquid. Since we are interested in a ratio, the term that needs to be considered is:

[*Eq. 12*] $$H_f = \sum_{i=1}^{n-1} \sum_{j=1}^{n-1} \left(X_i^S - X_i^L\right) g_{ji}^L dX_j^L$$

The reduction factor is then obtained by comparing solute trapping with equilibrium values:

[*Eq. 13*] $$f = \frac{H_f^{ST}}{H_f^{eq}}$$

Scheil Calculator Configuration Settings

The Graphical Mode settings are described in Configuration Window Settings.

T_13: Scheil Solidification with Solute Trapping

On the **Configuration** window, these are the relevant settings related to solute trapping:

- **Trans-interface diffusivity** (D_i): Smaller value leads to larger solute trapping effect. Be cautious that $D_i < 2.0 \times 10^{-9} \frac{m^2}{s}$ may result in complete solute trapping and possibly numerical errors.
- **Maximum velocity for infinite driving force** (v_0): Smaller values lead to a larger solute trapping effect.
- Choose the solute trapping **Model** (**Aziz** or **Hillert**): **Hillert** model usually leads to a larger solute trapping effect, though **Aziz** model is recommended for overall numerical performance including calculating the amount of non-primary solid phases.
- **Interface driving force**: **Driving energy** ΔG^{DE} or **Migration energy** ΔG^{ME}. Using migration energy option leads to larger solute trapping effect, while using driving energy option is numerically more stable. It is recommended to using driving energy option and adjusting other parameters (e.g., trans-interface diffusivity) for desired solute trapping effect.

A mobility database is required.
Scheil with solute trapping	SOLUTE_TRAPPING command (turn on) then use the START_WIZARD command to answer prompts	Scheil Calculator > click the **Scheil with solute trapping** button on the Configuration window then enter the settings as needed.
Fast diffusers and Classic Scheil	Use the START_WIZARD command to answer the prompt`Fast diffusing components`where you enter the elements that diffuse fast in solid phases and can assume to be in equilibrium in the whole phase. E.g. C in a steel.	Scheil Calculator > click the **Classic Scheil** button plus one or more of the **Fast diffuser** checkboxes next to the composition(s) on the Configuration window then enter the settings as needed.
Fast diffusers and Scheil with back diffusion in the primary phase	USE_BACK DIFFUSION command (turn on) then use the START_WIZARD command to answer the prompt `Fast diffusing components`where you enter the elements that diffuse fast in solid phases and can assume to be in equilibrium in the whole phase. E.g. C in a steel.	Scheil Calculator > click the **Scheil with back diffusion in the primary phase** button plus one or more of the **Fast diffuser** checkboxes next to the composition(s) on the Configuration window then enter the settings as needed. A mobility database is required.

Type of Calculation	*Console Mode*	*Graphical Mode*
Homogenization	Use the EVALUATE_SEGREGATION_PROFILE command before START_WIZARD to generate the segregation profile to file. In DICTRA_MONITOR use INPUT_SCHEIL_ PROFILE for use of segregated profile in simulation. An additional license to the Diffusion Module (DICTRA) is needed to work with more than three components.	Use the **Homogenization** template under **Non-Equilibrium** to automatically set up the project tree with the defaults needed to work with this. An additional license to the Diffusion Module (DICTRA) is needed to work with more than three components.

Scheil Calculations Frequently Asked Questions

Below are some frequently asked questions (FAQs) related to Scheil calculations in Thermo-Calc. It is not intended to cover all the scenarios that can occur with such complex calculations. A particular focus is on the use and definition of variables available for plotting latent heat, heat, and apparent heat capacity, and the differences between Graphical Mode and Console Mode.

Latent Heat

What is the latent heat evolution for a Scheil solidification simulation?

Theory usually defines the latent heat as the isothermal enthalpy change of phase transformation at any chosen temperature. It is called *latent* because it is regarded as a potential heat release or uptake. Usually this is the transformation from liquid to solid.

However, most alloys, if not all, solidify non-isothermally. In the Scheil calculation the plotted quantity called *latent heat* might not follow the theoretical definition of latent heat. It is the cumulative enthalpy change of phase transformation.

There is no contribution from heat capacity, only from phase transformation.

How can I plot the latent heat evolution after a Scheil simulation?

In Graphical Mode, on the Plot Renderer node, select one of the **Axis variables**—**Latent heat per mole** or **Latent heat per gram**—to plot the quantity.

In Console Mode, the corresponding quantities are `NHR` or `BHR`. If you plot NH in Console Mode, you get two curves. The bottom curve is NHR, or the latent heat. See State Variables for Scheil for a list of the other variables.

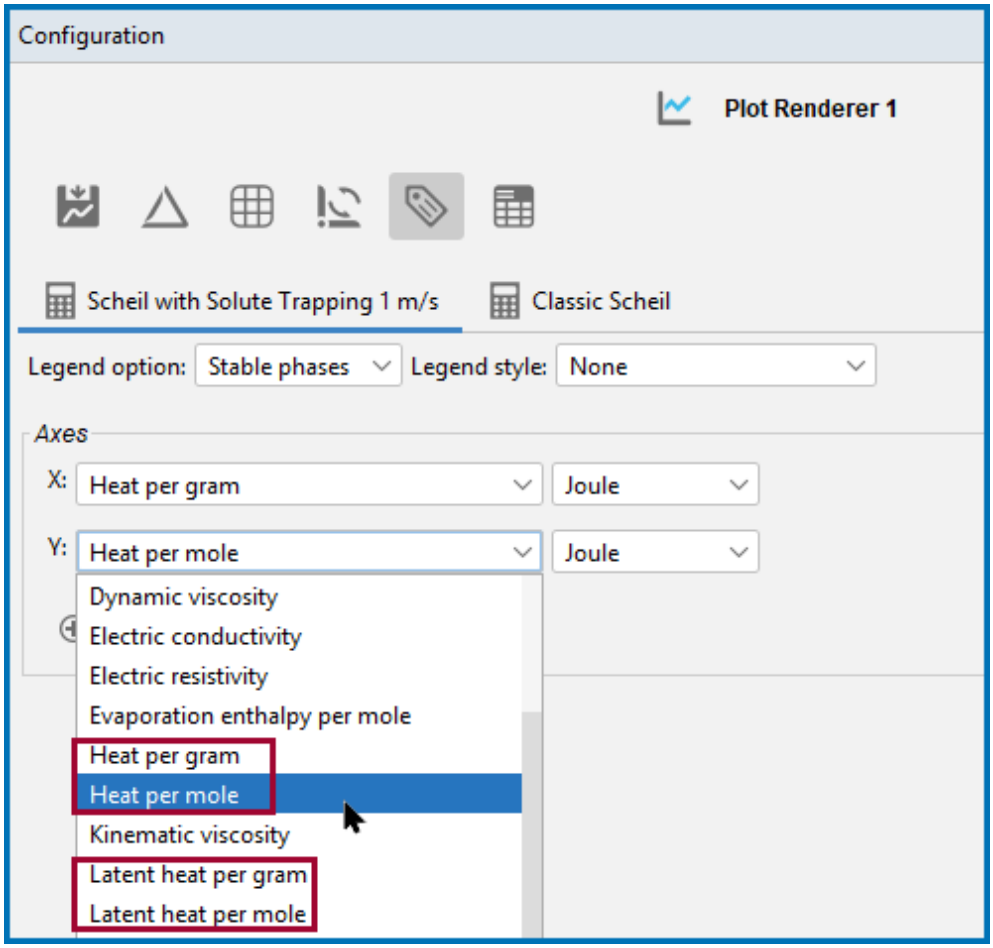
For more detail, see Why in Console Mode are there two curves when plotting heat evolution after a Scheil simulation?

Latent Heat vs Heat

What is the difference between the Latent heat per mole or gram and just Heat per mole or gram?

In Graphical Mode, on the Plot Renderer node, in addition to **Latent heat per mole** and **Latent heat per gram** you can also select one of the variables for each **Axes**—**Heat per mole** or **Heat per gram**. What is the difference?

Heat per mole or **Heat per gram** is the total molar (or specific) enthalpy of the system. This includes both the enthalpy change from phase transformations, and from the temperature change, which comes from the heat capacity.



Why in Console Mode are there two curves when plotting heat evolution after a

Scheil simulation?

The following is applicable to Console Mode.

The top curve is the total heat evolution and it is plotted with the quantity `NHV`. This is the total molar or specific enthalpy, including the contribution from both phase transformations and form heat capacity of the phases. The contribution from the solid phases are averaged.

The bottom curve is the axis quantity and it is plotted with the quantity `NHR`. This means that this is only the contribution of enthalpy changes from phase transformation from liquid; therefore it starts at 0 at the onset of melting.

Distribution of Component in Phase

How do you plot the distribution of component in phase?

In Graphical Mode the axis quantity is called **Distribution of component in phase**. This gives the distribution of that element as a fraction of the total molar inventory of that element, from 0 to 1 (0 to 100 % of the overall composition). For example, the total amount of Fe in all phases should then sum up to 1.

Be aware that if using the fast diffuser option there may be issues summing up to 1.

In Console Mode, `NN(Phase,Element)` shows the fraction of this element relative to its total amount in the system, residing in that phase. Here a value of 0.3 means 30 % of all the Fe in the system is in that particular phase.

You can also use wildcards, e.g. `NN(Phase,*)`, which shows all elements' respective fractions of the total in that phase (this does not sum up to 1). This is useful to get an overview of preferential partitioning of elements during the solidification process.

Also useful is plotting `NN(*,Element)`, where you see the distribution of the element over all phases in the system; these curves should all sum up to 1. Here, 0.3 of Fe in Liquid and 0.7 in FCC, would mean that 30 % of the total Fe-content in this alloy is still in the liquid, etc.

Due to calculation issues when working with fast diffusers, this command is not available in Console Mode.

Apparent Heat Capacity

What is the apparent heat capacity?

The apparent heat capacity is what is going to be measured experimentally; heat capacity is theoretically the derivative of enthalpy with respect to temperature. This apparent heat capacity includes both contributions from phase transformation and from temperature change.

Installed Examples

For Graphical Mode examples, see T_08: Scheil and Equilibrium Solidification, T_10: Scheil Solidification with Back Diffusion, and T_13: Scheil Solidification with Solute Trapping.

For Console Mode examples see Scheil-Gulliver Examples.

Website Video Tutorials and Application Example

Link to more information about Scheil Solidification Simulations on our website. There are also video tutorials related to some Scheil examples as part of a playlist on our YouTube channel and an application example using the Diffusion Module (DICTRA).

Self-paced Learning Hub

The Thermo-Calc Learning Hub has a module dedicated to Scheil Calculations.

Learn about Thermo-Calc and the Add-on Modules at your own pace with our comprehensive online Learning Hub. The Learning Hub includes courses for Thermo-Calc, the Diffusion Module (DICTRA), the Precipitation Module (TC-PRISMA), and the TC-Python SDK. In addition to introductory lectures, instructors walk through and discuss real world examples that correlate calculations with microstructures and other metallurgical concepts, spanning a wide range of material types.

Subscriptions also include access to live monthly office hours, where you can ask our experts about any of the content on the Learning Hub or your own materials challenges.

General Property Models

The Property Model Calculator is a calculator within Thermo-Calc that offers predictive models for material properties based on their chemical composition and temperature. The Property Model Calculator is included with all Thermo-Calc installations, along with a general set of models for setting up some of the most common calculations.

These General Property Models are briefly described here with links to configuration details available in the settings sections.

About the General Property Models

Property Models are used to predict and optimize properties of materials using models stored within the software where the calculations are set up in the Property Model Calculator.

As a starting point, the **Property Navigator** can more quickly help guide you to set up the initial simulation. See Creating a Project with the Property Navigator.

What Models Are Available to All Users?

The following **General** Property Models are available with the Property Model Calculator: Coarsening, Columnar to Equiaxed Transition (CET), Crack Susceptibility Coefficient, Driving Force, Equilibrium, Equilibrium with Freeze-in Temperature, Interfacial Energy, Liquid and Solidus Temperature, Phase Transition, Scheil, Spinodal, T-Zero Temperature, and Yield Strength.

The **General Models** are available to all users.

To run calculations with the Add-on Property Model Libraries all require a valid maintenance license plus a license for the specific database version: **Nickel Models** (TCNI11 and newer + MOBNI5 and newer; **Noble Metal Alloys Models** (TCNOBL3 and newer); **Steel Models** (TCFE9 and newer + MOBFE4 and newer); **Titanium Models** (TCTI6 and newer).

About the Steel Model Library Property Models, About the Nickel Model Library Property Models, and About the Titanium Model Library Property Models, and About the Noble Metal Alloys Model Library Property Models.

Coarsening

The **Coarsening** Property Model, available as a General model with the Property Model Calculator, calculates the coarsening rate coefficient K of a spherical precipitate phase in a matrix phase. The output is the coarsening rate coefficient for the precipitate phase and the

interfacial energy between matrix and the precipitate phase.

See About the Coarsening Property Model and Coarsening Property Model Settings for background theory and input parameter details.

Columnar to Equiaxed Transition (CET)

The **Columnar to Equiaxed Transition** Property Model, available as a General model with the Property Model Calculator, calculates the fraction of equiaxed grains that correlates with a certain solidification condition, specifically thermal gradient (G) and solidification growth rate (v) (defined as the migration rate of the interface between liquid and primary solid), so that valuable information on the solidification microstructure can be obtained.

The Model formulation consists of two essential steps (1) to determine the dendrite tip radius and tip undercooling, and (2) to apply the calculated undercooling to the CET Model.

See About the Columnar to Equiaxed Transition (CET) Property Model and Columnar to Equiaxed Transition (CET) Property Model Settings for background theory and input parameter details.

Crack Susceptibility Coefficient

The **Crack Susceptibility Coefficient** Property Model, available as a General model with the Property Model Calculator, calculates the crack susceptibility coefficient, which describes the risk or tendency of a material to experience cracking or *hot tearing* during solidification. Cracking/hot tearing is one of the most common and serious defects encountered during the casting of, for example, aluminum alloys. In general, it is defined by the formation of a macroscopic fissure in a casting because of stress and the associated strain, generated during cooling, at a temperature above the non-equilibrium solidus. Crack susceptibility is also referred to as solidification cracking, hot cracking, hot shortness, supersolidus cracking, and shrinkage brittleness. The Crack Susceptibility Coefficient (CSC) is calculated using Scheil results with three different model options: *Clyne and Davies*, *Kou*, and *Easton*.

See About the Crack Susceptibility Coefficient Property Model and Crack Susceptibility Coefficient Property Model Settings for background theory and input parameter details.

Driving Force

The **Driving Force** Property Model, available as a General model with the Property Model Calculator, calculates the thermodynamic driving force for a phase as well as the normalized thermodynamic driving force (i.e., the driving force divided by R*T where R is the ideal gas constant and T is the evaluation temperature).

See About the Driving Force Property Model and Driving Force Property Model Settings for input parameter details.

Equilibrium

The **Equilibrium** Property Model, available as a General model with the Property Model Calculator, calculates the equilibrium for the given conditions. You can also define additional function definitions.

When you use this Model with the **Property Model Calculator**, it is the same calculation result as when you are using an **Equilibrium Calculator** with the **Single equilibrium** calculation type.

See About the Equilibrium Property Model and Equilibrium Property Model Settings for input parameter details.

Equilibrium with Freeze-in Temperature

The **Equilibrium with Freeze-in Temperature** Property Model, available as a General model with the Property Model Calculator, calculates equilibrium at the freeze-in temperature and evaluates the properties at a different evaluation temperature. The assumption is that diffusion and phase transformations are negligible below the freeze-in temperature and, therefore, the phase amounts and phase compositions do not change below the freeze-in temperature. Typically, the freeze-in occurs during cooling where equilibrium can be assumed above the freeze-in temperature.

See About the Equilibrium with Freeze-in Temperature Property Model and Equilibrium with Freeze-in Temperature Property Model Settings for background information and input parameter details.

Interfacial Energy

The **Interfacial Energy** Property Model, available as a General model with the Property Model Calculator, estimates the interfacial energy between a matrix phase and a precipitate phase using thermodynamic data from a CALPHAD database. The approximation model is based on Becker's bond energy approach and is also available in Precipitation Module (TC-PRISMA).

In the actual calculation, the coefficients taken distinguish between only bcc and fcc structure for the (110) and (111) lattice plane, respectively. For other planes and/or other phases, the estimate is approximate. In most situations, it is recommended to perform calibrations against some experimental data because the interfacial energy is dependent on so many factors that are ignored in the estimation, for example entropy, incoherency, orientation, and curvature, etc. Uncertainty factors must also be considered as thermodynamic data in CALPHAD databases are not always accurate.

See About the Interfacial Energy Property Model and Interfacial Energy Property Model Settings for background information and input parameter details.

Liquid and Solidus Temperature

The **Liquid and Solidus Temperature** Property Model, available as a General model with the Property Model Calculator, calculates the equilibrium solidification range in terms of temperature. If only the liquidus temperature is required, the calculation times are reduced.

See About the Liquid and Solidus Temperature Property Model and Liquid and Solidus Temperature Property Model Settings for input parameter details.

Phase Transition

The **Phase Transition** Property Model, available as a General model with the Property Model Calculator, calculates the *phase transition* point, or the point at which a new phase may form from a matrix phase when varying a defined condition. This model can be useful to determine melting temperature, boiling temperature, or solubility limits. The Model performs searches for a phase transition between the matrix phase and the “phase to form” by varying either

temperature or composition of the system. The direction of the search (positive, negative, or both) can be specified.

See About the Phase Transition Property Model and Phase Transition Property Model Settings for input parameter details.

Scheil

The **Scheil** Property Model, available as a General model with the Property Model Calculator, calculates solidification under the Scheil assumption. Many model input parameters are taken from the Scheil Calculator, and model results are available for key aspects of solidification, i.e., liquidus, solidus, freezing range, and fractions of various phase combinations. In addition, properties of the as-solidified material can be evaluated below the solidification temperature. Three Scheil calculation types (Classic, Scheil with back diffusion in the primary phase, and Scheil with solute trapping) are available.

See About the Scheil Property Model, Scheil Property Model Settings, and Scheil Advanced Options: Property Models.

Spinodal

The **Spinodal** Property Model, available as a General model with the Property Model Calculator, calculates the spinodal line. The spinodal is defined by the condition where the second derivative of Gibbs free energy is zero (`d2G/dx2 = 0`). The Model searches for the Spinodal "solution" for the spinodal phase by varying either temperature or composition in mass percent, mole percent, mass fraction, or mole fraction (e.g. mass percent Fe, mole percent Fe, and so forth). Up to two spinodal solutions can be found.

When within the miscibility gap, but above the spinodal curve, phase transformation occurs by classical nucleation and growth of the spinodal phase. When within the miscibility gap, but below the spinodal curve, the phase transformation occur by spinodal decomposition of the spinodal phase.

See About the Spinodal Property Model and Spinodal Property Model Settings for background information and input parameter details.

T-Zero Temperature

The **T-Zero Temperature** Property Model, available as a General model with the Property Model Calculator, calculates the so-called $\mathbf{T_0}$ line.

The T_0 temperature is defined as the temperature where two phases of identical chemical composition have the same molar Gibbs free energy. This temperature is an important quantity in the field of diffusionless phase transformations, e.g. martensitic transformation, since it is the upper limit where diffusionless phase transformations can occur.

See About the T0 Temperature Property Model and T0 Temperature Property Model Settings for background information and input parameter details.

Yield Strength

The **Yield Strength** Property Model, available as a General model with the Property Model Calculator, calculates yield stress. It returns the calculated yield strength at the desired evaluation temperature for the specified material using the equilibrium phase fractions calculated at the annealing temperature. Then you can further define the following contributions to the total yield stress:

- Intrinsic strength (σ_i) for the pure elements,
- Grain boundary strengthening (σ_{gb}),
- Solid solution strengthening (σ_{ss}),
- Precipitation strengthening (σ_p), and
- A user set, constant strength contribution (σ_c).

See About the Yield Strength Property Model and Yield Strength: Simplified Mode Settings or Yield Strength: Advanced Mode Settings for background information and input parameter details.

Property Model Calculation Types

- **Single** to calculate a single point. Any model can use this calculation type and no additional settings are required. The results from this calculation are displayed in the **Event Log** or if a **Table Renderer** is used, in the **Visualizations** window.
- **One Axis**: To vary a quantity on the *X*-axis.
- **Grid**: Evaluates two axis variables of the selected quantities in the specified range and number of steps.

- **Min/Max**: Evaluates the Property Model(s) for all variations of the selected quantities at the given limits. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The total minimum and maximum of the model(s) results are shown in the **Event** log.
- **Uncertainty**: Evaluates the Property Model(s) where the values of the quantities are sampled from Gaussian distributions. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The result is visualized as a histogram or normal probability plot by adding a Plot Renderer activity.
- **Batch**: Use this to allow for high throughput calculations and read data from a file, such as a spreadsheet, rather than, for example, having a fixed grid or random values. Results from these batch calculations can then be compared to experimental values (as long as this data is included), using a **Cross plot** on the Plot Renderer.

Property Model Abbreviations

When working with result quantities or when choosing properties via the Property Navigator, it is important to know which specific Property Model it is associated with. It is useful in particular when you are calculating two or more Property Models that share names for the quantities or properties.

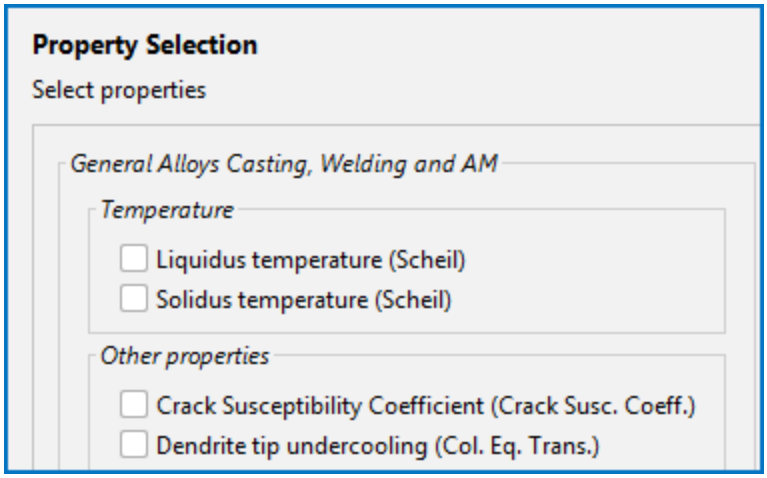
This is relevant, for example, when you are:

- Using the **Property Navigator** and on the **Property Selection** window.
- Selecting quantities on the **Plot Renderer** or **Table Renderer Configuration** windows.

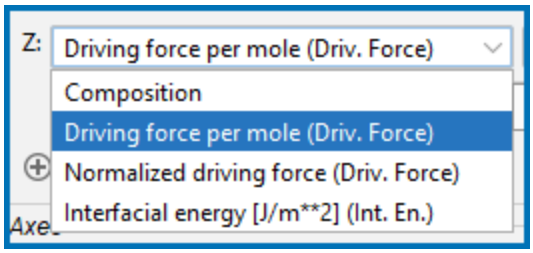
In these places, the quantity or property includes an abbreviated name for the Property Model in parentheses. Below are the full and abbreviated names for each Property Model.

This is not applicable to the **Equilibrium** Property Model.

Examples of Property and Quantity Selections



On the Property Navigator, the short names are included in parentheses next to the checkboxes for the available properties during the Property Selection step. In this example, for the Scheil (which does not need an abbreviation), Crack Susceptibility Coefficient (Crack Susc. Coeff.), and Columnar to Equiaxed Transition (Col. Eq. Trans) Models.



On a Plot Renderer, the short names are included in parentheses in the drop-down lists. In this example, for the Driving Force (Driv. Force) and Interfacial Energy (Int. En.) quantities.

Creating a Project with the Property Navigator and Plot Renderer: Configuration Settings

About the Columnar to Equiaxed Transition (CET) Property Model

The **Columnar to Equiaxed Transition** Property Model, available as a General model with the Property Model Calculator, calculates the fraction of equiaxed grains that correlates with a certain solidification condition, specifically thermal gradient (G) and solidification growth rate (v) (defined as the migration rate of the interface between liquid and primary solid), so that valuable information on the solidification microstructure can be obtained.

The Model formulation consists of two essential steps (1) to determine the dendrite tip radius and tip undercooling, and (2) to apply the calculated undercooling to the CET Model.

Use of this Property Model requires mobility data of liquid for the calculations. For all simulations both a thermodynamic and a mobility (kinetic) database must be selected on the System Definer.

Determine the Dendrite Tip Radius and Tip Undercooling

The first step determines the dendrite tip radius and tip undercooling, which is strongly dependent on v while slightly on G. For this Model, only primary solid is assumed to be stable while other secondary solid phases are ignored. Mullins and Sekerka instability analysis [1964Mul] and marginal stability criterion [1978(a)Lan; 1978(b)Lan; 1978Mül] are used to determine the tip radius. Meanwhile, tip undercooling, ΔT, is also calculated due to constitutional, curvature, and solute trapping effects. The multicomponent extension of this framework is achieved based on the approach developed by Hunziker [2001Hun]. It integrates with both thermodynamic and mobility databases so that key thermodynamic and kinetic properties for multicomponent alloy systems, such as liquidus, liquidus slope, solute partitioning coefficients, and diffusivities of liquid, etc., can be obtained directly from the databases. Solute trapping effects on liquidus, liquidus slope, and solute partitioning are also considered based on the model developed by Aziz [1982Azi] and extended to multicomponent systems.

Apply the Undercooling to the CET Model

The second step is to apply the calculated undercooling, ΔT, to the CET Model. The model developed by Gäumann et al. [2001Gäu] is used, which extended Hunt's model [1984Hun] to include high solidification rate. A slight modification [2018Hai] enables elimination of an

adjustment parameter by directly using ΔT. The model correlates G, ΔT (mostly in terms of v), and the fraction of equiaxed grains, ϕ, as

$$G = \frac{1}{n+1}\sqrt[3]{\frac{-4\pi N_0}{3\ln(1-\phi)}}\Delta T\left(1-\frac{\Delta T_n^{n+1}}{\Delta T^{n+1}}\right)$$

Where three materials related parameters are introduced:

- N_0: number of nucleation sites per unit volume, in the unit of 1/m^3
- ΔT_n: nucleation undercooling, in the unit of K
- n: exponent

About the Coarsening Property Model

The **Coarsening** Property Model, available as a General model with the Property Model Calculator, calculates the coarsening rate coefficient K of a spherical precipitate phase in a matrix phase. The output is the coarsening rate coefficient for the precipitate phase and the interfacial energy between matrix and the precipitate phase.

This Model requires that the thermodynamic database used includes descriptions of molar volume of the matrix and precipitates phases as well as a kinetic database with mobilities for the matrix phase.

Background Theory

In the coarsening regime where the driving force is capillarity, the change of mean particle radius evolves according to the equation:

$$\bar{r}^3 - \bar{r}_0^3 = Kt$$

Following Morral and Purdy [1994Mor], the rate constant of precipitating β phase in a multicomponent α phase is

$$K = \frac{8\sigma V_m^\beta}{9}\left[\left[c_i^\beta - c_i^\alpha\right]^T [M]^{-1}\left[c_k^\beta - c_k^\alpha\right]\right]^{-1}$$

The mobility matrix *M* is not the same as the mobilities that can be obtained directly from the Diffusion Module (DICTRA). The *M* matrix instead corresponds to the L'' matrix as defined by Andersson and Ågren [1992And].

Using the u-fractions that is defined as

$$u_k = \frac{x_k}{\sum_{j \in S} x_j}$$

where the summation only is performed over the substitutional elements give the final equation for the coarsening rate coefficient.

$$K = \frac{8\sigma V_m^\beta}{9}\left[\left[u_i^\beta - u_i^\alpha\right]^T [L''^\alpha_{jk}]^{-1}\left[u_k^\beta - u_k^\alpha\right]\right]^{-1}$$

The interfacial energy, σ, is calculated using the extended Becker's model (also available as the **Interfacial Energy** Property Model).

Configuration Settings

The settings are entered on the **Configuration** window for the Property Model Calculator and described in Coarsening Property Model Settings.

Example

For an example, see PM_G_02: Coarsening and Interfacial Energy.

About the Crack Susceptibility Coefficient Property Model

The **Crack Susceptibility Coefficient** Property Model, available as a General model with the Property Model Calculator, calculates the crack susceptibility coefficient, which describes the risk or tendency of a material to experience cracking or *hot tearing* during solidification. Cracking/hot tearing is one of the most common and serious defects encountered during the casting of, for example, aluminum alloys. In general, it is defined by the formation of a macroscopic fissure in a casting because of stress and the associated strain, generated during cooling, at a temperature above the non-equilibrium solidus. Crack susceptibility is also referred to as solidification cracking, hot cracking, hot shortness, supersolidus cracking, and shrinkage brittleness. The Crack Susceptibility Coefficient (CSC) is calculated using Scheil results with three different model options: *Clyne and Davies*, *Kou*, and *Easton*.

Input Parameters, Scheil Settings, and CSC Model Selection

The Crack Susceptibility Coefficient (CSC) is calculated using Scheil results with three different models to choose from: **Clyne and Davies** [1981Cly; 2006Yan], **Kou** [2015Kou], or **Easton** [2014Eas].

There are also several Scheil settings, including advanced options to choose from. Some additional theory and background is included below to supplement the settings input choices.

Clyne and Davis CSC Model Theory and Background

The original model assumptions are from Clyne and Davis [1981 Clyne]. Later, the experimental hot cracking susceptibility was collected from several sources by Yan and Lin [2006 Yan] and given as a probability 0-100%. The CSC calculated with the current model cannot be compared by absolute values with the experimental number; instead it is best to compare the trends, to see if it is increasing or decreasing. The experimental values are therefore given with relative coordinates and do not map directly to the calculated plot axes.

The following information describes the background when **Clyne and Davies** is chosen as the **CSC Model**.

The **Crack Susceptibility Coefficient** (CSC) was originally proposed by Clyne and Davies [1981Cly] to describe the effects of alloy composition on hot tearing.

The current model is based on the publication by Yan and Lin [2006Yan]. In Thermo-Calc, the CSC is calculated using Scheil and uses assumptions of cooling rates under the thermal conditions that the heat flow is proportional to $\frac{1}{\sqrt{time}}$.

The CSC is defined as $CSC = \frac{tV}{tR}$ where:

- tV is the time during solidification where the casting is vulnerable to cracking, and
- tR is the time available for the stress relief process.

The values for tV and tR are given by the thermal condition, the Scheil results, and the input parameters for the liquid fraction (defined on the **Configuration** window):

- Start of relaxation
- Transition to vulnerability
- Smallest for vulnerability

These liquid fraction parameters are elaborated on next using the results from a simulation using the TCS Al-based Alloy Database (TCAL) and the alloy Al-0.9Cu-10Mg-0.9Ni-12.2Si mass%.

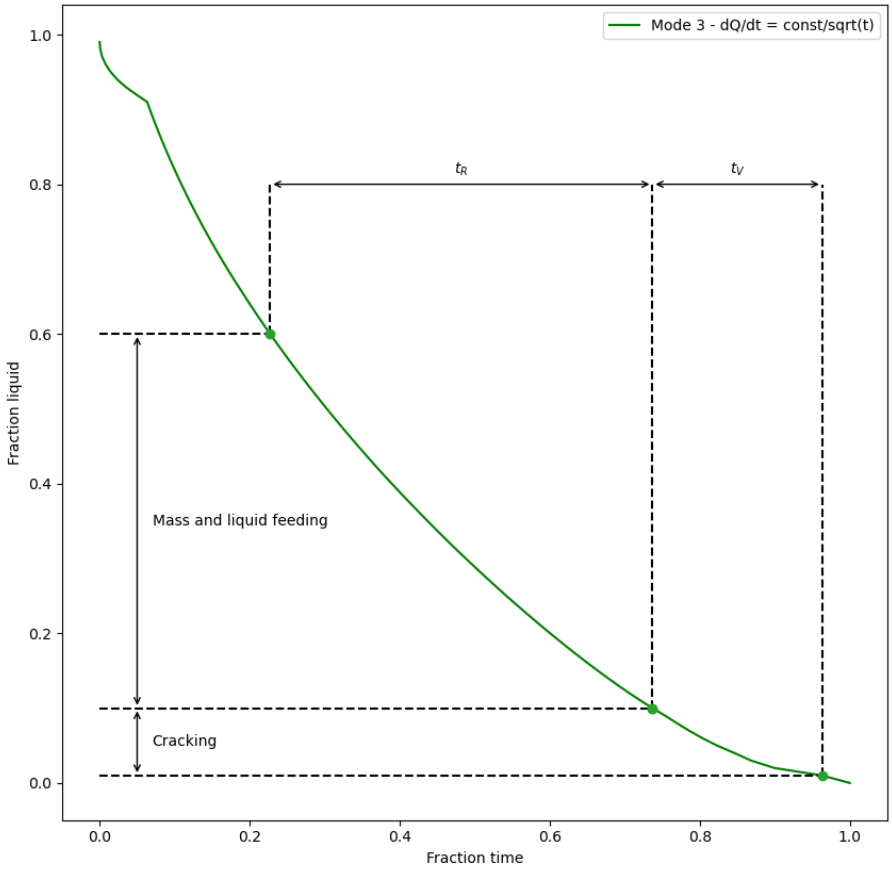

Figure 1: The results of the thermal condition in Mode 3, fraction of liquid, including the addition of lines and arrows to the plot for clarity. See the text for more detail.

Liquid Fraction Parameters

The **Crack Susceptibility Coefficient** Model is based on the concept of the existence of critical time periods during the solidification process when the structure is most vulnerable to cracking.

Clyne and Davies concluded that the mass and liquid feeding readily occurs at liquid volume fractions between about 0.6 and 0.1, so the time spent in these ranges was defined as time-relaxation (tR). At very low volume fractions of liquid, the material is too strong to crack. The authors chose a fraction of liquid between 0.1 and 0.01 as the vulnerable regime, and the time spent defined as tV. See Figure 1 for the results from a simulation using the TCS Al-based Alloy Database (TCAL) and the alloy Al-0.9Cu-10Mg-0.9Ni-12.2Si mass%.

The Scheil simulation takes temperature steps and does not regard time at all. See Figure 2 for the typical Scheil results of amount of solid phases as function of temperature. The simulation is made with the TCS Al-based Alloy Database (TCAL) and the alloy Al-0.9Cu-10Mg-0.9Ni-12.2Si mass%.

A thermal condition is assumed to connect the amount of liquid fraction to fraction of time.

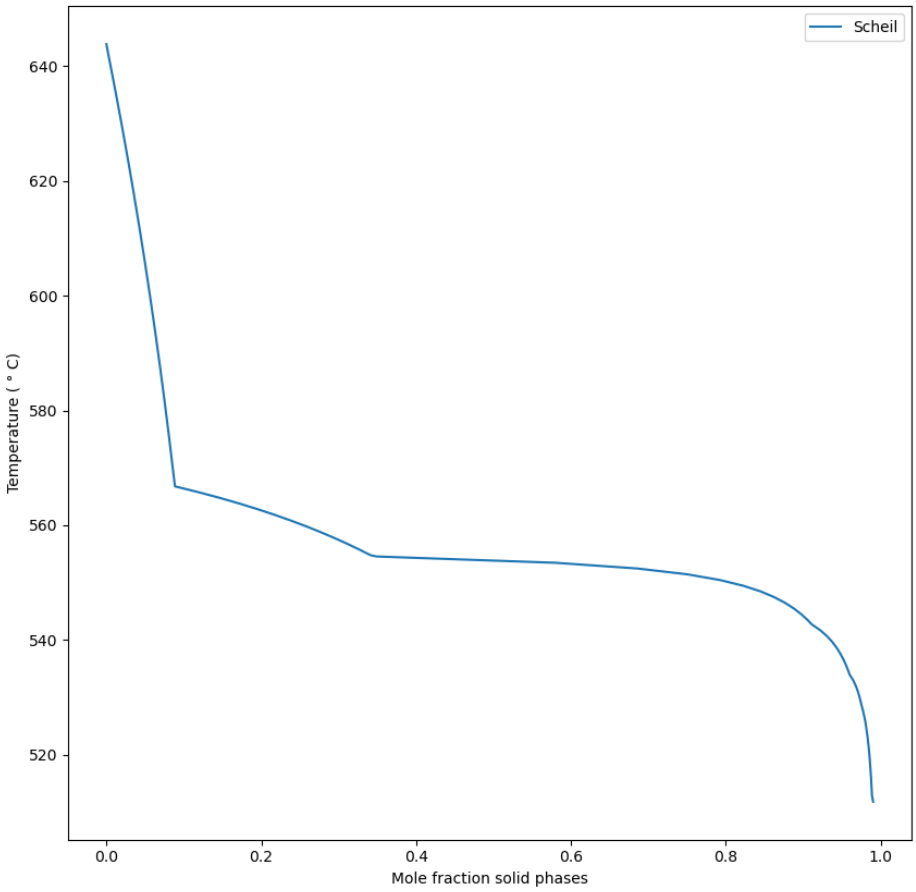

Figure 2: A Scheil simulation result of the mole fraction solid phases vs temperature (°C). See the text for more detail.

Following Clyne and Davies' approach, the cooling rates were then estimated under three different thermal conditions:

- Mode 1 with a constant cooling rate, dT/dt = constant
- Mode 2 with a constant heat flow, , dQ/dt = constant, and
- Mode 3 with a heat flow proportional to 1/sqrt(time)

Then:

- Liquid fraction: Start of relaxation
- Liquid fraction: Transition to vulnerability
- Liquid fraction: Smallest for vulnerability

The crack index can then be obtained from the Scheil simulation results: fraction liquid vs T curve and the thermal condition.

1-fraction solid phases = fraction liquid phase.

Figure 3 can be thought of as the 'master curve' for the connection between fraction of liquid and fraction of time. The limits of the amount of liquid 0.01, 0.1, and 0.6 and the corresponding fraction time are shown for each thermal condition. In Figure 1 , which is a less cluttered plot, the time spent in the relaxation and in the vulnerable regions are marked with lines and arrows for a single thermal mode.

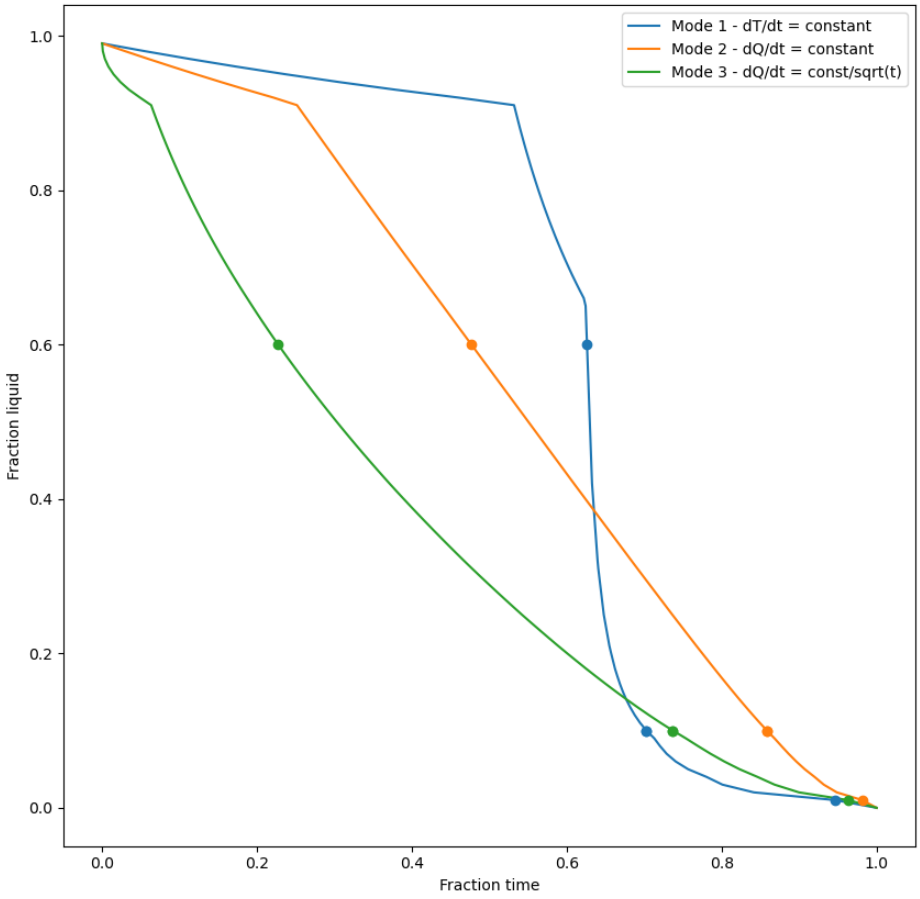

Figure 3: The results of the thermal condition in Modes 1-3, the fraction of time vs the fraction of liquid. See the text for more detail.

Kou CSC Model

When **Kou** is chosen as the **CSC Model** [2015Kou], the cracking susceptibility coefficient is defined as the absolute value of the derivative of the T vs $fs^{0.5}$ curve at the end of the solidification, where

- T = Temperature
- fs = fraction solid

Easton CSC Model

When **Easton** is chosen as the **CSC Model** [2014Eas], the cracking susceptibility coefficient is defined as the integral of $fs(T)$ between $T0$ and Tco where

- fs = fraction solid
- $T0$ = temperature for the solid fraction of a coherent dendrite structure.
- Tco = The temperature for the solid fraction of coalescence of dendrite structure. The user inputs are the solid fraction for coherency and coalescence.

About the Equilibrium with Freeze-in Temperature Property Model

The **Equilibrium with Freeze-in Temperature** Property Model, available as a General model with the Property Model Calculator, calculates equilibrium at the freeze-in temperature and evaluates the properties at a different evaluation temperature. The assumption is that diffusion and phase transformations are negligible below the freeze-in temperature and, therefore, the phase amounts and phase compositions do not change below the freeze-in temperature. Typically, the freeze-in occurs during cooling where equilibrium can be assumed above the freeze-in temperature.

The **Equilibrium above freeze-in temperature** checkbox is automatically selected for when the freeze-in occurs during cooling and where equilibrium can be assumed above the freeze-in temperature. Change the default (i.e. click to clear the checkbox) when the frozen structure should be evaluated at a higher temperature than the freeze-in temperature.

The electrical resistivity due to phase interface scattering is evaluated as the scattering constant times sum of the interaction between the volume fraction of all the phases. The default value for the constant is 4.0e-8 Ωm. The contribution to thermal conductivity is assumed to be related to that of electrical resistivity, following the Wiedemann-Franz law.

A selection of homogenization functions is available for the evaluation of thermal- and electric-properties. Thermal and electric properties depend on the microstructure and the geometrical representation of phases in the microstructure can be linked to different homogenization functions. The homogenization function is applied on thermal- and electrical-resistivity. The electric conductivity, thermal conductivity, and thermal diffusivity are evaluated from the resistivities.

Learn More

This Property Model uses thermophysical properties that are included with some Thermo-Calc databases such as the TCS Al-based Alloy Database (TCAL), which is used in the two examples included with your installation. For more information about the availability and the theory, see About Thermophysical Properties Data Parameters, Electrical Resistivity Model, and Thermal Conductivity Model.

Configuration Settings

The settings are entered on the **Configuration** window for the Property Model Calculator and described in Equilibrium with Freeze-in Temperature Property Model Settings.

Examples

For examples, see PM_G_10: Freeze-in Thermal Conductivity and PM_G_11: Freeze-in Electrical Resistivity.

About the Interfacial Energy Property Model

The **Interfacial Energy** Property Model, available as a General model with the Property Model Calculator, estimates the interfacial energy between a matrix phase and a precipitate phase using thermodynamic data from a CALPHAD database. The approximation model is based on Becker's bond energy approach and is also available in Precipitation Module (TC-PRISMA).

In the actual calculation, the coefficients taken distinguish between only bcc and fcc structure for the (110) and (111) lattice plane, respectively. For other planes and/or other phases, the estimate is approximate. In most situations, it is recommended to perform calibrations against some experimental data because the interfacial energy is dependent on so many factors that are ignored in the estimation, for example entropy, incoherency, orientation, and curvature, etc. Uncertainty factors must also be considered as thermodynamic data in CALPHAD databases are not always accurate.

Background Theory

Interfacial energy is an important parameter used in precipitation simulations to calculate the rates of nucleation, growth/dissolution, and coarsening. The value of interfacial energy can vary dramatically (usually between 0.01 to 2.0 J/m^2).

The extended Becker's model functions to estimate coherent interfacial energy by using thermodynamic data from existing CALPHAD thermodynamic databases:

$$\sigma_c = \frac{n_s z_s}{N_A z_l} \Delta E_s$$

where σ_c is the coherent interfacial energy, n_s is the number of atoms per unit area at the interface, z_s is the number of cross bonds per atom at the interface, z_l is the coordination number of an atom within the bulk crystal lattice, and ΔE_s is the energy of solution in a multicomponent system involving the two phases being considered [1938Bec].

About the Liquid and Solidus Temperature Property Model

The **Liquid and Solidus Temperature** Property Model, available as a General model with the Property Model Calculator, calculates the equilibrium solidification range in terms of temperature. If only the liquidus temperature is required, the calculation times are reduced.

Learn More

Configuration Settings

The settings are entered on the **Configuration** window for the Property Model Calculator and described in Liquid and Solidus Temperature Property Model Settings.

Example

For an example, see PM_G_12: Solidus and Liquidus Batch Calculation.

About the Phase Transition Property Model

The **Phase Transition** Property Model, available as a General model with the Property Model Calculator, calculates the *phase transition* point, or the point at which a new phase may form from a matrix phase when varying a defined condition. This model can be useful to determine melting temperature, boiling temperature, or solubility limits. The Model performs searches for a phase transition between the matrix phase and the "phase to form" by varying either temperature or composition of the system. The direction of the search (positive, negative, or both) can be specified.

Example

For an example, see PM_G_01: Phase Transition.

About the Scheil Property Model

The **Scheil** Property Model, available as a General model with the Property Model Calculator, calculates solidification under the Scheil assumption. Many model input parameters are taken from the Scheil Calculator, and model results are available for key aspects of solidification, i.e., liquidus, solidus, freezing range, and fractions of various phase combinations. In addition, properties of the as-solidified material can be evaluated below the solidification temperature. Three Scheil calculation types (Classic, Scheil with back diffusion in the primary phase, and Scheil with solute trapping) are available.

Example

For an example, see PM_G_20: Scheil for an Al-1Si-1Mn-0.7Mg-0.6Fe-0.1Cu Alloy.

About the Spinodal Property Model

The **Spinodal** Property Model, available as a General model with the Property Model Calculator, calculates the spinodal line. The spinodal is defined by the condition where the second derivative of Gibbs free energy is zero (`d2G/dx2 = 0`). The Model searches for the Spinodal "solution" for the spinodal phase by varying either temperature or composition in mass percent, mole percent, mass fraction, or mole fraction (e.g. mass percent Fe, mole percent Fe, and so forth). Up to two spinodal solutions can be found.

When within the miscibility gap, but above the spinodal curve, phase transformation occurs by classical nucleation and growth of the spinodal phase. When within the miscibility gap, but below the spinodal curve, the phase transformation occur by spinodal decomposition of the spinodal phase.

Example

For an example, see PM_G_08: Spinodal.

About the T_0 Temperature Property Model

The **T-Zero Temperature** Property Model, available as a General model with the Property Model Calculator, calculates the so-called $\mathbf{T_0}$ line.

The $\mathbf{T_0}$ temperature is defined as the temperature where two phases of identical chemical composition have the same molar Gibbs free energy. This temperature is an important quantity in the field of diffusionless phase transformations, e.g. martensitic transformation, since it is the upper limit where diffusionless phase transformations can occur.

Vary Evaluation Temperature or Composition

With this Model up to two solutions can be found. When searching for $\mathbf{T_0}$ you can vary the condition of the evaluation temperature or element composition in units of mass percent (e.g. mass percent Fe). This is managed using the settings **Condition to vary** and in some cases, **Manual search limits**.

When **Evaluation temperature** is the varied condition, T_0 is obtained as a solution. When a specific composition is selected as the condition to vary, then the evaluation temperature is calculated when the T_0 condition is fulfilled. So the resulting temperature is equal to T_0.

In most cases the curvature of the Gibbs energies of the two phases is different which results in multiple solutions for $\mathbf{T_0}$. If you keep the default settings (*Vary temperature or condition → Evaluation temperature* and with no manual search limits) the Property Model Calculator can store up to two solutions. If the solution of interest is not calculated, adjusting **Manual search limits** and/or changing the condition to vary to one of the listed compositions, allows you to find the solution of interest.

Gibbs Energy Addition

There is also an option to include a Gibbs energy addition to the second phase, which allows for inclusion of an energy barrier for martensitic phase transformations. This is done using the **Energy addition second phase [J/mol]** setting.

The energy addition field in Graphical Mode corresponds to the Console Mode command ADVANCED_OPTIONS PHASE_ADDITION (see EQUILIBRIUM_CALCUL for information). However, the energy addition can also be composition- and/or temperature-dependent, which is not possible in Console Mode. In addition, Property Models are not available in Console Mode. However, You can access the functionality using methods available with an applicable API such as TC-Python or TC-Toolbox for MATLAB®

Examples

For examples, see PM_G_09: T-Zero Temperature and PM_G_14: Ti-Fe T-Zero Martensite

About the Yield Strength Property Model

The **Yield Strength** Property Model, available as a General model with the Property Model Calculator, calculates yield stress. It returns the calculated yield strength at the desired evaluation temperature for the specified material using the equilibrium phase fractions calculated at the annealing temperature. Then you can further define the following contributions to the total yield stress:

- Intrinsic strength (σ_i) for the pure elements,
- Grain boundary strengthening (σ_{gb}),
- Solid solution strengthening (σ_{ss}),
- Precipitation strengthening (σ_p), and
- A user set, constant strength contribution (σ_c).

The Annealing temperature (T) is used to evaluate the equilibrium state of the system, and the resulting compositions and phase fractions are subsequently used in the evaluation of mechanical properties. The Evaluation temperature at which the mechanical properties are evaluated is room temperature by default but can be adjusted by the user. Below is a short summary for each of the contributions.

Intrinsic Strength

The *intrinsic strength* model formulation for this Property Model corresponds to a surface of reference with end-members. For example, for FCC_A1 modeled as (Fe,Ti)(C,Va), the intrinsic strength is a linear combination (as given by the composition) of Fe:Va (i.e. pure FCC Fe), Ti:Va (i.e. pure FCC Ti), Fe:C (i.e., FCC FeC) and Ti:C (i.e., FCC TiC). With such an implementation, it is possible to calculate yield strength for materials with a significant fraction of hard phases, such as carbides, embedded in a soft matrix and the intrinsic strengthening effect of interstitial elements.

The general form of the intrinsic strength model follows in the spirit of the Compound Energy Formalism (CEF) surface of reference term, where the intrinsic strength for, e.g., a two-sublattice phase model would correspond to:

$$\sigma_{\text{intrinsic}} = \Sigma_{i,j}\sigma_{i:j}y'_i y''_j$$

Such a formulation means that the intrinsic strength depends on the calculated site fractions from, e.g., an equilibrium calculation.

Phases with Assessed Intrinsic Strength

Not all compound phases are yet assessed in terms of intrinsic strength. The following phases are assessed: BCC_A2, CEMENTITE_D011, FCC_A1, FCC_L12, HCP_A3, M23C6_D84, M3C2_D510, M6C_E93, M7C3_D101, MC_SHP, MB2_C32, MOB2_C32, M3B2_D5A, M2B_CB, and MB_B33.

Temperature Dependence for Pure Elements

The following pure elements can be used to evaluate yield strength at non-room temperature conditions:

- Ag, Al, Au, Be, Ce, Co, Cr, Cu, Dy, Er, Fe, Gd, Hf, Ho, Ir, La, Mg, Mo, Nb, Nd, Ni, Pd, Pt, Rh, Sm, Ta, Ti, U, V, W, Y, Zn, and Zr

The temperature dependence is of the form:

$$ys_{pure} = A * exp(-B/T)$$

and is available for the listed pure elements where A and B are fitted to data from [1968Sam; 2017Wu]. This improves the results for evaluated yield strength at non-room temperature conditions.

The calculated solid solution strength can differ from versions of Thermo-Calc prior to 2022b where the pure element strength from Cordero et al. was used [2016Cor]. This is especially noticeable for pure element or dilute solution calculations. The pure element strength is only evaluated for FCC, BCC, and HCP.

Compound end-members of the intrinsic model are not modeled as temperature dependent, however, this should have only a small effect on most alloys.

Constant Addition of Strength

The *constant strength contribution* parameter, σ_c, is set by the user as a constant strength addition to the material.

Grain Boundary Strengthening

The *grain boundary strengthening*, σ_{gb}, is the contribution to the total strength stemming from the grain boundary's ability to hinder dislocation movement described by the Hall-Petch relation [2004Han].

The parameters entered are the Hall-Petch constant, k_{h-p}, in MPa $\mu m^{1/2}$, and the average grain diameter in µm.

Solid Solution Strengthening

The *solution strengthening*, σ_{ss}, is the contribution to total strength due to the elastic strains in the crystal lattice caused by alloying elements of a lattice parameter differing from the main constituent. For the solid solution strengthening the option of evaluating the strength at any temperature is available, by adjusting the Evaluation temperature field. The result is normalized with respect to the sum of all mole fractions for FCC, BCC, and HCP. This option still uses the phase fractions and compositions calculated at the Annealing temperature. The model by Walbrühl et al. [2017Wal] is implemented.

PM_G_06: Yield Strength HEA shows how this model is applied.

Precipitation Strengthening

The *precipitation strengthening*, σ_p, is the contribution to total strength due to precipitation of a secondary phase, e.g. gamma prime (γ') in Ni-base alloys or Al_3Sc precipitates in Al-base alloys. This model is available for any number of precipitating phases. The total particle strength is calculated by the square mean of the individual particle strength contributions:

$$\sigma_p = \sqrt{\sigma_{p1}^2 + \sigma_{p2}^2 + \ldots + \sigma_{pn}^2}$$

The Simplified model (general), Seidman model (Al-base), Reppich model (Ni-based), and Deschamps model (Al-base) are available as settings on the **Configuration** window to estimate the precipitation strengthening contribution. These are briefly described next.

Simplified Model (General)

The **Simplified model (general)** is based on the work by Zander et al. [2008Zan] and considers the general mechanisms of cutting and looping without regard to any detailed dislocation mechanisms. The default parameters are, however, optimized against experimental data for

the Al-0.3wt%Sc alloy described by Seidman et al. [2002Sei]. Also see Mean Precipitate Radius and Particle Size Distribution (PSD) below.

PM_G_04: Yield Strength compares the **Simplified model (general)**, **Seidman model (Al-base)**, and **Deschamps model (Al-base)** yield strength versus precipitate radius to experimental data for an Al-0.3wt%Sc alloy homogenized at 648 °C for 24 hours and subsequently aged at 350 °C.

Seidman Model (Al-base)

The **Seidman model (Al-base)** by Seidman et al. [2002Sei] considers several contributions to the overall precipitation strengthening - ordering, coherency stresses, shear modulus mismatch, and Orowan looping. The Seidman model is suitable for Al-base alloys with a low volume fraction of spherical precipitates. Also see Mean Precipitate Radius and Particle Size Distribution (PSD) below.

PM_G_04: Yield Strength compares the **Simplified model (general)**, **Seidman model (Al-base)**, and **Deschamps model (Al-base)** yield strength versus precipitate radius to experimental data for an Al-0.3wt%Sc alloy homogenized at 648 °C for 24 hours and subsequently aged at 350 °C.

Reppich Model (Ni-base)

The **Reppich model (Ni-base)** by Reppich et al. [1982aRep] considers both weak and strong coupling of dislocation as they propagate through an ordered secondary phase and is thus suitable for Ni-base alloys with relatively high volume fractions of gamma prime or gamma double prime. Also see Mean Precipitate Radius and Particle Size Distribution (PSD) below.

The Reppich model is not valid for very small values of volume fraction precipitate and precipitate radius.

PM_G_05: Yield Strength NiAlCr is an example of this model.

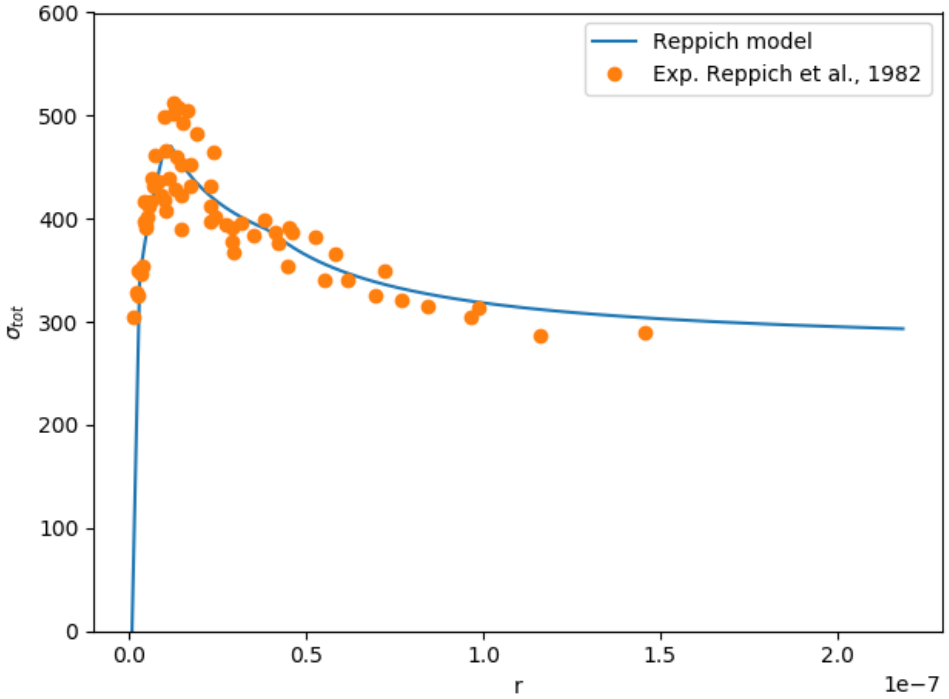

Figure 4: Reppich model plotted with results and experimental data for PE16 [1982bRep], all data is normalized with the square root of the volume fraction of precipitate.

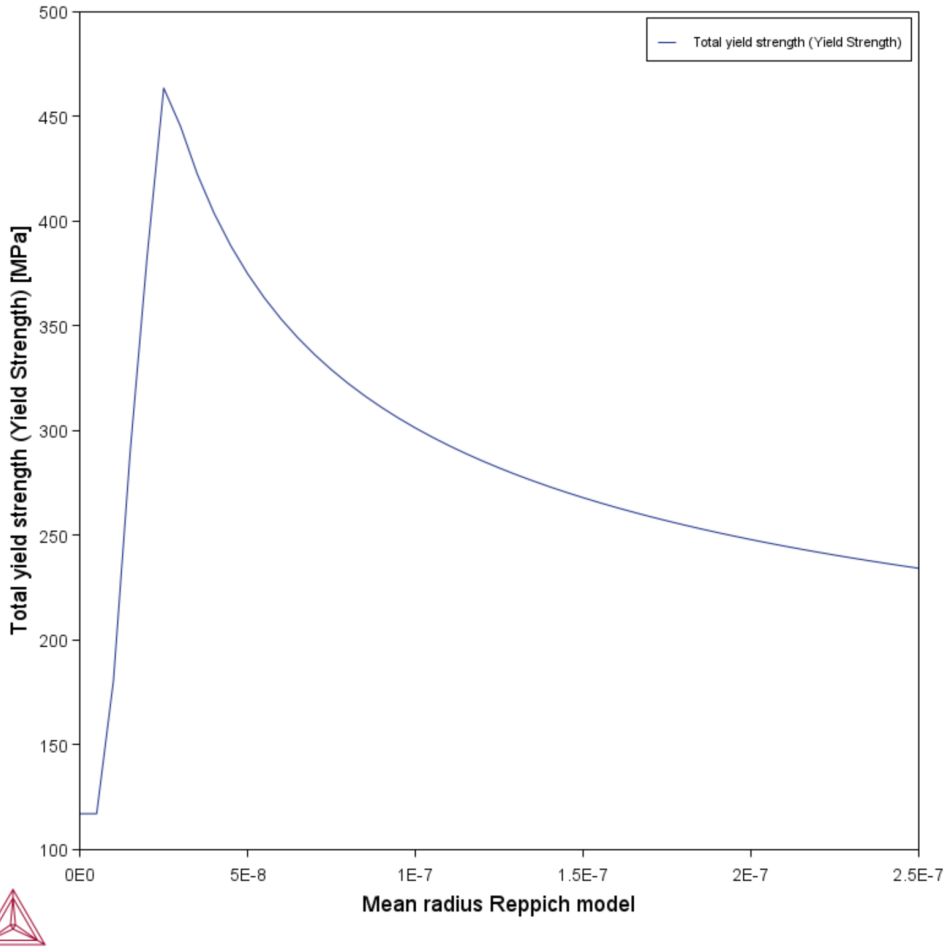

Figure 5: Reppich model yield strength vs mean precipitate radius for Ni-10Cr-10Al.

Deschamps Model (Al-base)

The **Deschamps model (Al-base)** by Deschamps and Brechet [1998Des] considers contributions to the overall precipitation strengthening precipitate from particle cutting and Orowan looping. The Deschamps model is suitable for Al-base alloys with a low volume fraction of spherical precipitates. However, it has been successfully validated against other alloy types, such as Fe-based ferritic materials with TiC precipitates. Also see Mean Precipitate Radius and Particle Size Distribution (PSD) below.

The Deschamps model considers Friedel statistics as a default setting, with the option to instead apply Kock's statistics, as shown in the PM_G_04 example.

PM_G_04: Yield Strength compares the **Simplified model (general)**, **Seidman model (Al-base)**, and **Deschamps model (Al-base)** yield strength versus precipitate radius to experimental data for an Al-0.3wt%Sc alloy homogenized at 648 °C for 24 hours and subsequently aged at 350 °C.

Mean Precipitate Radius and Particle Size Distribution (PSD)

The mean precipitate radius entered on the **Configuration** window for all precipitation strengthening models is transformed to a Lifshitz-Slyozov-Wagner (LSW) particle size distribution [2010Tir]. The distribution is stepwise integrated and the mean radius for all sections are used to calculate a partial precipitate strengthening contribution. The partial contributions are added as

$$\sigma_{tot}^2 = \sum(\sigma_p^2)$$

The use of a PSD smooths the transition between the cutting and Orowan regions. This change is implemented for the Simplified model (general) and Seidman model (Al-base).

When using the Yield Strength Model with the Precipitation Module (TC-PRISMA) the PSD as calculated by Precipitation Module (TC-PRISMA) is used for each time step. Also see Precipitation Calculator Plot Renderer for the settings input related to this.

Introduction to Aqueous Solutions and Pourbaix Diagrams

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

Learn More

Search the help (press F1 when in Thermo-Calc) for information about the Graphical Mode **Aqueous Calculator**, its template with predefined settings, and the aqueous properties. The help also has detailed information about the compatible and recommended database for use with all aqueous calculations.

Overview

Materials corrosion occurs almost everywhere. It can result in serious material damages, unexpected application failures, tremendous economic costs and environmental degradations. Consequently, scientists and engineers must often conduct expensive and time-consuming corrosion experiments as part of failure analyses, risk evaluations, quality improvements and application enhancements. With the aid of CALPHAD-based database and computational tools, you can first simulate the corrosion phenomena on a computer and then design proper experiments to validate the calculations.

Under certain temperature, pressure and gaseous conditions, when a metal or alloy is exposed to an aqueous solution with a concentration of inorganic/organic mixture, corrosion occurs at a corresponding degree. During corrosion, some metallic phases dissolve into the aqueous solution. The metal or alloy surface becomes damaged while some low-solubility secondary solid phases (such as oxides, hydroxides, silicates, sulphides, sulphates, carbonates, nitrates, phosphates, borates, or halides) form and precipitate at the solid-liquid interfaces. These corrosive chemical and electrochemical reactions can be studied by means of the so-called Pourbaix diagrams assuming the reactions reach their equilibrium states [1973Pou; 1974Pou; 2003Cra; 2011Tho; 2011Ver].

About Pourbaix Diagrams

Special Elements and Default Components

Heterogeneous equilibrium calculations involving aqueous solutions are not different from other equilibrium calculations of multiphase multicomponent systems, but the setup of the system and equilibrium conditions require more careful consideration. To study the dissociation of electrolytes the special element (ZE) is available to handle various charged aqueous species and internal electric balance in the aqueous solution phase. The aqueous species H^{+1} and OH^{-1} is modeled as the "compounds" H1ZE1 and H1O1ZE-1, respectively. By convention, the default component-set of aqueous system for H_2O is (H2O, H+1, ZE), where H2O is for the solvent, and H+1 and ZE are for the calculation of pH and Eh, respectively. For the sake of convenient calculations, the default reference state of H2O, H+1, ZE is usually set as AQUEOUS, SER, and REF_ELECTRODE, respectively. Thus, the following essential aqueous properties can be evaluated simply as:

1. Activity-of-Water = ACR(H2O)
2. pH = -LOG10(AC(H+1))
3. Eh = MUR(ZE)/RNF where RNF=96485.309 stands for the Faraday constant.

Aqueous Calculations Key Concepts

The following are key concepts important to understand how aqueous solutions behave and how an aqueous-bearing heterogeneous interaction system is properly defined and calculated in Thermo-Calc.

Effective Interaction Ratio

A pH-Eh plot is always related to a certain amount of initial alloys or other condensed materials that has effectively reacted with an aqueous solution in the system. This is the amount of condensed material that is fully in equilibrium with the defined aqueous solution phase. The amount is specified relative to an aqueous solution that is normally comprised of 1 kg of water with certain specified solute concentrations at certain temperature and pressure conditions. (This is why a calculated Pourbaix diagram is typically presented for an initial

amount of the interacting metal or alloy at a certain level, such as 10^{-6}, $1E^{-3}$, 0.1 or 1 mole of metal or alloy.) It is called the *Effective Interaction Ratio* (between the initial alloy or alloyed phases and the initial aqueous solution) and it is expressed in terms of molality (mol/kg).

The *Effective Interaction Ratio* is important for two reasons. First, the ratio has implications for kinetic or dynamic effects such as chemical reaction mechanisms and kinetics, fluid flow dynamics, surface area, and interaction time. Secondly, the ratio, being expressed as 10^{-6} mole of metal (or alloy), is the solubility limit that can be detected for cathodic corrosion protection by immunity.

It is essential to exercise caution when setting initial amounts and compositions in the original condensed materials, as well as when setting the initial concentrations of dissolved solutes in the original aqueous solution phase. It is often useful to make a series of calculations for different levels of initial amount of the interacting metal/alloy while the conditions are fixed for other settings (such as initial aqueous concentration, pressure, temperature, pH, and Eh).

Solubility

When a heterogeneous equilibrium involves a dissolving matrix solution or mixture phase and one or multi being dissolved stoichiometric or solution phases, then the concept of solubility becomes important. The solubility of a phase (the solute) is its property of dissolving in the solvent phase. This concept concerns the constitution of a phase and is applied where one or several of the constituents are dominant (which is highly concentrated and dissolving) while there are only small amounts of the other remaining species (which are less concentrated and dissolved). The dissolving solution or mixture phase can be liquid, gas, aqueous, or solid, as long as it has dissolving capacity. The solute phase has some constituents which tend to be dissolved into the dissolving solution or mixture phase.

An aqueous solution phase is always dominant in the solvent water, that is, H_2O. Under specific temperature, pressure, and aqueous composition conditions, any other element (such as Fe and C) or substance (such as a pure SO_2 gas, stoichiometric phase Cu_2S and the halite solution phase $(Fe,Ni)_1(O,Va)_1$) have a certain solubility limit in the defined aqueous solution.

Under certain temperature and pressure conditions, and under given certain concentrations of other dissolved species in the mixture, an O_2-dominant gaseous mixture phase can dissolve certain amounts of Fe^{+2} or Fe^{+3} species from magnetite (Fe_3O_4). The magnetite solid has solubility defined relative to the gaseous mixture under the given conditions.

About Pourbaix Diagrams

Introduction to Aqueous Solutions and Pourbaix Diagrams

Background

Marcel Pourbaix applied thermodynamics to predict materials corrosion resistance. He determined the phase stability relations in terms of varied pH and Eh values for an interaction system of metal and pure water or dilute aqueous solution. He presented the stability regions of metal and secondary phases (such as metal-oxides/hydroxides) on a pH-Eh diagram, which is now known as a Pourbaix diagram.

For some simple systems, thermodynamic approximations of pH-Eh calculations can be used to construct the conventional Pourbaix diagrams based on an *Equilibrium Constant* (EC) approach. But Thermo-Calc applies the *Gibbs Energy Minimization* (GEM) approach. The advantages of GEM are significant relative to EC. Calculations of Pourbaix diagrams and various property diagrams (One Axis calculations) are always done for the equilibrium states in the entire heterogeneous interaction system that includes multicomponent alloy solution phase(s), complex aqueous solution phase with various solutes and molalities, gaseous mixture phase and all possible (stable/metastable) secondary solid phases. Every single point or curve on a calculated Pourbaix diagram or similar is really in their full-equilibrium states. Besides the Pourbaix diagram, it is useful and desirable to calculate various property diagrams that are stepped along a controlling condition, e.g. pH, Eh, T, alloying-composition, salinity, etc.

What is a Pourbaix Diagram?

A Pourbaix diagram is a pH-Eh phase diagram where the tie-lines are not in the plane. The chemical potentials or activities of the two system components (H+1 and ZE) are used as mapping variables and the pH and Eh quantities are normally plotted on the X- and Y-axes of the diagram. You can use many other axis variables in various property diagrams for the heterogeneous interaction system at given conditions. The phase relations between the aqueous solution and various metal forms, oxides, hydroxides, sulphides, sulphates, nitrates, silicates, carbonates, and other solids, or gaseous mixtures, are represented as different fields defined by acidity and electric potential.

A Pourbaix diagram is a kind of phase diagram that shows the stability boundaries for a metal-aqueous interaction system. The phase boundaries are shown as a function of pH (acidity) and Eh (standard hydrogen electronic potential). The AQUEOUS solution phase is always present in such a system/diagram. At a given pH and Eh, a metal may lose its stability to a soluble or corrosive aqueous solution, or be in equilibrium with either the aqueous solution (insoluble/immune) or with a secondary-phase that has formed (consisting of oxides, hydroxides, sulphides, or other solids). In the latter case, further dissolution of the passive or protective metal is prevented.

The speciation and partition in the aqueous solution and the interacting phases depend not only on pH and Eh, but also on other factors such as the bulk composition, temperature, and pressure in the system. The interacting phases may be gas mixtures, stoichiometric solids, or solid solutions.

A Pourbaix diagram is divided in regions of *immunity*, *corrosion*, and *passivity*. These regions provide information about the stability of a particular metal or alloy in a specific aqueous electrochemical environment under certain pH, Eh, pressure, and temperature conditions.

- The *immunity* region is the region in which there is no metal dissolution.
- The *corrosion* region is the region in which there is active metal dissolution.
- The *passivity* region is the region in which a protective metal-oxide and other low solubility secondary solid film that prevents metal dissolution is formed.

Depending on the system's bulk chemical composition, secondary phases may form during the transformation process. In addition to oxides these can also be, for example, hydroxides, sulphides, sulphates, carbonates, nitrates, phosphates, borates, silicates, hydrous silicates, and halides. Information about these secondary phases may help you understand the passivation behaviors in corrosion processes. For example, it may be important to understand whether any secondary phases are formed in different pH-Eh regions during hydrolysis, oxidation, reduction, or other reaction processes.

In a Pourbaix diagram, the predominant ion boundaries are often represented by dashed and straight lines imposed on a traditional Pourbaix diagram for a simple interaction system [1973Pou; 1974Pou; 2003Cra; 2011Tho; 2011Ver]. Such a predominance boundary is normally an equal molality (or equal activity) line for a pair of two most-concentrated aqueous solute species (charged or neutral) involving a common metal. A line is then simply determined by a reaction constant of its corresponding electrochemical reaction in the homogeneous aqueous solution phase. However, this is not the case in Thermo-Calc where the advanced GEM rather than the simple EC approach is applied.

Each point on the line in a pH-Eh diagram in Thermo-Calc represents a certain minimum state of Gibbs energy. When a line is crossed, a phase transformation should occur. This means that a Pourbaix diagram in Thermo-Calc does not provide any information about any predominant ion boundary.

How are Pourbaix Diagrams Calculated?

Pourbaix diagrams can be calculated over a wide range of pressure, temperature, and composition conditions for complex heterogeneous interactions between multicomponent primary alloy solution or compound phases, concentrated aqueous solutions (with dissolved inorganic and organic substances), complicated secondary solids, and oxidizing/reducing gaseous mixtures.

Thermo-Calc implements comprehensive thermodynamic models and databases for various phases, which facilitates accurate calculation of Pourbaix diagrams and various property diagrams including aqueous properties in complex aqueous solutions in a variety of T, P, X conditions of multiphase multicomponent systems.

Besides a concentrated aqueous solution phase handled by a proper thermodynamic model named SIT [1981Hel] or HKF [1990Cia], it is also properly modeled the complex alloy solution phases or stoichiometric compound phases, as well as secondary solid phases and gaseous mixtures in Thermo-Calc.

Most frequently, a Pourbaix diagram is calculated for a specific alloyed phase with the initial alloying composition, such as the FCC solution phase in an austenite steel. However, it is possible to calculate a Pourbaix diagram for two co-existing phases, such as the FCC+BCC solution phases in a duplex steel for example, or even for more than two co-existing phases in a steel/alloy.

Aqueous and Pourbaix Diagram Examples Summary

There are examples available to show the application of aqueous solutions and Pourbaix diagrams depending on several factors:

- Whether you are using Console Mode or Graphical Mode (or an SDK such as TC-Python),
- Which version of the TCS Aqueous Solutions Database (TCAQ) you are using, or
- If you are using the free public PAQ2 database (i.e. you do not have a license for the TCAQ database OR are using TCAQ3.1 and older).

Free PAQ2 Database

Graphical Mode Installed Examples

- T_21: Pourbaix Diagrams of Fe with the Aqueous Calculator
- T_22: Aqueous pH of Solutions

T_21a is available with the Educational version of Thermo-Calc. It is slightly modified from T_21 to be compatible with the free demo version of the software.

Console Mode Installed Examples

- tcex40 and tcex53

TCS Aqueous Solutions Database (TCAQ) Version 4 and Newer

In the Help

When in Thermo-Calc, press F1 and see the examples available in the help under the **Databases > Aqueous Solutions > TCAQ** section.

Website

On our website there are several examples, which use a mix of Graphical Mode, Console Mode, or one of the SDKs (i.e. TC-Python) to generate examples:

- The TCAQ examples are available from the Aqueous Solutions Databases page.
- There are additional examples on the Pourbaix Diagram Module and Aqueous Calculator pages.
- By Process: Applications of Thermo-Calc: Corrosion

TCAQ3.1 and Earlier

Pourbaix Diagrams (Educational Material) in PDF Format

See the archived *Pourbaix Diagrams Educational Material* PDF available on the website or in earlier installed versions of Thermo-Calc.

The content related to the classic Console Mode Pourbaix Diagram module continues to be included in the help, however it is not a dedicated guide. Instead it is included generally with the Console Mode content until it can be integrated as the product evolves in future versions of the software and as customers are able to upgrade to the latest version 4 of the TCAQ database.

About the Thermodynamic Database Requirements

There are differences about the thermodynamic data requirements based on the database used and whether you are working in Console Mode or Graphical Mode. Pourbaix diagrams are available in both modes, but more advanced aqueous calculations are only in Graphical Mode and it is important to choose the optimal database as outlined in this section.

TCAQ4 and Newer

The latest TCS Aqueous Solutions Database (TCAQ) version 4 (TCAQ4 and newer), is the recommended database because it is optimized to be used with the Graphical Mode Aqueous Calculator (version 2026a and newer). The Aqueous Calculator, and associated Aqueous Calculation template that has predefined settings for all nodes, are designed to more easily set up aqueous calculations (including Pourbaix diagrams) than is possible in Console Mode. TCAQ4 is also compatible in Console Mode to continue to work with the POURBAIX diagram module.

TCAQ3.1 and Older

If you are working with the TCS Aqueous Solutions Database (TCAQ) version 3 (TCAQ3.1 and older) in Console Mode or with the classic POURBAIX_DIAGRAM module, then the aqueous solutions database requires appended gas and solid metallic and oxide phases from other compatible databases, for example, SGTE Substances Database (SSUB), SGTE Solutions Database (SSOL), or TCS Steel and Fe-alloys Database (TCFE).

Other Databases: PAQ2 and AQS

The public *PAQ2* (TCS Public Aqueous Solution Database) contains thermodynamic data for all four phase types and can be used for calculating Pourbaix diagrams. It is designed specifically for the purpose of demonstrating the POURBAIX module functionality in Thermo-Calc. However, this database only allow you to perform test calculations for simple cases with major phases in which only a few elements can be considered.

There are two examples in Graphical Mode (T_21 and T_22) that use the PAQ2 database to showcase aqueous calculation capabilities with the **Aqueous Calculator**.

TCS Aqueous Solution Database (AQS) version 2 is the other database which includes an aqueous solution phase. However, AQS2 does not include the gas or any solid phases.

Thermodynamic Data Requirements

As of 2026a, information about appending databases or retrieving thermodynamic data is only applicable if you are using TCAQ version 3.1 and older or one of the free databases. Otherwise it is recommended you upgrade to TCAQ version 4.0, which has access to many new phases and there is no need to append the gas solution phase, the metallic solid solutions, or any oxide phases. This is applicable to both Graphical Mode and Console Mode.

To calculate a Pourbaix diagram, thermodynamic data for at least the following four types of phases must be available:

- The aqueous solution phase which applies a certain aqueous solution model. In Thermo-Calc, information about this phase could be retrieved from, for instance, the TCAQ or AQS database (these also include data for the `REF_ELECTRODE` phase that is used for setting the reference state of the standard hydrogen electrode).
- The alloy solution and/or compound phases for the primary matrix phases (and possibly also for the precipitated phases in the alloy. Examples of such phases include FCC_A1, BCC_A2, HCP_A3, SIGMA, and CEMENTITE.
- In Thermo-Calc, information about such phases could be retrieved from, for example, the TCFE database for steels/Fe-alloys, the TCNI database for Ni-based superalloys, the TCAL database for Al-based alloys, the TCMG database for Mg-based alloys, the TCSLD for Sn-/Au-/Bi-/Zn-based solder alloys, or the SGTE Solutions Database (SSOL) for general alloys.
- The secondary solid phases that would form as a result of the heterogeneous chemical or electrochemical reactions. These phases could be, for example, oxides, hydroxides, silicates, hydrous silicates, sulphides, sulphates, carbonates, nitrates, phosphates, borates, or halides. In Thermo-Calc, information about such phases could be retrieved from, for example, the SGTE Substances Database (SSUB) for pure solid compounds or the TCS Metal Oxide Solutions Database (TCOX) for complex oxide solids.
- The gaseous mixture phase. Information about this phase could be retrieved from, for example, the SGTE Substances Database (SSUB). However, note that is also possible to perform Pourbaix diagram calculations that ignore the gaseous mixture phase.

All this thermodynamic data about the various phases must be critically assessed and internally consistent. Furthermore, when the data is retrieved from several databases, the data taken from each database must be consistent with the data taken from the other databases. When Pourbaix diagrams and other diagrams of steel corrosion processes are calculated, it is typically recommended that the TCAQ3.1 and older, TCFE, SSUB, and TCOX databases or the AQS, TCFE, SSUB, and TCOX are used in combination.

Links to Additional Information

Website

Go to the Aqueous Solutions Databases page on our website where you can access the latest TCAQ *Examples Collection* and the *Technical Information*. Also explore further options to work with aqueous solutions and this database using the Aqueous Calculator.

Help

Search the help (press F1 when in Thermo-Calc) for information about the Graphical Mode **Aqueous Calculator**, its template with predefined settings, and the aqueous properties. The help also has detailed information about the compatible and recommended database for use with all aqueous calculations.

Calculations in Graphical Mode

Thermo-Calc includes several built-in calculators that come standard with all licenses and allow for a broad range of calculations of thermodynamic significance.

These sections provide details about the Graphical Mode Calculators available with a standard Thermo-Calc license. Go to the Add-on Modules sections for details about Calculators requiring additional licenses, such as the Diffusion, Precipitation, Process Metallurgy, and AM (Additive Manufacturing), Calculators. This also includes the material-specific Property Models.

System Definer

In a **System Definer** activity, you select the database to use to retrieve thermodynamic data and define which elements the system has as components. You can also select the species to include as well as change the reference temperature and pressure for your components.

You can add the System Definer directly (right-click **My Project** and select it from the **Create New Activity** menu) or use a variety of the available templates to automatically add the node.

Many examples use the System Definer (see Graphical Mode Examples Listed by Product). For details about the templates, see Getting Started Links, Templates, and the Property Navigator and Creating a Project from a Template.

Once you have added a System Definer, the **Configuration** window has these settings tabs:

- Elements
- Species
- Phases and Phase Constitution
- Components
- Data Sources
- Description

To learn more about the many settings go to Configuration Window Settings.

Define the System

This topic describes how to define a system, specifically how to select one or more databases and define the elements in the system with the System Definer activity node.

1. Right-click **My Project** and from the menu select **Create New Activity → System Definer**. For many templates a System Definer is also added to the Project tree.
2. In the **Project** window, click the **System Definer** activity node.
3. In the **Configuration** window, choose **Databases** from the list or a database **Package**.

   About the Database Files

   OPTIONS:

   - From the **Databases** list, select **<User database>** to define your own.
   - You can choose to add one or more databases by clicking the **Add a database** button.
   - From the **Package** list, choose a predefined database package to add multiple databases at a time. Depending on your license, there are predefined database packages available to select.

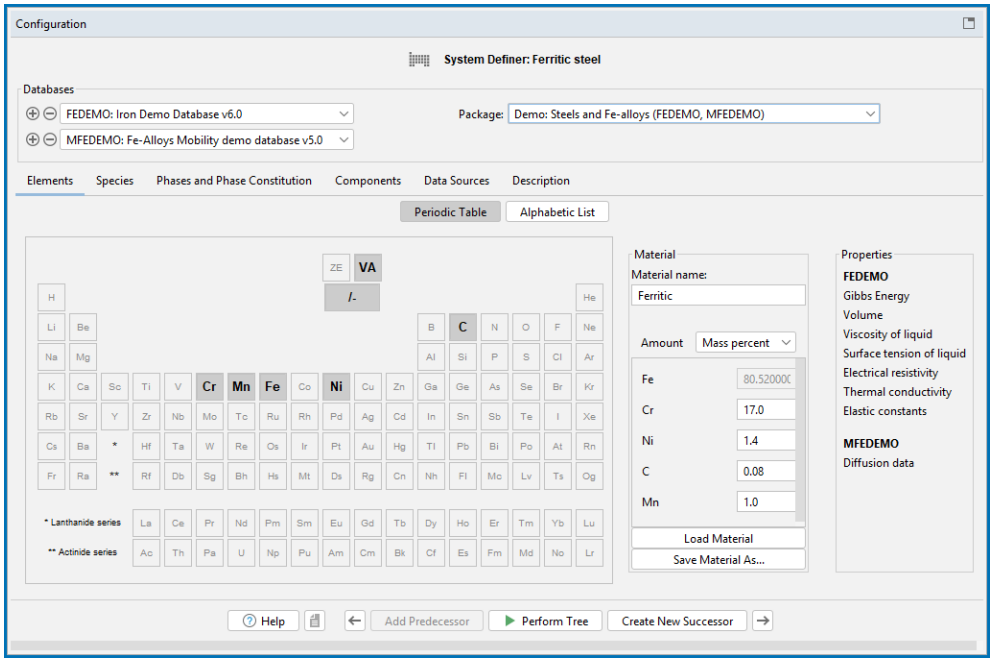
4. Select the **Elements** tab to choose the elements in the **Periodic Table** or use the **Alphabetic List** to choose elements for the system.
5. As required click the tabs to make edits: **Species**, **Phases and Phase Constitution**, and **Components**. The **Data Sources** and **Description** tabs provide information based on the database.

   Configuration Window Settings

6. Click **Perform** to start the System Definer activity immediately and retrieve data about the system. Click the **Event Log** window to watch the progress of the job.

Configuration Window Settings

The System Definer Configuration window has many settings available, which are briefly described below.

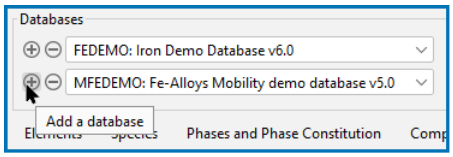


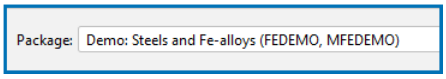
Learn More

Loading or Saving a Material

This uses PM_G_02: Coarsening and Interfacial Energy to show these features.

Choose Database(s) or a Database Package



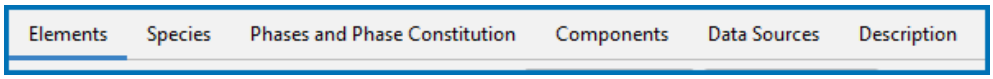


At the top of the **Configuration** window you can choose to add one or more **Databases** by clicking the ⊕ **Add a database** button and choosing it from the list of available databases. You can also choose a predefined or custom database **Package** from the list. Depending on your license, there are predefined databases and packages available to select. After adding a database, click ⊖ **Remove this database** button as required for your simulation.

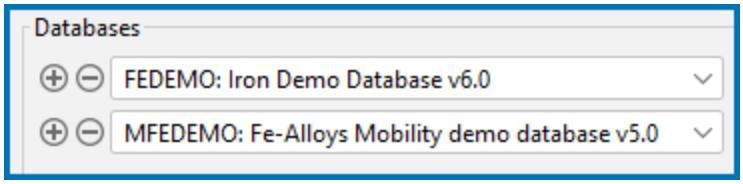
If you have chosen a database package and then remove or change a database, a message displays *Selected databases and selected package may differ*. This means that the original package you selected, which added preset databases, does not match the databases you are using for the project. For information about how to clear the message, see Global Settings: System Definer.

Global Settings: System Definer

There are several settings tabs available for the System Definer activity.



The following example uses the FEDEMO and MFEDEMO databases and Graphical Mode example **PM_G_02**, which you can open from the **Help** → **Examples Files** menu or from the top **My Project** Configuration window.



Elements

On the **Elements** tab, and based on the databases or database package selected, you can select and review elements using a **Periodic Table** or **Alphabetic List** format. Unavailable elements, which are based on the selected database, are greyed out.

Elements: Advanced Database Options

Also on the **Elements** tab, there are three special elements used in the databases.

On the **Periodic Table** view, there are three buttons. For the **Alphabetic List**, the buttons are available each as a checkbox. In both cases you toggle ON (click to select the button or checkbox) or toggle OFF (click to deselect the button or checkbox, in other words, you are *rejecting* the phase).

From this tab, you are choosing to include or reject the *whole system of phases*. Click the **Phase and Phase Constituent** tab if you want to select specific phases to reject.

This is an advanced feature. The details of these options are described for Console Mode and generally in the *Database Manager User Guide*. For example, see ELEMENT. For the purposes of Graphical Mode, the use of the buttons or checkboxes either include or reject (exclude) the vacancies (**VA**) or charged species (*I*-). It is recommended to keep the default after selecting the database(s). In general, these three special elements should not be rejected from the **System Definer > Phases and Phase Constitution** tab (Graphical Mode) or GES module (Console Mode).

There is a training module related to this feature available via the Thermo-Calc online Learning Hub. Subscriptions also include access to live monthly office hours, where you can ask our experts about any of the content on the Learning Hub or your own design simulation challenges.

Vacancy

VA. This allows a vacancy as a species. Toggled ON to include all vacancies or OFF to reject all vacancies in the phase constitution. VA itself is electrical neutral. It is usually a constituent of a phase. The element VA does not take any degree of freedom in an equilibrium calculation.

Electron Gas

/-. This represents ELECTRON_GAS with -1 net charge. It is implemented in the database which includes ionic-modeled phases, i.e. with net-charged constituents. The charged species can be formed by combining **/-** (for negative charge) or **/+** (for positive charge) with other ordinary elements, e.g. O^{-2} from O1/-2 or FE^{+2} from FE1/+2.

The element **/-** does not take any degree of freedom in an equilibrium calculation. You can combine the elements VA and /- to model charged vacancies, e.g. VA^{-2} results from VA1/-2.

To reject all charged species in the system, click to deselect (i.e. turn off). This is relevant to such databases as TCS Metal Oxide Solutions Database (TCOX), TCS Aqueous Solutions Database (TCAQ), and the OXDEMO database.

For most databases, there is an extensive list of all the phase models included with the technical information. Press F1 when in Thermo-Calc and search or navigate to the Databases section for the specific database in question.

ZE (Unit Charge)

The element **ZE** represents UNIT_CHARGE with +1 net charge. It is implemented and required only in the databases that contains the AQUEOUS solution phase such as the TCS Aqueous Solutions Database (TCAQ).

The special element Ze handles various charged aqueous species and internal electro-balance in the aqueous solution phase. The hypothetical electrode phase REF_ELECTRODE contains only the unary Ze.

- ZE should never be rejected from the **System Definer > Phases and Phase Constitution** tab (Graphical Mode) or GES module (Console Mode).
- ZE itself is the only constituent of the phase REF_ELECTRODE, i.e. the reference electrode for ZE potential. This phase (REF_ELECTRODE) should always be suspended/dormant from the **System Definer > Phases and Phase Constitution** tab (Graphical Mode) or the POLY module (Console Mode).

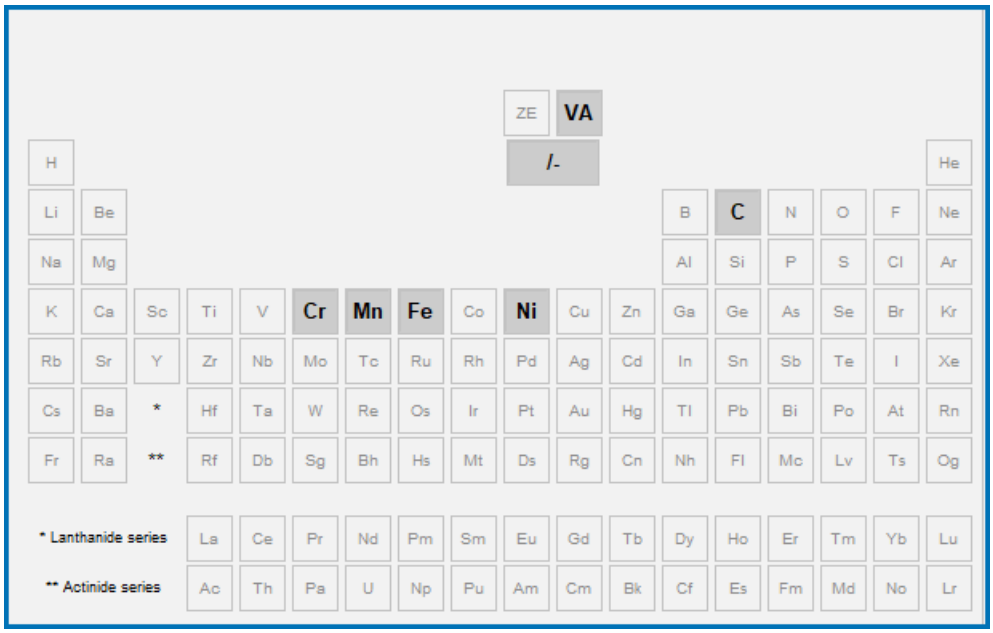
- Combining ZE with other ordinary elements forms aqueous species with net charge, e.g. the species H^{+1} results from H1ZE1 while OH^{-1} from H1O1ZE-1. The element ZE, like other ordinary elements, takes one degree of freedom in System Definer (Graphical Mode) or POLY module (Console Mode) in an equilibrium calculation.
- The *Aqueous properties* quantity, **Electric potential** is proportional to the chemical potential of ZE that is a default condition when using the Aqueous Calculator.

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

Search the help (press F1 when in Thermo-Calc) for information about the Graphical Mode **Aqueous Calculator**, its template with predefined settings, and the aqueous properties. The help also has detailed information about the compatible and recommended database for use with all aqueous calculations.

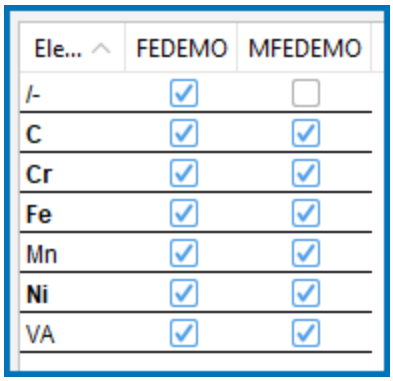
Periodic Table

In this example, using the demonstration databases FEDEMO and MFEDEMO, there are only a select number of elements to choose from when it is a DEMO database. These are selected for this example (Cr, Mn, Fe, Ni, C). The FEDEMO database is a subset of the main steel database TCS Steel and Fe-alloys Database (TCFE) and MFEDEMO is a subset of TCS Steels/Fe-Alloys Mobility Database (MOBFE).



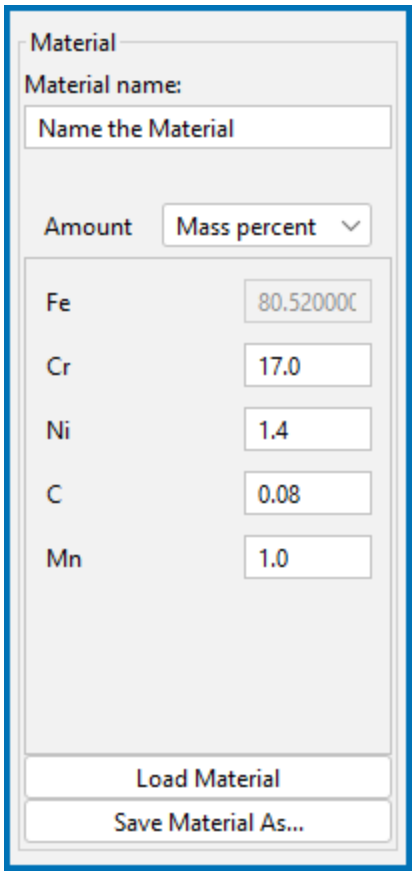
Alphabetic List

Click **Alphabetic List** to view a list of available and used elements.



Material Composition

After selecting the elements and in the **Periodic Table** view, under *Material*, you can enter a **Material name** and define the material composition **Amount** in **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**.



Properties

After selecting the thermodynamic database and, when applicable, mobility database, the **Properties** section summarizes some of the key database properties included.

The software simulates many more properties than those listed.

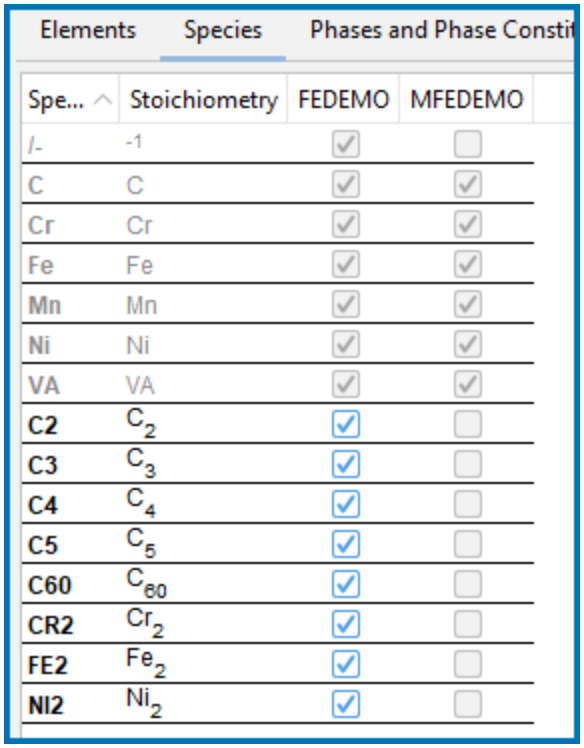
The list includes some key database-specific properties, which are roughly divided into group types (in *italics*) and then the property listed in the box in **bold**:

- *Physical properties*: **Gibbs Energy**, **Volume**, **Viscosity of liquid**, **Surface tension of liquid**, **Electrical resistivity**, and **Thermal conductivity**. If the database has no volume parameters but includes a gas phase, then **Volume (gas only)** is indicated.
- *Elastic properties*: In applicable databases containing **Elastic constants**.

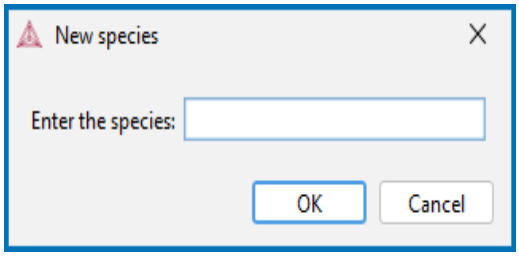
- **Diffusion data**: Indicates there are properties available from a mobility/kinetic database.
- **Aqueous**: Indicates that the group of *Aqueous properties* are available for calculations using databases including the aqueous phase.

Species

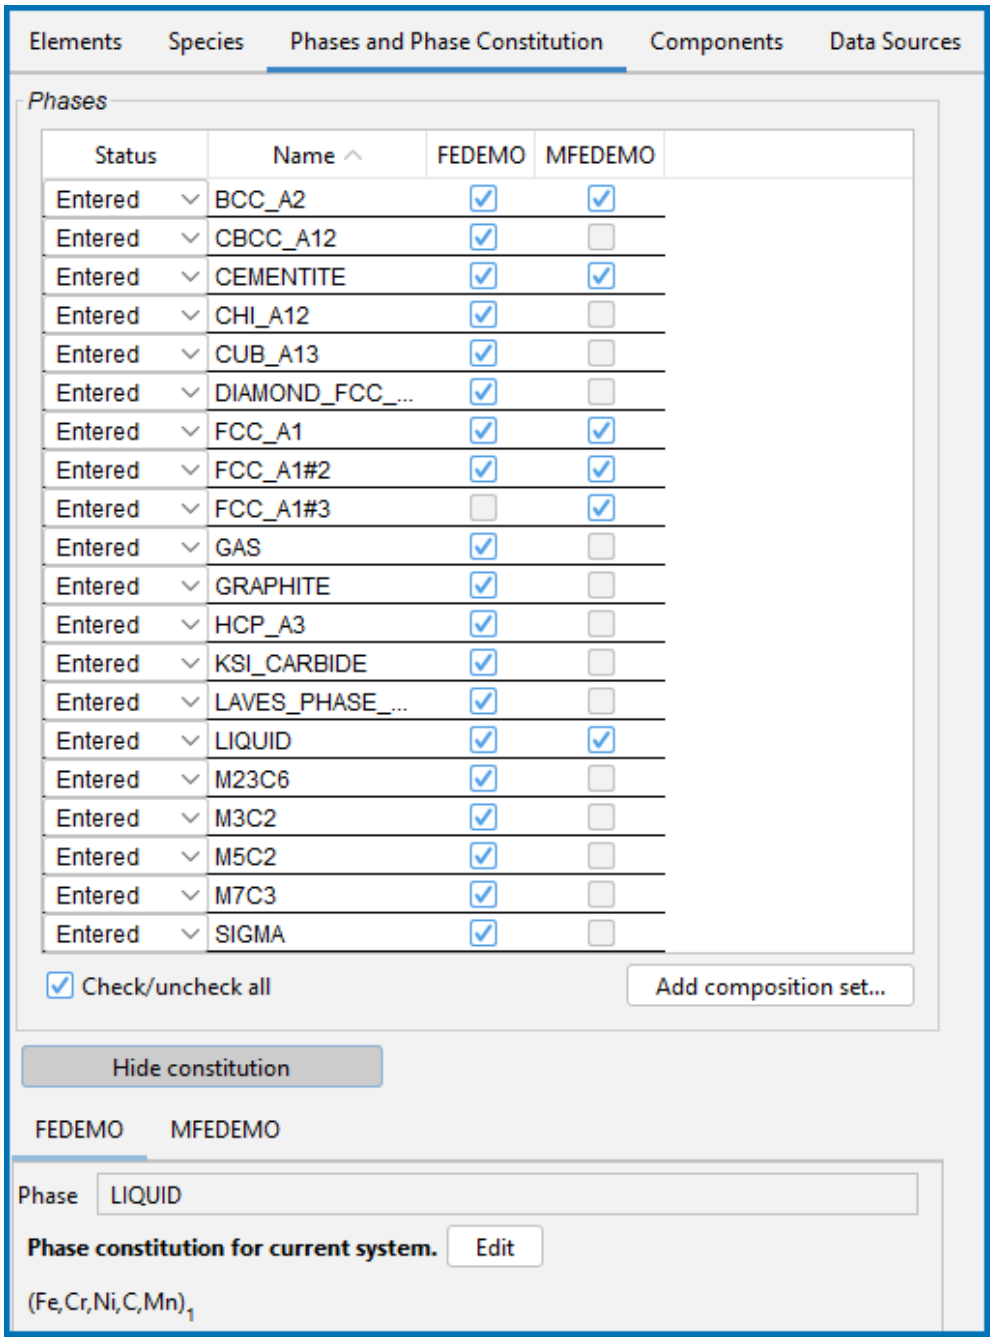
On the **Species** tab for each database you can select and edit the *Species* and view the *Stoichiometry* for the selected database species.



At the bottom of the window, click **Add new species** and enter a **New species** name in the field.



Phases and Phase Constitution

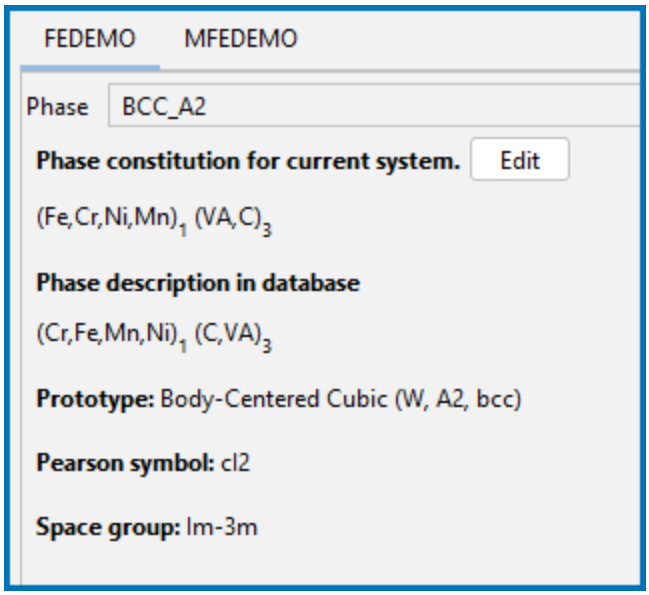


At the top of the **Phases and Phase Constitution** tab for each database you can review and edit the **Status** (**Entered** or **Dormant**) for the selected *Phases*.

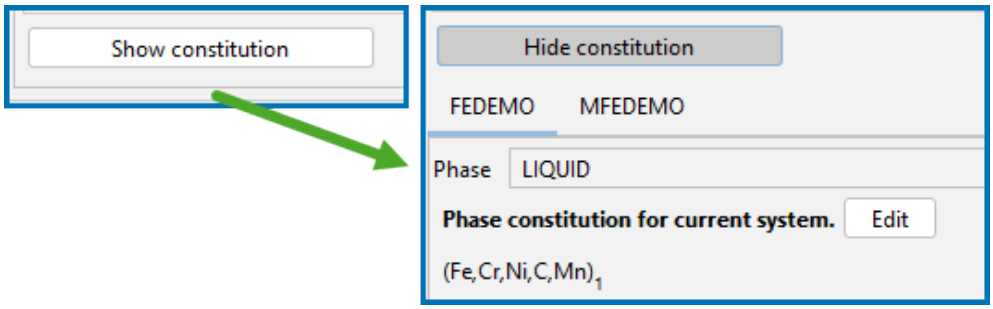
Select the **Check/uncheck all** checkbox to toggle between the options.

From this tab, you can also choose specific phases to include or exclude the **VA** and *I*- database species instead of doing it for the whole system as per Configuration Window Settings.

To review the Phase constitution for a specific phase, click it in the *Phase* list (for example **BCC_A2**) and its details are displayed at the bottom of the window for the database selected. Click the relevant database tab to see its constitution by phase. Click **Edit** then click an element to select or reject a constituent. The last remaining constituent on a sublattice cannot be rejected.

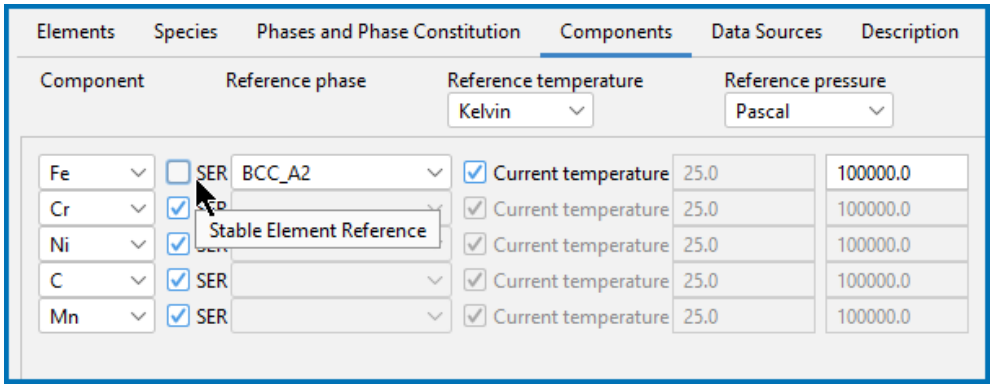


You can click the **Show constitution** or **Hide constitution** buttons found between the Phase table and Constitution details. Use this to toggle showing or hiding the details as needed. This is particularly useful when there is a long list and you are working on smaller displays where it may be difficult to scroll easily.



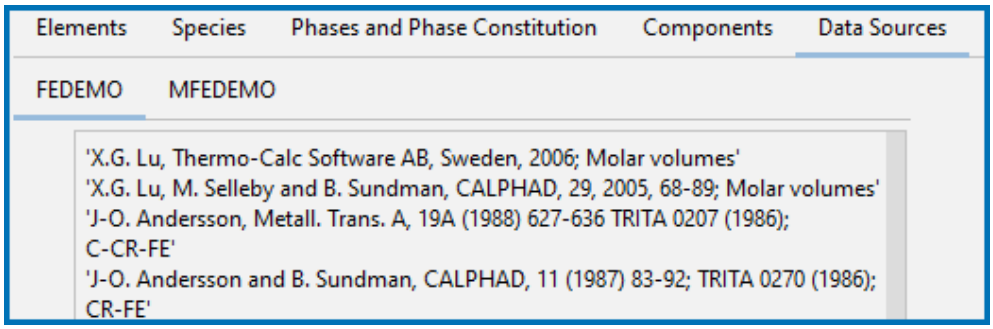
Components

The **Components** tab is where you can review and edit the **Component**, **Reference phase**, **Reference temperature**, and **Reference pressure**. Click to toggle the **SER** (Stable Element Reference) checkbox on and off. Then choose a **Reference phase** from the list and edit accordingly. Choose a unit for the **Reference temperature** (**Kelvin**, **Celsius**, or **Fahrenheit**) and **Reference pressure** (**Pascal**, **Atmospheres**, or **Bar**).



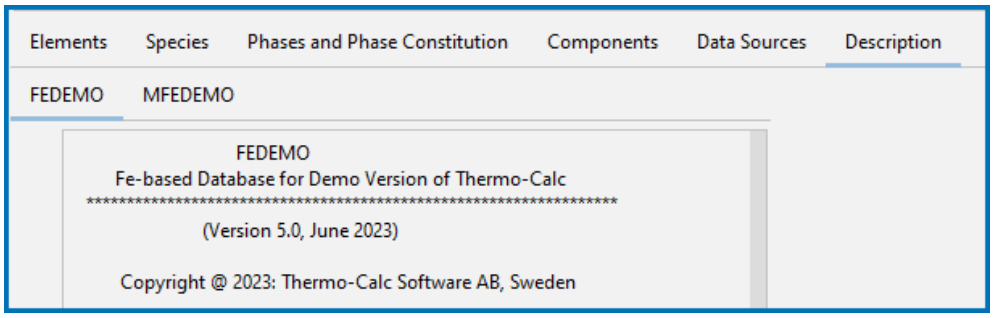
Data Sources

Data source references are shown after performing the activity. Click **Perform** or **Perform Tree** at the bottom of the window when your system is set up.



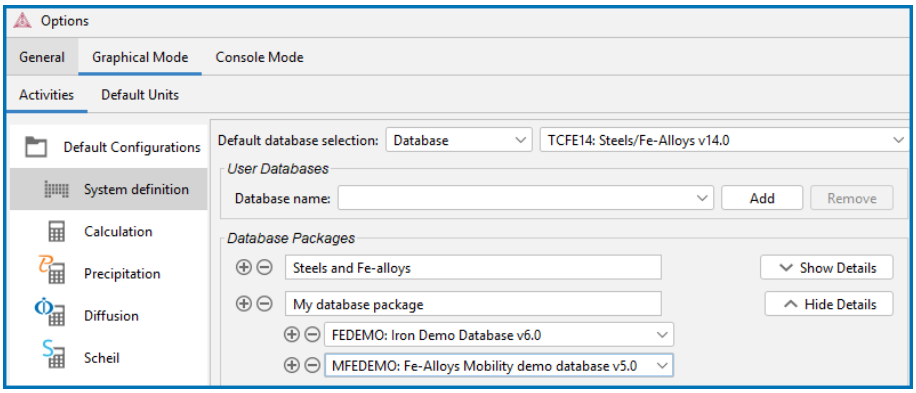
Description

The **Description** tab displays a description of the selected database(s). In this example, **FEDEMO**, or click **MFDEMO** to view that information.

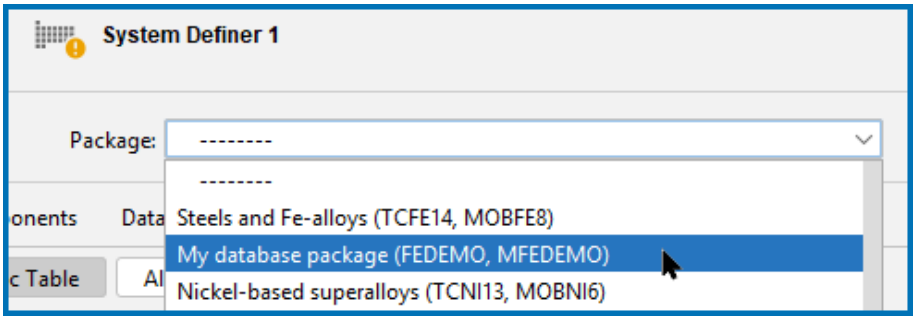


Creating a Database Package

1. From the main menu select **Tools** → **Options** .
2. Click the **Activities** tab and click **System definition**.
3. Under *Database Packages*, click the **Add a database package** ⊕ button.
4. Replace the default text *<Package #1>* with a name for the package, for example **My database package**.
5. Select a database from the **Choose database** list, for example, **FEDEMO Iron Demo Database**.
6. Click the ⊕ **Add a database** button and from the **Choose database** list, select another database.
7. Click **OK**. The software needs to relaunch for the Database Package to be available to choose as the default for new System Definer activities.



The package is available for new System Definer nodes defined after adding the package.



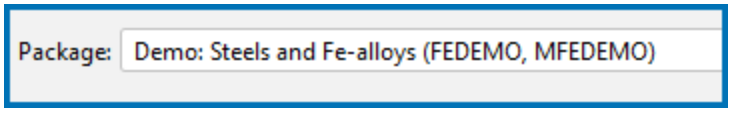
Clearing a Database Package Message and Global Settings: System Definer

Clearing a Database Package Message

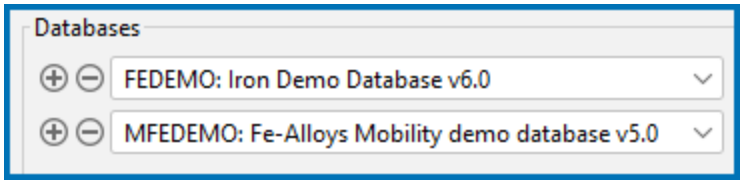
Sometimes when working on the System Definer **Configuration** window, you may add or delete Databases. If you originally added a Database Package, the addition or removal of a database means that the original package you selected does not now match the databases you are using. To clear the message *Selected databases and selected package may differ* and reset the databases you need to either:

- Change the newly added database back to the one that matches the database package, or
- Choose another package from the **Package** list, then select the package you want.

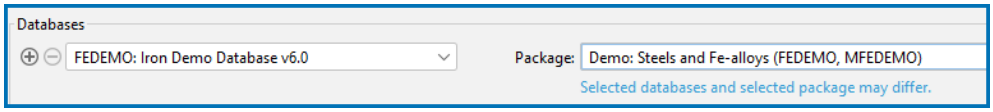
For example, from the **Package** list you select **Demo: Steels and Fe-alloys**.



This adds the **FEDEMO** and **MFEDEMO** databases.



If you add or remove **Databases**, in this example **MFEDEMO** is removed, then this does not match the **Package** and the message displays:



To clear the message, click the ⊕ **Add a database** button and from the **Choose database** list, select the database that belongs with the package, in this example, **MFEDEMO**. The message is cleared.

You can also choose another package from the list, which changes the databases, and then re-select the original package to reset the message.

Creating a Database Package and Global Settings: System Definer

About the Material Files

When you are working with the System Definer or Material to Material Calculator in Graphical Mode you can open the default **Materials** folder included with your installation. The files are in .xml format and the data contained are from some common alloys. You can also save and create your own materials files or copy the xml files to the Materials folder.

Installed Examples, Manuals, and Materials Folders and Loading or Saving a Material

My Materials

This is where you can add your own material files to be able to load it to the System Definer or Material to Material Calculator. When you are in the System Definer **Configuration** window, you define your material then click **Save material as**. You can save the profile to this folder or create a folder with a new name.

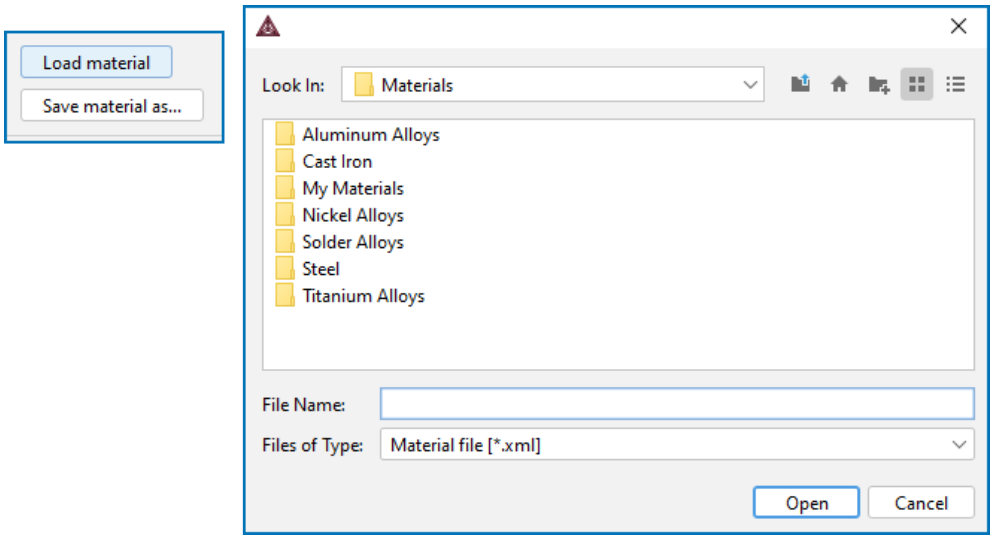
Loading or Saving a Material

This topic is applicable to the System Definer and the Material to Material Calculator.

Click **Load material** to open a material file. The default folder opens to the **Materials** folder included with your installation.



You can click **Save material as** to save the material you defined, for example **Ferritic**. Add your own folders as needed.

For the **System Definer**, and if you load a material file and then change the composition, a message displays *The composition has changed*. This means that the original values/composition do not match the values you are using for the project. The message is cleared by either reloading the material file or editing the composition field to the original value.

Equilibrium Calculator

An **Equilibrium Calculator** allows you to set the conditions for, and perform, a calculation. You can add the calculator to the System Definer directly (right-click and select it from the **Create New Successor** menu) or use a variety of the available templates.

Once you have added an Equilibrium Calculator, the **Configuration** window has these settings tabs. An Equilibrium Calculator that is the successor of another Equilibrium Calculator inherits all the settings of the predecessor.

- **Conditions**: Set the conditions for your calculation that define the stepping or mapping axis variables. Click the **Switch to Simplified Mode** and **Switch to Advanced Mode** buttons to toggle between those settings.
- **Functions**: Define your own quantities and functions, which you then can calculate and plot.
- **Options**: Modify numerical settings that determine how equilibria are calculated, as well as how stepping and mapping calculations are performed.

Next Steps: Define the Equilibrium Calculator.

Learn More

The **Options** tab is where you can locally define specific settings. These settings can also be applied globally. To open the **Options** window: From the main menu select **Tools** → **Options** and click the **Activities** tab. Then click **Calculation**.

There are these templates available under **Equilibrium** that use an Equilibrium Calculator: **Single Point**, **One Axis**, and **Phase Diagram**. Choose one of these to quickly set up a simulation. The **Quick Start** wizard is also an option. See Getting Started Links, Templates, and the Property Navigator.

Define the Equilibrium Calculator

1. Add an Equilibrium Calculator node to the System Definer. If you used the **Single Point**, **One Axis**, or **Phase Diagram** templates (on the **My Projects Configuration** window under **Equilibrium**), click the **Equilibrium Calculator** node to display the **Configuration** settings window.
2. In the **Configuration** window, enter the settings described in Conditions Tab Settings. For the **Options** and **Functions** tab settings, see
   - Options Tab Settings
   - Functions Tab Settings
3. Once you have finished defining the Equilibrium Calculator, you also choose settings on the Plot Renderer.

Learn More

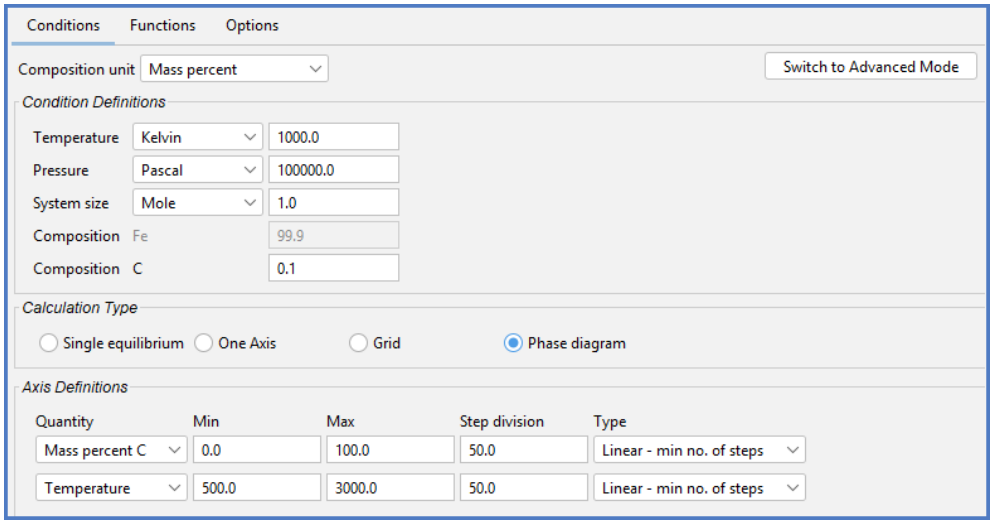
There are several examples that use an Equilibrium Calculator. As a start, see T_01: Calculating a Single-Point Equilibrium.

For an example of how serially coupled Equilibrium Calculators can be used, see T_06: Serially Coupled Equilibrium Calculators.

Fixed Phases

Conditions Tab Settings

Conditions and axis variables for the **Equilibrium Calculator** are set in the **Conditions** tab on the **Configuration** window. The tab can be viewed in two modes: **Simplified** (the default) or **Advanced** (see About Advanced Mode below). The conditions to set depend on the type of calculation.



Composition Unit and Condition Definitions

Composition Unit

Select the **Composition unit**: **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**.

Condition Definitions

Specify the values (and units) of the state variables: **Temperature**, **Pressure**, and **System size** or any other available lists under *Condition Definitions*.

Calculation Type

Click to select a *Calculation Type*:

- **Single equilibrium** (no axes): To calculate a single point. The results from this calculation are displayed in the **Event Log**.
- **One Axis**: To vary a quantity on the X-axis.

- **Grid**: Computes the equilibrium of each grid point in a two-dimensional grid.
- **Phase diagram**: To calculate in a defined multicomponent heterogeneous system, from one or more initial equilibria. A phase diagram is usually mapped within a specific space that is constructed by two (or more) defined independent mapping axis-variables.

For **Single equilibrium**, no additional settings are required. Add a **Table Renderer** to perform the calculation and view the details in the **Visualizations** window.

When you use the Equilibrium Property Model Settings with the **Property Model Calculator**, it is the same calculation result as when you are using an **Equilibrium Calculator** with the **Single equilibrium** calculation type.

Axis Definitions

- **One Axis**: Define the axis variable using these fields and menus: **Quantity**, **Min**, **Max**, **Step division**, **Type**, and **Step Method**.
- **Grid**: Define the two axis variables using these fields and menus: **Quantity**, **Min**, **Max**, and **Number of steps**.
- **Phase diagram**: Define the two axis variables using these fields and menus: **Quantity**, **Min**, **Max**, **Step division**, and **Type**.

If the Calculator already has a Plot Renderer as a successor and you change the stepping/mapping quantities, then the quantities represented on the X- and Y-axis are automatically updated in the Plot Renderer.

Depending on the calculation type selected, there are also a variety of Plot Types to choose from.

Step Division and Type (One Axis and Phase Diagram)

Enter a **Step division** and select a **Type**: **Linear - min no. of steps**, **Linear - max step size**, or **Logarithmic - scale factor**.

- For **Linear - min no. of steps**, the **Step division** value specifies a minimum number of steps that is calculated between the minimum and maximum value during the stepping/mapping operation.
- For **Linear - max step size**, the **Step division** sets the maximum size of each step. For **Logarithmic - scale factor**, **Step division** specifies the scale factor of a logarithmic function that distributes the steps from the initial equilibrium to the minimum and maximum values defined.

Step Method (One Axis)

From the **Step Method** list, choose **Normal** or **Separate phases**.

- **Normal** allows a stepping calculation with the chosen independently-varying equilibrium condition (axis-variable). Only the step axis value is changed between each step.
- **Separate phases** calculates how the Gibbs energy for a number of phases varies for different compositions. This is particularly useful to calculate Gibbs energies for complex phases with miscibility gaps and for an ordered phase that is never disordered (e.g. SIGMA-phase, G-phase, MU-phase, etc.).

Number of Steps (Grid)

Set a fixed **Number of steps**. The number of steps along with the minimum and maximum values for the axes define a grid. For each grid point an equilibrium is calculated.

About Advanced Mode

Click **Switch to Advanced Mode** to:

- Add and remove conditions
- Define phase options
- Set additional axis definitions.

> The number and types of conditions set must still conform to the Gibbs' phase rule. The **Number of missing conditions is** field, at the top of the tab shows how many conditions that you have left to set. If the number is negative, then that number of conditions need to be removed.

List of Advanced Mode Condition Definitions

> When applicable, these quantities are grouped together as **Phase equilibria** on the Plot Renderer. See Quantities Groups Available for Plots and Tables.

- Activity of component
- Activity referred to a phase
- Amount of component
- Amount of component in a phase
- Amount of phase
- Chemical potential of a component
- Chemical potential referred to a phase
- Composition
- Enthalpy
- Entropy
- Fix phase
- Gibbs energy
- Helmholtz energy
- Internal energy
- In(activity of component)
- In(activity referred to a phase)

- Pressure
- Site fraction
- System size
- Temperature
- User-defined
- Volume

Phase Options (Advanced Mode)

Click **Switch to Advanced Mode** to access the *Phase Options* section.

Phase Status

Click the add ⊕ button to **Add a phase** or the minus ⊖ button to **Remove a phase**. Click the **Phase status** checkbox to choose a phase from the list. Then choose **Entered**, **Dormant**, or **Suspended** for the chosen phase.

Phase Energy Addition

Click the add ⊕ button to **Add a phase** or the minus ⊖ button to **Remove a phase**. Click the **Phase energy addition** checkbox to choose a phase from the list. Then enter a value in the field with a **J/mol formula unit**.

Use this to adjust the stability of a phase, e.g. to slightly change a transformation temperature or the equilibrium amount.

Learn More

Also see Options Tab Settings, Functions Tab Settings, and Fixed Phases . Depending on the calculation type selected, there are also a variety of Plot Types to choose from.

T_01: Calculating a Single-Point Equilibrium

T_02: Stepping in Temperature in the Fe-C System

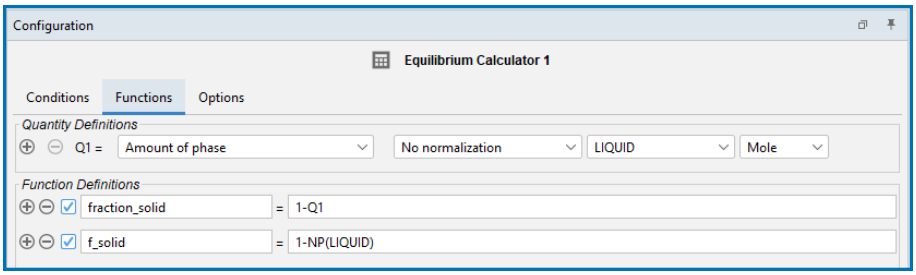
T_05: Stable and the Metastable Fe-C Phase Diagrams.

Functions Tab Settings

The **Functions** tab for an **Equilibrium Calculator** allows you to define your own functions that can be plotted in a Plot Renderer.

Calculating and Plotting Functions

1. Add an **Equilibrium Calculator** node and click it in the **Project** window.
2. In the **Configuration** window click the **Functions** tab.
3. Under **Quantity Definitions**, define **Q1**. Click the add ⊕ button to **Add a new quantity**. Then from the lists, choose the variable for each quantity to define. The quantities are called **Q1**, **Q2**, **Q3** and so on. In this example, the quantity **Q1** is defined as the **Amount of phase**, with **No normalization**, **LIQUID** in **Mole** units.



4. Under **Function Definitions**, click the add ⊕ button to add a new function. In the left field edit the default name of each function and enter the function itself in the right field after the equal sign. In this example, the quantity defined as Q1 is renamed to **fraction_solid**, which gives as its output the fraction of solid phase (**1-Q1**).

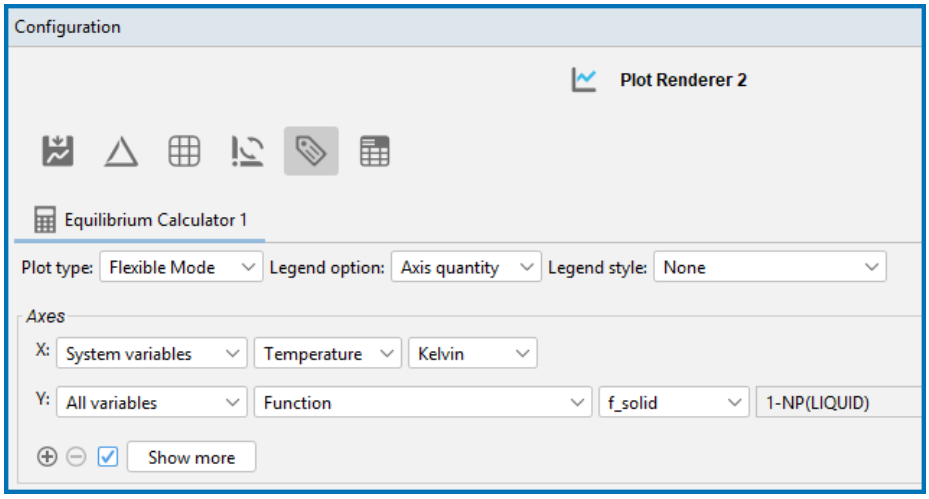
> You can also use Console Mode syntax when entering the function. For example, the function above can be entered as `1-NP(LIQUID)`. See Parameters, Functions, and Variables.

5. To plot the defined function, right-click **Equilibrium Calculator** and choose **Create New Successor → Plot Renderer** .
6. Click the new **Plot Renderer** node.
   a. For the axis variable, which is grouped under an *Axes* section (**Flexible Mode**), or listed individually as *X*, *Y*, or *Z* (**Grouped Mode**), choose **All variables** from the first list.

b. Select **Function** from the second list.

c. From the third list, choose the function you defined on the Equilibrium Calculator Functions tab. In this example the Y axis is set to plot the value of the function **f_solid**.

d. When run, the Plot Renderer plots the value of the function.



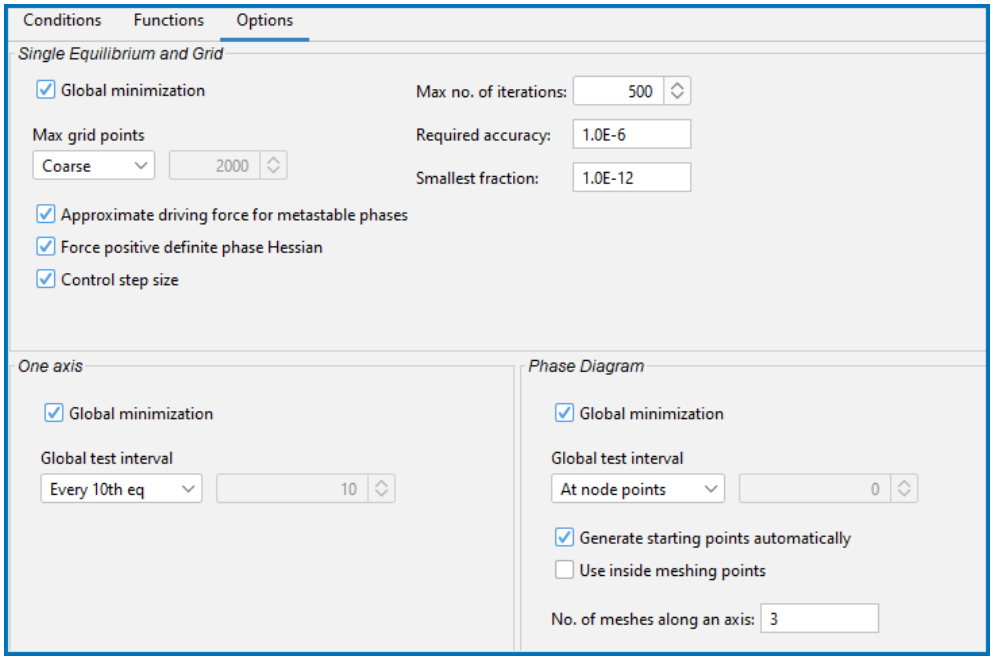
Learn More

Also seeConditions Tab Settings, Options Tab Settings, and Fixed Phases .

For an example of how you can use functions that you define, see T_07: User-Defined Functions.

Options Tab Settings

These settings are for the **Equilibrium Calculator** and are located on the **Configuration** window → **Options** tab.



Single Equilibrium and Grid

Under *Single Equilibrium and Grid*, there are these *Calculation Type* setting options.

Global Minimization

The **Global minimization** checkbox is selected by default to ensure that the most stable minimum under the specified conditions is computed.

Max Grid Points

For the **Max grid points**, the default is **Coarse** (2000 grid points), or choose **Medium** (20,000 grid points), **Fine** (200,000 grid points), or **Custom** to set your own number of grid points.

Approximate Driving Force for Metastable Phases

The **Approximate driving force for metastable phases** checkbox is selected by default. Click to clear the checkbox to change the default as required and based on the options described below.

This setting involves the convergence of metastable phases and affects their driving forces. It can also have an effect on when an equilibrium is considered successful.

The default is to allow an equilibrium with metastable phases that have not converged, as long as the stable phases have converged. This is efficient but often causes approximate values of the driving forces for the metastable phases.

If you change the default, it enforces metastable phases to converge. This gives accurate driving forces for metastable phases as well as stable phases. It can however take a slightly longer time, and if metastable phases do not converge it causes the equilibrium calculation to fail.

Force Positive Definite Phase Hessian

The **Force positive definite phase Hessian** checkbox is selected by default and this setting determines how to reach the minimum of an equilibrium state.

ADVANCED_OPTIONS

Control Stepsize

The **Control stepsize** checkbox is selected by default and this setting determines how to reach the minimum of an equilibrium state.

ADVANCED_OPTIONS

Max No of Iterations

Enter or choose a value for the **Max no. of iterations**. By default, the program tries 500 iterations before it gives up. As some models give computation times of more than 1 CPU second/iteration, this number is also used to check the CPU time and the calculation stops if 500 CPU seconds/iterations are used.

The default value for an **Aqueous Calculator** is `1000`. This is because there is usually a very small amount in the AQUEOUS phase and this default increases the stability of the calculation.

Required Accuracy

The default **Required accuracy** is `1.0E-6`. This is a relative accuracy, and the program requires that the relative difference in each variable must be lower than this value before it has converged. A larger value normally means fewer iterations but less accurate solutions. The value should be at least one order of magnitude larger than the machine precision.

Smallest Fraction

The default **Smallest fraction** (or **Smallest fraction in a phase** for Property Models) is `1.0E-12`. This is the value assigned to constituents that are unstable. It is normally only in the gas phase you can find such low fractions.

The default value for the smallest site-fractions is `1E-12` for all phases except for IDEAL phase with one sublattice site (such as the GAS mixture phase in many databases) for which the default value is always as `1E-30`.

The default value for an **Aqueous Calculator** is `1E-16`. This is because there is usually a very small amount in the AQUEOUS phase and this default increases the stability of the calculation.

In Console Mode, the default of 1E-30 for IDEAL phases is true unless you are using the command SET_NUMERICAL_LIMITS to reset an even-lower value (e.g. `1E-45`, that is naturally enforced to all the phases in the system.

One Axis

Under *One Axis*, there are these *Calculation Type* setting options.

Global Minimization

The **Global minimization** checkbox is selected by default to ensure that the most stable minimum under the specified conditions is computed.

ADVANCED_OPTIONS

Global Test Interval

The default **Every 10th eq** is the recommended **Global test interval** i.e. every tenth step and at each phase change during calculations. Or choose **Always** or **Custom**.

If you choose **Custom**, the integer number determines how often the global minimization should be used during step and mapping. Any other positive integer number, n, suggests it performs a global minimization test at every *n*-th step during calculations.

Phase Diagram

Under *Phase diagram*, there are these *Calculation Type* setting options.

Global Minimization

The **Global minimization** checkbox is selected by default to ensure that the most stable minimum under the specified conditions is computed.

Global Test Interval

The default **At node points** is the recommended **Global test interval** and is used only at node points during the calculations.

- If you choose **Every 10th eq**, this is every tenth step and at each phase change during calculations.
- If you choose **Custom**, the integer number determines how often the global minimization should be used during step and mapping. Any other positive integer number, n, suggests it performs a global minimization test at every *n*-th step during calculations.

Generate Starting Points Automatically

The **Generate starting points automatically** checkbox is selected by default.

Use Inside Meshing Points

Click the **Use inside meshing points** checkbox as required. The initial mesh consists of initial equilibrium points added only along the edge/border of the diagram defined by the axis-variables. If you select the checkbox, then the initial equilibrium points added are also added to the inside edge.

No of Meshes Along an Axis

The default **No of meshes along an axis** is 3 , which represents how many intervals of initial equilibrium points are added along an edge in the diagram. For example, if set to 2 (two), initial equilibrium points are added at the beginning, center, and end of each axis-variable forming 2 intervals.

Learn More

Also seeConditions Tab Settings, Functions Tab Settings, and Fixed Phases .

This topic also includes information about the Aqueous Calculator **Options** tab, which has the same settings.

You can change these settings locally for a specific Calculator or globally for some defaults in the **Options** *window* (a different location than the tab).

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** <*version*> → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Graphical Mode** tab and the **Calculation** node in the tree.

Fixed Phases

This topic is for the **Equilibrium Calculator** where you work on the **Configuration** window on the **Conditions** tab. It describes how to use the **Advanced Mode** to set a phase to be fixed at a certain amount. This allows you to, for example, find out at what temperature a material starts to melt. If you set the phase to be fixed to liquid phase at zero amount, and do not define the temperature state variable, then you can calculate at what temperature the material enters a state where the liquid phase is no longer zero (that is, when it starts to melt).

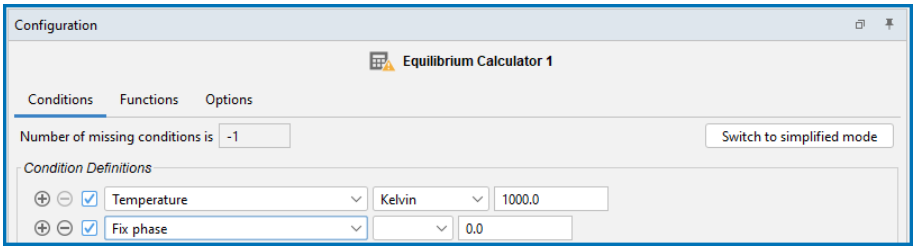
Calculating with a Fixed Phase

For a fixed phase equilibrium calculation, it is recommended to serially couple the Equilibrium Calculators. This is where one Equilibrium Calculator activity is the successor to another Equilibrium Calculator activity that performs an ordinary equilibrium calculation, and then, for the condition you are interested in, you make a rough estimate of the value. This gives the fixed phase calculation better starting values.

1. Right-click a node that can add an **Equilibrium Calculator** to your project.
2. In the **Project** window, click the **Equilibrium Calculator** activity node.
3. In the **Configuration** window, click **Switch to Advanced Mode**.

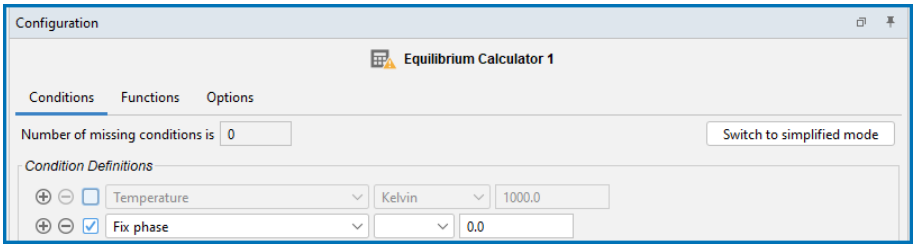
   If the **Default calculation mode** is globally set to **Advanced** then by default the Configuration window is already in advanced mode.

4. Under *Condition Definitions*, click the **Add quantity** button.
5. Select **Fix phase** from the first menu.
6. Select the phase that you want to fix in the second menu, and set the amount of that phase you want to fix the phase to. For example, if you want to know when your material starts to melt, set the phase to **LIQUID** and the value to **0.0**:



Above the *Condition Definitions*, the **Number of missing conditions is** field is probably **-1**. This means that you must remove one condition.

7. To remove a condition, either click the ⊖ **Remove** button, or click to clear the checkbox. For example, if you want to know at what temperature your material starts to melt, then you cannot have a fixed temperature, in which case the temperature condition is not selected:



The **Number of missing conditions is** field displays **0**. When you have set all your conditions, you can perform the Equilibrium Calculator (now or later).

Material to Material Calculator

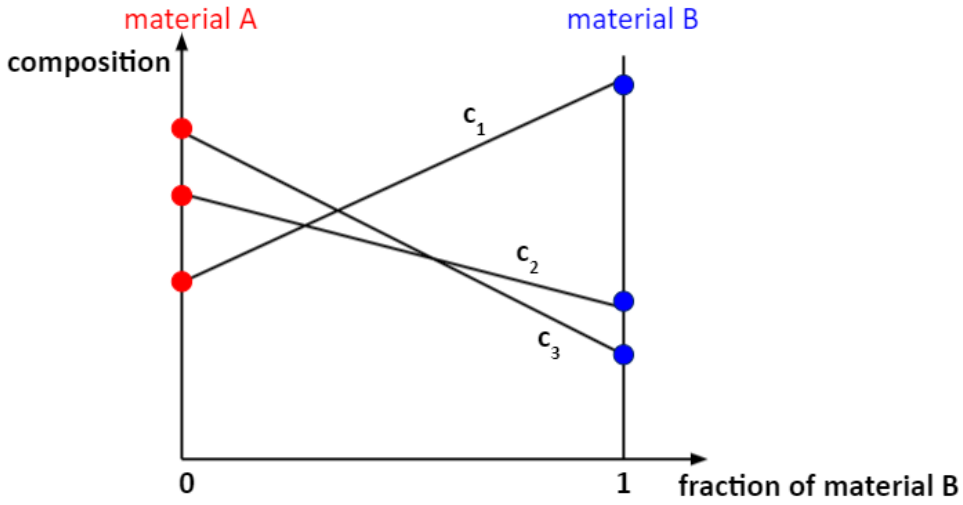
A **Material to Material Calculator** allows you to set the conditions for, and perform, a calculation to examine how materials transition from one into the other. You can add the calculator to the **System Definer** directly (right-click and select it from the **Create New Successor** menu).

There is a **Material to Material** template available under **Equilibrium** that you can use to quickly set up a simulation. See Getting Started Links, Templates, and the Property Navigator.

Typical applications are for graded materials, non-similar material joints (without requiring a diffusion calculation), or a reaction of two materials, e.g. influence of volcanic ash on a turbine component in an engine.

For example, you can look at the transitions of phase compositions (c_1, c_2, c_3 in the diagram) for two materials, A and B and then calculate an equilibrium, one axis (similar to a property diagram), or phase diagram to examine, for example, what phases are forming at the interfaces or to see what kinds of reactions there are at specific points in the transition.

Composition of the elements is evolving versus the fraction of the second material.



Once you have added a **Material to Material Calculator**, the **Configuration** window has these settings tabs.

- **Conditions**: Set the conditions for your calculation that define the stepping or mapping axis variables.
- **Functions**: Define your own quantities and functions, which you then can calculate and plot.
- **Options**: Modify numerical settings that determine how equilibria are calculated, as well as how stepping and mapping calculations are performed.

Learn More

Define the Material to Material Calculator

Read more on our website about the Material to Material Calculator. If you are in Thermo-Calc, press F1 to search the help.

Define the Material to Material Calculator

This topic lists the basic steps to define a **Material to Material Calculator**.

1. Add a Material to Material Calculator node to the System Definer. If you used the **Material to Material** template (on the **My Projects Configuration** window under **Equilibrium**), click the **Material to Material Calculator** node to display the **Configuration** settings window.
2. In the **Configuration** window, enter the settings described in Material to Material Calculator Conditions Tab Settings.

   For the **Options** and **Functions** tabs, the settings are the same as the Equilibrium Calculator. See Options Tab Settings and Functions Tab Settings.

3. Once you have finished defining the Material to Material Calculator, you also choose settings on the Plot Renderer.

For an example, see T_14: Fe-Cr-Ni Transition Comparison Using the Material to Material Calculator.

Material to Material Calculator Conditions Tab Settings

Conditions and axis variables for the **Material to Material Calculator** are set in the **Conditions** tab on the **Configuration** window. The conditions to set depend on the type of calculation.

The **Material to Material** template (on the **My Projects Configuration** window under **Equilibrium**) creates a project to perform calculations to examine how materials transition from one into the other. The project consists of a System Definer, Material to Material Calculator, and a Plot Renderer.

General Settings

The following outlines what you can set on the **Conditions** tab.

Loading or Saving a Material

Composition Unit

Select the **Composition unit**: **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**.

Condition Definitions

Under *Condition Definitions*:

- For both the **First material** and **Second material**, define the values (and units) of the state variables **Temperature** and **Pressure**.
- Enter a **Fraction of second material**.
  - For a **Single equilibrium** calculation this is used as condition for the calculation.
  - For a **One Axis** calculation this is used as the start value for the calculation.
  - For a **One Axis** or **Phase diagram** calculation, and if the **Fraction of second material** is chosen as the *Axis Definition>Quantity*, then it is stepping between the *Min* and *Max*.
- For both materials, select the **Dependent component**.
- Select the **Activity conditions** checkbox to define the **Activity of component** for one or more components. By default this is not selected. Click the **Add quantity** and

Remove quantity buttons to add and remove conditions.

- The reference state is defined on the System Definer.

Condition Definitions > Define the First and Second Materials

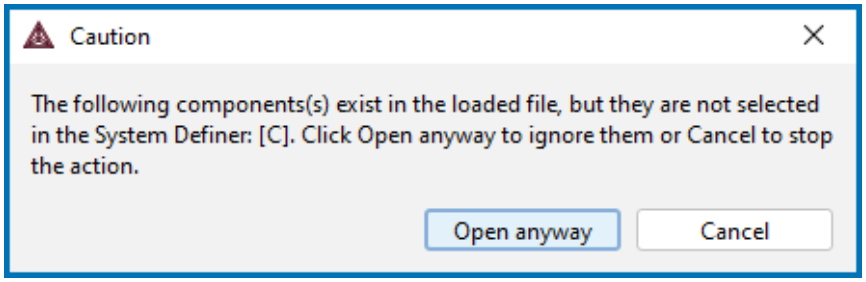
For each **First material** and **Second material** component there are individual settings to define as follows.

Enter a unique **Material name** for each. This name is used on the plots and in the quantity definitions so it is good to use as concise a name as possible that clearly identifies each material. For example, `Martensitic Steel` for the **First material** and `Alloy 800` for the **Second material**.

For each **Composition** field, enter numeric values for each material.

- Click **Save material as** after defining a composition to add it for reuse in other projects and calculations.
- Click **Load material** to add the composition of a predefined material from an xml file. Also see Material to Material Calculator Conditions Tab Settings

If the user-defined material file includes one or more components not defined on the System Definer, then you are prompted to make a decision:



Click **Open anyway** to continue to load the material file even with the undefined component(s). However, this means the undefined component is excluded at first from calculations until it is further defined on the System Definer. Once the material is defined then it is automatically included the next time calculations are run. Otherwise, click **Cancel** to stop the action and either edit the material file or manually define the component(s) in the System Definer.

Calculation Type and Axis Definitions

Click to select a *Calculation Type*:

- **Single equilibrium** (no axes): To calculate a single point. The results from this calculation are displayed in the **Visualizations** window if a Table Renderer is used.
- **One Axis**: To vary a quantity on the *X*-axis; the fraction of one of the materials or temperature.
- **Phase diagram**: To calculate a section in a multicomponent system between two materials, transitioning from one into the other. The phase diagram is mapped within a specific space that is constructed by the two mapping axis-variables; the fraction of one of the materials and temperature.

Step Division and Type (One Axis and Phase Diagram)

Enter a **Step division** and select a **Type**: **Linear - min no. of steps**, **Linear - max step size**, or **Logarithmic - scale factor**.

- For **Linear - min no. of steps**, the **Step division** value specifies a minimum number of steps that is calculated between the minimum and maximum value during the stepping/mapping operation.
- For **Linear - max step size**, the **Step division** sets the maximum size of each step. For **Logarithmic - scale factor**, **Step division** specifies the scale factor of a logarithmic function that distributes the steps from the initial equilibrium to the minimum and maximum values defined.

Axis Definitions

- **One Axis**: Define the axis variable using these fields and menus: **Quantity**, **Min**, **Max**, **Step division**, **Type**, and **Step Method**.
- **Phase diagram**: Define the two axis variables using these fields and menus: **Quantity**, **Min**, **Max**, **Step division**, and **Type**.

Also see additional setting details for **Step division**, **Type**, and **Step Method**.

If the Calculator already has a Plot Renderer as a successor and you change the stepping/mapping quantities, then the quantities represented on the X- and Y-axis are automatically updated in the Plot Renderer.

Step Method (One Axis)

From the **Step Method** list, choose **Normal** or **Separate phases**.

- **Normal** allows a stepping calculation with the chosen independently-varying equilibrium condition (axis-variable).
- **Separate phases** calculates how the Gibbs energy for a number of phases varies for different compositions. This is particularly useful to calculate Gibbs energies for complex phases with miscibility gaps and for an ordered phase that is never disordered (e.g. SIGMA-phase, G-phase, MU-phase, etc.).

Learn More

Functions: This is the same as the Equilibrium Calculator. See Functions Tab Settings

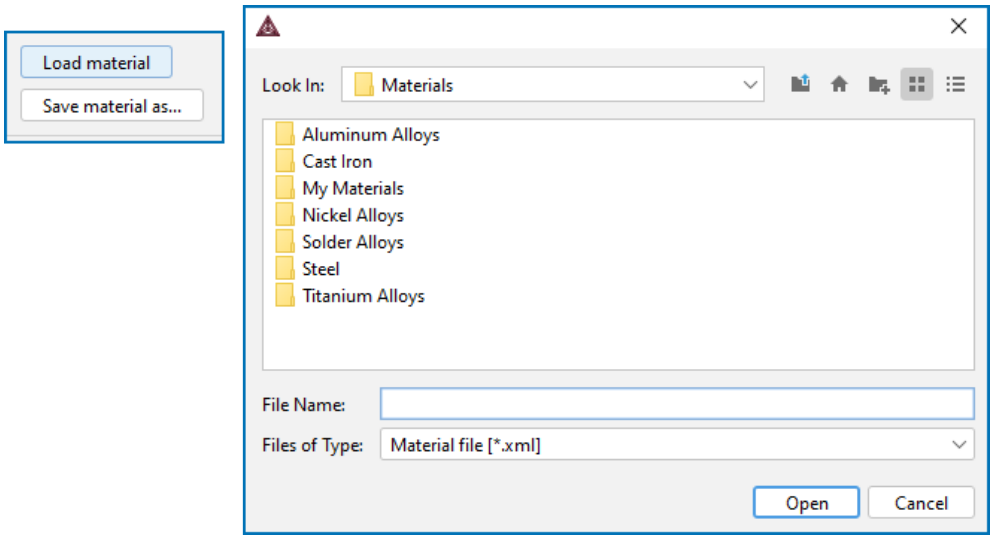
Options: This is the same as the Equilibrium Calculator. See Options Tab Settings

For an example, see T_14: Fe-Cr-Ni Transition Comparison Using the Material to Material Calculator.

Loading or Saving a Material

This topic is applicable to the System Definer and the Material to Material Calculator.

Click **Load material** to open a material file. The default folder opens to the **Materials** folder included with your installation.



You can click **Save material as** to save the material you defined, for example **Ferritic**. Add your own folders as needed.

For the **System Definer**, and if you load a material file and then change the composition, a message displays *The composition has changed*. This means that the original values/composition do not match the values you are using for the project. The message is cleared by either reloading the material file or editing the composition field to the original value.

Binary Calculator

A **Binary Calculator** can be used for some calculations involving two components. You can think of this activity as a combination of a System Definer and an Equilibrium Calculator, but designed to simplify setting up and performing calculations on binary systems.

The Binary Calculator relies on some specifications that are not supported by all databases. You need a specially designed database for the Binary Calculator such as the TCBIN database.

Template

There is a **Binary** template available on the **My Projects Configuration** window under **Equilibrium** that you can use to quickly set up a simulation. See Getting Started Links, Templates, and the Property Navigator.

Learn More

Configuration Settings

See Configuration Window Settings.

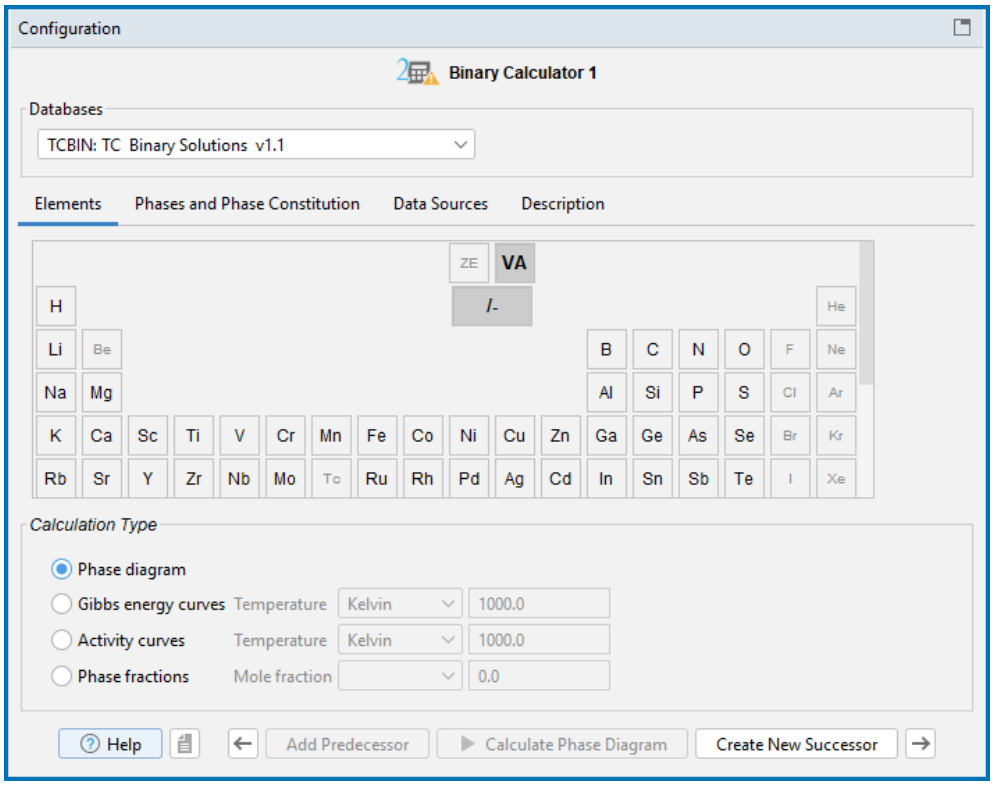
Example

For an example see T_03: Fe-C Phase Diagrams.

Configuration Window Settings

The **Binary Calculator Configuration** settings window and the associated tabs are similar to what you see on a System Definer. The database TCBIN is added by default when you use the **Binary** template (on the **My Projects Configuration** window under **Equilibrium**), but you can choose an installed and licensed database from the list.

> The various versions of the TCS Steel and Fe-alloys Database (TCFE) are not compatible with the Binary Calculator.



Elements

On the **Elements** tab, and based on the database selected, select and review elements from the periodic table. Unavailable elements, which are based on the selected database, are greyed out.

Phases and Phase Constitution

At the top of the **Phases and Phase Constitution** tab, and based on the selected database, you can review the *Status* for the selected *Phases*. Select the **Check/uncheck all** checkbox to toggle between the options.

To review the **Phase constitution** for a specific phase, click it in the *Phase* list (for example **BCC_A2**) and its details are displayed below the *Phases* list. Click **Edit** then click an element to select or reject a constituent. The last remaining constituent on a sublattice cannot be rejected.

Data Sources

Data sources are not available until the activity is performed. Click **Perform Tree** at the bottom of the window to display available data sources.

Description

The **Description** tab displays a description of the selected database.

Calculation Type

Click to choose a *Calculation Type*.

- **Phase diagram**: To calculate in a defined multicomponent heterogeneous system, from one or more initial equilibria. A phase diagram is usually mapped within a specific space that is constructed by two (or more) defined independent mapping axis-variables.
- **Gibbs energy curves**: To calculate at a constant temperature over the whole composition range.
- **Activity curves**: To calculate at a constant temperature over the whole composition range.
- **Phase fractions**: To calculate as a function of temperature at a constant composition.

Then:

- For **Gibbs energy curves** and **Activity curves**, select a unit from the **Temperature** list: **Kelvin**, **Celsius**, or **Fahrenheit** and enter a value in the field.
- For **Phase fractions**, select and enter the **Mole fraction** component and enter a value in the field.

Learn More

For the Plot Renderer, there is an option to use the **Table View** button to convert plots to table data for all calculation types and calculators. See Plot Renderer: Convert a Plot to a Table and Export the Data.

Ternary Calculator

A **Ternary Calculator** is used for some calculations involving three components. You can think of this activity as a combination of a System Definer and an Equilibrium Calculator, but designed to simplify setting up and performing calculations on ternary systems.

Template

There is a **Ternary** template available on the **My Projects Configuration** window under **Equilibrium** that you can use to quickly set up a simulation. See Getting Started Links, Templates, and the Property Navigator.

Learn More

Configuration Settings

See Configuration Window Settings.

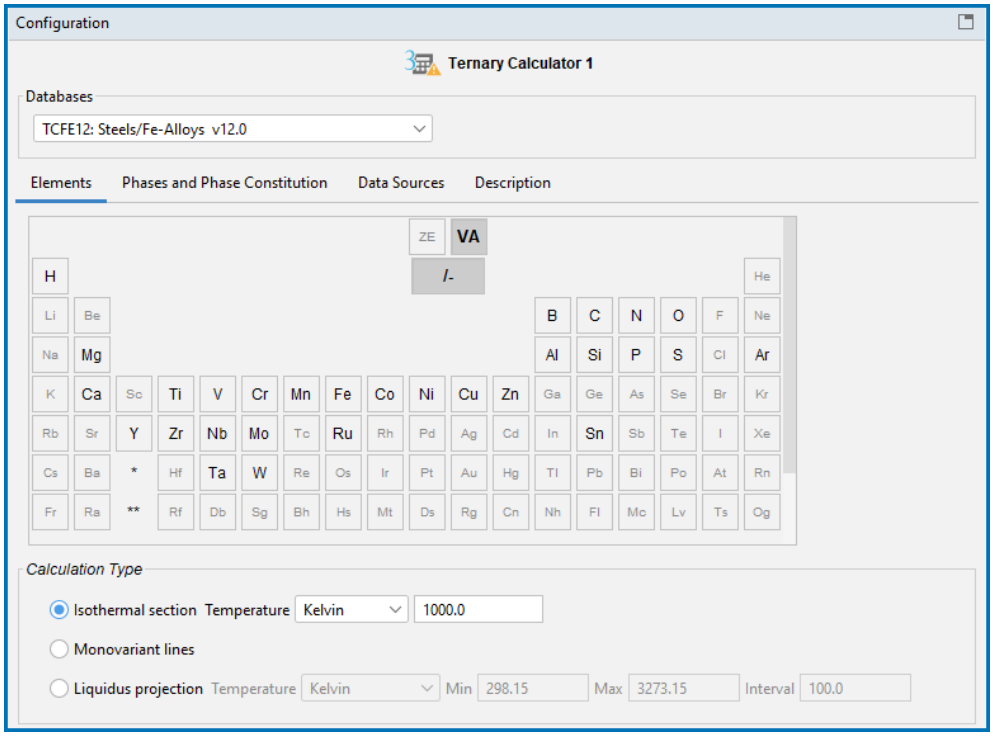
Examples

For examples, see

- T_04: Fe-Cr-C Ternary Phase Diagram at 1000 K
- T_20: Ternary Diagram with Clockwise Plot Axes

Configuration Window Settings

The **Ternary Calculator Configuration** settings window is described in this section that lists the available settings that must be configured before performing the calculation.



Databases

Select a database that contains specifications dedicated to the Ternary Calculator.

Elements

On the **Elements** tab, and based on the database selected, select and review elements from the periodic table. Unavailable elements, which are based on the selected database, are greyed out.

Phases and Phase Constitution

At the top of the **Phases and Phase Constitution** tab, and based on the selected database, you can review the *Status* for the selected *Phases*. Select the **Check/uncheck all** checkbox to toggle between the options.

To review the **Phase constitution** for a specific phase, click it in the *Phase* list (for example **BCC_A2**) and its details are displayed below the *Phases* list. Click **Edit** then click an element to select or reject a constituent. The last remaining constituent on a sublattice cannot be rejected.

Data Sources

Data sources are not available until the activity is performed. Click **Perform Tree** at the bottom of the window to display available data sources.

Description

The **Description** tab displays a description of the selected database.

Calculation Type

Click to choose a *Calculation Type*.

- **Isothermal section**: To calculate the ternary system for the whole composition range.
- **Monovariant lines**: To calculate the variation of the liquid compositions with temperature.
- **Liquidus projection**: The projection liquid surface and the monovariant lines are calculated over the given temperature range.

Then for **Isothermal section** and **Liquidus projection**, select a unit from the **Temperature** list: **Kelvin**, **Celsius**, or **Fahrenheit** and enter a value in the field.

Learn More

For the Plot Renderer, there is an option to use the **Table View** button to convert plots to table data for all calculation types and calculators. See Plot Renderer: Convert a Plot to a Table and Export the Data.

Scheil Calculator

In Graphical Mode, you use the **Scheil Calculator** to set up the various Scheil solidification simulations outlined in more detail in Scheil-Gulliver Solidification Calculations.

About the Scheil Calculation Options

The available Scheil-Gulliver solidification simulations are *classic* Scheil, Scheil with *back diffusion* in the primary phase, or Scheil with *solute trapping*. There are also configuration options available with *fast diffusers* for the classic and back diffusion models.

There is also connectivity to the Diffusion Module (DICTRA) and *homogenization* where you collect data from a Scheil solidification calculation, which is then used as part of the kinetic homogenization simulation of segregated composition profiles.

Scheil in Graphical Mode vs Console Mode

The Scheil with back diffusion feature is only available for systems with diffusion data, i.e. this model requires the use of a mobility database.

In Thermo-Calc, the Scheil calculation allows the calculation of:

- The solidification range of an alloy.
- Depression of the solidus temperature due to segregation.
- Composition of the last liquid to disappear in segregation pockets.
- Phases formed on final solidification in segregation pockets.
- The composition gradient in the primary solid phase(s) (segregation profile).
- Solute trapping to simulate deviation from local equilibrium for the primary phase
- Kinetic homogenization simulation of segregated composition profile (diffusion calculations)

How Can I Add a Scheil Calculator to My Project?

There are several options to get started with a Scheil simulation using the Scheil Calculator.

- On the **My Project** window under **Getting Started**, use the **Quick Start → Scheil Solidification Simulation** option to set up a Classic Scheil simulation. This adds a tree of nodes where you can then choose to simulate using the other options on the Scheil Calculator. See Creating a Project with the Quick Start Assistant.

- Use the **Scheil Solidification** template under **Non-Equilibrium** to add a project tree consisting of **System Definer**, **Scheil Calculator**, and **Plot Renderer** nodes. See Getting Started Links, Templates, and the Property Navigator.

- Use the **Homogenization** template under **Non-Equilibrium** to add a project tree consisting of **System Definer**, **Scheil Calculator**, **Diffusion Calculator**, and two **Plot Renderer** nodes. See Getting Started Links, Templates, and the Property Navigator.

  When working with the **Homogenization** template, this also includes a **Diffusion Calculator**, which may require additional licenses to run with more than three components. Information, such as the Scheil segregation profiles available with the Diffusion Calculator, is described with that content.

- Build your own tree by right-clicking and adding nodes from **My Project**. Then go to Configuration Window Settings to enter settings directly.

- Open an example and use this as a template.

When you are working with the Additive Manufacturing (AM) Module, a **Scheil Calculator** is also included with one of the Additive Manufacturing Templates or can be added as a predecessor to the **AM Calculator**, where it is used to generate the materials property data required for these simulations.

Learn More

The Scheil Calculator is also used in combination with the specialized Add-on Modules such as the Diffusion Module (DICTRA) and Additive Manufacturing (AM) Module.

By default, a Plot Renderer successor to a Scheil Calculator has the plot axes defined as **Mole fraction of solid** (X-axis) and **Temperature Celsius** (Y-axis). When these default axes are used and the setting **Include one axis equilibrium calculation** is enabled (see Advanced Options), the results of solidification under equilibrium conditions are automatically plotted in the same diagram as the Scheil calculations.

Define the Scheil Calculator

This topic lists the basic steps to define a **Scheil Calculator**.

1. Add a **Scheil Calculator** node to the System Definer. If you used the **Scheil Solidification** or **Homogenization** templates on the **My Project Configuration** window under **Non-Equilibrium** (or opened an example), click the node to display the **Configuration** settings window.

2. Enter the settings described in Configuration Window Settings. The **Configuration** tab as all the main settings and the permutations related to the types of Scheil simulations available such as back diffusion and solute trapping.

   When working with the **Homogenization** template, this also includes a **Diffusion Calculator**, which may require additional licenses to run with more than three components. Information, such as the Scheil segregation profiles available with the Diffusion Calculator, is described with that content.

   When you are working with the Additive Manufacturing (AM) Module, a **Scheil Calculator** is also available in some cases where it is used to generate the materials property data required for these simulations.

3. As needed you can also change default settings from the **Advanced Options** tab (see Advanced Options).

4. Once you have finished defining the Scheil Calculator, you also choose settings and variables on the Plot Renderer. For a list of available variables see Scheil Calculator Available Plot Variables.

Learn More

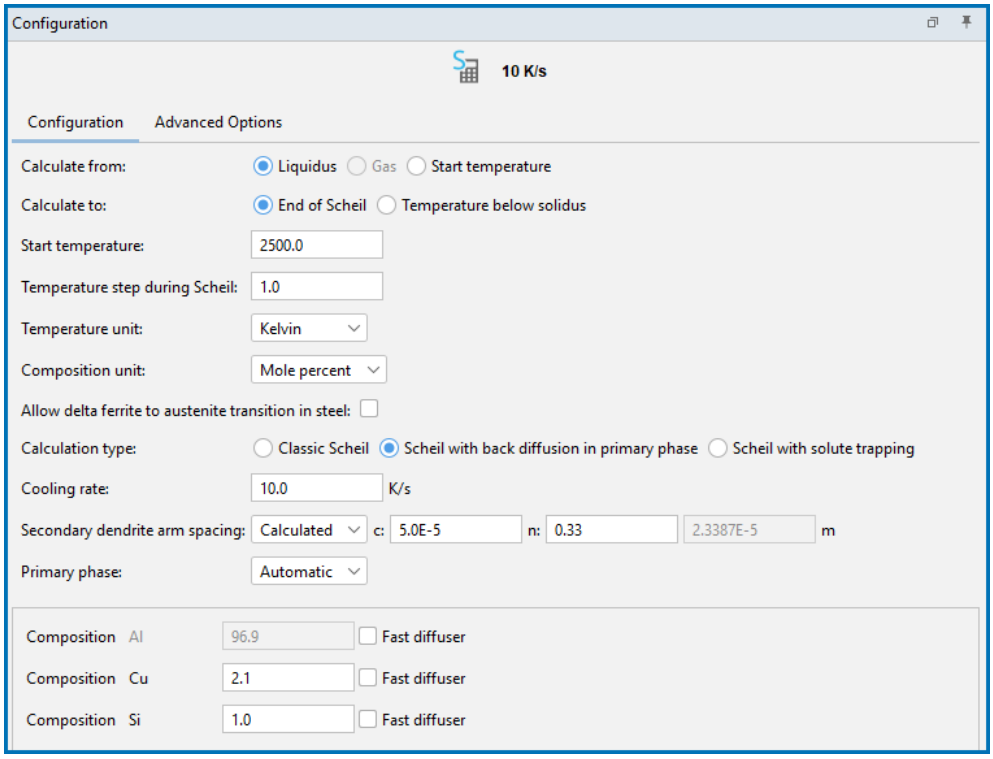
For examples using the Scheil Calculator, see:

- T_08: Scheil and Equilibrium Solidification
- T_10: Scheil Solidification with Back Diffusion
- T_13: Scheil Solidification with Solute Trapping

There are also Console Mode, TC-Python, Diffusion Module (DICTRA), and Additive Manufacturing (AM) Module examples described elsewhere in the content.

Configuration Window Settings

An example of the main **Scheil Calculator Configuration** window is shown below using the T_10: Scheil Solidification with Back Diffusion example.



An example of the Scheil Calculator Configuration window with the back diffusion option selected. There are different settings available and described below based on the calculation type selected.

Calculation Settings

Calculate From

Use the **Calculate from** setting to choose from where the calculation should start. With this setting it is possible to obtain properties of the gas and/or liquid phase before the solidification starts.

Some of the temperature definitions related to these choices are:

- *Liquidus*, the temperature where solidification starts.
- *Gas / Liquid*, the temperature above which the liquid phase is no longer stable.
- *Liquid / Gas*, the temperature below which the gas phase is no longer stable.

Click a button to choose **Liquidus**, **Gas**, or **Start temperature**.

Depending on the choice for this setting (**Liquidus**, **Gas**, or **Start temperature**), one or more of the following temperature values is calculated and collected in the **Event Log** at the end of the calculation: *Liquidus*, *Gas / Liquid*, or *Liquid / Gas*.

By default, **Liquidus** is selected. The results are calculated from the start of the solidification.

Select **Gas** (after a gas phase is selected on the System Definer) to perform single equilibrium calculations from the *Gas / Liquid* temperature.

- The equilibrium calculations are performed at 5 Kelvin (K) intervals in the two-phase region between the *Gas/ Liquid* temperature and the *Liquid / Gas* temperature.
- In the fully liquid region below the *Liquid / Gas* temperature single equilibrium calculations are performed at 50 K intervals until the *Liquidus* temperature is reached. After that the Scheil solidification calculation proceeds as usual.

Select **Start temperature** if you want to obtain properties of the liquid phase (and gas phase if selected) before the solidification starts.

- Ordinarily the start temperature is only used as a start point in the search of the liquidus temperature, as the Scheil calculation starts from the *Liquidus* temperature.
- For this choice, single equilibrium calculations are performed at specific intervals from the temperature entered in the start temperature field, down to the *Liquidus* temperature, and after that the Scheil solidification calculation proceeds as usual.
- The equilibrium calculations are performed at 50 Kelvin (K) intervals in the fully liquid region and at 5 K intervals in a possible two-phase (*Liquid / Gas*) region.

Calculate To

Use the **Calculate to** setting to choose from where the calculation should end, **End of Scheil** or **Temperature below solidus**, where a frozen structure is assumed below solidus.

- **End of Scheil** stops the calculation when the Scheil calculation is finished.
- **Temperature below solidus** calculates the properties in the solid state, for the phase compositions and fractions at the end of the Scheil calculation. The default **Final temperature** is room temperature. Click **Show advanced options** to adjust the *Temperature below solidus settings*: Change the **Final temperature** and/or define the **No. of points**.

See Advanced Options.

Temperature Settings

Start Temperature

Enter a **Start temperature** that is higher than the liquidus temperature of the alloy, in other words, the temperature at which the alloy is completely melted.

Temperature Step during Scheil

Enter a **Temperature step during Scheil**. The temperature step is given in the same unit as **Start temperature**. Decreasing the temperature step increases the accuracy, but the default value is usually adequate.

Temperature Unit

Select the **Temperature unit**: **Kelvin**, **Celsius** or **Fahrenheit**.

Other Settings

Composition Unit

Select the **Composition unit**: **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**.

Allow Delta Ferrite to Austenite Transition in Steel

Select the **Allow delta ferrite to austenite transition in steel** checkbox to enable BCC to FCC transition.

This feature should only be used for such steels for which it is reasonable to assume infinitely fast diffusion (equilibrium conditions) when delta ferrite is present. When the **Allow delta ferrite to austenite transition in steel** checkbox is selected in Graphical Mode or the DELTA_FERRITE_AUSTENITE_TRANSITION command used in Console Mode, this essentially assumes that diffusion can be considered (infinitely) fast when delta ferrite is present as a solid phase, i.e assumes an equilibrium condition. After delta ferrite is no longer stable, the usual Scheil assumptions for the selected calculation type are in effect. This setting is therefore not suitable for steels where you DO NOT have a complete BCC to FCC transition during solidification. This setting is also NOT available in combination with solute trapping.

Calculation Type Settings: Classic, Back Diffusion, Solute Trapping

The available settings are based on the chosen model. See Scheil-Gulliver Solidification Calculations for descriptions.

Click to select a **Calculation type**: **Classic Scheil**, **Scheil with back diffusion in primary phase**, or **Scheil with solute trapping**. Then based on this selection, additional settings are made available as indicated.

Back diffusion requires the use of a mobility database.

The back diffusion and solute trapping options are available to select after adding a mobility database and once components are defined on the System Definer.

Composition

The **Composition** settings display after you add components to the **System Definer**.

Fast Diffuser

The **Fast diffuser** checkboxes are available after you add components to the System Definer. Click the checkbox to allow redistribution of this component in both the solid and liquid parts of the alloy.

Cooling Rate (Back Diffusion)

This field is available when **Scheil with back diffusion in primary phase** is selected.

Specify the **Cooling rate** in Kelvin per second (K/s). An increased value moves the result from equilibrium toward a Scheil-Gulliver calculation.

Secondary Dendrite Arm Spacing (Back Diffusion)

This field is available when **Scheil with back diffusion in primary phase** is selected.

The **Secondary dendrite arm spacing** is the distance in meters between two secondary dendrite arms. It can be either a **Constant** or **Calculated** from the cooling rate as c*(cooling rate)$^{-n}$ where c and n are entered in these fields.

Select **Calculated** or **Constant**.

- For **Calculated**, enter values for **c** and **n**.
- For **Constant**, enter a value (unit = m) in the field.

Primary Phase (Back Diffusion and Solute Trapping)

This field is available when **Scheil with back diffusion in primary phase** or **Scheil with solute trapping** is selected.

The primary solidified phase is the phase where the back diffusion or solute trapping takes place.

If **Automatic** (Scheil Calculator) or **Any phase** (Property Models) is selected (or kept as the default), the program tries to find the phase which gives the most back diffusion or solute trapping.

To override this setting, choose a specific primary phase from the list:

- For back diffusion, only phases with diffusion data can be used as primary phases.
- For solute trapping, only phases that dissolve all elements in the system can be used as primary phases.

Scanning Speed, Alpha, and Calculated Solidification Speed (Solute Trapping)

These fields are available when **Scheil with solute trapping** is selected.

As needed, enter **Scanning speed** and **α** to define the **Calculated solidification speed**.

On the Scheil Calculator, the **Calculated solidification speed** is shown. For Property Models, below is how the values are calculated from the **Scanning speed** and **α** values entered.

The **Calculated Solidification Speed** is Vs = $V_{scanning}$ * cos(α) m/s, where $V_{scanning}$ is the user specified **Scanning speed** in m/s and **α** is the alpha angle, α, between the solid/liquid boundary and scanning direction.

Trans-interface Diffusivity (Solute Trapping)

These fields are available when **Scheil with solute trapping** is selected.

Select a **Trans-inteface Diffusivity** option: **Same for all elements** or **Per element**.

Smaller value leads to larger solute trapping effect. Be cautious that $D_i < 2.0 \times 10^{-9} \frac{m^2}{s}$ may result in complete solute trapping and possibly numerical errors.

- For **Same for all elements**, enter one **Pre-exponential factor** (default `5.0E-9` m^2/s) and **Activation energy** (default `0` J/mol) in the fields for the solute diffusivity across the interface between liquid and primary dendrite phase.
- For **Per element**, enter individual values for each one in the provided fields for **Pre-exponential factor** (default `5.0E-9` m^2/s) and **Activation energy** (default `0` J/mol) for the solute diffusivity across the interface between liquid and primary dendrite phase.

Maximum Velocity for Infinite Driving Force (Solute Trapping)

This field is available when **Scheil with solute trapping** is selected.

Enter a **Maximum velocity for infinite driving force**. The default is `2000` m/s. This is the maximum migration speed of the liquid/primary solid interface when the driving force is infinite. Smaller values lead to a larger solute trapping effect.

Model (Solute Trapping)

This option is available when **Scheil with solute trapping** is selected.

Choose a **Model** to calculate the relation between migration speed and solute partitioning at the liquid/primary solid interface, developed by either **Aziz** or **Hillert**.

The **Hillert** model usually leads to a larger solute trapping effect, though **Aziz** model is recommended for overall numerical performance including calculating the amount of non-primary solid phases.

Interface Driving Force (Solute Trapping)

This option is available when **Scheil with solute trapping** is selected.

Choose the **Interface driving force**, where this driving force (free energy change at the liquid/primary solid interface) is used to evaluate the migration speed in comparison with the maximum velocity.

- **Driving energy**: Uses the overall free energy change.
- **Migration energy**: Uses free energy change due to migration, i.e. the overall free energy change excluding that contributes to diffusion.

Selecting **Migration energy** leads to a larger solute trapping effect. It is generally recommended to select **Driving energy** as this is numerically more stable, and then adjust the other settings (e.g., **Trans-interface diffusivity**) for the desired solute trapping effect.

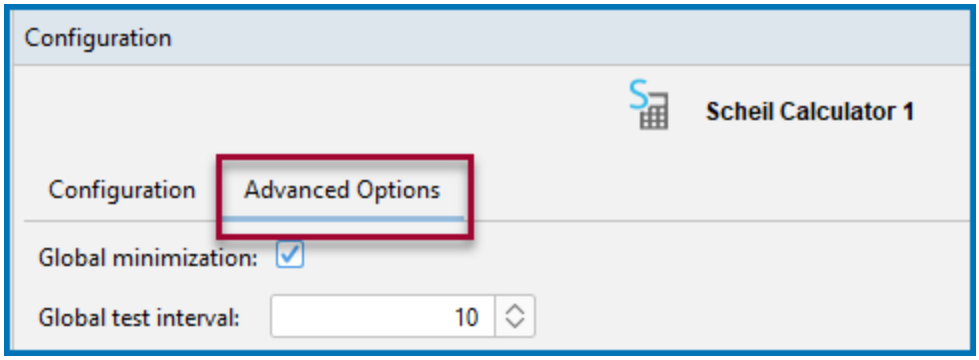
Learn More

Scheil-Gulliver Solidification Calculations is a general overview of the Scheil options. For more details about the *solute trapping* related settings, see the theory in About Scheil with Solute Trapping.

There are additional settings found on the **Advanced Options** tab and based on the type of Scheil calculation. See Advanced Options.

Advanced Options

This topic list the **Advanced** settings information for the **Scheil Calculator Configuration** window. The main settings are on the **Configuration** tab. Click the **Advanced Options** tab to adjust the following default settings as needed.



Advanced Scheil Calculator Settings

Global Minimization

Global minimization is enabled by default i.e. the **Global minimization** checkbox is selected.

> It is recommended to keep global minimization on as it makes the calculation more accurate. However, turn it off if you find that the calculation is taking too long for any particular system, and accuracy is not the highest priority.

For this setting, a global equilibrium test is performed at selected intervals when an equilibrium is reached. By default it is at every 10 th Scheil step but this can be changed using the **Global test interval** setting. The global equilibrium test is also done every time the set of stable phases tries to change. This costs more computer time but the calculations are more robust.

Global Test Interval

Use the **Global test interval** setting to change the interval at which a global equilibrium test is done, which by default is every 10th step as long as there are no changes in the set of stable phases. Every time the set of stable phases tries to change, a global equilibrium test is also

done regardless of the test interval value chosen. A global equilibrium test means that the calculated equilibrium state obtained by the ordinary minimization calculation is tested against the Global Minimization Technique, and if the result is found unstable then the full global minimization calculation is performed instead.

Max Grid Points

Use the **Max grid points** to set the maximum number of grid points per phase for global minimization. The default is 2000.

Liquid Phase

The default in the list is the **LIQUID** phase already defined in the chosen database.

Gas Phase

The default in the list is the **Gas phase** already defined in the database

Calculate Evaporation Properties

Select the **Calculate evaporation properties** checkbox to calculate the **Molar mass of gas**, **Driving force for evaporation**, and **Evaporation enthalpy** properties.

A gas phase is required to calculate these properties.

This option sets the gas phase to dormant, meaning that the thermodynamic properties of the gas are evaluated, without the gas being allowed to form. This enables the calculation of the following properties: **Molar mass of gas**, **Evaporation enthalpy**, and **Driving force** for evaporation. Driving force for evaporation is positive when the gas is stable (temperature above evaporation temperature). A negative driving force means the gas is metastable.

Terminate Scheil On

This setting controls when a Scheil calculation should terminate. From the **Terminate Scheil on** list, choose **Fraction of liquid phase** (unit = mole fraction) or **Temperature** and enter a value in the field.

Max No. of Iterations

Enter or choose a value for the **Max no. of iterations**. By default, the program tries 500 iterations before it gives up. As some models give computation times of more than 1 CPU second/iteration, this number is also used to check the CPU time and the calculation stops if 500 CPU seconds/iterations are used.

The default value for an **Aqueous Calculator** is `1000`. This is because there is usually a very small amount in the AQUEOUS phase and this default increases the stability of the calculation.

Required Accuracy

The default **Required accuracy** is `1.0E-6`. This is a relative accuracy, and the program requires that the relative difference in each variable must be lower than this value before it has converged. A larger value normally means fewer iterations but less accurate solutions. The value should be at least one order of magnitude larger than the machine precision.

Smallest Fraction

The default **Smallest fraction** (or **Smallest fraction in a phase** for Property Models) is `1.0E-12`. This is the value assigned to constituents that are unstable. It is normally only in the gas phase you can find such low fractions.

The default value for the smallest site-fractions is `1E-12` for all phases except for IDEAL phase with one sublattice site (such as the GAS mixture phase in many databases) for which the default value is always as `1E-30`.

The default value for an **Aqueous Calculator** is `1E-16`. This is because there is usually a very small amount in the AQUEOUS phase and this default increases the stability of the calculation.

In Console Mode, the default of 1E-30 for IDEAL phases is true unless you are using the command SET_NUMERICAL_LIMITS to reset an even-lower value (e.g. `1E-45`, that is naturally enforced to all the phases in the system.

Approximate Driving Force for Metastable Phases

The **Approximate driving force for metastable phases** checkbox is selected by default. Click to clear the checkbox to change the default as required and based on the options described below.

This setting involves the convergence of metastable phases and affects their driving forces. It can also have an effect on when an equilibrium is considered successful.

The default is to allow an equilibrium with metastable phases that have not converged, as long as the stable phases have converged. This is efficient but often causes approximate values of the driving forces for the metastable phases.

If you change the default, it enforces metastable phases to converge. This gives accurate driving forces for metastable phases as well as stable phases. It can however take a slightly longer time, and if metastable phases do not converge it causes the equilibrium calculation to fail.

Include One Axis Equilibrium Calculation

The **Include one axis equilibrium calculation** checkbox is selected by default and a **One Axis** (also called *step*) calculation is performed before the actual Scheil calculation. It produces the solidification curve under equilibrium conditions and it is shown on the plot if the default axis variables are used. This is sometimes referred to as the *equilibrium line*.

If a comparison to equilibrium is not necessary, change the default setting and then only a Scheil calculation is performed. This results in a much faster calculation, which for a complex system may be preferable.

Temperature Below Solidus Settings

The **Temperature below solidus settings** are available when **Temperature below solidus** is selected for **Calculate to**. This calculates the properties for the given number of temperatures, down to the final temperature for the phase compositions and fractions at the solid phases at the end of the Scheil calculation.

- Enter the **No. of points**. The default is 50.
- Enter the **Final temperature**. The default is room temperature (298.15 K).

Learn More

Configuration Window Settings

To make global default setting changes, see Global Settings: Scheil Calculator.

Scheil Calculator Available Plot Variables

When working with Scheil calculations in Graphical Mode, there are several plot variables available with the **Plot Renderer** that is a successor to the **Scheil Calculator**.

The following list is specific to a Plot Renderer that is a successor to a Scheil Calculator. The software includes relevant variables in the *Axis variable* list based on the set up of the Scheil Calculator.

Scheil Plot Quantities

Quantities			
Apparent heat capacity per gram	Apparent heat capacity per mole	Apparent volumetric CTE	Average composition of solid phases
Composition of a phase	Density	Distribution of component in phase	Driving force for evaporation per mole
Dynamic viscosity	Electric conductivity	Electric resistivity	Evaporation enthalpy per mole
Heat per gram	Heat per mole	Kinematic viscosity	Latent heat per gram
Latent heat per mole	Mass fraction of liquid	Mass fraction of solid	Mass fraction of solid phase
Molar mass of gas	Molar volume	Molar volume of phase	Mole fraction of liquid
Mole fraction of solid	Mole fraction of solid phase	Site fraction	Surface tension
Temperature	Thermal conductivity	Thermal diffusivity	Thermal resistivity
Volume fraction of liquid	Volume fraction of solid	Volume fraction of solid phase	

Learn More

There may be some additional variables available if the calculation involves the Diffusion Module (DICTRA) and/or other specialized databases are used.

When certain variables are selected (i.e. electric or thermal conductivity, electric or thermal resistivity, or thermal diffusivity), there are additional settings related to these described in Plot Renderer: Configuration Settings.

Quantities Groups Available for Plots and Tables

For a comparable list in Console Mode, see State Variables for Scheil.

Aqueous Calculator

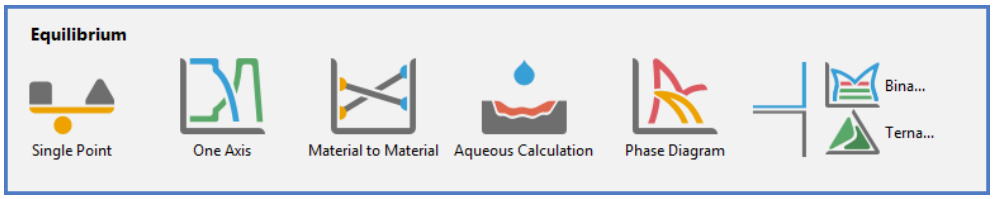
An **Aqueous Calculator** allows you to set the conditions for, and perform, an aqueous calculation. This calculator is a specialized Equilibrium Calculator and is set up to help you quickly define and run aqueous or Pourbaix calculations in Graphical Mode.

Aqueous Calculation Template

It is recommended that you set up your calculation using the *Aqueous Calculation* template, which automatically sets up a variety of predefined settings on the **System Definer**, **Aqueous Calculator**, and **Plot Renderer**. For the System Definer it also automatically makes a Default Database Selection (Template Use Only).

The **Aqueous Calculation** template is available on the **My Project Configuration** window under **Equilibrium** or by right-clicking **My Project** and adding it from the **Create New Activity > Use Template** menu.



You can also add the Aqueous Calculator to the **System Definer** directly—right-click and select it from the **Create New Successor** menu. In this case there are limited predefined settings included. *For this reason it is recommended to use the template with the predefined settings since all settings can still be adjusted for your particular simulation needs.*

Once you have added the template that includes an **Aqueous Calculator**, the **Configuration** window has these settings tabs.

- **Conditions**: Set the conditions for your calculation that define the stepping or mapping axis variables. For settings details, see Conditions Tab Settings.
- **Functions**: Define your own quantities and functions, which you then can calculate and plot. See Functions Tab Settings.

- **Options**: Modify numerical settings that determine how equilibria are calculated, as well as how stepping and mapping calculations are performed. Except for one default setting difference, these settings are the same as for the Equilibrium Calculator. See Options Tab Settings.

The **Options** tab is where you can locally define specific settings. These settings can also be applied globally. To open the **Options** window: From the main menu select **Tools** → **Options** and click the **Activities** tab. Then click **Calculation**.

Default Database Selection (Template Use Only)

When the Aqueous Calculator is added to your project using the template, this allows for efficient setup of advanced aqueous calculations. For optimal results, the latest version (TCAQ4) of the TCS Aqueous Solutions Database (TCAQ) is recommended as it is designed specifically for this. Although other versions (TCAQ 3.1 and older) and the free PAQ2 database can be used, there are limitations and additional requirements to conduct more complex simulations.

By default on the **System Definer**, and only when you use the **Aqueous Calculation** template, the software selects the best database for you based on your license. The following is the order of selection.

1. The most recent available version of TCS Aqueous Solutions Database (TCAQ): TCAQ4, then earlier versions (TCAQ 3.1 and older).
2. The free PAQ2 database, which is included with all Thermo-Calc installations as well as the Educational version.
3. TCS Aqueous Solution Database (AQS) version AQS2.

T_21a is available with the Educational version of Thermo-Calc. It is slightly modified from T_21 to be compatible with the free demo version of the software.

Until an aqueous databases is selected (i.e. TCAQ, AQS or PAQ2), the **Perform** button is greyed out and a message *No database with aqueous properties is selected* displays.

Predefined Settings when Using an Aqueous Calculation Template

The predefined settings are listed by node.

System Definer

On the **Elements** tab:

- The applicable Default Database Selection (Template Use Only) is made for you.
- Hydrogen (**H**) and oxygen (**O**) are selected in the **Periodic Table**.
- The **ZE** electron is also added to the *Material* amount and adjusts based on the **Components** added.

The special element Ze handles various charged aqueous species and internal electro-balance in the aqueous solution phase. The hypothetical electrode phase REF_ELECTRODE contains only the unary Ze.

On the **Phases and Phase Constitution** tab:

- The **REF_ELECTRODE** phase is set to **Dormant** to not participate in any calculations.

On the **Components** tab:

- **H2O** and **H+1** are selected by default and the *SER* checkbox is selected.
- **Ze** is automatically set up default to use the **REF_ELECTRODE** phase. The *SER* checkbox is not selected.
- By default, the *Reference temperature* unit is **Kelvin** and the *Reference pressure* is **Pascal**.

Aqueous Calculator

This calculator is a tailored version of the Equilibrium Calculator where there are only advanced options available.

On the **Conditions** tab:

- By default always has these *Condition Definitions* added: **Temperature**, **Pressure**, **Electric Potential**, 1 kg of **H2O** (as the **Amount of component**), and **pH of aqueous solution** is set at **8.0**.
- Any other **Components** added to the System Definer are also shown in this section.
- By default a **One Axis** *Calculation Type* is selected. The **pH of AQUEOUS** phase is then selected as the *Quantity* for the Axis Definitions for an aqueous calculation.
- For a Pourbaix diagram, select the **Phase diagram** *Calculation Type*. Then the default quantities are **pH of AQUEOUS** phase on the X-axis plus **Eh relative to SHE** (standard hydrogen electrons) on the Y-axis.

Plot Renderer

Aqueous Properties are available from the drop-down lists in Graphical Mode.

- By default, **pH of aqueous solution** is selected for the X-axis and **Amount of phase** for the Y-axis.

Quantities Groups Available for Plots and Tables

Legend and Label Styles (for example of Common Phase names).

The **Legend style** is by default to show **Common phase name**. However, this is not available for the PAQ2 or TCAQ databases so select another option from the list as needed.

Learn More

For more background information, see Introduction to Aqueous Solutions and Pourbaix Diagrams and About Pourbaix Diagrams.

It is recommended to add the **Aqueous Calculation** template that ensures all nodes (i.e. **System Definer**, **Aqueous Calculator**, and **Plot Renderer**) have the necessary default predefined settings to more easily conduct aqueous simulations.

T_21: Pourbaix Diagrams of Fe with the Aqueous Calculator and T_22: Aqueous pH of Solutions

Define the Aqueous Calculator

This topic lists the basic steps to define an **Aqueous Calculator**.

1. It is recommended to use the **Aqueous Calculation** template (on the **My Projects Configuration** window under **Equilibrium**), which automatically selects the appropriate database on the **System Definer** and adds the **Aqueous Calculator** node with several predefined settings. Click **Aqueous Calculator** to display the **Configuration** settings window.
2. In the **Configuration** window, review and adjust any of the settings described in Conditions Tab Settings and Functions Tab Settings.

   For the **Options** tab, the available settings are the same as the Equilibrium Calculator. See Options Tab Settings to review as needed.

3. Once you have finished defining the Aqueous Calculator, you also choose settings on the Plot Renderer.

Until an aqueous databases is selected (i.e. TCAQ, AQS or PAQ2), the **Perform** button is greyed out and a message *No database with aqueous properties is selected* displays.

Learn More

T_21: Pourbaix Diagrams of Fe with the Aqueous Calculator and T_22: Aqueous pH of Solutions

T_21a is available with the Educational version of Thermo-Calc. It is slightly modified from T_21 to be compatible with the free demo version of the software.

Conditions Tab Settings

Conditions and axis variables for the **Aqueous Calculator** are set in the **Conditions** tab on the **Configuration** window. The conditions to set depend on the type of calculation.

It is recommended to add the **Aqueous Calculation** template that ensures all nodes (i.e. **System Definer**, **Aqueous Calculator**, and **Plot Renderer**) have the necessary default predefined settings to more easily conduct aqueous simulations.

Conditions Tab Settings

The following outlines what you can set on the **Conditions** tab.

Number of missing conditions is

When there are missing conditions, **Number of missing conditions is** field indicates the number to resolve.

Condition Definitions

Under *Condition Definitions*, several defaults are predefined when you add an **Aqueous Calculator** using the *Aqueous Calculation* template.

Accept the defaults or specify different values (and units) of the state variables. The table only lists the predefined conditions that help specifically with the aqueous calculations.

Condition	*Default Unit*	*Default Value (s)*	*Notes*
Temperature	Celsius	25.0	
Pressure	Pascal	100000.0	
Electric potential	Volt	0.0	
Amount of component	No normalization	H2O, Kilogram, 1.0	

Condition	Default Unit	Default Value (s)	Notes
pH of aqueous solution	n/a	8.0	

Phase Options

Phase Status

Click the add ⊕ button to **Add a phase** or the minus ⊖ button to **Remove a phase**. Click the **Phase status** checkbox to choose a phase from the list **AQUEOUS**, **GAS**, or **REF_ELECTRODE**.

Then choose **Entered**, **Dormant**, or **Suspended** for the chosen phase.

Phase Energy Addition

Click the add ⊕ button to **Add a phase** or the minus ⊖ button to **Remove a phase**. Click the **Phase energy addition** checkbox to choose a phase from the list **AQUEOUS**, **GAS**, or **REF_ELECTRODE**. Then enter a value in the field with the unit **J/mol formula unit**.

Calculation Type

Click to select a *Calculation Type*:

- **Single equilibrium** (no axes): To calculate a single point. The results from this calculation are displayed in the **Event Log**.
- **One Axis**: To vary a quantity on the X-axis. This is useful for stepping in pH and Eh for aqueous calculations.
- **Phase diagram**: To calculate in a defined multicomponent heterogeneous system, from one or more initial equilibria. A phase diagram is usually mapped within a specific space that is constructed by two (or more) defined independent mapping axis-variables. This is how to produce a Pourbaix diagram with the Aqueous Calculator.

For **Single equilibrium**, no additional settings are required. Add a **Table Renderer** to perform the calculation and view the details in the **Visualizations** window.

Axis Definitions

- **One Axis**: Define the axis variable using these fields and menus: **Quantity**, **Min**, **Max**, **Step division**, **Type**, and **Step Method**.
- **Phase diagram**: Define the two axis variables using these fields and menus: **Quantity**, **Min**, **Max**, **Step division**, and **Type**.

If the Calculator already has a Plot Renderer as a successor and you change the stepping/mapping quantities, then the quantities represented on the X- and Y-axis are automatically updated in the Plot Renderer.

Depending on the calculation type selected, there are also a variety of Plot Types to choose from.

Step Division and Type (One Axis and Phase Diagram)

Enter a **Step division** and select a **Type**: **Linear - min no. of steps**, **Linear - max step size**, or **Logarithmic - scale factor**.

- For **Linear - min no. of steps**, the **Step division** value specifies a minimum number of steps that is calculated between the minimum and maximum value during the stepping/mapping operation.
- For **Linear - max step size**, the **Step division** sets the maximum size of each step. For **Logarithmic - scale factor**, **Step division** specifies the scale factor of a logarithmic function that distributes the steps from the initial equilibrium to the minimum and maximum values defined.

Step Method (One Axis)

From the **Step Method** list, choose **Normal** or **Separate phases**.

- **Normal** allows a stepping calculation with the chosen independently-varying equilibrium condition (axis-variable). Only the step axis value is changed between each step.

- **Separate phases** calculates how the Gibbs energy for a number of phases varies for different compositions. This is particularly useful to calculate Gibbs energies for complex phases with miscibility gaps and for an ordered phase that is never disordered (e.g. SIGMA-phase, G-phase, MU-phase, etc.).

Axis Quantities

Choose a **Quantity** from the list:

- **Temperature**
- **Pressure**
- **Eh relative to SHE**
- **Amount of H2O**
- **pH of AQUEOUS**

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

Quantities Groups Available for Plots and Tables

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Aqueous Calculator.

- Activity of water in aqueous phase
- Affinity per electron
- Electric potential
- Ionic strength
- Logarithm of electron activity
- Molality
- Mole fraction solvent
- Mole number
- Osmotic coefficient
- pH of aqueous solution
- Total molality

Learn More

For the Aqueous Calculator, the **Options** tab settings are the same as for the Options Tab Settings.

Depending on the calculation type selected, there are also a variety of Plot Types to choose from.

Functions Tab Settings

The **Functions** tab for an **Aqueous Calculator** allows you to define your own functions that can be plotted in a Plot Renderer.

It is recommended to add the **Aqueous Calculation** template that ensures all nodes (i.e. **System Definer**, **Aqueous Calculator**, and **Plot Renderer**) have the necessary default predefined settings to more easily conduct aqueous simulations.

Calculating and Plotting Functions

1. Click **Aqueous Calculator** to display the **Configuration** settings window.
2. Click the **Functions** tab.
3. Under **Quantity Definitions**, **Q1** is assigned by default to the **Activity of component**. Click the add ⊕ button to **Add a new quantity**. Then from the lists, choose the variable for each quantity to define. The quantities are called **Q1**, **Q2**, **Q3** and so on.
4. The **SER** checkbox and **Ze** are selected by default.
5. Under **Function Definitions**, click the add ⊕ button to add a new function. In the left field edit the default name of each function and enter the function itself in the right field after the equal sign.

   You can also use Console Mode syntax when entering the function. For example, the function above can be entered as `1-NP(LIQUID)`. See Parameters, Functions, and Variables.

6. To plot the defined function, right-click **Aqueous Calculator** and choose **Create New Successor → Plot Renderer** .
7. Click the new **Plot Renderer** node.
   a. For the axis variable, which is grouped under an *Axes* section (**Flexible Mode**), or listed individually as *X*, *Y*, or *Z* (**Grouped Mode**), choose **All variables** from the first list.
   b. Select **Function** from the second list.

c. From the third list, choose the function you defined on the Aqueous Calculator Functions tab.

d. When run, the Plot Renderer plots the value of the function.

Until an aqueous databases is selected (i.e. TCAQ, AQS or PAQ2), the **Perform** button is greyed out and a message *No database with aqueous properties is selected* displays.

Property Model Calculator

A **Property Model Calculator** enables you to predict and optimize material properties based on their chemical composition and thermal history.

Different models capture thermal history or heat treatments at varying levels of approximation, ranging from idealized thermodynamic equilibrium assumptions to more detailed representations that incorporate kinetic effects and non-equilibrium processes.

The available calculation types are **Single**, **One Axis**, **Grid**, **Min/Max**, **Uncertainty**, and **Batch**.

Using these, you can evaluate models simultaneously over a range of compositions and temperatures and cross plot the results, then conduct an uncertainty analysis and plot the results as either a histogram or a probability plot. The **Batch** calculation further enables you to read input from a file, such as a spreadsheet.

There are **General Models** plus material specific Model Libraries for **Nickel Models**, **Noble Metal Alloys Models**, **Steel Models**, and **Titanium Models** available. For more information start with the section About the General Property Models.

Property Model Calculator Workflow

At the start when you are designing a project, it is recommended you first test it by performing a **Single** calculation type. This verifies that the configuration of the model is valid, otherwise you will get a *Not a Number* result in the Event Log Window, which indicates the calculation did not work correctly.

Once the Single calculation performs successfully, you can experiment with other calculation types such as **Grid**, **Min/Max**, **Uncertainty**, or **Batch**. Best practice for both Grid and Uncertainty is to start with a small number of steps (Grid) or samples (Uncertainty) to confirm that it works before increasing the number of steps or samples. For Batch calculations, it is good practice to first review the data file requirements described in Working with Batch Calculations.

For a Grid calculation, you can additionally plot a *Heat map*, *Contour*, or *3D* diagram. This setting is done on the Plot Renderer, which has several Plot Types, Plotting Options, and Plot Types available.

In general, the workflow for each model differs. A recommended start point is to do a **One Axis** calculation (using the Equilibrium Calculator) to determine what phases you get and where the transitions are before setting up the Property Model Calculator.

Templates and the Property Navigator

There are a variety of related templates both for the equilibrium One Axis calculations and to add a **Property Model** node structure.

As a starting point, the **Property Navigator** can more quickly help guide you to set up the initial simulation. See Creating a Project with the Property Navigator.

In addition there are **Steel TTT** and **Steel CCT** templates that you can use to quickly set up a simulation for the Steel Model Library. For details, see Getting Started Links, Templates, and the Property Navigator.

Learn More

Configuration Settings

Each Property Model has its own set of configuration parameters. There are some standard ones entered starting with the Configuration Window Settings topic.

Define the Property Model Calculator

This topic lists the basic steps to define a **Property Model Calculator**.

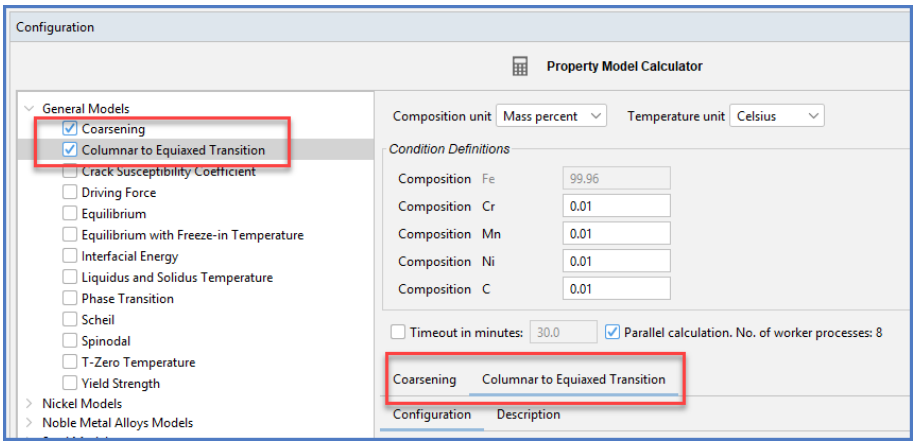
1. Add a **Property Model Calculator** node to the **System Definer**. If you used the **Property Models** template or **Property Navigator**, click the node to display the **Configuration** settings window.

   As a starting point, the **Property Navigator** can more quickly help guide you to set up the initial simulation. See Creating a Project with the Property Navigator.

2. From the left side of the **Configuration** window, click to select one or more of the checkboxes under the **General Models**. If you have licenses for the material specific libraries, you can also select and run the Property Models from the **Nickel Models**, **Noble Metal Alloys Models**, **Steel Models**, or **Titanium Models** folders.

   For the material specific libraries these are only available if you have the applicable licenses. If you are interested in learning more about the available models, go to our website.

   A tab with the same name as the Property Model opens in the right side of the window under *Condition Definitions*. When you select more than one Model at a time, a matching tab is added in the same order that the checkbox is selected.



3. For each Model on the **Configuration** tab, select or enter settings described in Configuration Window Settings and based on the *Calculation Type* chosen.

4. Once you have finished defining the Property Model Calculator, you also choose settings on the Plot Renderer.

Learn More

About the General Property Models

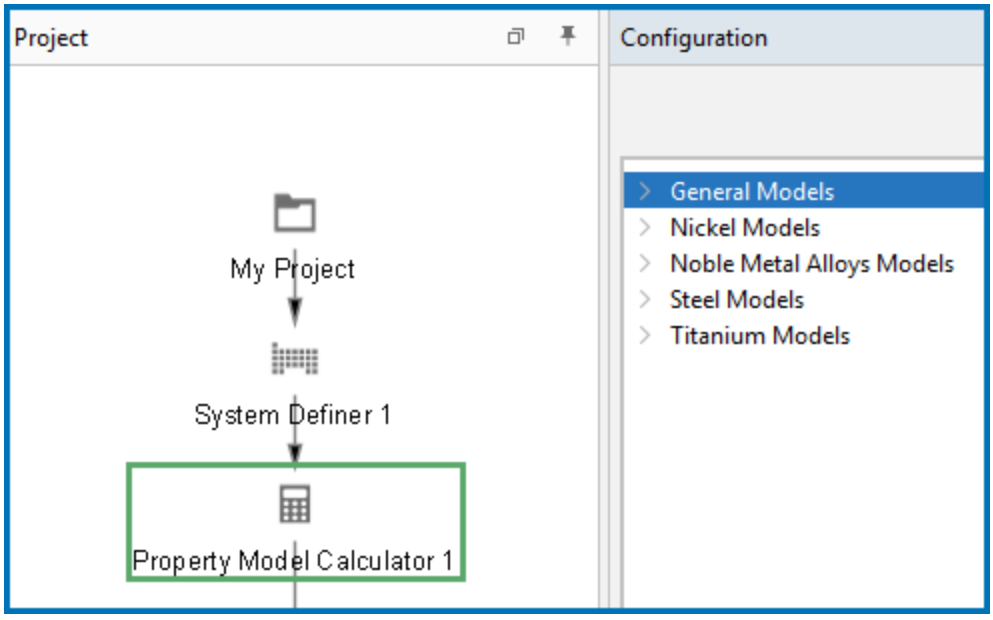
When working in the **Configuration** window, click the **Description** tab for more information about the Model.

Thermo-Calc General Property Models Examples Collection

Configuration Window Settings

Click the **Property Model Calculator** node in the **Project** window to view the **Configuration** window. The settings available vary based on such choices as the Property Model and calculation type selected.

For links to each Model with the settings details, see About the General Property Models.



Depending on your license, there are many Property Models available and the available options on the Configuration window vary. The General Models are available to all users.

General Configuration Settings

Composition Unit and Temperature Unit

Select the **Composition unit**: **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**.

Select the **Temperature unit**: **Kelvin**, **Celsius**, or **Fahrenheit**.

Condition Definitions

The values entered in *Condition Definitions* are used as the start values for the different calculation types.

The applicable **Composition** values are taken from what is entered on the System Definer.

Timeout in Minutes

Select the **Timeout in minutes** checkbox to enter a time when a calculation will stop trying to complete the evaluation. This is useful if it is a complex or unknown calculation outcome and you want to prevent it from taking too much computer time or resources. The number entered in the field means that this is the maximum amount of time that each line can take for an individual calculation. This is useful in particular for Batch or Uncertainty calculations.

Parallel Calculation

By default, the **Parallel calculation** (Property Model Calculator Configuration window) and **Parallel calculation for Property Model Calculator** (Options window for a Global setting) checkbox is selected.

The number of parallel branches (the **No. of worker processes**) can only be changed globally via the Options window. The default number of worker processes is based on the number of physical cores available on the computer. You can adjust the number of worker processes as needed, however it is still dependent on the available cores on the computer.

This checkbox is used for all the calculation types available with the Property Model Calculator in Graphical Mode. When you click **Perform**, the grid points calculated are distributed among these worker processes, which enables parallel calculations and speeds up the calculation. Click to deselect the checkbox as needed to not use these worker processes.

Calculation Type and Related Definitions

Click to select a *Calculation Type*:

- **Single** to calculate a single point. Any model can use this calculation type and no additional settings are required. The results from this calculation are displayed in the **Event Log** or if a **Table Renderer** is used, in the **Visualizations** window.
- **One Axis**: To vary a quantity on the *X*-axis.
- **Grid**: Evaluates two axis variables of the selected quantities in the specified range and number of steps.

- **Min/Max**: Evaluates the Property Model(s) for all variations of the selected quantities at the given limits. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The total minimum and maximum of the model(s) results are shown in the **Event** log.
- **Uncertainty**: Evaluates the Property Model(s) where the values of the quantities are sampled from Gaussian distributions. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The result is visualized as a histogram or normal probability plot by adding a Plot Renderer activity.
- **Batch**: Use this to allow for high throughput calculations and read data from a file, such as a spreadsheet, rather than, for example, having a fixed grid or random values. Results from these batch calculations can then be compared to experimental values (as long as this data is included), using a **Cross plot** on the Plot Renderer.

Grid Definitions

For **One Axis**, select a **Quantity** to vary along the X-axis, for example, **Evaluation temperature** then enter a **Min**, **Max** and **Number of steps**.

For the **Grid** calculation type, define the two axes variables using the fields and menus: **Quantity**, **Min**, **Max**, and **Number of steps**. The number of steps along with the minimum and maximum values for the axes define a grid. For each grid point the selected models are evaluated.

For a **Grid**, on the Plot Renderer, you can choose to plot a *Heat map*, *Contour*, or *3D* diagram.

Plot Type: Heat Map, Contour, and 3D

Min/Max Definitions

For the **Min/Max** calculation type, click to select the applicable checkboxes under **Quantity to enable or disable an axis**. The **Mean** field is as defined under *Condition Definitions* for the respective quantity.

Enter numerical values in the Δ **Min/Max** fields to evaluate the change to the quantity. The highest and lowest value of each selected model results are shown in the **Event Log**.

Sampling of Data from Gaussian Distributions

For the **Uncertainty** calculation type, click to select the applicable checkboxes under **Quantity to vary this quantity**. The **Mean** field is for the distribution function as defined under *Condition Definitions* for the respective quantity. The default ΔMin/Max is a 95% confidence interval.

About the Uncertainty Calculations

Sampling Parameters

For the **Uncertainty** calculation type, choose a number of **Standard deviations** where you want to **Truncate the distribution**. Choose the **Total number of samples**.

About the Uncertainty Calculations

Batch Controls

For more details about the format of a data file used to define the compositions, parameters, experimental data, or skipping validation, see Working with Batch Calculations.

In the **Data file** field, either enter a file path or click the load data file button ( ) to navigate to a data file such as an Excel spreadsheet (with `*.xls` or `*.xlsx` extensions) or a `*.csv` file. You can also use other programs (e.g. Google Sheets) to enter data and export to a CSV format that can be read by the software.

Click **Open** to import the data. In the **Data file** field you can see the file path to the selected file. The next time you click the load data file button ( ) the program remembers the last location from where the file is opened.

Choose the delimiter—**Comma** (`,`), **Colon** (`:`), **Equals sign** (`=`), **Semicolon** (`;`), or **Tab**—that matches the delimiter in the data file and click the **Reload** () button.

The data is imported and displays on the Property Model Calculator:

- The data are used for the applicable fields that must match what already exists as a Property Model parameter (e.g. critical radius, grain size, etc.) as well as the composition, temperature, and units that you want to run the calculation for. Also, if the dependent element composition is not included in the data file, the batch calculation then sets the dependent element to be the same as defined in the user interface.
- The calculation runs once for every row of data included in the file.

When the data file is imported into Thermo-Calc, there is also a **Row** column autogenerated by Thermo-Calc.

Select the **Set zero amount to value (in mole-/mass-fraction)** to enter a small value for the mole/mass-fraction in cases where a Property Model has problems calculating zero amounts of elements.

Select the **Skip validation of data file** checkbox to allow a calculation to perform using the data file even when certain criteria are not met.

When selected, the validation of the data file is skipped:

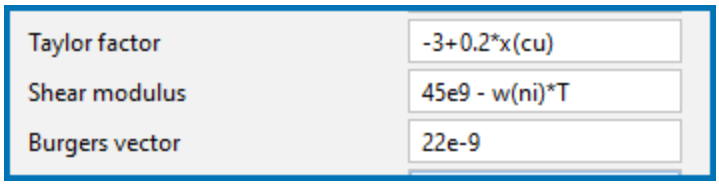
- If the **Composition** (elements) do not match the system composition entered on the GUI in the System Definer or Property Model Calculator.
- If one or more **Parameters** are not correctly entered, not selected for the specific Property Model, or are unavailable with the selected Property Model, then these are ignored in the calculation.

If there are any data file validation error(s), a tooltip on the **Perform** button lists and describes these.

Entering Model Parameters as Functions

For many model parameters that are defined as a numeric value this can be entered in number format or as a user-defined function (an expression).

An exception to this is the Yield Strength Model *Advanced Mode* setting for *Solid solution strengthening* and when entering the **Solid solution strengthening temperature**. This field must be entered in number format i.e. it does not accept a user-defined function.



Guidelines for Entering Functions

- The user-defined function can contain the operators for multiplication (`*`), division (`/`), addition (`+`), subtraction (`-`), and exponentiation (`**` or (`^`).
- If an invalid function is entered, the **Event Log** warns you of the error.
- If an expression is entered as a parameter/function value, then that parameter is not available to select as a quantity on the Plot Renderer, i.e. as an axis quantity.

Only the thermodynamic quantities for composition (mole fraction and weight fraction) and temperature can be used in functions and these must be entered using a specific syntax (which uses Console Mode format). An example of a valid function for composition (mole fraction) and temperature is `x(Fe)*2 - T^(1.0/3.0)`.

Quantity	*Syntax*
Mole fraction	`x(element)`
Weight fraction	`w(element)`
Temperature	`T`

About the Temperature Options for Property Models

When working with the settings for most Property Models, there are several types of temperature fields available for you to define. Details are included with each Property Model settings section or in tooltips. Below is a summary of the general information about the use of each field.

Annealing Temperature

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Property Models

- **General**: Yield Strength
- **Noble Metal Alloys**: Optical Properties - Noble Metals
- **Steel Models**: Bainite, CCT Diagram, Ferrite, Martensite Fractions, Martensitic Steel Strength, Martensite Temperatures, Pearlite, TTT Diagram

End Temperature

Enter an **End temperature**, which is the temperature at which the property evaluation ends.

Property Models

- **General**: Scheil
- **Steel Models**: CCT Diagram

Equilibrium Above Freeze-in Temperature

The **Equilibrium above freeze-in temperature** checkbox is selected by default and it calculates equilibrium above freeze-in temperature. Click to clear the checkbox when evaluating the frozen-in structure at higher temperatures than the freeze-in temperature.

Property Models

- **General**: Equilibrium with Freeze-in Temperature
- **Nickel Models**:Equilibrium with Freeze-in Temperature - Ni

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Property Models

- **General**: Coarsening, Driving Force, Equilibrium, Equilibrium with Freeze-in Temperature, Interfacial Energy
- **Nickel Models**: Antiphase Boundary Energy, Coarsening - Ni, Equilibrium with Freeze-in Temperature - Ni, Strain-Age Cracking
- **Steel Models**: Bainite, Ferrite, Martensitic Steel Strength, Pearlite, TTT Diagram
- **Titanium Models**: Alloy Strength - Ti

Freeze-in Temperature

Enter a **Freeze-in temperature**, which is the temperature at which the freeze-in occurs.

Property Models

- **General**: Equilibrium with Freeze-in Temperature
- **Nickel Models**: Antiphase Boundary Energy and Equilibrium with Freeze-in Temperature - Ni

High Temperature Limit

Enter a **High temperature limit** for the evaluation.

Property Models

- **General**: Liquid and Solidus Temperature
- **Nickel Models**: Solvus for Ordered Phase, Strain-Age Cracking
- **Steel Models**: Critical Transformation Temperatures

Initial Temperature

Enter an **Initial temperature**, which is the temperature at which the initial equilibrium state is obtained.

Property Models

- **Nickel Models**: Solvus for Ordered Phase

Low Temperature Limit

Enter a **Low temperature limit** for the evaluation.

Property Models

- **General**: Liquid and Solidus Temperature
- **Nickel Models**: Solvus for Ordered Phase, Strain-Age Cracking
- **Steel Models**: Critical Transformation Temperatures

Quench Temperature

Enter a **Quench temperature**, which is the temperature at which the quench occurs.

Property Models

- **Steel Models**: Martensite Fractions, Martensitic Steel Strength

Start Temperature

Enter a **Start temperature**, which is the temperature at which the property evaluation starts.

Property Models

- **General**: Crack Susceptibility Coefficient, Scheil
- **Steel Models**: CCT Diagram

Tempering Temperature

The **Tempering temperature** is the temperature at which tempering is performed. This is used to estimate martensite hardness after tempering.

Property Models

- **Steel Models**: Martensitic Steel Strength

Coarsening Property Model Settings

The **Coarsening** Property Model, available as a General model with the Property Model Calculator, calculates the coarsening rate coefficient K of a spherical precipitate phase in a matrix phase. The output is the coarsening rate coefficient for the precipitate phase and the interfacial energy between matrix and the precipitate phase.

This Model requires that the thermodynamic database used includes descriptions of molar volume of the matrix and precipitates phases as well as a kinetic database with mobilities for the matrix phase.

Configuration Settings

The settings are found on the Property Model Calculator when **Coarsening** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Matrix Phase

Choose a **Matrix phase**.

Precipitate Phase

Choose a **Precipitate phase** to calculate its coarsening rate. Click the **Add phase** button to add another Precipitate phase. Click the **Remove phase** button to remove a phase.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Coarsening rate coefficient Ni [m^3/s]** for the precipitate phase.
- **Evaluation temperature**
- **Interfacial energy Ni [J/m^2]** for it to be between the matrix and precipitate phase.

Learn More

About the Coarsening Property Model

For an example, see PM_G_02: Coarsening and Interfacial Energy.

Columnar to Equiaxed Transition (CET) Property Model Settings

The **Columnar to Equiaxed Transition** Property Model, available as a General model with the Property Model Calculator, calculates the fraction of equiaxed grains that correlates with a certain solidification condition, specifically thermal gradient (G) and solidification growth rate (v) (defined as the migration rate of the interface between liquid and primary solid), so that valuable information on the solidification microstructure can be obtained.

The Model formulation consists of two essential steps (1) to determine the dendrite tip radius and tip undercooling, and (2) to apply the calculated undercooling to the CET Model.

System Definer Configuration Settings

Use of this Property Model requires mobility data of liquid for the calculations. For all simulations both a thermodynamic and a mobility (kinetic) database must be selected on the System Definer.

Property Model Calculator Configuration Settings

The settings are found on the Property Model Calculator when the **Columnar to Equiaxed Transition** Model is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Primary Phase

Select the **Primary phase** from the list. This is the primary solid phase to form the dendrite.

Interfacial Energy

Enter a value for the **Interfacial energy [J/m^2]**, which is between the liquid and primary phase. The default is `0.25` J/m^2.

Number of Nucleation Sites

Enter a value for the **Number of nucleation sites [/m^3]** for equiaxed grains per cubic meter. The default is `2.0E15` / m^3.

Nucleation Undercooling

Enter a value for the **Nucleation undercooling [K]**, which is the critical undercooling for nucleation of equiaxed grains. The default is `2.5` K.

Equiaxed Exponent

Enter a value for the **Equiaxed exponent**. The Equiaxed exponent is used in the equation that calculates the fraction of equiaxed grains. This is usually a value between 3 and 5.

Solve For, Temperature Gradient, and Equiaxed Fractions

Select an option from the **Solve for** list (**Equiaxed fraction** or **Thermal gradient**) and then enter the required secondary information as indicated.

- **Equiaxed fraction**: Solve for the equiaxed fraction given the thermal gradient. When **Equiaxed fraction** is selected, then enter a value for the **Temperature gradient**, which is the temperature gradient of the liquid ahead of the dendrite tip. The default is `1000` K/m.
- **Thermal gradient** [K/m]: Solve for the thermal gradient given the equiaxed fraction(s). When **Thermal gradient** is selected, then enter a value for the **Equiaxed fractions**. This finds the thermal gradient for the given equiaxed fractions. The values entered should be between 0.001 and 0.99. If more than one fraction, separate the values with a space. The default is `0.0066 0.49 0.99`.

Growth Rate

Select a **Growth rate** from the list then enter a value in the field.

- If **v** is selected, then enter a value for the solidification growth rate, **v**. The default is `0.1` m/s.
- If **log10(v)** is selected, then enter a value for the logarithm of growth rate, **log10(v)**. The default is `-1.0` m/s.

Solute Trapping

Select the **Solute trapping** checkbox to enable solute trapping at the tip interface. By default this is not selected.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Dendrite tip undercooling [K]**
- **Fraction of equiaxed grains**
- **Liquidus**
- **log10(v) [m/s]**
- **Solidification rate**
- **Thermal gradient**
- **Tip radius**

Learn More

For theory, see About the Columnar to Equiaxed Transition (CET) Property Model.

For examples see:

- PM_G_15: Columnar to Equiaxed Transition (CET) of a NiAlCr Alloy
- PM_G_16: Columnar to Equiaxed Transition of a CMSX-4 Alloy,
- PM_G_17: Columnar to Equiaxed Transition of an IN718 Alloy

Crack Susceptibility Coefficient Property Model Settings

The **Crack Susceptibility Coefficient** Property Model, available as a General model with the Property Model Calculator, calculates the crack susceptibility coefficient, which describes the risk or tendency of a material to experience cracking or *hot tearing* during solidification. Cracking/hot tearing is one of the most common and serious defects encountered during the casting of, for example, aluminum alloys. In general, it is defined by the formation of a macroscopic fissure in a casting because of stress and the associated strain, generated during cooling, at a temperature above the non-equilibrium solidus. Crack susceptibility is also referred to as solidification cracking, hot cracking, hot shortness, supersolidus cracking, and shrinkage brittleness. The Crack Susceptibility Coefficient (CSC) is calculated using Scheil results with three different model options: *Clyne and Davies*, *Kou*, and *Easton*.

When the default **Clyne and Davies** is selected as the **CSC Model**, the calculations use Scheil and assumptions of cooling rates under three different thermal conditions:

- Constant cooling rate, dT/dt = constant
- Constant heat flow, dQ/dt = constant
- Heat flow proportional to 1/sqrt(time)

Configuration Settings

These settings are found on the Property Model Calculator when **Crack Susceptibility Coefficient** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Scheil Parameters

These parameters are the same as those used for the Scheil Property Model although some setting names are slightly different. The **Show advanced Scheil options** settings are described with Scheil Advanced Options: Property Models.

Start Temperature

Enter a **Start temperature**, which is the temperature at which the property evaluation starts.

Scheil Calculation Type

Click to select a **Calculation type**: **Classic Scheil**, **Scheil with back diffusion in primary phase**, or **Scheil with solute trapping**. Then based on this selection, additional settings are made available as indicated.

Back diffusion requires the use of a mobility database.

Fast Diffusers

Enter the element/component to make as **Fast diffusers**. Include a space between each entry, `C N`, for example, is the default entered for Carbon and Nitrogen to be fast diffusers.

Allow Delta Ferrite to Austenite Transition in Steel

This is available when **Classic Scheil** or **Scheil with back diffusion in primary phase** is selected.

Select the **Allow delta ferrite to austenite transition in steel** checkbox to enable BCC to FCC transition.

This feature should only be used for such steels for which it is reasonable to assume infinitely fast diffusion (equilibrium conditions) when delta ferrite is present. When the **Allow delta ferrite to austenite transition in steel** checkbox is selected in Graphical Mode or the DELTA_FERRITE_AUSTENITE_TRANSITION command used in Console Mode, this essentially assumes that diffusion can be considered (infinitely) fast when delta ferrite is present as a solid phase, i.e assumes an equilibrium condition. After delta ferrite is no longer stable, the usual Scheil assumptions for the selected calculation type are in effect. This setting is therefore not suitable for steels where you DO NOT have a complete BCC to FCC transition during solidification. This setting is also NOT available in combination with solute trapping.

Show Advanced Scheil Options

Click the **Show advanced Scheil options** checkbox to enter several settings related to Scheil calculations. See Scheil Advanced Options: Property Models.

CSC Model Selection

CSC Model

Choose a **CSC Model**: **Clyne and Davies** (the default), **Kou**, or **Easton**.

Then continue with these additional settings:

- For **Clyne and Davies** go to Thermal Mode and Liquid Fraction Parameters (Clyne and Davies).
- For **Easton**, go to Solid Fraction for Coherency and Solid Fraction for Coalescence (Easton)

For details and references about these models, see About the Crack Susceptibility Coefficient Property Model.

Additional Scheil Calculation Type Settings

Cooling Rate (Back Diffusion)

This field is available when **Scheil with back diffusion in primary phase** is selected.

Specify the **Cooling rate** in Kelvin per second (K/s). An increased value moves the result from equilibrium toward a Scheil-Gulliver calculation.

Secondary Dendrite Arm Spacing (Back Diffusion)

This field is available when **Scheil with back diffusion in primary phase** is selected.

The **Secondary dendrite arm spacing** is the distance in meters between two secondary dendrite arms. It is calculated from the cooling rate as c*(cooling rate)$^{-n}$ where c and n are entered in these fields.

Enter values for **Secondary dendrite arm spacing c** and **Secondary dendrite arm spacing n**.

Primary Phase (Back Diffusion and Solute Trapping)

This field is available when **Scheil with back diffusion in primary phase** or **Scheil with solute trapping** is selected.

The primary solidified phase is the phase where the back diffusion or solute trapping takes place.

If **Automatic** (Scheil Calculator) or **Any phase** (Property Models) is selected (or kept as the default), the program tries to find the phase which gives the most back diffusion or solute trapping.

To override this setting, choose a specific primary phase from the list:

- For back diffusion, only phases with diffusion data can be used as primary phases.
- For solute trapping, only phases that dissolve all elements in the system can be used as primary phases.

Scanning Speed and α (Solute Trapping)

These fields are available when **Scheil with solute trapping** is selected.

As needed, enter **Scanning speed** and **α** to define the **Calculated solidification speed**.

On the Scheil Calculator, the **Calculated solidification speed** is shown. For Property Models, below is how the values are calculated from the **Scanning speed** and **α** values entered.

The **Calculated Solidification Speed** is Vs = $V_{scanning}$ * cos(α) m/s, where $V_{scanning}$ is the user specified **Scanning speed** in m/s and **α** is the alpha angle, α, between the solid/liquid boundary and scanning direction.

Thermal Mode and Liquid Fraction Parameters (Clyne and Davies)

These settings are available when **Clyne and Davies** is selected as the **CSC Model**.

Thermal Mode

Select a **Thermal mode** for the solidification simulation:

- **Constant cooling rate, dT/dt = constant**
- **Constant heat flow, dQ/dt = constant**
- **Heat flow proportional to 1/sqrt(time)** (i.e. heat flow is proportional to $\frac{1}{\sqrt{time}}$)

Liquid Fraction for Start of Relaxation

Enter a value for the **Liquid fraction for start of relaxation**.

Liquid Fraction Transition to Vulnerability

Enter a value for the **Liquid fraction transition to vulnerability**.

Liquid Fraction Smallest to Vulnerability

Enter a value for the **Liquid fraction smallest to vulnerability**.

Solid Fraction for Coherency and Solid Fraction for Coalescence (Easton)

These settings are available when **Easton** is selected as the **CSC Model**.

Solid Fraction for Coherency

Enter a value in the **Solid fraction for coherency** field, which is the solid fraction for a coherent dendrite structure. The default is 0.7.

Solid Fraction for Coalescence

Enter a value in the **Solid fraction for coalescence** field, which is the solid fraction for coalescence of a dendrite structure. The default is 0.98.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Composition**
- **Crack Susceptibility coefficient**. The tendency for the material to crack during solidification.
- **Freezing range [K]**. The solidification freezing range (Liquidus - Solidus) given in Kelvin.
- **Liquidus temperature**
- **Solidus temperature**
- **Start temperature**

Learn More

For details about this more advanced model, see About the Crack Susceptibility Coefficient Property Model.

For an example, see PM_G_07: Hot Crack Susceptibility.

Driving Force Property Model Settings

The **Driving Force** Property Model, available as a General model with the Property Model Calculator, calculates the thermodynamic driving force for a phase as well as the normalized thermodynamic driving force (i.e., the driving force divided by R*T where R is the ideal gas constant and T is the evaluation temperature).

Configuration Settings

The settings are found on the Property Model Calculator when **Driving force** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Matrix Phase

Choose a **Matrix phase**, the single phase region to start in. Select **Any phase** to use the phases that take part of the initial equilibrium or choose a specific phase.

Precipitate Phase

Choose a **Precipitate phase** to calculate its driving force. Click the plus and minus buttons to add or remove **Precipitate phases** as needed.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Composition**
- **Driving force per mole** and then choose a unit: **Joule**, **Calorie**, **Electron volt**, **Gigajoule**, **Watt hour**, or **Kilowatt hour**.
- **Evaluation temperature**
- **Interfacial energy Ni [J/m^2]**
- **Normalized driving force**

Learn More

For an example, see PM_G_03: Driving Force and Interfacial Energy.

Equilibrium Property Model Settings

The **Equilibrium** Property Model, available as a General model with the Property Model Calculator, calculates the equilibrium for the given conditions. You can also define additional function definitions.

When you use this Model with the **Property Model Calculator**, it is the same calculation result as when you are using an **Equilibrium Calculator** with the **Single equilibrium** calculation type.

Configuration Settings

The settings are found on the Property Model Calculator when **Equilibrium** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Equilibrium Minimization Strategy

Select an **Equilibrium minimization strategy**. The default uses the **Global test preferred** option. For this Property Model, and for either Global option, also enter the **Max number of global gridpoints**, where the default is 2000.

The **Minimization Strategy** setting is used to ensure that the most stable minimum under the specified conditions is computed.

With either the *Global test preferred* or *Local minimization preferred* setting, the program cycles through options before it gives up:

- For **Global test preferred** the minimization starts with a global test and if that fails it runs full global minimization.
- For **Local minimization preferred** the minimization starts with a local minimization, in case of failure it tries a global test and finally a full global minimization.

If you choose **Local minimization only** or **Global minimization only**, the program just tries the one setting and gives up if it fails.

For general information about global minimization, see the topic related to the Console Mode command, GLOBAL_MINIMIZATION.

Quantity Definitions

For *Quantity Definitions* define **Q1**. Click the **Add** button to define additional items and the **Remove** button to delete items.

Then from the lists, choose the variable for each quantity to define. The quantities are called **Q1**, **Q2**, **Q3** and so on.

All quantities that normally can be obtained from an equilibrium calculation can also be obtained when plotting the results.

Function Definitions

For *Function Definitions*, define **Function 1**. Click the **Add** button to define additional items and the **Remove** button to delete items. In the left field edit the default name of each function and enter the function itself in the right field after the equal sign.

To learn about using variables and functions, in Graphical Mode, see T_07: User-Defined Functions and in Console Mode, see example 44 .

You can also use Console Mode syntax when entering the function. See Parameters, Functions, and Variables.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

All quantities that normally can be obtained from an equilibrium calculation can also be obtained when plotting the results as well as the defined functions.

For this Property Model, the plot quantity you select is the **Evaluation temperature** instead of **Temperature**.

Conditions Tab Settings

Equilibrium with Freeze-in Temperature Property Model Settings

The **Equilibrium with Freeze-in Temperature** Property Model, available as a General model with the Property Model Calculator, calculates equilibrium at the freeze-in temperature and evaluates the properties at a different evaluation temperature. The assumption is that diffusion and phase transformations are negligible below the freeze-in temperature and, therefore, the phase amounts and phase compositions do not change below the freeze-in temperature. Typically, the freeze-in occurs during cooling where equilibrium can be assumed above the freeze-in temperature.

Configuration Settings

The settings are found on the Property Model Calculator when the **Equilibrium with Freeze-in Temperature** Model is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Freeze-in Temperature

Enter a **Freeze-in temperature**, which is the temperature at which the freeze-in occurs.

Equilibrium Above Freeze-in Temperature

The **Equilibrium above freeze-in temperature** checkbox is selected by default and it calculates equilibrium above freeze-in temperature. Click to clear the checkbox when evaluating the frozen-in structure at higher temperatures than the freeze-in temperature.

Evaluate for Single Phase Only

Select the **Evaluate for a single phase only** checkbox to evaluate the properties of a specific phase or deselect to evaluate the properties for the entire system.

Phase for Evaluation

This setting is available when the **Evaluate for a single phase only** checkbox is selected.

From the **Phase for evaluation** list, select any available phase or **None**.

Equilibrium Minimization Strategy

Select an **Equilibrium minimization strategy**. The default uses the **Local minimization preferred** option.

The **Minimization Strategy** setting is used to ensure that the most stable minimum under the specified conditions is computed.

With either the *Global test preferred* or *Local minimization preferred* setting, the program cycles through options before it gives up:

- For **Global test preferred** the minimization starts with a global test and if that fails it runs full global minimization.
- For **Local minimization preferred** the minimization starts with a local minimization, in case of failure it tries a global test and finally a full global minimization.

If you choose **Local minimization only** or **Global minimization only**, the program just tries the one setting and gives up if it fails.

For general information about global minimization, see the topic related to the Console Mode command, GLOBAL_MINIMIZATION.

Homogenization Function

The **Homogenization function** is used for the evaluation of the systems thermal and electric properties. The function is applied on thermal- and electrical-resistivity. The electric conductivity, thermal conductivity, and thermal diffusivity are evaluated from the resistivities.

The geometrical interpretation of the Hashin-Shtrikman bounds are concentric spherical shells of each phase.

- **Rule of mixtures (upper Wiener bound)**: the geometrical interpretation are continuous layers of each phase parallel with the direction of evaluation of the property.
- **Inverse rule of mixtures (lower Wiener bound)**: The geometrical interpretation are continuous layers of each phase orthogonal to the direction of evaluation of the property.
- **General lower Hashin-Shtrikman bound**: The outermost shell consists of the phase with the most sluggish property.
- **General upper Hashin-Shtrikman bound**: The innermost shell consists of the phase with the most sluggish property.
- **Hashin-Shtrikman bound with majority phase as matrix phase**: The outermost shell consists of the phase with the highest local volume fraction.

Account for Phase Interface Scattering

The **Account for phase interface scattering** checkbox is selected by default.

The electrical resistivity due to phase interface scattering is evaluated as the scattering constant times sum of the interaction between the volume fraction of all the phases. The default value for the constant is 4.0e-8 Ωm. The contribution to thermal conductivity is assumed to be related to that of electrical resistivity, following the Wiedemann-Franz law.

Phase Interface Scattering Constant

This setting is available when the **Account for phase interface scattering** checkbox is selected.

The **Phase interface scattering constant** default value is 4.0e-8 Ωm.

Set Reference Temperature for Technical CTE

This setting is available when the **Account for phase interface scattering** checkbox is selected.

In the field, enter the **Reference temperature for technical CTE**, where CTE is the coefficient of thermal expansion. Typically room temperature is used as the default 293.15 K (20 °C).

Define User Functions

Select the **Define user functions** checkbox to enter up to two **User-defined functions** using the Console Mode syntax.

For an example of user-defined functions, see T_07: User-Defined Functions.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Density (g/cm^3)**
- **Elastic constants**
- **Elastic moduli**
- **Electric conductivity (S/m)**
- **Electric resistivity (ohm m)** (Ωm)
- **Evaluation temperature**
- **Freeze-in temperature**
- **Heat capacity (J/mol K))**
- **Linear CTE (physical) (1/K)**: Fractional change of length per unit temperature change. Assumed Isotropic material.

- **Linear CTE (technical) (1/K)**: Fractional change of length per unit temperature change. Calculated as (L1-L0)/(T1-T0)/L0, where L0 is the length at a reference temperature T0. T0 is by default equal to room temperature. Assumed Isotropic material.
- **Thermal conductivity (W/(mK))**
- **Thermal diffusivity (m^2/s)**
- **Thermal resistivity (mK/W)**
- **Volume (m^3/mol)**
- **Volumetric CTE (physical) (1/K)**: Fractional change of volume per unit temperature change.
- **User-defined function** and **2nd user-defined function**: Available when the **Define user functions** checkbox is selected and the functions are defined.

Elastic moduli is available to plot when the thermodynamic database selected includes elastic properties. However, even if the database does not have elastic constants, the quantity is visible to select from the list even. In this case there is a message in the Event Log to indicate there is no elastic data and the value will be NaN.

Learn More

For theory, see About the Equilibrium with Freeze-in Temperature Property Model.

For examples, see:

PM_G_10: Freeze-in Thermal Conductivity

PM_G_11: Freeze-in Electrical Resistivity

Interfacial Energy Property Model Settings

The **Interfacial Energy** Property Model, available as a General model with the Property Model Calculator, estimates the interfacial energy between a matrix phase and a precipitate phase using thermodynamic data from a CALPHAD database. The approximation model is based on Becker's bond energy approach and is also available in Precipitation Module (TC-PRISMA).

In the actual calculation, the coefficients taken distinguish between only bcc and fcc structure for the (110) and (111) lattice plane, respectively. For other planes and/or other phases, the estimate is approximate. In most situations, it is recommended to perform calibrations against some experimental data because the interfacial energy is dependent on so many factors that are ignored in the estimation, for example entropy, incoherency, orientation, and curvature, etc. Uncertainty factors must also be considered as thermodynamic data in CALPHAD databases are not always accurate.

Configuration Settings

The settings are found on the Property Model Calculator when **Interfacial energy** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Matrix Phase

Choose a **Matrix phase** to calculate the interfacial energy [J/m^2].

Precipitate Phase

- Choose a **Precipitate phase** to calculate the interfacial energy [J/m^2].

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Evaluation temperature**
- **Interfacial energy Ni [J/m^2]** for it to be between the matrix and precipitate phase.

Learn More

For theory see About the Interfacial Energy Property Model.

For an example, see PM_G_03: Driving Force and Interfacial Energy.

Liquid and Solidus Temperature Property Model Settings

The **Liquid and Solidus Temperature** Property Model, available as a General model with the Property Model Calculator, calculates the equilibrium solidification range in terms of temperature. If only the liquidus temperature is required, the calculation times are reduced.

Configuration Settings

The settings are found on the Property Model Calculator when **Liquidus and solidus temperature** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Only Calculate Liquidus Temperature

Select the **Only calculate liquidus temperature** checkbox as required. When selected, this improves the calculation speed but the solidus is not calculated.

Liquid Phase

Choose the **Liquid phase** of the system. This is a fallback choice. Normally this should be handled automatically, even if multiple liquid phases are present.

Low Temperature Limit

Enter a **Low temperature limit** for the evaluation.

High Temperature Limit

Enter a **High temperature limit** for the evaluation.

Solid Fraction for Evaluating Liquidus Temperature

Enter a value for the **Solid fraction for evaluating liquidus temperature**. The default value is 0.001. Set this to a small value to ignore any high temperature stable phases that sometimes form with a small fraction at hundreds of degrees above liquidus for primary phase.

Max. Number of Iterations

Enter a **Max. number of iterations**, which is the maximum number of phase transformation iterations performed. The default is 10.

Global Minimization (Liquidus and Solidus)

Select the **Global minimization for liquidus** and/or **Global minimization for solidus** checkboxes to find all phases present in the equilibria.

Selecting one or both checkboxes can significantly slow down the calculations but ultimately it produces more reliable results.

Global minimization recommendation: First try to calculate without global minimization, then if inaccuracies occur, switch global minimization on. Problems mostly occur if many phases are present at a given temperature.

Suspend Gas Phase

Select the **Suspend gas phase** checkbox as required. The occurrence of a gas phase may mislead the liquidus temperature determination. If the presence of the gas phase is absolutely required, you can activate it and then choose a user-defined phase.

Gas Phase

Choose a **Gas phase** from the list.

Print Results in Event Log

Select the **Print results in Event Log** checkbox to display/include all results in the Event Log window. This includes the **First solidified phase**, **Liquidus (K)**, **Solidus (K)**, and **Composition** information. Choose the **Output type**: **Single row** or **Full list for each iteration**.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Composition**
- **High temperature limit**
- **Liquidus temperature**
- **Low temperature limit**
- **Max number of iterations**
- **Solid fraction for evaluating liquidus temperature**
- **Solidus temperature**

Learn More

For an example, see PM_G_12: Solidus and Liquidus Batch Calculation.

Phase Transition Property Model Settings

The **Phase Transition** Property Model, available as a General model with the Property Model Calculator, calculates the *phase transition* point, or the point at which a new phase may form from a matrix phase when varying a defined condition. This model can be useful to determine melting temperature, boiling temperature, or solubility limits. The Model performs searches for a phase transition between the matrix phase and the "phase to form" by varying either temperature or composition of the system. The direction of the search (positive, negative, or both) can be specified.

Configuration Settings

The settings are found on the Property Model Calculator when **Phase transition** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Matrix Phase

Choose a **Matrix phase**, the single phase region to start in. Select **Any phase** to use the phases that take part of the initial equilibrium or choose a specific phase.

Phase to Form

For the new **Phase to form**, select **Any phase** or choose a specific phase.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature. If the temperature is selected as the relaxed condition, this is treated as the starting value for the search.

Vary Temperature or Composition

Choose an option to vary when searching for the phase transition.

From the **Vary temperature or composition** list, choose **Evaluation temperature** or **Composition**. For **Composition**, also choose the **Condition to vary**.

Condition to Vary

From the **Condition to vary** list select an option to vary when calculating the phase transition. Options are based on the composition (e.g. Fe, Cr, etc.) and unit (i.e. Mass percent, Mole percent, Mass fraction, or Mole fraction). For example, **Mass percent Cr**.

Suspend All Other Phases

Select the **Suspend all other phases** checkbox to suspend the phases that are not of interest, which allows for a faster calculation. However, this could mean that metastable equilibria are in fact calculated.

It is best practice to suspend phases on the **System Definer** by selecting the applicable phases on the **Phases and Phase Constitution** tab.

Search Direction

For the composition or temperature condition being varied, choose the **Search direction** to be in a **Positive**, **Negative**, or **Positive and Negative** direction.

The start value is taken from *Condition Definitions*. The closer the start value is to the actual transition point, the more likely it is that the model will find the transition. Note that the phase transition for a given phase may actually occur in the opposite direction from the selected one.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Composition**
- **Evaluation temperature**
- **Phase transition: Composition**
- **Phase transition: Temperature**

Since only one variable can serve as a **Phase transition** per calculation, the quantity that is not relaxed has a NaN result in its corresponding result quantity. The **Evaluation temperature** result quantity inherits the unit set in the conditions while the **Composition** result quantity inherits the normalization (mole or mass) but always returns a fraction.

Learn More

For an example, see PM_G_01: Phase Transition.

Scheil Property Model Settings

The **Scheil** Property Model, available as a General model with the Property Model Calculator, calculates solidification under the Scheil assumption. Many model input parameters are taken from the Scheil Calculator, and model results are available for key aspects of solidification, i.e., liquidus, solidus, freezing range, and fractions of various phase combinations. In addition, properties of the as-solidified material can be evaluated below the solidification temperature. Three Scheil calculation types (Classic, Scheil with back diffusion in the primary phase, and Scheil with solute trapping) are available.

Configuration Settings

The settings are found on the Property Model Calculator when **Scheil** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

The advanced Scheil settings are described with Scheil Advanced Options: Property Models. This is applicable to the **Scheil** and **Crack Susceptibility Coefficient** Property Models.

These parameters are the same as those used for the Scheil Calculator although some setting names are slightly different.

Start Temperature

Enter a **Start temperature**, which is the temperature at which the property evaluation starts.

Calculation Type

Click to select a **Calculation type**: **Classic Scheil**, **Scheil with back diffusion in primary phase**, or **Scheil with solute trapping**. Then based on this selection, additional settings are made available as indicated.

Back diffusion requires the use of a mobility database.

Fast Diffusers

Enter the element/component to make as **Fast diffusers**. Include a space between each entry, `C N`, for example, is the default entered for Carbon and Nitrogen to be fast diffusers.

Calculate To

Use the **Calculate to** setting to choose from where the calculation should end, **End of Scheil** or **Temperature below solidus**.

- **End of Scheil** stops the calculation when the Scheil calculation is finished.
- **Temperature below solidus** is where a frozen structure is assumed below solidus. When this is selected also enter a **Temperature below solidus** in the field. The default is `298.15`.

End Temperature

This is available when **Temperature below solidus** is selected for **Calculate to**.

Enter an **End temperature**, which is the temperature at which the property evaluation ends.

Allow Delta Ferrite to Austenite Transition in Steel

This is available when **Classic Scheil** or **Scheil with back diffusion in primary phase** is selected.

Select the **Allow delta ferrite to austenite transition in steel** checkbox to enable BCC to FCC transition.

This feature should only be used for such steels for which it is reasonable to assume infinitely fast diffusion (equilibrium conditions) when delta ferrite is present. When the **Allow delta ferrite to austenite transition in steel** checkbox is selected in Graphical Mode or the DELTA_FERRITE_AUSTENITE_TRANSITION command used in Console Mode, this essentially assumes that diffusion can be considered (infinitely) fast when delta ferrite is present as a solid phase, i.e assumes an equilibrium condition. After delta ferrite is no longer stable, the usual Scheil assumptions for the selected calculation type are in effect. This setting is therefore not suitable for steels where you DO NOT have a complete BCC to FCC transition during solidification. This setting is also NOT available in combination with solute trapping.

Show Advanced Scheil Options

Click the **Show advanced Scheil options** checkbox to enter several settings related to Scheil calculations. See Scheil Advanced Options: Property Models.

Cooling Rate (Back Diffusion)

This field is available when **Scheil with back diffusion in primary phase** is selected.

Specify the **Cooling rate** in Kelvin per second (K/s). An increased value moves the result from equilibrium toward a Scheil-Gulliver calculation.

Secondary Dendrite Arm Spacing (Back Diffusion)

This field is available when **Scheil with back diffusion in primary phase** is selected.

The **Secondary dendrite arm spacing** is the distance in meters between two secondary dendrite arms. It is calculated from the cooling rate as $c*(\text{cooling rate})^{-n}$ where c and n are entered in these fields.

Enter values for **Secondary dendrite arm spacing c** and **Secondary dendrite arm spacing n**.

Primary Phase (Back Diffusion and Solute Trapping)

This field is available when **Scheil with back diffusion in primary phase** or **Scheil with solute trapping** is selected.

The primary solidified phase is the phase where the back diffusion or solute trapping takes place.

If **Automatic** (Scheil Calculator) or **Any phase** (Property Models) is selected (or kept as the default), the program tries to find the phase which gives the most back diffusion or solute trapping.

To override this setting, choose a specific primary phase from the list:

- For back diffusion, only phases with diffusion data can be used as primary phases.
- For solute trapping, only phases that dissolve all elements in the system can be used as primary phases.

Scanning Speed and α (Solute Trapping)

These fields are available when **Scheil with solute trapping** is selected.

As needed, enter **Scanning speed** and **α** to define the **Calculated solidification speed**.

On the Scheil Calculator, the **Calculated solidification speed** is shown. For Property Models, below is how the values are calculated from the **Scanning speed** and **α** values entered.

The **Calculated Solidification Speed** is Vs = $V_{scanning}$ * cos(α) m/s, where $V_{scanning}$ is the user specified **Scanning speed** in m/s and **α** is the alpha angle, α, between the solid/liquid boundary and scanning direction.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Electric conductivity (S/m)**
- **Electric resistivity (ohm m)**
- **Eutectic fraction**: Eutectic fraction at eutectic point (evaluated using Gibbs phase rule).
- **Freezing range [K]**. The solidification freezing range (Liquidus - Solidus) given in Kelvin.
- **Liquidus temperature**
- **Mole fraction of solid phases**: The mole fraction of solid phases (evaluated at the lowest temperature from the simulation)
- **Solidus temperature**
- **Thermal conductivity (W/mK))**
- **Thermal diffusivity (m2/s)**
- **Thermal resistivity (MK/W)**
- **Total fraction of solid phases**: The total mole fraction of solid phases (evaluated at the lowest temperature from the simulation)
- **Volume fraction of solid phases**: The volume fraction of solid phases (evaluated at the lowest temperature from the simulation)
- **Volumetric shrinkage (vol-%)**

Learn More

For theory or background details about Scheil, start by reviewing Scheil-Gulliver Solidification Calculations.

For an example, see PM_G_20: Scheil for an Al-1Si-1Mn-0.7Mg-0.6Fe-0.1Cu Alloy.

Scheil Advanced Options: Property Models

The **Scheil** Property Model, available as a General model with the Property Model Calculator, calculates solidification under the Scheil assumption. Many model input parameters are taken from the Scheil Calculator, and model results are available for key aspects of solidification, i.e., liquidus, solidus, freezing range, and fractions of various phase combinations. In addition,

properties of the as-solidified material can be evaluated below the solidification temperature. Three Scheil calculation types (Classic, Scheil with back diffusion in the primary phase, and Scheil with solute trapping) are available.

Advanced Configuration Settings

This topic has advanced settings information for the **Show advanced Scheil options** checkbox that is available for a Property Model **Configuration** windows. The main settings are on the **Configuration** tab.

This is applicable to the **Scheil** and **Crack Susceptibility Coefficient** Property Models.

These settings are based on the Scheil Calculator settings with minor differences in wording or application. See Advanced Options.

For theory or background details about Scheil, start by reviewing Scheil-Gulliver Solidification Calculations.

Temperature Step during Scheil

Enter a **Temperature step during Scheil** for the Scheil simulation. Temperature step is given in the same unit as the temperature in the **Condition Definitions**.

Global Minimization

Global minimization is enabled by default i.e. the **Global minimization** checkbox is selected.

It is recommended to keep global minimization on as it makes the calculation more accurate. However, turn it off if you find that the calculation is taking too long for any particular system, and accuracy is not the highest priority.

For this setting, a global equilibrium test is performed at selected intervals when an equilibrium is reached. By default it is at every 10 th Scheil step but this can be changed using the **Global test interval** setting. The global equilibrium test is also done every time the set of stable phases tries to change. This costs more computer time but the calculations are more robust.

Global Test Interval

Use the **Global test interval** setting to change the interval at which a global equilibrium test is done, which by default is every 10th step as long as there are no changes in the set of stable phases. Every time the set of stable phases tries to change, a global equilibrium test is also done regardless of the test interval value chosen. A global equilibrium test means that the calculated equilibrium state obtained by the ordinary minimization calculation is tested against the Global Minimization Technique, and if the result is found unstable then the full global minimization calculation is performed instead.

Liquid Phase

The default in the list is the **LIQUID** phase already defined in the chosen database.

Solid Fraction for Evaluating Liquidus Temperature

Enter a value for the **Solid fraction for evaluating liquidus temperature**. A small fraction larger than zero can be used to avoid small amounts of high temperature stable phases for the evaluation of liquidus temperature.

Terminate at Fraction of Liquid Phase Amount

Enter a value in the field for **Terminate at fraction of liquid phase amount**.

For **Crack Susceptibility Coefficient** model, the value should not be larger than the setting **Liquid fraction: Smallest for vulnerability**.

Max No. of Iterations

Enter or choose a value for the **Max no. of iterations**. By default, the program tries 500 iterations before it gives up. As some models give computation times of more than 1 CPU second/iteration, this number is also used to check the CPU time and the calculation stops if 500 CPU seconds/iterations are used.

The default value for an **Aqueous Calculator** is `1000`. This is because there is usually a very small amount in the AQUEOUS phase and this default increases the stability of the calculation.

Required Accuracy

The default **Required accuracy** is `1.0E-6`. This is a relative accuracy, and the program requires that the relative difference in each variable must be lower than this value before it has converged. A larger value normally means fewer iterations but less accurate solutions. The value should be at least one order of magnitude larger than the machine precision.

Smallest Fraction in a Phase

The default **Smallest fraction** (or **Smallest fraction in a phase** for Property Models) is `1.0E-12`. This is the value assigned to constituents that are unstable. It is normally only in the gas phase you can find such low fractions.

The default value for the smallest site-fractions is `1E-12` for all phases except for IDEAL phase with one sublattice site (such as the GAS mixture phase in many databases) for which the default value is always as `1E-30`.

The default value for an **Aqueous Calculator** is `1E-16`. This is because there is usually a very small amount in the AQUEOUS phase and this default increases the stability of the calculation.

Smallest Fraction for Alloy Composition

The default **Smallest fraction for alloy composition** is 1.0E-7. A smallest value assigned to alloy mole/mass fraction in case a smaller input value for an element is entered.

Approximate Driving Force for Metastable Phases

The **Approximate driving force for metastable phases** checkbox is selected by default. Click to clear the checkbox to change the default as required and based on the options described below.

This setting involves the convergence of metastable phases and affects their driving forces. It can also have an effect on when an equilibrium is considered successful.

The default is to allow an equilibrium with metastable phases that have not converged, as long as the stable phases have converged. This is efficient but often causes approximate values of the driving forces for the metastable phases.

If you change the default, it enforces metastable phases to converge. This gives accurate driving forces for metastable phases as well as stable phases. It can however take a slightly longer time, and if metastable phases do not converge it causes the equilibrium calculation to fail.

Spinodal Property Model Settings

The **Spinodal** Property Model, available as a General model with the Property Model Calculator, calculates the spinodal line. The spinodal is defined by the condition where the second derivative of Gibbs free energy is zero (`d2G/dx2 = 0`). The Model searches for the Spinodal "solution" for the spinodal phase by varying either temperature or composition in mass percent, mole percent, mass fraction, or mole fraction (e.g. mass percent Fe, mole percent Fe, and so forth). Up to two spinodal solutions can be found.

When within the miscibility gap, but above the spinodal curve, phase transformation occurs by classical nucleation and growth of the spinodal phase. When within the miscibility gap, but below the spinodal curve, the phase transformation occur by spinodal decomposition of the spinodal phase.

Configuration Settings

These settings are found on the Property Model Calculator when **Spinodal** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Spinodal Phase

From the **Spinodal phase** list select the applicable phase you want to search for the spinodal.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature. If the temperature is selected as the relaxed condition, this is treated as the starting value for the search.

Vary Temperature or Composition

Choose an option to vary when searching for the spinodal.

From the **Vary temperature or composition** list, choose **Evaluation temperature** or **Composition**. For **Composition**, also choose the **Condition to vary**.

Condition to Vary

From the **Condition to vary** list select an option to vary when searching for the spinodal. Up to two spinodals can be found. Options are based on the composition (e.g. Fe, Cr, etc.) and unit (i.e. Mass percent, Mole percent, Mass fraction, or Mole fraction). For example, **Mass percent Cr**.

Manual Search Limits

The **Manual search limits** checkbox is not selected by default and this sets automatic search limits.

Select the checkbox to enter user-defined search limits in the fields. Enter the **Lower condition limit** and **Upper condition limit**. Then enter the number of steps when estimating the position (s) of the spinodal(s)in the **Steps when estimating spinodal** field.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Composition**
- **Evaluation temperature**
- **Spinodal**: The first spinodal regardless of search condition type.
- **Spinodal - 2nd solution**: The second spinodal regardless of search condition type.

- **Spinodal temperature**: The first spinodal when the search condition is temperature.
- **Spinodal temperature - 2nd solution**: The second spinodal when the search condition is temperature.

Learn More

For theory, see About the Spinodal Property Model.

For an example, see PM_G_08: Spinodal.

T_0 Temperature Property Model Settings

The **T-Zero Temperature** Property Model, available as a General model with the Property Model Calculator, calculates the so-called T_0 line.

The T_0 temperature is defined as the temperature where two phases of identical chemical composition have the same molar Gibbs free energy. This temperature is an important quantity in the field of diffusionless phase transformations, e.g. martensitic transformation, since it is the upper limit where diffusionless phase transformations can occur.

Configuration Settings

These settings are found on the Property Model Calculator when **T-Zero Temperature** is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

First Phase

From the **First phase** list select the applicable phase you want to search for the evaluation of Gibbs energy.

Second Phase

From the **Second phase** list select the applicable phase you want to search for the evaluation of Gibbs energy.

Energy Addition Second Phase

Use the **Energy addition second phase [J/mol]** field to include a Gibbs energy addition to the second phase. This allows for inclusion of an energy barrier for martensitic phase transformations.

For an example of this see PM_G_14: Ti-Fe T-Zero Martensite.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature. If the temperature is selected as the relaxed condition, this is treated as the starting value for the search.

Vary Temperature or Composition

Choose an option to vary when searching for $\mathbf{T_0}$.

From the **Vary temperature or composition** list, choose **Evaluation temperature** or **Composition**. For **Composition**, also choose the **Condition to vary**.

When **Evaluation temperature** is the varied condition, T_0 is obtained as a solution. When a specific composition is selected as the condition to vary, then the evaluation temperature is calculated when the T_0 condition is fulfilled. So the resulting temperature is equal to T_0.

In most cases the curvature of the Gibbs energies of the two phases is different which results in multiple solutions for $\mathbf{T_0}$. If you keep the default settings (*Vary temperature or condition → Evaluation temperature* and with no manual search limits) the Property Model Calculator can store up to two solutions. If the solution of interest is not calculated, adjusting **Manual search limits** and/or changing the condition to vary to one of the listed compositions, allows you to find the solution of interest.

Condition to Vary

From the **Condition to vary** list select an option to vary when searching for $\mathbf{T_0}$. Up to two solutions can be found. Options are based on the composition (e.g. Fe, Cr, etc.) and unit (i.e. Mass percent, Mole percent, Mass fraction, or Mole fraction). For example, **Mass percent Cr**.

Manual Search Limits

The **Manual search limits** checkbox is not selected by default and this sets automatic search limits.

Select the checkbox to enter user-defined search limits in the fields. Enter the **Lower condition limit** and **Upper condition limit**. Then in the **Steps when estimating root(s)** field, enter the number of steps in a linear grid when estimating the position(s) of the conditions.

Root means a solution of $\mathbf{T_0}$, so a composition and temperature where the Gibbs energies are the same. In other words, it finds the "root(s)" where the two selected phases have equal Gibbs energy. Think of the "root" as the conditions (temperature, composition) where the Gibbs energy of the two selected phases intersect, i.e. have equal Gibbs energies.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Select from these plot quantities:

- **Composition**, when the search condition is temperature
- **Evaluation temperature**, when the search condition is composition (in this case temperature is equal to T-Zero).
- **T-Zero**: The first root (solution) when the search condition is temperature.
- **T-Zero - 2nd solution**: The second root (solution) when the search condition is temperature.
- **Varied condition**: The first varied condition regardless of search condition type.
- **Varied condition - 2nd solution**: The second varied condition regardless of search condition type.

Learn More

For theory see About the T0 Temperature Property Model.

For examples, see:

- PM_G_09: T-Zero Temperature
- PM_G_14: Ti-Fe T-Zero Martensite

Yield Strength: Simplified Mode Settings

This section has information about the **Simplified** mode configuration settings available for the **Yield Strength** Property Model.

The **Yield Strength** Property Model, available as a General model with the Property Model Calculator, calculates yield stress. It returns the calculated yield strength at the desired evaluation temperature for the specified material using the equilibrium phase fractions calculated at the annealing temperature. Then you can further define the following contributions to the total yield stress:

- Intrinsic strength (σ_i) for the pure elements,
- Grain boundary strengthening (σ_{gb}),
- Solid solution strengthening (σ_{ss}),
- Precipitation strengthening (σ_p), and
- A user set, constant strength contribution (σ_c).

General Configuration Settings

The settings for these contributions are found on the Property Model Calculator when the **Yield Strength** Model is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

There are settings described elsewhere when **Yield Strength** is selected as an axis variable for a Plot Renderer or Table Renderer that are successors to the Precipitation Calculator.

Learn More

These contributions are defined in About the Yield Strength Property Model.

For examples using the Property Model Calculator, see PM_G_04: Yield Strength, PM_G_05: Yield Strength NiAlCr, and PM_G_06: Yield Strength HEA.

For an example when it is available as an axis variable with the Precipitation Calculator, see P_01: Isothermal Precipitation of Al3Sc.

Simplified Mode Settings

Select **Simplified** as the **Mode**.

If the following set up is not sufficient for your simulation, see the Yield Strength: Advanced Mode Settings for more detailed options.

For all calculations in Simplified Mode, the automatically applied settings are as follows:

- Equilibrium minimization strategy is Global test preferred.
- The matrix phase is automatically identified.
- Burgers vector is calculated.
- Shear modulus for the matrix is calculated.

Solid Solution Strengthening (Simplified Mode)

The **Solid solution strengthening** checkbox is selected by default to include solid solution strengthening in the calculation. Click to deselect the checkbox to exclude it as needed.

Grain Boundary Strengthening and Grain Size (Simplified Mode)

The **Grain boundary strengthening** checkbox is selected by default to include calculated grain boundary strengthening (σ_{gb}). Click to deselect the checkbox to exclude it as needed.

When the checkbox is selected, enter the **Grain size [um]**, which is the grain diameter in micrometers (µm).

Precipitation Strengthening (Simplified Mode)

Click to select the **Precipitation strengthening** checkbox to include calculated precipitation strengthening (σ_p).

In Simplified Mode, the default **Precipitation strength model** is automatically the **Deschamps model (Al-base)**. However, if the major element is Ni and gamma prime is present in the system, the **Reppich model (Ni-base)** is used instead.

Then enter the following settings.

- Select a **Precipitate** from the list.
- Enter a **Mean precipitate radius**. The unit is meter (m).
- Enter a **Critical radius** (r_c), which determines the mean precipitate radius where transition between cutting and looping occurs. The unit is meter (m).

Constant Strength Addition (Simplified Mode)

Enter a value for the **Constant strength addition**, σ_c. The unit is MPa.

Additional Settings

- Yield Strength: Calculation Type and Grid Definitions
- Yield Strength: Calculation Type and Grid Definitions
- Yield Strength: Plot and Table Settings

Yield Strength: Advanced Mode Settings

This section has information about the **Advanced** mode configuration settings available for the **Yield Strength** Property Model.

The **Yield Strength** Property Model, available as a General model with the Property Model Calculator, calculates yield stress. It returns the calculated yield strength at the desired evaluation temperature for the specified material using the equilibrium phase fractions calculated at the annealing temperature. Then you can further define the following contributions to the total yield stress:

- Intrinsic strength (σ_i) for the pure elements,
- Grain boundary strengthening (σ_{gb}),
- Solid solution strengthening (σ_{ss}),
- Precipitation strengthening (σ_p), and
- A user set, constant strength contribution (σ_c).

General Configuration Settings

The settings for these contributions are found on the Property Model Calculator when the **Yield Strength** Model is selected under **General Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

There are settings described elsewhere when **Yield Strength** is selected as an axis variable for a Plot Renderer or Table Renderer that are successors to the Precipitation Calculator.

Learn More

These contributions are defined in About the Yield Strength Property Model.

For examples using the Property Model Calculator, see PM_G_04: Yield Strength, PM_G_05: Yield Strength NiAlCr, and PM_G_06: Yield Strength HEA.

For an example when it is available as an axis variable with the Precipitation Calculator, see P_01: Isothermal Precipitation of Al3Sc.

Advanced Mode Settings

Select **Advanced** as the **Mode**. Available settings are displayed based on the choice.

For the specific **Simplified** settings, go to Yield Strength: Simplified Mode Settings.

Annealing Temperature

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Set Matrix Phase Explicitly

Select the **Set matrix phase explicitly** checkbox and choose a **Matrix** phase from the list. This allows forcing a specific phase to be considered as the matrix phase.

This is an important parameter as it impacts the evaluation of the shear modulus and affects the result for the precipitation strengthening contribution.

The solid solution strengthening contribution is not affected by choice of matrix phase, since all stable FCC, BCC, and HCP phases always are evaluated for solid solution strength contributions. If this option is not selected, the matrix phase is automatically determined by the model.

Solid Solution Strengthening (Advanced Mode)

The **Solid solution strengthening** checkbox is selected by default to include solid solution strengthening in the calculation. Click to deselect the checkbox to exclude it as needed.

Evaluate at Higher Temperature (Evaluation Temperature)

This checkbox is available when the **Solid solution strengthening** checkbox is selected. By default the checkbox is not and the simulation is evaluated at room temperature.

Select the **Evaluate at higher temperature** checkbox to evaluate the contribution σ_{ss} at temperatures higher than room temperature.

When selected, enter an **Evaluation temperature** in the field in numeric format (no expressions/functions are accepted). The unit of temperature is the same as that selected above under *Condition Definitions*.

If no **Evaluation temperature** is entered, the default, room temperature, is used.

Grain Boundary Strengthening and Grain Size (Advanced Mode)

The **Grain boundary strengthening** checkbox is selected by default to include calculated grain boundary strengthening (σ_{gb}). Click to deselect the checkbox to exclude it as needed.

When the checkbox is selected, enter the **Grain size [um]**, which is the grain diameter in micrometers (µm).

User-defined Hall-Petch Coefficient

By default, a suitable default **Hall-Petch coefficient** is automatically calculated by the model. Select the **User defined Hall-Petch coefficient** checkbox to enter a different **Hall-Petch coefficient**: k_{h-p} in MPa $\mu m^{1/2}$.

Precipitation Strengthening (Advanced Mode)

Click to select the **Precipitation strengthening** checkbox to include calculated precipitation strengthening (σ_p). Then enter the settings that follow under the **Precipitation Strengthening Model** section.

The **Precipitate** list defaults to **Any phase**.

- If **Any phase** is selected as a Precipitate phase, the non-matrix-like phase with the highest volume fraction is selected. If more than one precipitate is defined and set to **Any phase**, non-matrix-like phases are selected in order of descending volume fraction.
- If more precipitates with **Any phase** are defined than there are stable non-matrix-like phases in the system, the redundant precipitates are ignored.
- Graphite is prohibited to be set as a precipitate phase.

Otherwise, select another phase from the list. Click the ⊕ and ⊖ buttons to add and remove additional Precipitates that can have different settings.

Precipitation Strengthening Model

The precipitation strengthening contribution (σ_p) is calculated by one of these models, which are further described below.

Select a **Precipitation strengthening model** from the list:

- **Simplified model (general)**
- **Seidman model (Al-base)**: Preferentially used for Al-based alloys.
- **Reppich model (Ni-base)**: Preferentially used for Ni-based alloys.

> The Reppich model is not valid for very small values of volume fraction precipitate and precipitate radius.

- **Deschamps model (Al-base)**: Preferentially used for Al-based alloys.

Simplified Model (General) Settings

For the **Simplified model (general)**, enter values in the fields for the following. The default values of k_p and r_c are optimized against experiments for Al-Sc.

- **Mean radius Simplified model**: The precipitate mean radius. The unit is meter (m). Also see Mean Precipitate Radius and Particle Size Distribution (PSD)
- **Critical radius** (r_c), which determines the mean precipitate radius where transition

between cutting and looping occurs. The unit is meter (m).

- $\mathbf{k}_p$: The prefactor for the **Simplified model**, which adjusts the overall height of the yield precipitation strength curve.

Seidman Model (Al-base) Settings

For the **Seidman model (Al-base)**, enter values in the fields for the following. The default parameters are optimized against experiments.

- **Mean radius Seidman model**: The precipitate mean radius. The unit is meter (m). Also see Mean Precipitate Radius and Particle Size Distribution (PSD)
- **Anti-phase boundary energy**: γ_{apb}, which is the average anti-phase boundary energy for the precipitate phase. The unit is Jm^{-2}.
- **m**: A Seidman exponent, it is a constant in the expression for strengthening by modulus mismatch. See [1985Ard] for details.
- α: A Seidman prefactor. It is a fitting constant in the expression for coherency strengthening. See [1985Ard] for details.

Reppich Model (Ni-base) Settings

For the **Reppich model (Ni-base)**, enter values in the fields for the following. The default parameters are optimized against experiments.

- **Mean radius Reppich model**: The precipitate mean radius. The unit is meter (m).
- **Anti-phase boundary energy**: γ_{apb}, which is the average anti-phase boundary energy for an L12 ordered precipitate phase. The unit is Jm^{-2}.
- **Calculate anti-phase boundary energy**: Select the checkbox to use calculated anti-phase boundary energy in the yield strength calculation. The software uses the standalone APBE model in the Ni-library from within the Yield Strength Model for the calculation.

> The APBE can only be calculated for gamma prime (γ'). If the selected precipitate phase is not γ', the user-defined value in the configuration window is used.

- **w**: A parameter that accounts for elastic repulsion between strongly coupled dislocations.
- **A**: Numerical factor reflecting particle morphology (0.72 for spherical). See [1982Rep] for details.
- **C**: Correction factor in the Labusch hardening regime, i.e. for gamma prime hardened Ni-base alloys. Should be larger than or equal to unity. Set to 0 in order to disable correction.

Dechamps Model (Al-base) Settings

For the **Dechamps model (Al-base)** enter values in the fields for the following. The default parameters are optimized against experiments.

- **Mean radius Dechamps model**: Precipitate mean radius. The unit is meter (m).
- **Critical radius** (r_c), which determines the mean precipitate radius where transition between cutting and looping occurs. The unit is meter (m).
- β: A parameter used to evaluate the dislocation line tension. Usually close to 1/2 but can deviate from this value.
- **Use Kock's statistics**: By default, Friedel statistics are used. Select the checkbox to use Kock's statistics instead. See [1998Des].

Additional Precipitation Parameters (Advanced Mode)

The following are available for all models and when the **Additional precipitation parameters** checkbox is selected.

Taylor Factor

Enter a value for the **Taylor factor**.

The value of the Taylor factor accounts for texture in the material. Normally the value is between 2.24 and 3.06 for random orientations.

Shear Modulus

Enter a value for the **Shear modulus** of the matrix phase in Pa.

Burgers Vector

Enter a value for the **Burgers vector**. The unit is meter (m).

Constant Strength Addition (Advanced Mode)

Select the **Constant strength addition** checkbox and enter a value for the **Constant strength addition**, σ_c. The unit is MPa This accounts for any contributions not accounted for in the Yield Strength model, e.g. martensite strengthening.

Equilibrium Minimization Strategy

Select an **Equilibrium minimization strategy**. The default uses the **Global test preferred** option.

The **Minimization Strategy** setting is used to ensure that the most stable minimum under the specified conditions is computed.

With either the *Global test preferred* or *Local minimization preferred* setting, the program cycles through options before it gives up:

- For **Global test preferred** the minimization starts with a global test and if that fails it runs full global minimization.
- For **Local minimization preferred** the minimization starts with a local minimization, in case of failure it tries a global test and finally a full global minimization.

If you choose **Local minimization only** or **Global minimization only**, the program just tries the one setting and gives up if it fails.

For general information about global minimization, see the topic related to the Console Mode command, GLOBAL_MINIMIZATION.

Precipitation Calculator Setting - Density of Points

This setting is only available for a precipitation calculation using the Precipitation Module (TC-PRISMA).

Select the **Density of points: Low** (the default), **Medium**, or **High**. This is a measure of how many time steps yield strength is calculated.

Yield Strength: Calculation Type and Grid Definitions

This section has information about the *Calculation Type* and *Grid Definitions* **Configuration** settings available for the **Yield Strength** Property Model. It is a continuation from **Simplified** or **Advanced Mode** setting entries:

- Yield Strength: Simplified Mode Settings
- Yield Strength: Advanced Mode Settings

Calculation Type Settings

Calculation Type

- **Single** to calculate a single point. Any model can use this calculation type and no additional settings are required. The results from this calculation are displayed in the **Event Log** or if a **Table Renderer** is used, in the **Visualizations** window.
- **One Axis**: To vary a quantity on the *X*-axis.
- **Grid**: Evaluates two axis variables of the selected quantities in the specified range and number of steps.
- **Min/Max**: Evaluates the Property Model(s) for all variations of the selected quantities at the given limits. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The total minimum and maximum of the model(s) results are shown in the **Event** log.
- **Uncertainty**: Evaluates the Property Model(s) where the values of the quantities are sampled from Gaussian distributions. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The result is visualized as a histogram or normal probability plot by adding a Plot Renderer activity.
- **Batch**: Use this to allow for high throughput calculations and read data from a file, such as a spreadsheet, rather than, for example, having a fixed grid or random values. Results from these batch calculations can then be compared to experimental values (as long as this data is included), using a **Cross plot** on the Plot Renderer.

Axis Definition

For **One Axis**, select a **Quantity** to vary along the X-axis, for example, **Evaluation temperature** then enter a **Min**, **Max** and **Number of steps**.

Grid Definition Settings

Grid Definitions

For the **Grid** calculation type, define the two axes variables using the fields and menus: **Quantity**, **Min**, **Max**, and **Number of steps**. The number of steps along with the minimum and maximum values for the axes define a grid. For each grid point the selected models are evaluated.

For a **Grid**, on the Plot Renderer, you can choose to plot a *Heat map*, *Contour*, or *3D* diagram.

Plot Type: Heat Map, Contour, and 3D

Min/Max Definitions

For the **Min/Max** calculation type, click to select the applicable checkboxes under **Quantity to enable or disable an axis**. The **Mean** field is as defined under *Condition Definitions* for the respective quantity.

Enter numerical values in the Δ **Min/Max** fields to evaluate the change to the quantity. The highest and lowest value of each selected model results are shown in the **Event Log**.

Sampling of Data from Gaussian Distributions

For the **Uncertainty** calculation type, click to select the applicable checkboxes under **Quantity to vary this quantity**. The **Mean** field is for the distribution function as defined under *Condition Definitions* for the respective quantity. The default ΔMin/Max is a 95% confidence interval.

About the Uncertainty Calculations

Sampling Parameters

For the **Uncertainty** calculation type, choose a number of **Standard deviations** where you want to **Truncate the distribution**. Choose the **Total number of samples**.

Yield Strength: Plot and Table Settings

Yield Strength: Plot and Table Settings

This section has information about the Plot Renderer and Table Renderer Configuration settings available for the **Yield Strength** Property Model. It is a continuation from **Simplified** or **Advanced Mode** setting entries:

- Yield Strength: Simplified Mode Settings
- Yield Strength: Advanced Mode Settings
- Yield Strength: Calculation Type and Grid Definitions

Plot Quantities

The various *hardness* or *hardening* quantities are treated separately from the various *strength* or *strengthening* quantities and each (hardness and strength) are plotted on the respective axes. When setting up the simulation, the **Configuration** window (when in *Grouped Mode*) shows either *Vickers Hardness* or *Strength*. This corresponds to the labeling of axes in the **Visualizations** window when plotting two or more quantities of the same type. The legend then lists the specific quantity names selected on the **Configuration** window.

These plot quantities are available:

- **Annealing temperature**
- **Constant strength addition**
- **Evaluation temperature**
- **Grain boundary strengthening**
- **Intrinsic strength**
- **Mean Radius Reppich model**
- **Precipitation strengthening per phase**
- **Solid solution strengthening**
- **Solid solution strengthening BCC**
- **Solid solution strengthening FCC**
- **Solid solution strengthening HCP**

- **Total precipitation strengthening**
- **Total yield strength** - this is the default Y-axis quantity for this Model.
- **Volume fraction of precipitate phase**
- **Volume fraction of stable phase(s)**

For all strength quantities, there is a corresponding hardness quantity:

- **Constant hardness addition**
- **Grain boundary hardening**
- **Intrinsic hardness**
- **Precipitation hardening per phase**
- **Solid solution hardening FCC**
- **Solid solution hardening BCC**
- **Solid solution hardening HCP**
- **Total hardness**
- **Total precipitation hardening**
- **Total solid solution hardening**

Plot Renderer and Plot Renderer: Configuration Settings

Table Renderer and Table Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

When selecting quantities on the Plot Renderer or Table Renderer, the quantity names include an abbreviated name for the Property Model it is associated to. This is useful in particular when you are calculating two or more Property Models that share names for the quantities. The short name identifying the specific Property Model is included in parentheses after the name of the quantity. Below are the full and abbreviated names for each Property Model.

For a list see Property Model Abbreviations.

Calculations can be performed over a range for the model parameters available in each sub-model. If, for example, the mean precipitate radius in a precipitation strengthening model is set as the variable to step over, it becomes available as a plot quantity in the Plot Renderer.

Scheduler and Event Log Windows

Topics to Explore

Using the Scheduler **463**

About the Scheduler Jobs *463*

Managing the Schedule *464*

Event Log Window **465**

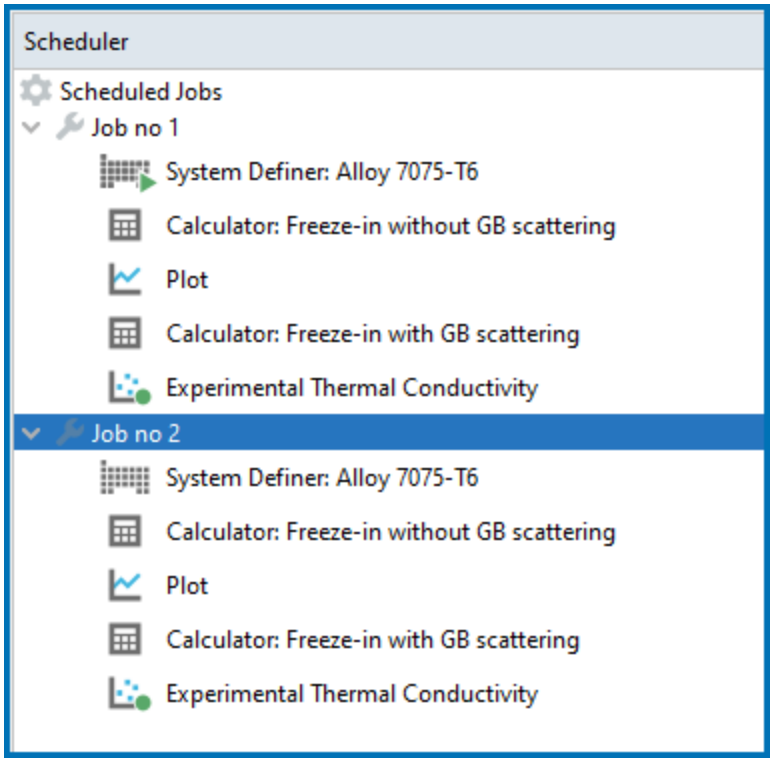
Using the Scheduler

The **Scheduler** window has activity information about current or scheduled jobs. A *job* is any activity you have selected to be performed. The Scheduler also indicates if there is an error during a job and when a job has stopped. If you have set an activity, tree or project to be performed at a later time then this is also listed.

About the Scheduler Jobs

- Whenever you trigger the performance of a whole project, tree or individual activity, all the activities to be performed are shown under a job heading.
- When all the activities belonging to a job are completed the job and its activities disappear from the Scheduler window.
- If there is an error during the performance of an activity, icons for that job and activity remain in the Scheduler window until removed.

Node or Window Status Markers



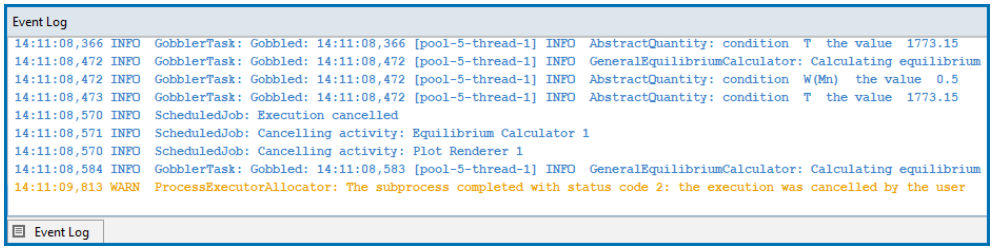
Managing the Schedule

In the Scheduler window, you can cancel scheduled jobs, remove errors and show information about errors.

- To cancel all jobs: Right-click the **Scheduled Jobs** label or the cogwheel icon, and select **Cancel All Jobs**.
- To remove (clear) all failed activities and jobs: Right-click the **Scheduled Jobs** label or the cogwheel icon, and select **Clear All Errors**.
- To cancel a specific job: Right-click the job label (for example, **Job no 1**) and select **Cancel Job**.
- To remove (clear) a specific failed job: Right-click the job label (for example, **Job no 1**) and select **Cancel Job**.
- To open a window with error details: Right-click the label for the failed job (for example, **Job no 1**), and select **Show Error Log**.

Event Log Window

The **Event Log** window is closed by default. Information about what Thermo-Calc is processing or doing is in blue text, an error message is in red text, and caution/warning information is in yellow text.



- To open the Event Log window: Click the **Event Log** window once to expand it or select it from the **Window → Event Log** menu. Double-clicking the window maximizes it.
- To clear all messages in the window, right-click in the text area and select **Clear**.
- To specify the level of detail in the Event Log, open the **Options** window:
  - Windows: Select **Tools →** **Options**.
  - Mac: Select **Thermo-Calc** *<version>* **→ Preferences** or **Settings** or press <⌘> on the keyboard.

  then click the **General** tab and set the **Log level** slide bar to anything between **Debug** (most detailed) and **Error** (least detailed).

Experimental File Reader

Topics to Explore >

Experimental File Reader **467**

Learn More *467*

Plotting with an Experimental Data File **468**

Experimental File Reader

The **Experimental File Reader** activity node is added as a predecessor from the top **My Project** node. This allows you to use (or "read") the data contained in an experimental data file (with the file extension `*.EXP`) and then plot the data on one or more Plot Renderers.

The `EXP` file is a type of data file with information specifying a plotted diagram and it is written in the DATAPLOT graphical language. From this activity node you can plot the EXP file or save a copy of the file to another location.

Learn More

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

Creating Activities and Successors and Plotting Experimental Data Files

If you are a Console Mode user, this is the same concept as using the Experimental Data Files (*.POP, *.DOP).

Plotting with an Experimental Data File

When you are working with the Experimental File Reader, this is how you plot.

1. Right-click **My Project** and from the **Create New Activity** submenu choose **Experimental File Reader**.
2. In the **Configuration** window in the *EXP file* field, enter the name of the EXP file to plot. Or click the **Select Exp file** button to navigate to a location on the computer to add the dataset.
3. Once the .EXP file is added, under **Dataset Selection** you can choose to include or exclude specific datasets. Use the **Select/Deslect all datasets** checkbox as required.
4. Right-click the **Experimental File Reader** node and from the **Create New Successor** submenu choose **Plot Renderer**.

   If the source EXP file is changed, you can also click the **Reload the selected EXP file from disk** button to refresh the data. If you want to save or export the loaded file, click the **Save EXP file** button, then navigate to where you want to save it and give it a file name.

5. In the **Configuration** window click **Perform** or right-click the **Plot Renderer** node and select **Perform**.

Visualizations in Graphical Mode

The power of simulation is in its visualization capabilities. Working with the standard Thermo-Calc Graphical Mode visualization includes using plots and table to review the results of your calculations.

Additional extended visualization is available with the Add-on Modules, in particular with the Additive Manufacturing (AM) Module.

Plot Renderer

The Plot Renderer is where you define the settings and output results in a diagram that displays in the **Visualizations** window. The available Plot Renderer settings are based on the System Definer and/or calculator activity node predecessor (i.e. Equilibrium Calculator, Scheil Calculator, Property Model Calculator, and so forth). Settings availability is also determined by the *Calculation Type* as well as if you have an Add-on Module. If you used any of the templates, the Plot Renderer is automatically added to the Project tree.

Learn More

For the standard plot settings, see Plot Renderer: Configuration Settings. There are additional details for more advanced settings in Plotting Options.

There are additional details for the Add-on Modules:

- Diffusion Calculator Plot Renderer
- Precipitation Calculator Plot Renderer
- AM Calculator: Plot Renderer Settings

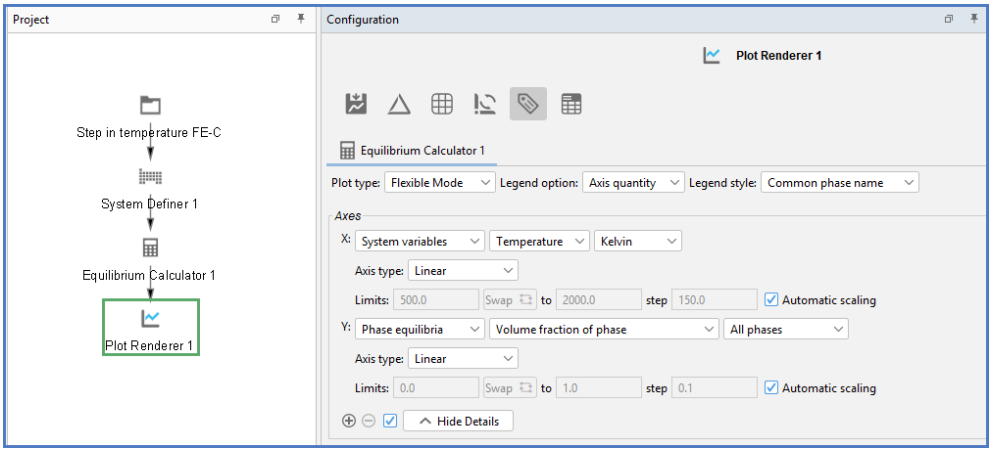
Plot Toolbar

For any Plot Renderer, there is a toolbar available.

Button	*Name*	*Description*
	Save Diagram	Save the plot diagram. From the **Save** window, choose the file type–png (the default), jpg, ps, pdf, gif, svg, or emf. For PNG and JPG files you can also change the image quality. Saving and Printing the Output in Graphical Mode
	Toggle Triangular/Regular Diagram	Display the diagram in triangular form, with the X-axis along the base and the Y-axis along the left side. Such a diagram is often useful if you want to plot the fractions of two components in a ternary diagram.
	Show Grid	Overlay a grid on the diagram.
	Switch Axes	Show the plotting X-axis variable on the diagram's Y-axis, and the Y-axis variable on the diagram's X-axis.
	Retain Labels	The default is to keep labels displaying, i.e. retained, on the plot. This keeps all labels on the plot each time you click **Perform** or **Perform Tree**. If the **Retain Labels** button is clicked to turn this off, then it clears all labels fully and the label needs to be added again before performing.
	Table View	Toggle to switch between displaying a Plot or the results of a Table in the **Visualizations** window. This is available for single equilibrium or stepping calculations. When you click to toggle ON, click **Perform** to regenerate as a Table. When you click to toggle OFF, click **Perform** to regenerate the Plot. For example, set up the Plot Renderer and click **Perform** to display the Plot. Then click **Table View** and **Perform** to see the results in a Table format in the **Visualizations** window. When toggled ON, click **Save table** to export the table data. Choose the **Decimal digits** and **Number format** (**Auto**, **Decimal**, or **Scientific**). Saving and Printing the Output in Graphical Mode

Plot Renderer: Configuration Settings

Click the **Plot Renderer** node in the **Project** window to view the **Configuration** window. The settings available vary based on such choices as the specific calculator used and calculation type selected.



The options along the top of the window are available depending on the calculation type.

Add an Axis and Remove this Axis Buttons

Use the ⊕ **Add an axis** and ⊖ **Remove this axis** buttons to add additional *X*- and/or *Y*-axes to a plot or to merge plots (to overlay one plot with another in the same diagram). When merging plots, you define this variable as the *Z*-axis.

Plot Type

There are a variety of combinations of Calculator and *Calculation Type* that offer different Plot Types. These are described in separate topics:

- Plot Type: Cross Plot and Statistical
- Plot Type: Heat Map, Contour, and 3D
- Plot Type: Parallel Coordinates
- Plot Type: Flexible Mode and Grouped Mode

- Plot Type: CCT Mode
- Plot Type: TTT Mode
- Plot Type: Simple Mode and Advanced Mode

Tie-Lines and Filter

Tie-lines

Select how many tie-lines to be plotted in the diagram. Every n^{th} number of tie-line is plotted, where *n* is the number set here. Consequently, the higher the number, the fewer the number of plotted tie-lines in the diagram.

This setting is not available if the Plot Renderer is a successor to an Equilibrium Calculator where only one axis is defined and varied (that is, an Equilibrium Calculator that has performed a stepping calculation).

Filter (Property Models and Process Metallurgy Module

This is available with the **Property Model Calculator** and **Process Metallurgy Calculator**.

Use the **Filter** checkbox to add various filters to the plot or table based on the set up of the calculation. When selected, click the **Add quantity** and **Remove quantity** buttons to add filters. For example, enter a **Min** and **Max** and choose an axis variable such as **Ms Temperature** and the unit **Kelvin** to adjust the output in the **Visualizations** window. Click **Perform** each time you add or remove a filter for the results to update.

Legends and Labels

Legend Option

Select whether the diagram's legend displays the **Stable phases**, the **Axis quantity**, or choose **Off** for no legend.

Legend Style

You can select a **Legend style** for the **Stable phases** or **Axis quantity** selected for **Legend option**. Choose **None**, **All**, **Common phase name**, **Constitution description**, or **Ordering description**.

About Legend Styles

Label Decimal Digits

Choose the number of decimal digits to display in the plot label. The default is **2**.

Label Number Format

Choose from **Auto** (the default), **Decimal**, or **Scientific**.

Axis and Scaling

Axes Definitions

Set the state variable you want plotted along the *X*-axis and the *Y*-axis (and *Z*-axis for **Grid** calculations).

The quantities are sometimes grouped into categories on the Plot Renderer or Table Renderer. Availability of the list and the variables themselves, is based on several factors, including the database selected, the Calculator used, and the type of calculation being performed. Other differences are based on the *Plot type* selected, e.g. what you see on the **Configuration** window changes if you use **Flexible Mode** or **Grouped Mode**. Other plot types do not group the quantities and each Calculator handles the information differently.

When working on a Plot Renderer (e.g. associated to the *Axes* X, Y, and Z) or Table Renderer (associated to *Columns*), there is sometimes the option to choose a quantity group from a list. When applicable, these are the categories:

- All variables
- System variables
- Phase equilibria
- Physical properties

- Aqueous properties
- Kinetic properties
- Elastic properties

After selecting the group, you next choose from the available variables and continue to define each based on the additional settings specifically available, i.e. select a unit or a phase, and many other options that are only displayed when relevant.

Quantities Groups Available for Plots and Tables

There are various items to note regarding the **Axes**.

- If the stepping/mapping variables are changed in the Equilibrium Calculator that precedes the Plot Renderer, then the variables to be plotted along the diagram's *X*- and *Y*-axes are automatically updated to the appropriate quantities.
- For a **Grid***Calculation Type*, the *X*- and *Y*-axes always represent the quantities that define the calculation axes, but you need to set a variable for the *Z-axis* (the axis perpendicular to the plane defined by the *X*- and *Y*-axes).
- For a **Batch***Calculation Type*, the available options from the *X*- and *Y*- axes lists are based on the data file contents, i.e. if experimental data is included, then these are listed. See Working with Batch Calculations for details. Additional Plot Types are also available.
- For a **Parallel coordinates** *Plot type*, and only for parameterized result quantities, you can choose to show all or one specific quantity on the plot. By default, and when you first choose these types of results quantities, **All** quantities are plotted in the **Visualizations** window output after performing the first calculation. Once the secondary list is available you can then choose to plot only one of the quantities at a time. The availability of the filter list is dependent on the result of the initial calculation. See Plot Type: Parallel Coordinates for details.

Axis Type

Select the type of axis scale: **Linear**, **Logarithmic**, **Logarithmic 10**, or **Inverse**.

Automatic Scaling

The **Automatic scaling** checkbox is selected by default to allow the program to set the limits.

Limits

This setting is available when the **Automatic scaling** checkbox is cleared (the scaling is turned off).

Enter the lower and upper **Limits** of the variables to display on the axis. You can also determine the **step** size between the tick marks along each axis.

If the **Automatic scaling** is turned off (i.e. the checkbox is not selected) then it is important to enter a large enough number in the *step* field for the numerical values to display correctly on the axis. That is, if the step size is too small, the program ignores this setting and the axis labels will not be as expected.

For logarithmic axes, the step size is related to the exponent. For example, if the step entered is 1.0, then the exponent increases by one each time (10^{-9}, 10^{-8}, 10^{-7} and so forth).

Batch Calculations

Show Limits (Batch)

This is available for the **Batch** calculation type, **Cross plot**.

Click the **Show limits** checkbox and then choose **RMS** (root mean squared), **Absolute**, or **Relative in % limits**. For **Absolute** or **Relative in %** enter a value in the field (the default is 15.0). A "perfect fit" line is added (solid line) to the plot and then the upper and lower limits shown on the plot are based on the type of limit selected.

- When **RMS** is selected, a "perfect fit" line is added (solid line) plus the upper and lower limits (dashed lines), which are calculated for the experimental data points (read from the data file). The RMS error value is shown in the plot legend. The upper and lower limits are then this calculated value plus and minus from the perfect fit line.
- When **Absolute** is selected, the value entered (e.g. the default is 15), then this is the plus or minus value from the perfect fit line.

- When **Relative in %** is selected, the value entered (e.g. the default is 15%), then this is the upper and lower limit that is plotted and this value is plus or minus percent from the perfect fit line as is calculated and shows in the plot legend.

Show Calculation Failures at Value (Batch)

This is available for the **Batch** calculation type, **Cross plot**.

Click the **Show calculation failures at value** checkbox and enter a value in the field. Use this checkbox to include any values that failed in the calculation and you want to see these on the plot. The value entered in the field replaces the non-existing calculated value(s) and can be cross plotted against experimental results from that data file.

Grid Calculations

Interpolate (Grid)

From the **Interpolate** list, choose to interpolate data **Never** (the default), **Once**, **Twice** or **3 times**. This means points are put in between calculated points in the grid and interpolated instead of calculated in the calculation engine.

Choose how many points of data to interpolate to improve curve smoothness – **Never**, **20x20**, **50x50**, or **100x100**. Try different settings for your own set of data.

Contour Plots

Contour Values and Use Custom Contour Values (Z-axis, Contour Plots)

The **Use custom contour values** checkbox is available when **Contour** is selected as the **Plot type**. Select this checkbox to enter one or a series of numbers in the **Contour values** field. Numbers can only be separated by a space.

Scheil Calculations

Account for Interface Scattering (Scheil)

Scheil Calculator Available Plot Variables

The **Account for interface scattering** checkbox is available when any of the following quantities are selected for an axis for a Scheil Calculator:

- Electric conductivity
- Electric resistivity
- Thermal conductivity
- Thermal diffusivity
- Thermal resistivity

The electrical resistivity due to phase interface scattering is evaluated as the scattering constant times sum of the interaction between the volume fraction of all the phases. The default value for the **Phase interface scattering constant** is found to be `4.0e-8` Ωm for aluminum alloys produced with conventional methods. A higher value could be required for the AM process where the rapid solidification results in a very fine microstructure with a large amount of phase interfaces.The contribution to thermal conductivity is assumed to be related to that to electrical resistivity, following the Wiedemann-Franz law.

Either keep the default **Phase interface scattering constant**, which is a constant for evaluating thermal conductivity due to scattering at phase interfaces, or enter another value.

Process Metallurgy Module

Also see Tie-Lines and Filter.

Slag Property Options (Process Metallurgy)

For the Process Metallurgy Calculator when you are selecting axis variables on the Plot Renderer, there is the option to choose **Slag property**. The associated quantity that you select from the next drop-down list has these options to choose: **All**, **B2**, **B3**, **B4**, **Bas2**, **Bells ratio**, **Ls**, or **Log10 (Sulphur capacity)**.

Also choose **In liquid slag only**, **In solid slag only**, or **In all slag**.

References and equations for these properties are described in Process Metallurgy Slag Properties.

Unit (Process Metallurgy)

For the Process Metallurgy Calculator select a **Unit** for the quantity to plot: **Tonne**, **Kilogram**, **Gram**, or **Pound**

Learn More

Visualizations in Graphical Mode and Plotting Options.

For the Add-on Modules with additional specialized functionality also see:

- Diffusion Calculator Plot Renderer
- Precipitation Calculator Plot Renderer
- AM Calculator: Plot Renderer Settings

Table Renderer

A **Table Renderer** visualizes calculation results in a table. Several Table Renderer activities (as well as Plot Renderer activities) can be shown in the **Visualizations** window as different tabs.

You can add the Table Renderer directly (right-click a calculator node and select it from the **Create New Successor** menu) or use a variety of the available templates to automatically add the node. For example, on the **My Projects Configuration** window under **Equilibrium**, choose the **Single Point** or **One Axis** templates.

You can only successfully tabulate the results of a single equilibrium calculation or a stepping (i.e. property diagram) operation. The tabulated data from an equilibrium calculation is different from the tabulated data from a stepping calculation.

Table Button

Button	*Name*	*Description*
	Save Table	Once a calculation is performed and there is data in the table, click to save it. Saving and Printing the Output in Graphical Mode

For the Plot Renderer, there is an option to use the **Table View** button to convert plots to table data for all calculation types and calculators. See Plot Renderer: Convert a Plot to a Table and Export the Data.

Results from an Equilibrium Calculation

The following tab shows the result of an equilibrium calculation (from example T_01: Calculating a Single-Point Equilibrium).

Table Renderer 1

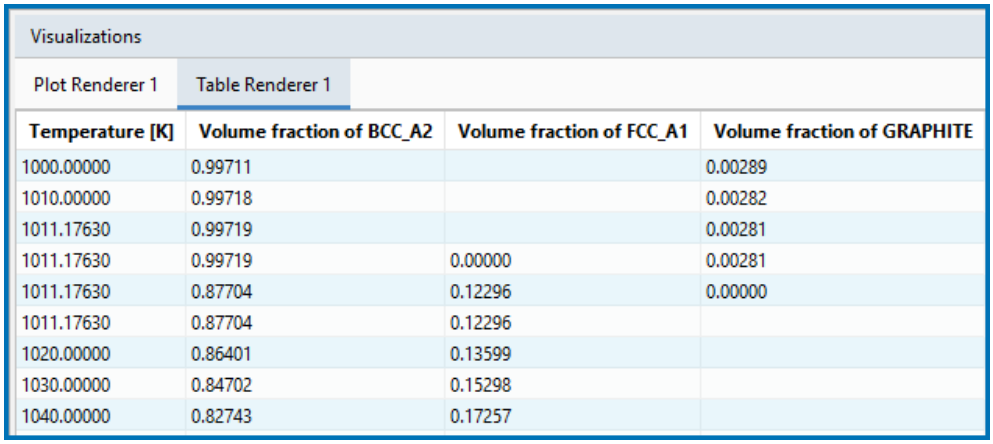
System				
Moles	1.00000			
Mass	55.64392	[g]		
Temperature	1000.00000	[K]		
Total Gibbs Energy	-42140.55264	[J]		
Enthalpy	24707.16903	[J]		
Volume	7.29746E-6	[m3]		
Component	*Mole Fraction*	*Mass Fraction*	*Activity*	*Potential*
Fe	0.99537	0.99900	0.00619	-42277.77189
C	0.00463	0.00100	0.21818	-12658.35450
Stable Phases				
	Moles	*Mass*	*Volume Fraction*	
BCC_A2#1	0.99609	55.59691	0.99711	Composition and constitution
Composition				
Component	*Mole Fraction*	*Mass Fraction*		
Fe	0.99928	0.99984		
C	0.00072	0.00016		
Constitution	$(Fe)_1 (C,VA)_3$			
	Constituent	*Site Fraction*		
Sublattice 1:				
	Fe	1.00000		
Sublattice 2:				
	VA	0.99976		
	C	0.00024		

For each stable phase listed, from the **Composition and constitution** menu you can select the information to view. In this example, the maximum amount of information is shown and includes details about both composition and constitution for **BCC_A2#1**.

The default for the Phase description detail can be changed globally from the **Options** window. When available, common phase names are included and taken from specific databases. See Working with Common Phase Names for more information.

Results from a Stepping Operation

The **Table Render 1** tab in the example shows the results of a stepping calculation (where a Table Renderer is added to the example in T_02: Stepping in Temperature in the Fe-C System).

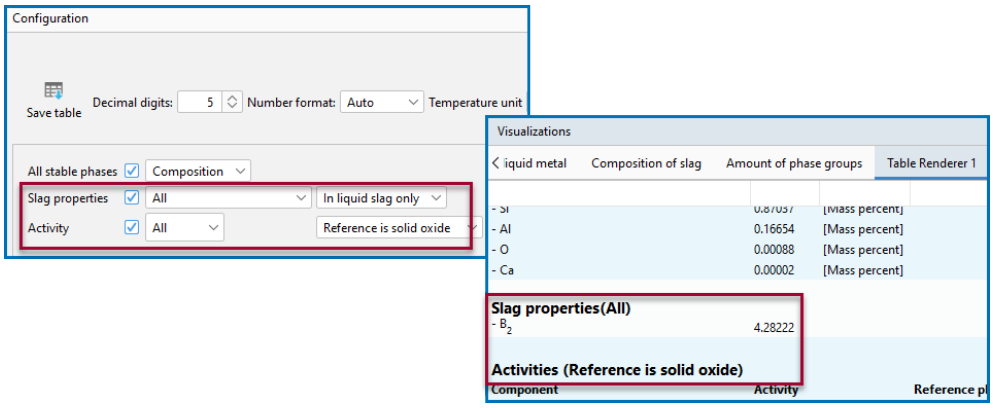


Temperature [K]	Volume fraction of BCC_A2	Volume fraction of FCC_A1	Volume fraction of GRAPHITE
1000.00000	0.99711		0.00289
1010.00000	0.99718		0.00282
1011.17630	0.99719		0.00281
1011.17630	0.99719	0.00000	0.00281
1011.17630	0.87704	0.12296	0.00000
1011.17630	0.87704	0.12296	
1020.00000	0.86401	0.13599	
1030.00000	0.84702	0.15298	
1040.00000	0.82743	0.17257	

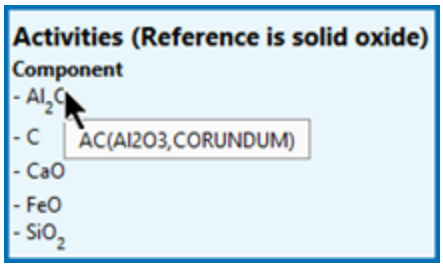
Process Metallurgy Module Single Equilibrium

When you use a Process Metallurgy Calculator with a **Single** equilibrium calculation, there is a variety of additional information you can display in the table such as the **Slag properties** (see Process Metallurgy Slag Properties for equations and references) and the **Activities**.

PMET_01: Basic Oxygen Furnace (BOF). Using version 01b, added a Table Renderer and did a **Single** calculation.



For the activities in the table, you can hover over the Component and the syntax of the activity displays.

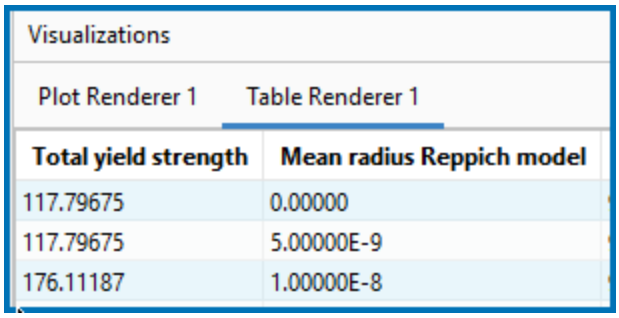


Yield Strength Property Model

The Yield Strength: Simplified Mode Settings is available with the Property Model Calculator. After defining the Model and adding a Table or Plot, all yield strength quantities are available to select from this list. These yield strength quantities are also accessible via a Table Renderer (or Plot Renderer) that is a successor to the Precipitation Calculator.

For details about the quantities, see About the Yield Strength Property Model.

This uses the PM_G_05: Yield Strength NiAlCr example and then a Table Renderer is added. Alternatively, you can click the **Table View** button and reperform the Plot Renderer for the same results.



An example of the results when yield strength is chosen as the Axis variable for a Table Renderer that is a successor to the Property Model Calculator.

Precipitation Calculator Multimodal PSD and 3D --> 2D Settings

These settings are described in the Precipitation Calculator Plot Renderer.

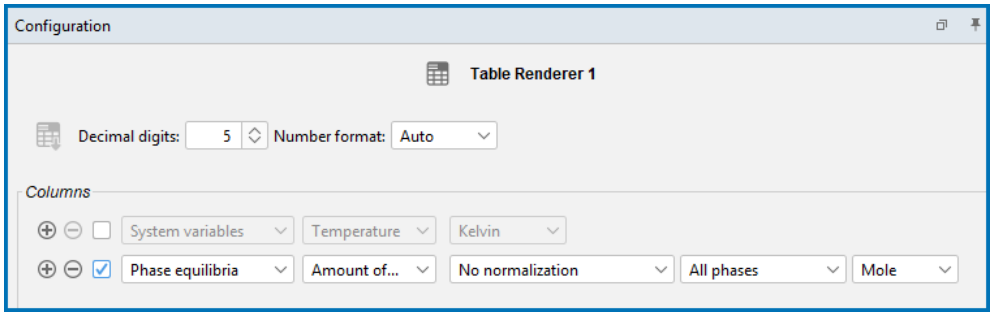
Learn More

The settings are described in the section Table Renderer: Configuration Settings.

For details about the templates, see Getting Started Links, Templates, and the Property Navigator and Creating a Project from a Template.

Table Renderer: Configuration Settings

The Table Renderer settings are done on the **Configuration** window. Depending on what calculator node the table is a successor to, you can have different settings available. For most tables, this is where you set the level of detail for the columns.



Save the Table

To save all the data in a table as a Character separated (`.csv`), Hyper Text Markup (`.html`), or Excel (`.xls`), in the **Configuration** window click **Save Table** or in the **Visualizations** window right-click in the table and select **Save As**.

To copy the data from a single cell of a table to the clipboard, right-click the cell and select **Copy**. To copy the whole table to the clipboard, select **Copy all**.

The data saved is what is shown in the **Table Renderer** tab on the **Visualizations** window. If data is calculated (and not displayed) it is not saved.

Number of Decimal Digits and Number Format

The table results can be presented in ordinary decimal number format or with normalized scientific notion. Choose **Scientific** or **Decimal** to increase or decrease the number of **Decimal digits** used in the table. The default is 5 digits. The **Number format** defaults to **Auto** to use the most appropriate format based on the tabulated data.

The defaults for these settings can be changed globally.

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **Tabulation** node in the tree.

About Quantity Categories

The quantities are sometimes grouped into categories on the Plot Renderer or Table Renderer. Availability of the list and the variables themselves, is based on several factors, including the database selected, the Calculator used, and the type of calculation being performed. Other differences are based on the *Plot type* selected, e.g. what you see on the **Configuration** window changes if you use **Flexible Mode** or **Grouped Mode**. Other plot types do not group the quantities and each Calculator handles the information differently.

When working on a Plot Renderer (e.g. associated to the *Axes* X, Y, and Z) or Table Renderer (associated to *Columns*), there is sometimes the option to choose a quantity group from a list. When applicable, these are the categories:

- All variables
- System variables
- Phase equilibria
- Physical properties
- Aqueous properties
- Kinetic properties
- Elastic properties

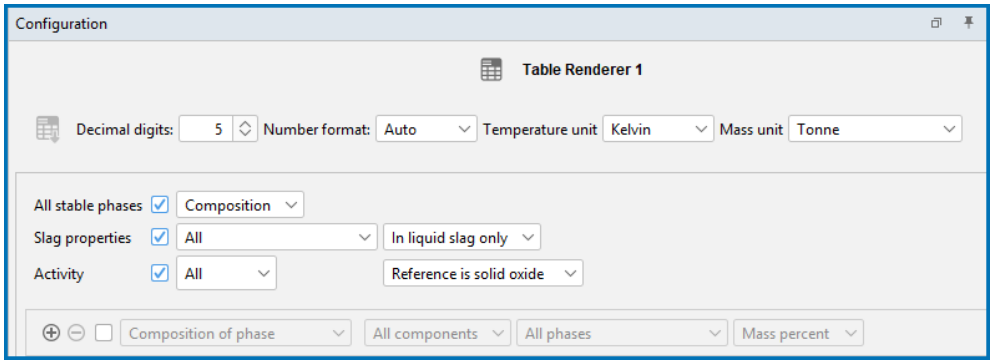
After selecting the group, you next choose from the available variables and continue to define each based on the additional settings specifically available, i.e. select a unit or a phase, and many other options that are only displayed when relevant.

Quantities Groups Available for Plots and Tables

Process Metallurgy Module

For the Process Metallurgy Calculator there are additional settings available.

PMET_01: Basic Oxygen Furnace (BOF). Using version 01b, a Table Renderer is added and on the Process Metallurgy Calculator, changed the *Calculation Type* to **Single**.



- Choose a **Temperature unit**: **Kelvin**, **Celsius** or **Fahrenheit**.
- Choose a **Mass unit**: **Tonne**, **Kilogram**, **Gram**, or **Pound**.
- Select the **All stable phases** checkbox and choose **Composition** or **Condensed** from the list.
- Select the **Slag properties** checkbox and choose the associated quantity from the next drop-down list: **All**, **B2**, **B3**, **B4**, **Bas2**, **Bells ratio**, **Ls**, or **Log10 (Sulphur capacity)**.
- Also choose **In liquid slag only**, **In solid slag only**, or **In all slag**.

  Details, including references and equations, are described in Process Metallurgy Slag Properties.

- Select the **Activity** checkbox then from the first list choose a component (or keep the default **All**). Then from the second list select **Reference solid oxide** or **Reference liquid slag**.

  The activity is always given relative to a phase. The liquid slag is always the IONIQ_LIQ phase. The composition set of ION_LIQ depends on the calculation and the slag always contains a high amount of oxygen. The reference phase for the solid oxides depends on the components and it is always listed in the table.

Precipitation Module (TC-PRISMA)

Precipitation Calculator Separate Multimodal PSD and 3D > 2D

When certain axis variables are selected on the Plot Renderer or Table Renderer that is a successor to the Precipitation Calculator, the **Separate multimodal PSD** and **3D > 2D** checkboxes are available for the Precipitation Module (TC-PRISMA).

Another requirement is that the *Precipitate Phase***Morphology** is set to **Sphere** on the Precipitation Calculator.

See the specialized section for the Plot Renderer for details.

Precipitation Calculator Plot Renderer

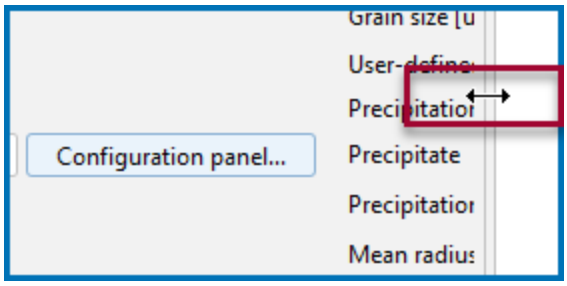
Precipitation Calculator with Yield Strength

When you use a Precipitation Calculator and choose **Yield strength** as an *Axis variable*, there are additional settings available.

If you choose **Yield strength** as an *Axis variable*, you can further define the model. Click to expand the drop down list to the right of the *Axis variable*, then select any or all of the checkboxes listed below to plot the respective contributing elements to the yield strength.

Click **Configuration Panel** toggle between the settings options and to further fine-tune the model. These options are described for the Yield Strength: Simplified Mode Settings and Yield Strength: Advanced Mode Settings. The greyed out sections (e.g. the **Matrix**, **Precipitate** phases, and **Grain size**) are defined on the **Precipitation Calculator** and cannot be changed.

To see these settings after clicking **Configuration Panel**, you need to expand the **Plot Renderer Configuration** window to the right. Either detach the window to resize, or hover with the mouse until you see the double arrow, then click and drag to expand the window.



- Total yield strength
- Intrinsic strength
- Solid solution strengthening
- Solid solution strengthening FCC
- Solid solution strengthening BCC
- Solid solution strengthening HCP
- Grain boundary strengthening
- Total precipitation strengthening
- Precipitation strengthening per phase
- Constant strength addition

The **P_01: Isothermal Precipitation of Al3Sc** example demonstrates the use of this Yield Strength Model.

Yield Strength: Simplified Mode Settings

Quantities Groups Available for Plots and Tables

The following table lists the common quantities available as axis variables (plots) or columns (tables) when working in Graphical Mode. All the quantities are listed alphabetically in conditions, quantity function definitions, and table and plot results.

About Quantity Groups

The quantities are sometimes grouped into categories on the Plot Renderer or Table Renderer. Availability of the list and the variables themselves, is based on several factors, including the database selected, the Calculator used, and the type of calculation being performed. Other differences are based on the *Plot type* selected, e.g. what you see on the **Configuration** window changes if you use **Flexible Mode** or **Grouped Mode**. Other plot types do not group the quantities and each Calculator handles the information differently.

When working on a Plot Renderer (e.g. associated to the *Axes* X, Y, and Z) or Table Renderer (associated to *Columns*), there is sometimes the option to choose a quantity group from a list. When applicable, these are the categories:

- All variables
- System variables
- Phase equilibria
- Physical properties
- Aqueous properties
- Kinetic properties
- Elastic properties

After selecting the group, you next choose from the available variables and continue to define each based on the additional settings specifically available, i.e. select a unit or a phase, and many other options that are only displayed when relevant.

These quantities are also available in Console Mode but are entered manually.

Quantity Group Definitions

Each quantity is selected on the **Configuration** window as required either as **Axis variables** for the Plot Renderer or when choosing the **Columns** for a Table Renderer.

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Activity of component	Phase equilibria	dimensionless	Click to deselect the SER checkbox to use the reference state you have selected. Choose an element from the list or choose All.
Activity of water in aqueous phase	Aqueous properties	dimensionless	
Activity referred to a phase	Phase equilibria	dimensionless	Choose a phase and an element.
Affinity per electron	Aqueous properties	Joule, Calorie, Electron volt, Gigajoule, Watt hour, Kilowatt hour	
Amount of component	Phase equilibria	Mole, Gram, Kilogram, Tonne, Pound	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Choose a specific element or All and a unit.
Amount of component in phase	Phase equilibria	Mole, Gram, Kilogram, Tonne, Pound	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Choose a specific element or All, then a specific phase or All phases, and a unit.
Amount of phase	Phase equilibria	Mole, Gram, Kilogram, Tonne, Pound	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Choose a specific phase or All phases and a unit.

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Bohr magneton number	Phase equilibria	dimensionless	Choose a specific phase or All phases
Bulk modulus	Elastic properties	Pascal, Gigapascal, Atmospheres, Bar	Choose All phases or a specific phase. Select a unit.
Chemical diffusion coefficient	Kinetic properties	m^2/s	Choose the diffusing element, Gradient element, and Reference element.
Chemical potential of component	Phase equilibria	Joule, Calorie, Electron volt, Gigajoule, Watt hour, Kilowatt hour	Click to deselect the SER checkbox to use the reference state you have selected.
Chemical potential referred to a phase	Phase equilibria	Joule, Calorie, Electron volt, Gigajoule, Watt hour, Kilowatt hour	Choose a phase, an element, and a unit.
Composition	System variables	Mass percent, Mole percent, Mass fraction, Mole fraction	Choose All or a specific element and a unit.
Composition of a phase	Phase equilibria	Mass percent, Mole percent, Mass fraction, Mole fraction	Choose a specific element or All, then a specific phase or All phases, and a unit.
Curie temperature	Phase equilibria	Kelvin, Celsius, Fahrenheit	Choose a specific phase or All phases, and a unit.
Density	Physical properties	Gram per cubic meter, Kilogram per cubic meter, Gram per cubic centimeter, Pound per cubic inch	Choose All phases, an individual phase, or System. Choose a unit.

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Dynamic viscosity	Physical properties	Pascal-second, milliPascal-second, Poise, centiPoise	This defaults to the LIQUID phase. Choose a unit. About Thermophysical Properties Data Parameters
Electric conductivity	Physical properties	S/m	Choose All phases, an individual phase, or System. About Thermophysical Properties Data Parameters
Elastic constant	Elastic properties	Pascal, Gigapascal, Atmospheres, Bar	Choose the elastic constant C11, C12, C13, C33, or C44. Choose All phases or an individual phase. Select a unit. Elastic Properties Variables
Electric potential (Eh)	Aqueous properties	Volt, Millivolt	
Electric resistivity	Physical properties	Ωm	Choose All phases, an individual phase, or System. About Thermophysical Properties Data Parameters
Enthalpy	Physical properties	Joule, Calorie, Electron volt, Gigajoule, Watt hour, Kilowatt hour	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Click to deselect the SER checkbox to use the reference state you have selected. Choose All phases, an individual phase, or System. Select a unit.
Entropy	Physical properties	Joule per Kelvin, Calorie per Kelvin, Electron volt per Kelvin	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Click to deselect the SER checkbox to use the reference state you have selected. Choose All phases, an individual phase, or System. Select a unit.

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Function	All variables	No units.	This option is only available when you choose the group **All variables**. Select **Function** when you want to choose a user-defined function. For example, if `fraction_solid` is predefined defined on the **Functions** tab for an Equilibrium Calculator and you want to plot this, choose **Function**.
Gibbs energy	Physical properties	Joule, Calorie, Electron volt, Gigajoule, Watt hour, Kilowatt hour	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Click to deselect the SER checkbox to use the reference state you have selected. Choose All phases, an individual phase, or System. Select a unit.
Heat capacity	Physical properties	Joule per mole Kelvin, Calorie per mole Kelvin, Joule per kilogram Kelvin, BTU per pound Fahrenheit	Choose All phases, an individual phase, or System. Select a unit.
Helmholtz energy	Physical properties	Joule, Calorie, Electron volt, Gigajoule, Watt hour, Kilowatt hour	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Click to deselect the SER checkbox to use the reference state you have selected. Choose All phases, an individual phase, or System. Select a unit.
In(activity of component)	Phase equilibria	dimensionless	Click to deselect the SER checkbox to use the reference state you have selected. Choose an element from the list or choose All.
In(activity referred to a phase)	Phase equilibria	dimensionless	Choose a phase and an element.

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Internal energy	Physical properties	Joule, Calorie, Electron volt, Gigajoule, Watt hour, Kilowatt hour	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Click to deselect the SER checkbox to use the reference state you have selected. Choose All phases, an individual phase, or System. Select a unit.
Intrinsic diffusion coefficient	Kinetic properties	m^2/s	Choose the diffusing element, Gradient element, and Reference element.
Ionic strength	Aqueous properties	dimensionless	
Isothermal compression	Physical properties	1/Pa	Choose All phases, an individual phase, or System.
Kinematic viscosity	Physical properties	Square meter per second, Stokes, Centistokes	This defaults to the LIQUID phase. Choose a unit. About Thermophysical Properties Data Parameters
L''	Kinetic properties	m^2/Js	Choose the diffusing element, Gradient element, and Reference element.
log10(Chemical diffusion coefficient)	Kinetic properties	m^2/s	Choose the diffusing element, Gradient element, and Reference element.
log10(Intrinsic diffusion coefficient)	Kinetic properties	m^2/s	Choose the diffusing element, Gradient element, and Reference element.
log10(Mobility)	Kinetic properties	m^2/s	
log10(Tracer diffusion coefficient)	Kinetic properties	m^2/s	

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Logarithm of electron activity	Aqueous properties	dimensionless	
Mobility	Kinetic properties	m^2/s	
Molality	Aqueous properties	mol/kg H_2O	Choose **All** or select specific solute species from the list.
Mole fraction solvent	Aqueous properties	dimensionless	
Mole number	Aqueous properties	Mole	Choose **All** or select specific solute species from the list.
Normalized driving force	Phase equilibria	dimensionless	Select the Normalization variable - Per mole, Per mass in gram, Per volume in cubic meter, or Per mole formula unit. Then choose All phases or a specific phase.
Osmotic coefficient	Aqueous properties	dimensionless	
Phase stability function	Phase equilibria	dimensionless	Choose All phases or a specific phase.
pH of aqueous solution	Aqueous properties	dimensionless	
Pressure	System variables	Pascal, Atmospheres, Bar	Choose a unit.
Shear modulus	Elastic properties	Pascal, Gigapascal, Atmospheres, Bar	Choose All phases or an individual phase. Select a unit. Elastic Properties Variables
Site fraction	Phase equilibria	dimensionless	Choose All phases or a specific phase. Where applicable for individual phases also select a sublattice and then a specific element for the sublattice.

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Surface tension	Physical properties	Joule per m^2, Millijoule per m^2	This defaults to the LIQUID phase. Choose a unit. About Thermophysical Properties Data Parameters
System size	System variables	Mole, Gram, Kilogram, Tonne, Pound	Choose a unit.
Temperature	System variables	Kelvin, Celsius, Fahrenheit	Choose a unit.
Thermal conductivity	Physical properties	W/mK	Choose All phases, an individual phase, or System. About Thermophysical Properties Data Parameters
Thermal diffusivity	Physical properties	m^2/s	Choose All phases, an individual phase, or System. About Thermophysical Properties Data Parameters
Thermal expansivity	Physical properties	per Kelvin, per Fahrenheit	Choose Linear or Volumetric. Choose All phases, an individual phase, or System. Select a unit.
Thermal resistivity	Physical properties	mK/W	Choose All phases, an individual phase, or System. About Thermophysical Properties Data Parameters
Thermodynamic factor	Kinetic properties	J/mol	Choose the diffusing element, Gradient element, and Reference element.
Total molality	Aqueous properties	moles per kg	

Quantity	*Group (when available)*	*Units*	*Additional Settings or Link to More Information*
Tracer diffusion coefficient	Kinetic properties	m^2/s	
u-fraction	Phase equilibria	dimensionless	Choose an element and then from the Components in denominator list, you can select or deselect specific elements using the checkboxes. The u-Fraction Variable
User-defined	System variables	No units.	Enter another axis variable.
Volume	Phase equilibria	Cubic meter, Cubic decimeter, Cubic centimeter, Normal cubic meter	Select the Normalization variable or No normalization if you do not want to normalize the quantity. Click to deselect the SER checkbox to use the reference state you have selected. Choose All phases, an individual phase, or System. Choose a unit.
Volume fraction of phase	Phase equilibria	dimensionless	Choose All phases or an individual phase.
Young's modulus	Elastic properties	Pascal, Gigapascal, Atmospheres, Bar	Choose All phases or an individual phase. Select a unit. Elastic Properties Variables

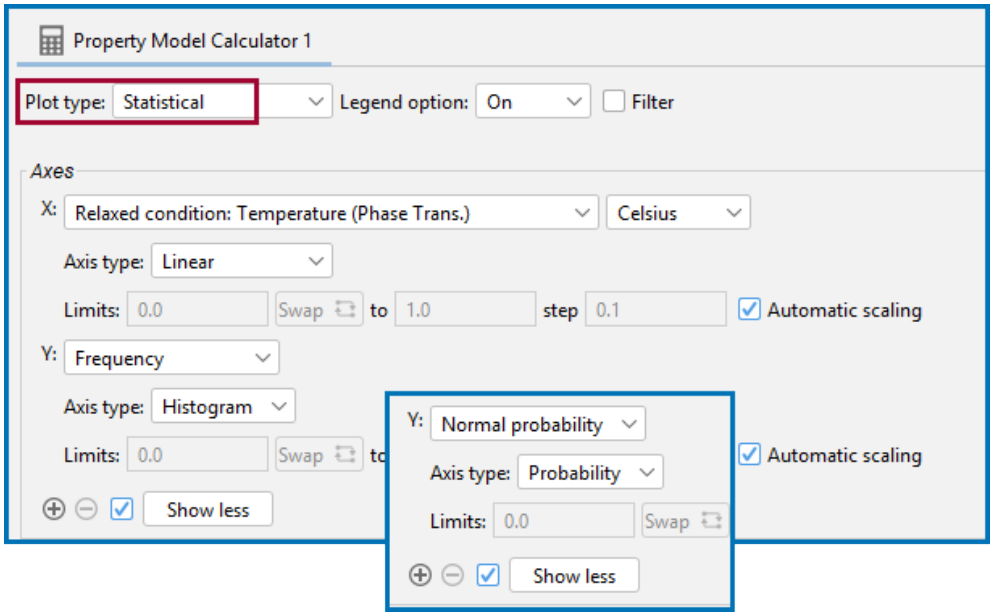
Plot Type: Cross Plot and Statistical

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and Calculation Type selected.

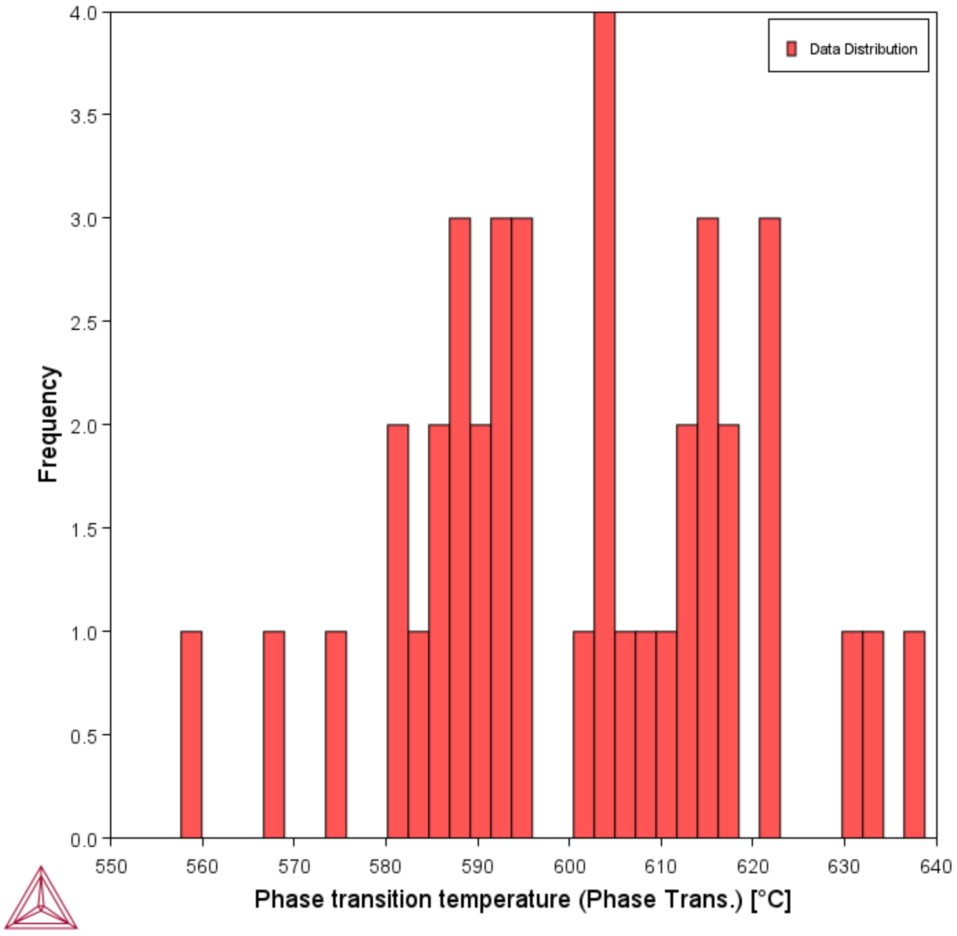
Statistical (with a Histogram or Probability Axis Type)

Use a **Statistical** *Plot type* to select **Frequency** or **Normal probability** as the *Axis variable*. The *Axis type* is then set to **Histogram** or **Probability**, respectively.

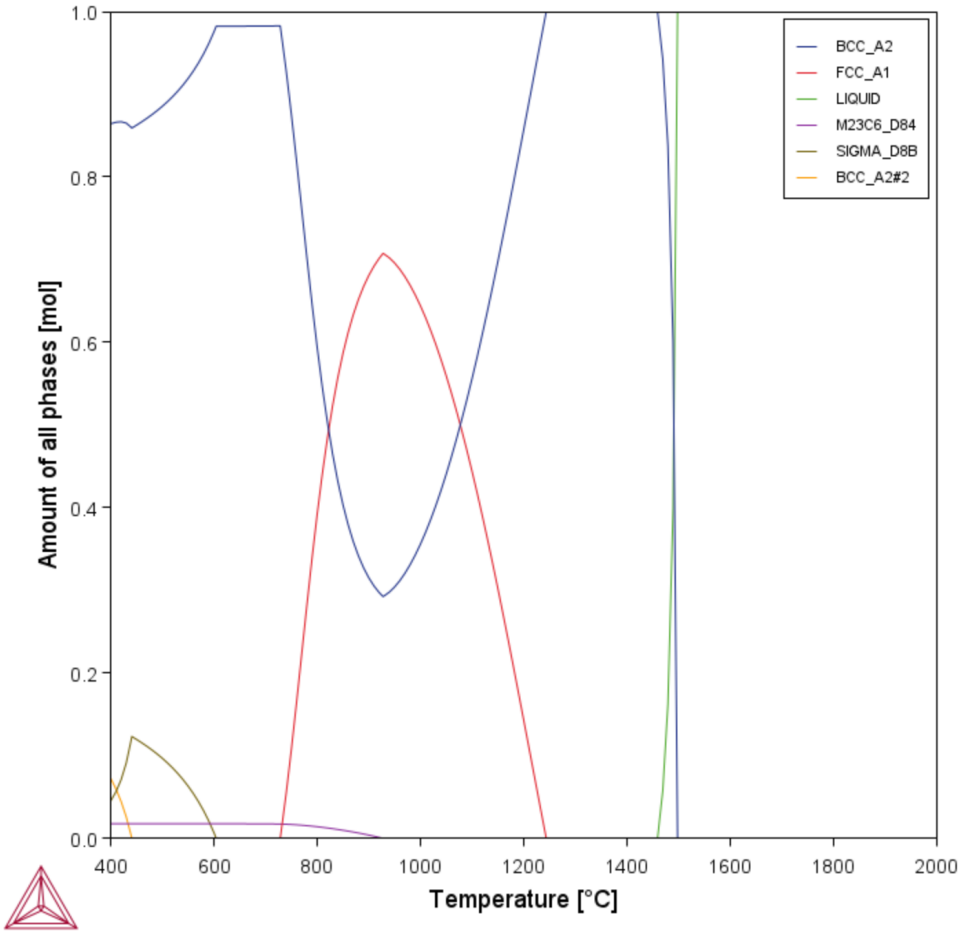
The following uses a General Property Model example: PM_G_01: Phase Transition.



The two combination options, Frequency → Histogram or Normal probability → Probability, selected with Statistical on a Plot Renderer as a successor to a Property Model Calculator.



A Statistical Plot type, with the Frequency Axis variable and Histogram Axis type selected.

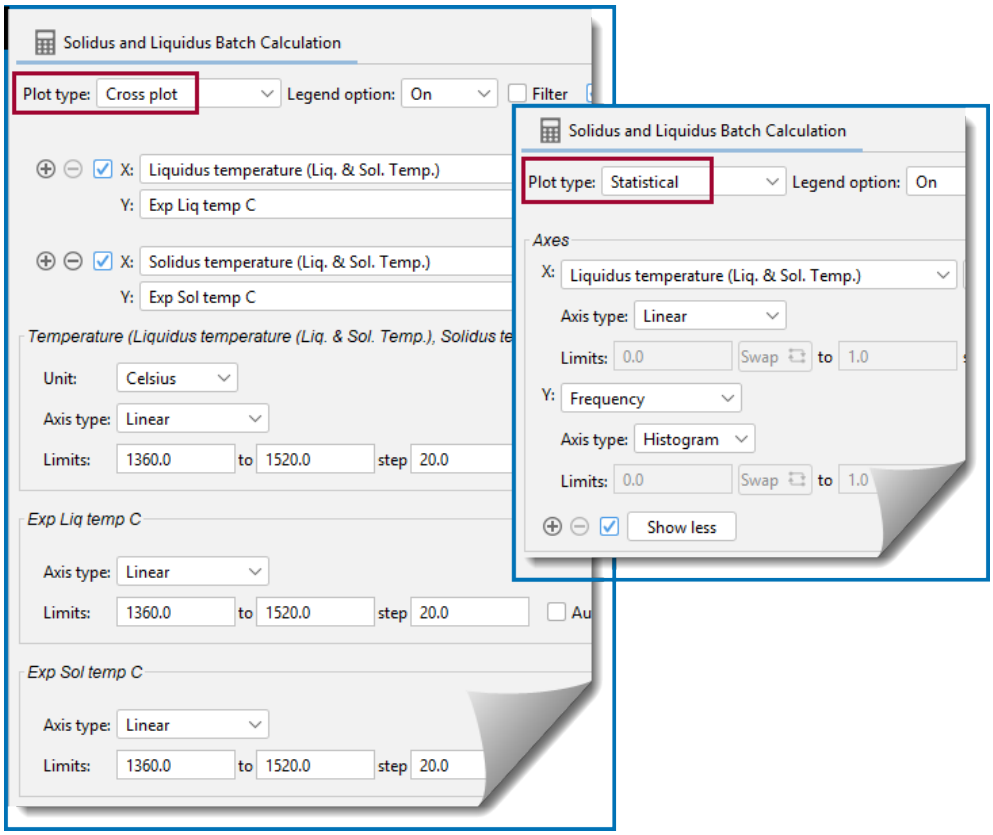


A Statistical Plot type, with the Normal probability Axis variable and Probability Axis type selected.

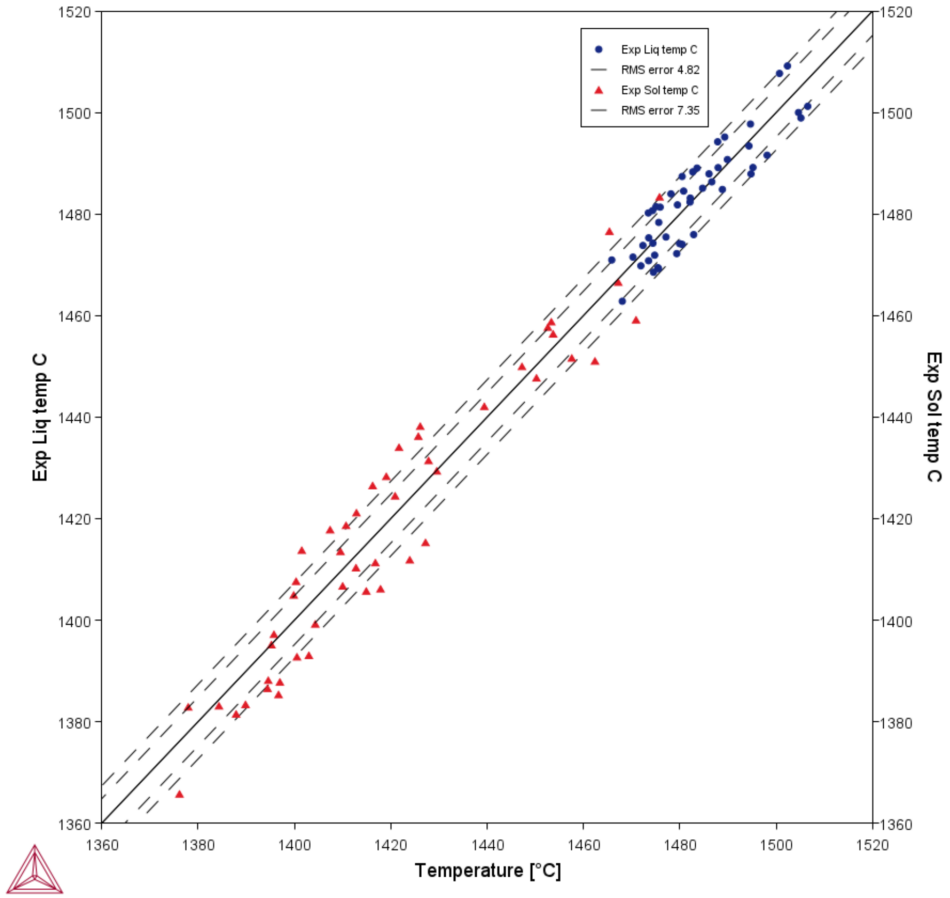
Cross Plot (Parity Plot)

Use **Cross plot** to plot the experimental data from a Batch calculation with the calculated result, e.g. you might be looking at liquidus temperature and now can plot both to compare the experimental data against the Thermo-Calc calculated results. You choose the experimental data value (which is read from the data file) as an *X*- or *Y*-axis variable and then the calculated result as the other *X*- or *Y*-axis variable. This is also known as a *parity* plot.

The following uses a General Property Model example: PM_G_12: Solidus and Liquidus Batch Calculation.



For a Batch calculation, and when the data file contains experimental (Exp) data, you can use Cross plot on a Plot Renderer to compare it to the simulated results.



A comparison of experimental liquidus and solidus data using a Cross plot with a Batch calculation. A root mean square (RMS) setting shows the distribution of the data points.

There is a news article related to ICME Workflows that provides an additional example about the use of cross plots.

Another example showing the use of cross plots is PM_G_03: Driving Force and Interfacial Energy, which also has a video to accompany it.

Calculation Types in Graphical Mode

See Plot Types detailing availability *By Calculator*, *By Plot Type*, or *By Calculation Type*.

Plot Type: Parallel Coordinates

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and Calculation Type selected.

The **Parallel coordinates** plot type is available when using the Property Model Calculator with a **Grid**, **Batch**, or **Uncertainty** *Calculation Type*.

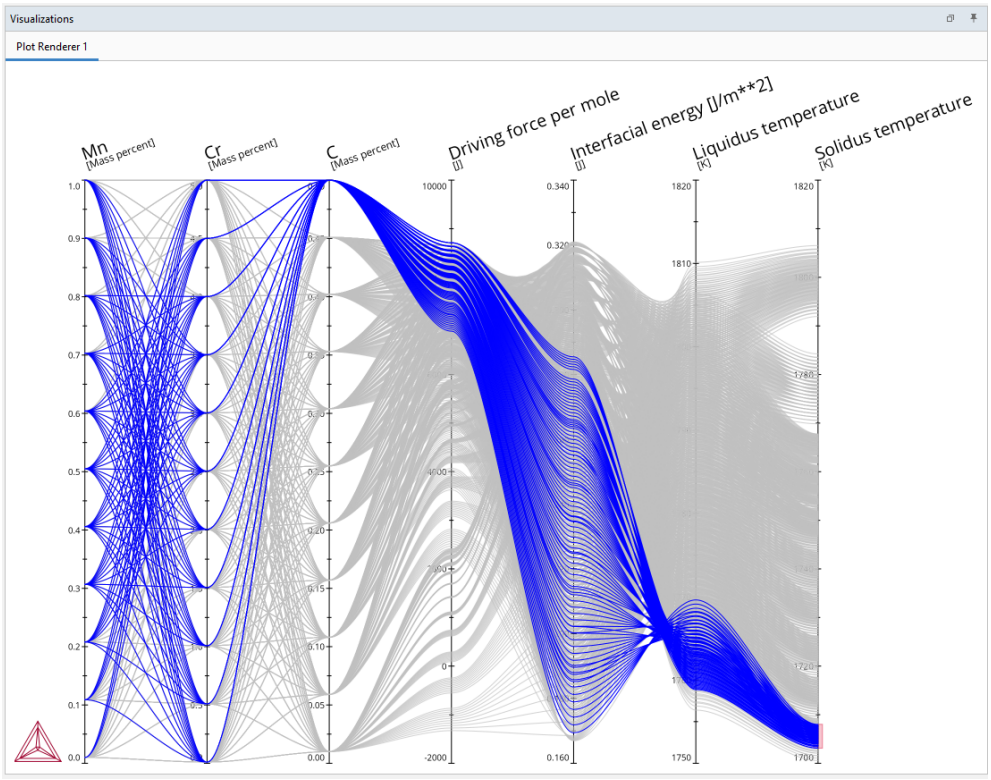

Figure 1: Parallel coordinates plot showing multidimensional data.

About the Parallel Coordinates Plot

The **Parallel coordinates** plot is useful when interpreting multidimensional data and to compare how different parameters affect each other. This is especially useful in materials design after performing a batch or uncertainty set of evaluations when multiple inputs are varied at the same time and multiple model outputs are given as a result.

It is recommended that you detach the **Visualizations** window and then drag the edges of it to fully display (i.e. stretch out) the results for this detailed plot.

For this plot type, there are some differences compared to other plots as to what can be done on the **Visualizations** window and the **Plot Renderer Configuration** window.

- **Visualizations** window: After a plot is generated, the options available when you right-click are slightly different. You can choose to **Select/Deselect a line** (to display additional information), and to **Save As** and **Copy** plot images. See Visualization Window Plot Options.

  Other options such as Plot Themes and plot formatting options are not available.

- **Plot Renderer Configuration** window: You can select the **Filter** checkbox and then filter one or more quantities. For some parameterized plot quantities, there is a filter list made available after the first time the quantity is plotted. See Plot Renderer Configuration Window Options.

To access this plot type on the Plot Renderer for a **Grid** calculation, at least three quantities under *Grid Definitions* must be selected on the Property Model Calculator.

Tips to Interpret the Plot Data

- When most lines between two parallel axes are somewhat parallel to each other, there is a positive relationship between these two dimensions.
- When lines cross in a kind of superposition of X-shapes, that is a negative relationship.
- When lines cross randomly it means that there is no particular relationship.

Overlay Compositions on the Same Plot

For this plot, you can combine and overlay calculated results from two or more Property Model Calculators and show it on one plot in the Visualizations window, even if they have been set up for different grids. This is available for a Grid calculation and when you are including three or more axis quantities for two Property Model Calculators. Each composition has its own line and it is color coded so you can identify which Property Model Calculator a given result is from.

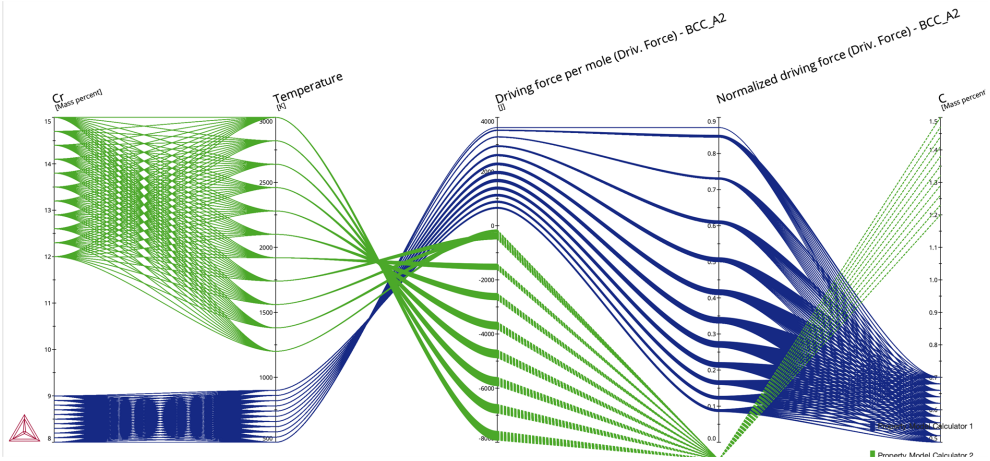

Figure 2: Parallel coordinates plot with two sets of composition data overlaid and color coded for each Property Model Calculator.

Visualization Window Plot Options

Once the plot is generated in the Visualizations window, you can right-click and choose one of these options:

- **Select/Deselect a line** (or Ctrl + right-click). For this option, you must right-click directly on an axis line to view the details and highlight the relevant information.
- **Save As** to save the plot (in its current state) as a **jpg**, **png**, or **gif** file.
- **Copy** to copy the plot (in its current state) to a clipboard. Then you can paste it into any supported application. The pasted image defaults to a **png** format.

For both **Save As** and **Copy** actions, the image is saved in the current state that the both the plot and Visualizations window is in, i.e. if you have selected one or more lines to display information, then this is what is included in the saved file. It is also saved based on the current size of the Visualizations window, i.e. to ensure that the entire plot is saved, you may need to expand the window to the full view you want to capture. Sometimes it is also useful to detach the window and drag it to full size before saving the image.

There are examples using this plot type available:

A Nickel Model Library example PM_Ni_04: Strain Age Cracking (SAC).

A Steel Model Library example PM_Fe_11: Steel Design Using the Parallel Coordinates Plot.

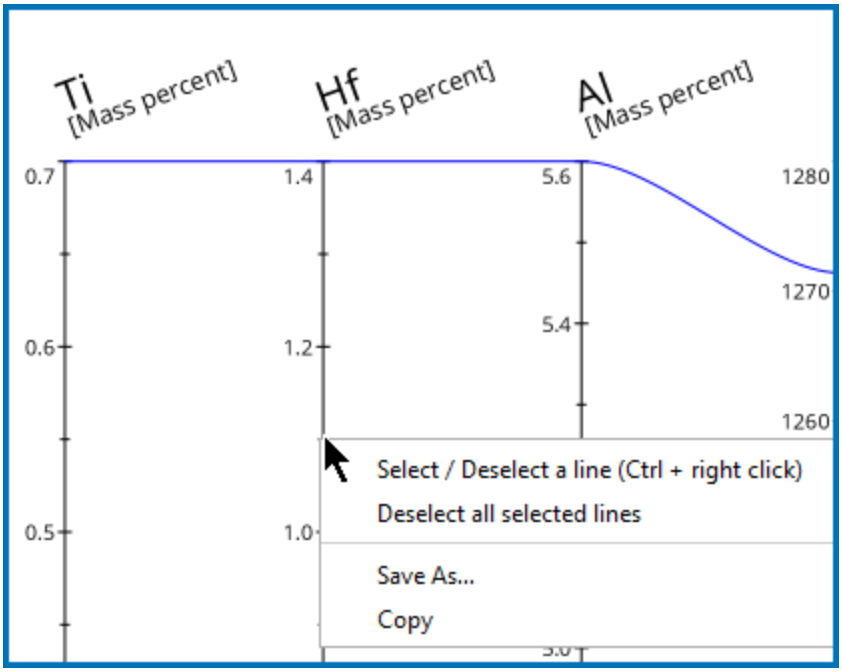
Select and Deselect Lines

In the **Visualizations** window, you can highlight and display details about any plot axis, which is useful particularly with complex plots.

You must directly right-click the axis line to turn it on (select) or off (deselect); it does not work to just right-click anywhere in the Visualizations window for this action.

To toggle the **Select/Deselect a line** option on (select a line) and off (deselect a line), hover over an axis line then:

- Ctrl + right-click or
- Right-click and choose **Select/Deselect a line**.



To deselect all lines, either do this one at a time or when several lines are selected, you can right-click to choose **Deselect all selected lines**.

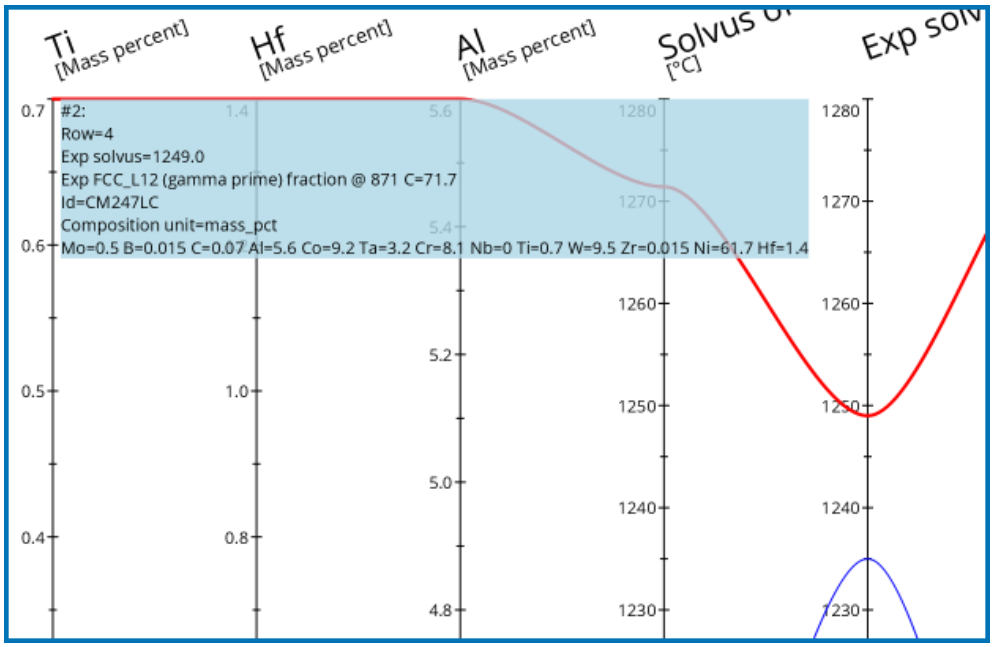


Figure 3: Choosing to display specific axes lines and the associated information on the Visualizations window for a Parallel coordinates plot type.

Save As

1. Once the plot is generated in the **Visualizations** window, right-click anywhere in the window and choose **Save As**.
2. In the **Save** window:
    a. Navigate to where you want to save the plot.
    b. Enter a **File Name**.
    c. From the **Files of Type** list choose **png** (the default), **jpg**, or **gif**.
    d. When you are ready, click **Save**.

Copy

1. Once the plot is generated in the **Visualizations** window, right-click anywhere in the window and choose **Copy**.
2. Navigate to where you want to paste the image (i.e. Word, Slack, email, and so forth) and Ctrl + V to paste it. The pasted image defaults to a **png** format.

Plot Renderer Configuration Window Options

Filter Quantities

Use the **Filter** checkbox on a Plot Renderer to add various filters to the **Parallel coordinates** plot or table and based on the set up of the calculation.

When selected, click the **Add quantity** and **Remove quantity** buttons to add filters. For example, enter a **Min** and **Max** and choose an axis variable such as **Composition Cr** and the unit **Mass percent** to adjust the output in the **Visualizations** window. Click **Perform** each time you add or remove a filter for the results to update.

Filter Parameterized Quantities

For a **Parallel coordinates** *Plot type*, and only for parameterized result quantities, you can choose to show all or one specific quantity on the plot. By default, and when you first choose these types of results quantities, **All** quantities are plotted in the **Visualizations** window output after performing the first calculation. Once the secondary list is available you can then choose to plot only one of the quantities at a time. The availability of the filter list is dependent on the result of the initial calculation.

This filter option does NOT use the **Filter** checkbox. The filter list displays AFTER clicking **Perform** for the chosen quantity. Once the quantity is plotted you can choose to filter by the individual quantities included in the list. Initially, **All** quantities are plotted.

1. From the **Axis variable** list, choose a quantity. For example, for the Martensitic Steel Strength Property Model, you can choose **Precipitate fraction (Tempering)**.
2. Continue adding and selecting any quantity you want to include in the **Parallel coordinates** plot.
3. Click **Perform**. Go to the **Visualizations** window to view your results.
4. If the type of quantity you selected has additional filtering options, on the **Plot Renderer Configuration** window, next to the original quantity chosen, there is now a secondary filter list available. It defaults to include **All** quantities or from the list you can choose to plot a specific quantity. When you use this list to filter, it includes **All** or one quantity, i.e. you cannot choose more than one option.
5. Click **Perform** each time you change the selection in order to regenerate the plot.

To plot more than one specific parameterized quantity at a time, click the **Add quantity** button, select the same quantity again (e.g. **Precipitate fraction (Tempering)**) and then after performing the calculation, from the secondary filter list choose the second quantity you want to include. That is, add the parameterized quantity twice, perform to access the secondary filter list, then individually choose the two quantities you want to plot. Remember to click **Perform** to regenerate the plot.

Learn More

Calculation Types in Graphical Mode

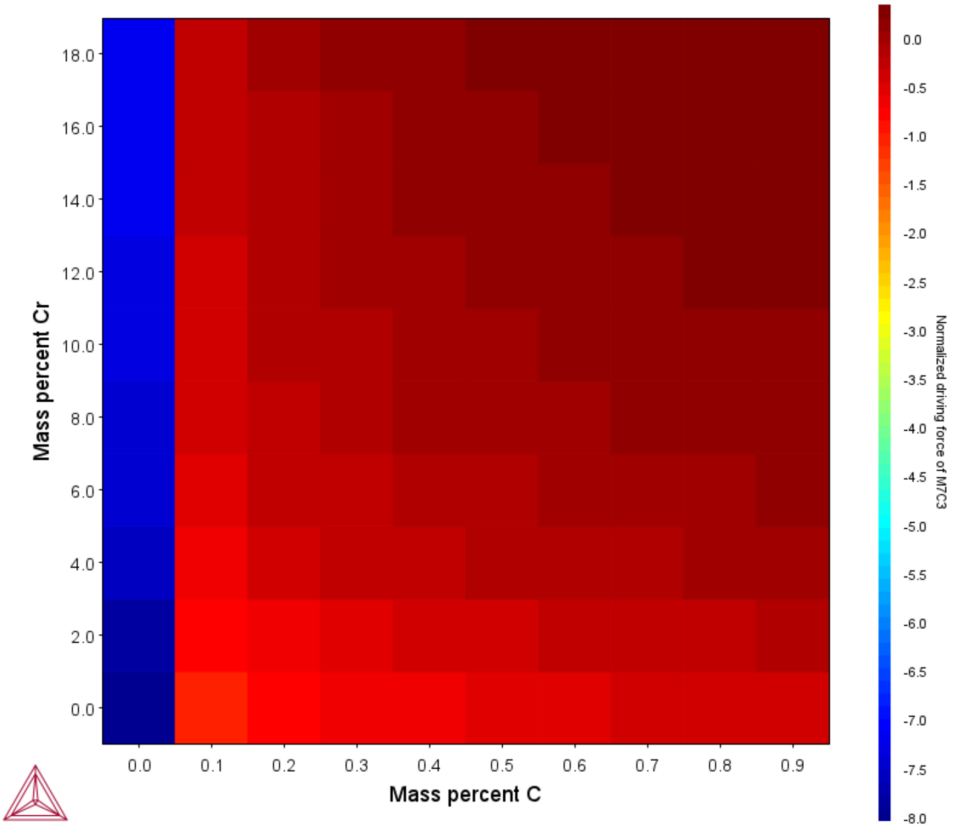
See Plot Types detailing availability *By Calculator*, *By Plot Type*, or *By Calculation Type*.

Plot Type: Heat Map, Contour, and 3D

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and Calculation Type selected.

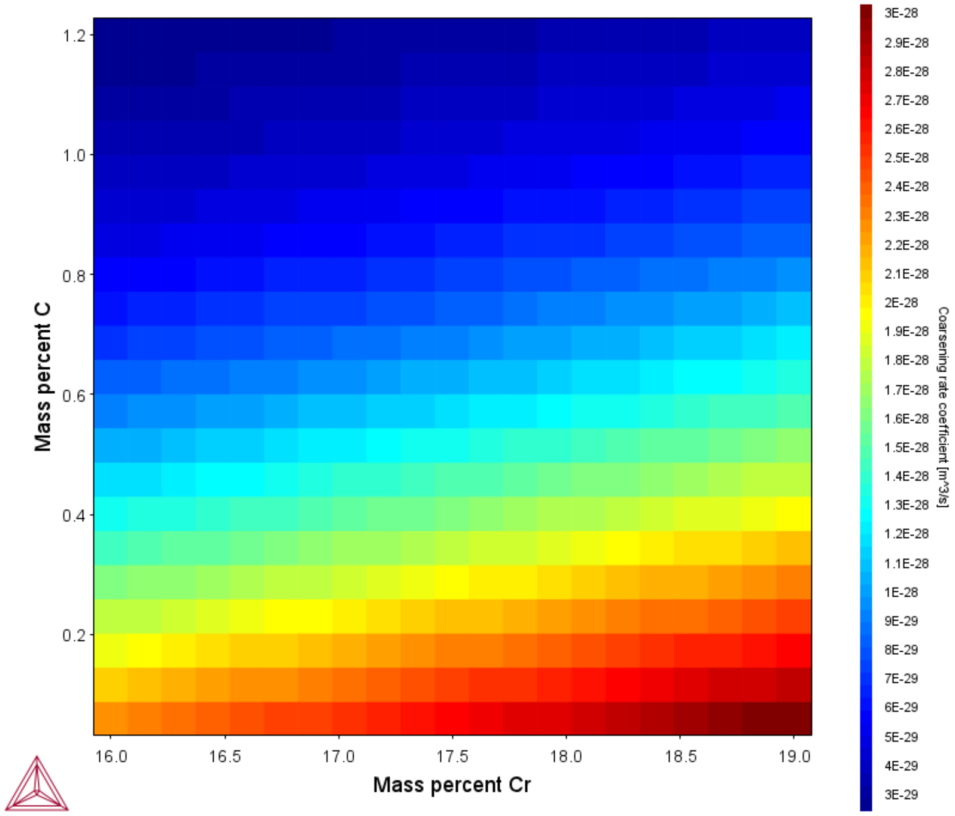
Heat Map

For a **Heat map** plot, each *Z*-axis variable value in the grid is represented by a color-coded area, where dark red represents the highest *Z*-axis variable value and dark blue represents the lowest *Z*-axis variable value.



Thermo-Calc example T_09 uses an Equilibrium Calculator with a Grid Calculation Type to generate a Heat map plot.

T_09: Carbide Driving Force Heat Map

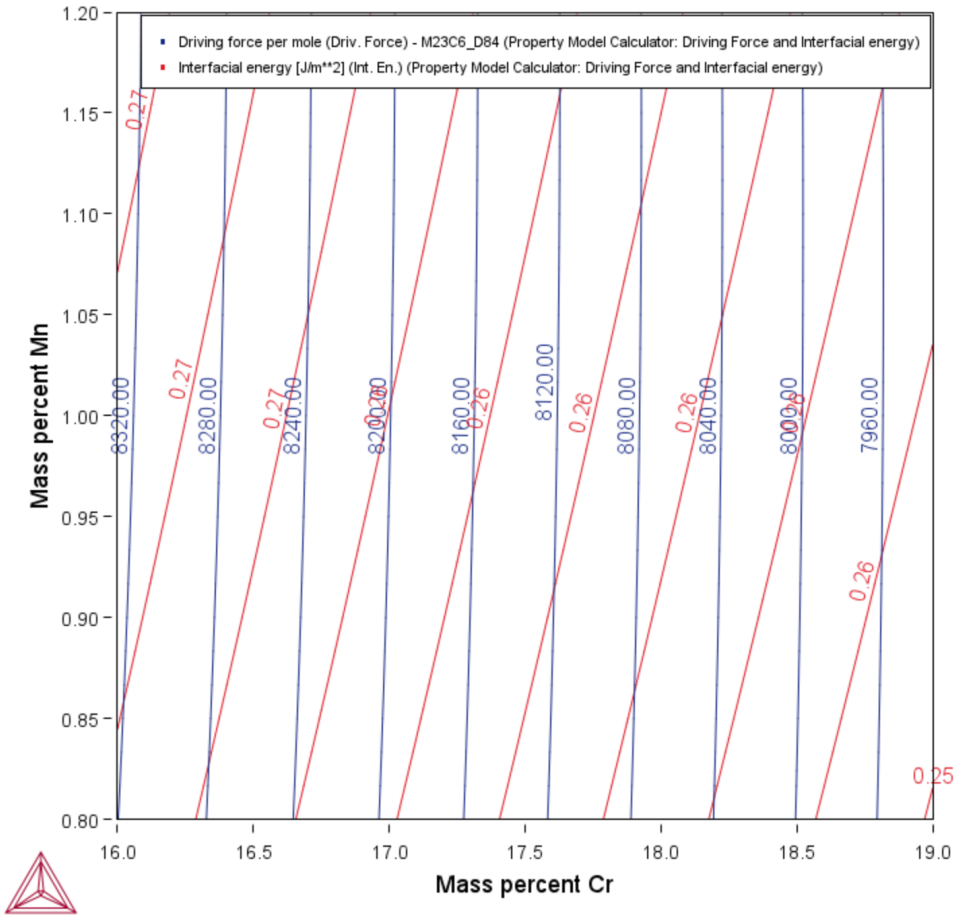


Thermo-Calc General Property Model example PM_G_02 uses a Property Model Calculator with a Grid Calculation type to plot the coarsening rate coefficient as a Heat map.

PM_G_02: Coarsening and Interfacial Energy

Contour

For a **Contour** plot, *Z*-axis variable values are traced with curves in the same way that height values are traced with curves on a topographical map. The colors used originate from the different data series.

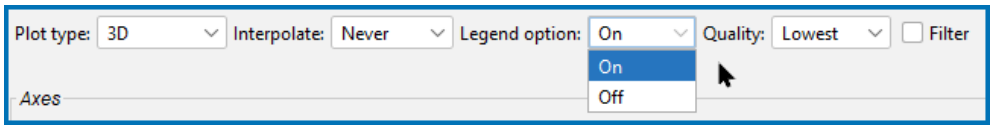


Thermo-Calc General Property Model example PM_G_03 uses a Property Model Calculator with a Grid Calculation type to compare the driving force and interfacial energy on an overlaid contour plot.

PM_G_03: Driving Force and Interfacial Energy

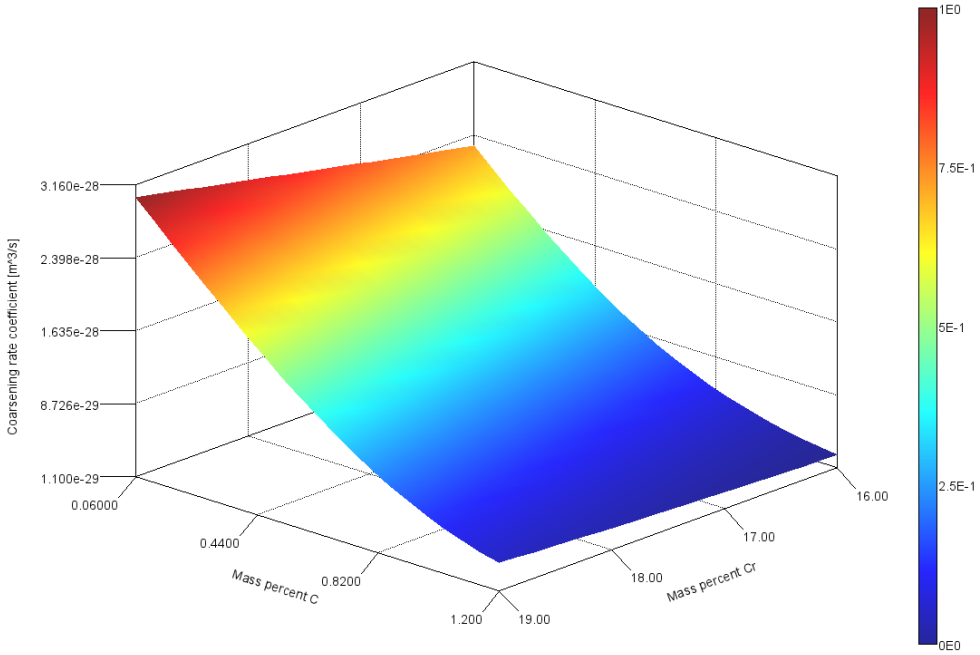
3D

For a **3D** plot, the 3D surface is created by Delaunay tesselation of the calculated data. The surface uses a cold to warm color map where red represents the highest *Z*-axis variable value and blue represents the lowest *Z*-axis variable value. The color map color legend can be turned on or off with the legend option.



3D Plots with additional functionality are also available with the Add-on Additive Manufacturing (AM) Module. The information is described separately and included with the Module's documentation.

When in the Thermo-Calc help (press F1), go to Rotating 3D Plots to watch a short video showing you how to rotate this plot in the Visualizations window.



Thermo-Calc General Property Model example PM_G_02 uses a Property Model Calculator with a Grid Calculation type to plot the coarsening rate coefficient as a 3D plot.

PM_G_02: Coarsening and Interfacial Energy

Calculation Types in Graphical Mode

See Plot Types detailing availability *By Calculator*, *By Plot Type*, or *By Calculation Type*.

Plot Type: Flexible Mode and Grouped Mode

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and Calculation Type selected.

Flexible Mode

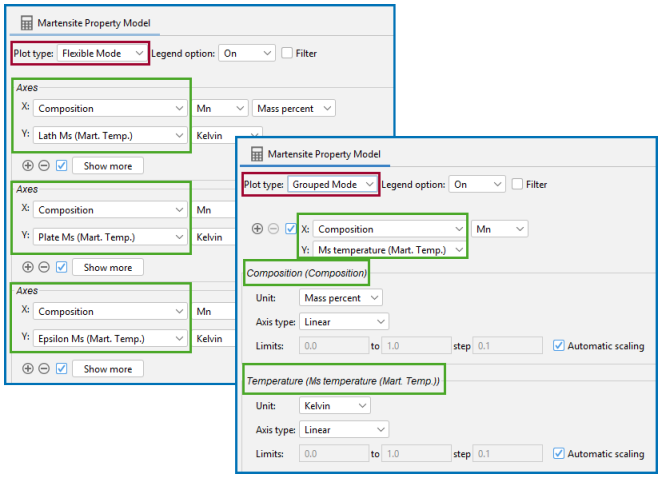
Use **Flexible Mode** to individually add and configure axes quantities and change the units or other associated settings one at a time.

Grouped Mode

Use **Grouped Mode** to add and configure groups of axis quantities at the same time and of the same type. For example, change units or settings in groups with similar settings like temperature units or axis types.

Switching Between Modes

If you have a license for the Steel Model Library, you can try yourself to switch between Flexible Mode and Group Mode and then change the settings to how you want it using the **Steels** example PM_Fe_02: Fe-Mn Martensite Morphologies.



Comparing Flexible Mode (left) to Grouped Mode (right) on a Plot Renderer as a successor to a Property Model Calculator. The advantage of Grouped Mode is that you can, for example, configure or edit settings in one place, making it easier to manage and work with the plot quantities.

To experiment using the **Equilibrium Calculator**, see Thermo-Calc example T_02: Stepping in Temperature in the Fe-C System.

To experiment using the **Material to Material Calculator**, see Thermo-Calc example T_14: Fe-Cr-Ni Transition Comparison Using the Material to Material Calculator.

Learn More

Calculation Types in Graphical Mode

See Plot Types detailing availability *By Calculator*, *By Plot Type*, or *By Calculation Type*.

Plot Type: CCT Mode

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and Calculation Type selected.

Use **CCT Mode** to make a CCT diagram from a **One Axis** calculation with a *Quantity* of **Log10 (cooling rate [K/s])** selected for the CCT Diagram Property Model. The *X*- and *Y*-axes are *Time* and *Temperature*, respectively. Result quantities defined as time-temperature pairs are identified and plotted. Cooling curves are also automatically added in the plot.

When is CCT Mode Available?

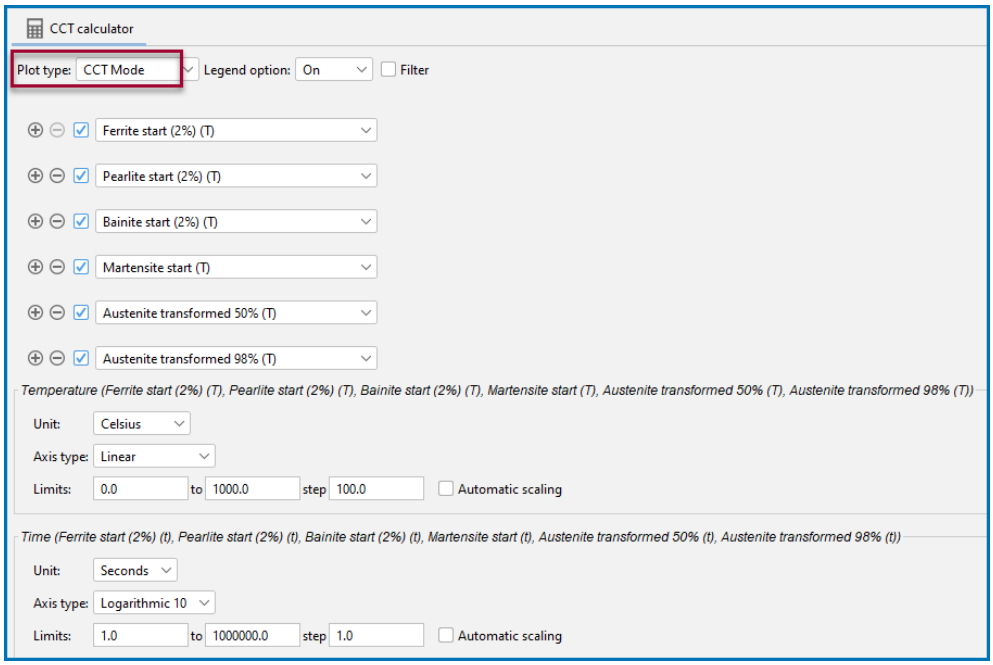
This plot type is available with the Steel Model Library, which requires specific maintenance and database licenses. See About the Steel Model Library Property Models.

In general, this plot type is available from the drop-down list in these situations:

- When you add the **Steel - CCT** template (on the **My Project Configuration** window under **Property Models**), it is the default type on the Plot Renderer (renamed CCT in the template).
- If a user-defined Property Model has both **Time** and **Temperature** quantities defined in a coupled manner, for example if you create your own Property Model with TC-Python. That is, if you select or create any model where the resulting combination of stepping-quantity and result-quantities has both time and temperature definitions.

Example of CCT Mode

The settings example below uses Property Model example PM_Fe_08: CCT Diagram for Fe-C-Mn-Si-Cr-V.



CCT Mode on a Plot Renderer as a successor to a Property Model Calculator.

Learn More

- Calculation Types in Graphical Mode and Plot Types detailing availability *By Calculator*, *By Plot Type*, or *By Calculation Type*.
- Configuration Window Settings and Plot Renderer: Configuration Settings
- Steel Library CCT Diagram Template

Plot Type: TTT Mode

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and Calculation Type selected.

Use **TTT Mode** to make a TTT diagram from a **One Axis** calculation with temperature. The *X*- and *Y*-axes are *Time* and *Temperature*, respectively. Time quantities (such as *Pearlite start*, *Bainite start*) are plotted as functions of temperature. Temperature quantities (such as *Martensite start*, *Martensite 50%*) are independent of time and plotted as horizontal lines.

When is TTT Mode Available?

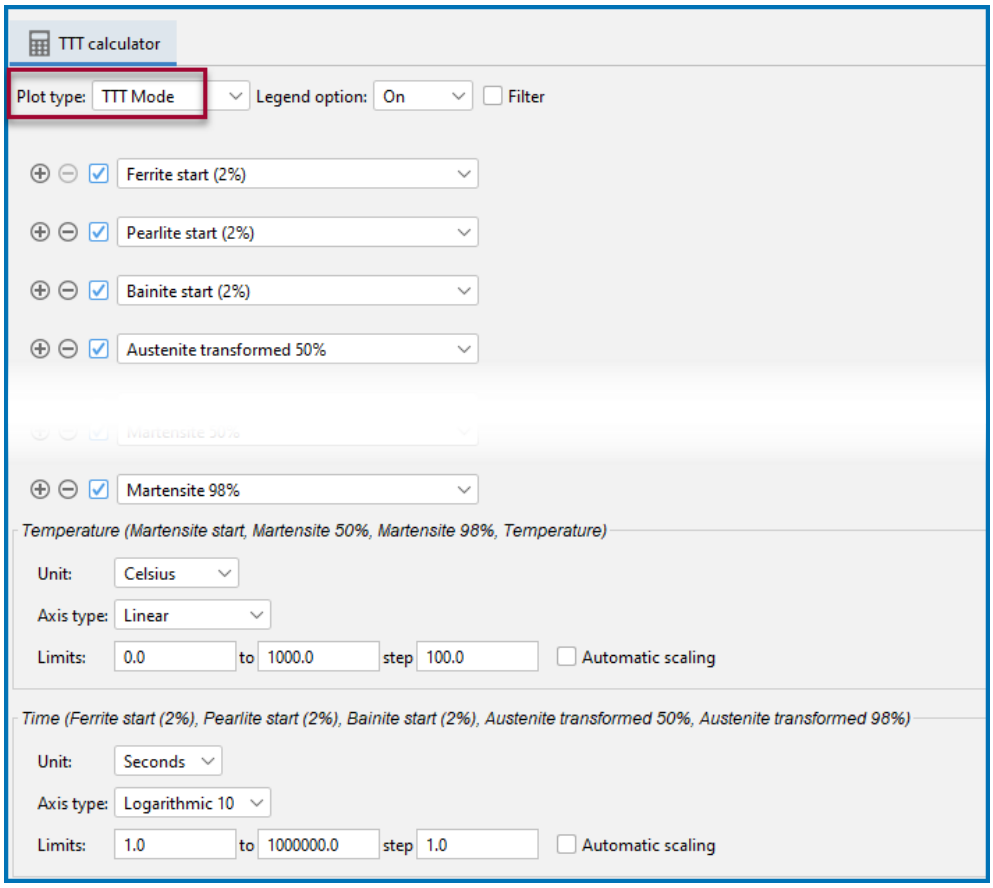
This plot type is available with the Steel Model Library, which requires specific maintenance and database licenses. See About the Steel Model Library Property Models.

In general, this plot type is available from the drop-down list in these situations:

- When you add the **Steel - TTT** template (on the **My Projects Configuration** window under **Property Models**), it is the default type on the Plot Renderer (renamed TTT in the template).
- When you are using at least one of these Steel Property Models—**Martensite Temperatures**, **Pearlite**, or **Bainite** with a **One Axis** calculation and when both time and temperature quantities are selected on the Plot Renderer—the TTT Mode is available.
- If a user-defined Property Model has both time and temperature quantities defined in a coupled manner, for example if you create your own Property Model with TC-Python. That is, if you select or create any model where the resulting combination of stepping-quantity and result-quantities has both time and temperature definitions.

Example of TTT Mode

The settings example below uses Property Model example PM_Fe_06: TTT Diagram for Fe-C-Mn-Si-Cr-V.



TTT Mode on a Plot Renderer as a successor to a Property Model Calculator.

Plotting Options

The Plot Renderer is a dynamic activity node with options such as being able to:

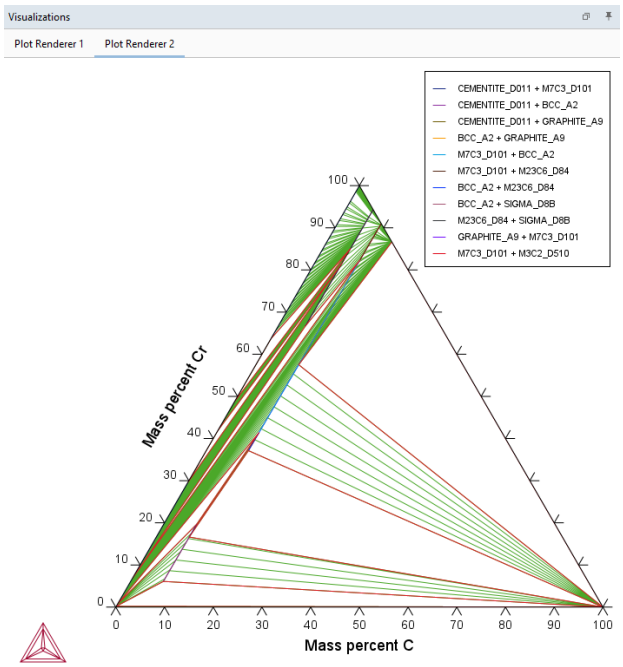
- add more than one Plot Renderer to its predecessor node (i.e. one of the calculator activities),
- add axes to the plots,
- merge results in one plot,
- filter quantities (only for a Parallel coordinates plot), and
- choose from a variety of plot types based on the selected combination of Calculator and Calculation Type.

Additional settings are also described in Plot Renderer: Configuration Settings.

Plots Can Have More Than One Predecessor

A Plot Renderer can have several predecessors (if you want to plot several calculations in the same diagram), in which case there are several tabs in the Configuration window, one for each predecessor.

Plotting Several Calculations in One Diagram



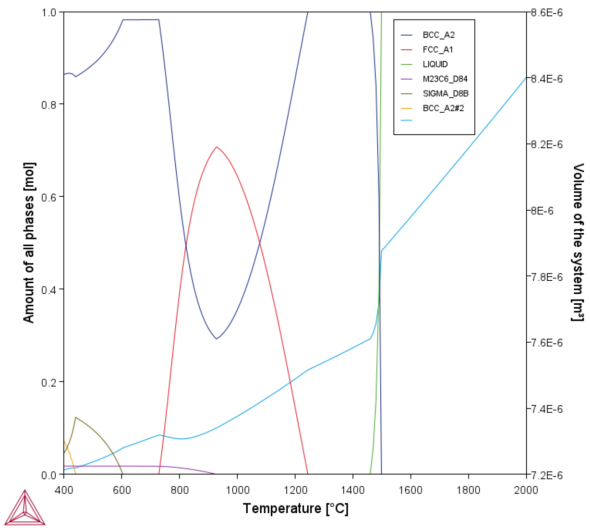
Several Plot Renderer activities (as well as Table Renderer activities) can be shown in the Visualizations window as different tabs. This is an example from Thermo-Calc Graphical Mode T_04_Fe-Cr-C_ternary_phase_diagram.

Add Axes to Plots

You can add additional axes (*X*, *Y*, and *Z* for **Grid** calculations) to a plot to compare two or more variables at the same time.

- To add an axis setting section, click the **Add an axis** button.
- Once a new axis settings section is added, click **Remove this axis** button to delete it.
- Wherever you see these plus or minus buttons, click to add or remove a section then define the axis as needed.

Adding Axes to a Diagram



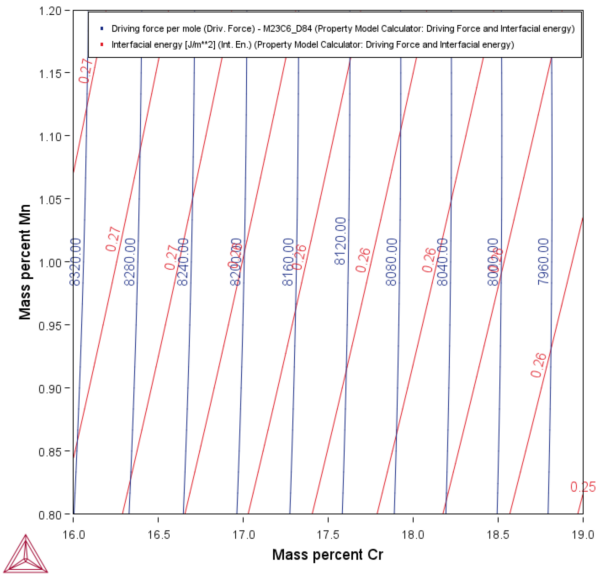
Two variables plotted on the Y-axis.

Merge Results in One Plot

You can merge (or overlay) calculated results for several variables into one plot. This is similar to adding an axis, but instead of displaying different variables along the *X*- and/or *Y*-axes, the same X and Y variables are used to compare the third variable (defined in the Plot Renderer as the *Z*-axis).

As in the figure (from example *PM_G_03* in Graphical Mode), the driving force and interfacial energy results are combined into one diagram. The *X*- and *Y*-axis is the same for both (Mass percent Cr/Mass percent Mn).

Merging Plots into One Diagram



A contour plot showing both the driving force and interfacial energy calculation results comparing Mass percent Cr to Mass percent Mn. From example PM_G_03.

Filter Quantities on a Parallel Coordinates Plot

Use the **Filter** checkbox on a Plot Renderer to add various filters to the **Parallel coordinates** plot or table and based on the set up of the calculation.

When selected, click the **Add quantity** and **Remove quantity** buttons to add filters. For example, enter a **Min** and **Max** and choose an axis variable such as **Composition Cr** and the unit **Mass percent** to adjust the output in the **Visualizations** window. Click **Perform** each time you add or remove a filter for the results to update.

Choose a Plot Type

When you set up most Calculators, there are calculation types to choose from on the **Configuration** window. The selection of the *Calculation Type* also provides options to choose from the *Plot type* menu for some of the associated **Plot Renderer** windows.

For a list of calculations for each Calculator, see Calculation Types in Graphical Mode.

There are a variety of combinations of Calculator and *Calculation Type* that offer different Plot Types. These are described in separate topics:

- Plot Type: Cross Plot and Statistical
- Plot Type: Heat Map, Contour, and 3D
- Plot Type: Parallel Coordinates
- Plot Type: Flexible Mode and Grouped Mode
- Plot Type: CCT Mode
- Plot Type: TTT Mode
- Plot Type: Simple Mode and Advanced Mode

If you also have a license for the Additive Manufacturing Module, there are additional plots available and described elsewhere, i.e. see About the AM Plot Types.

Saving and Printing the Output in Graphical Mode

In Graphical Mode the output is displayed in the **Visualizations** window. The output can be in the form of a table or a diagram (plot). In both cases you can save from the **Configuration** or **Visualizations** windows. You can print the table or diagram from the **Visualizations** window.

Saving a **Parallel coordinates** plot from the **Visualizations** window has less file type options. See Plot Type: Parallel Coordinates.

Terminology

Output can refer to results in the form of tabulated data in a table or a diagram.

The terms *diagram* and *plot* are interchangeable. The commands in Console Mode generally use the term diagram and in Graphical Mode it is also called a plot (e.g. the Plot Renderer).

Saving Diagrams

You can save the output in a variety of file formats. For JPG and PNG images you can also adjust the image quality.

In Console Mode, the diagram is output to the **Console Results** window after using the PLOT_DIAGRAM command.

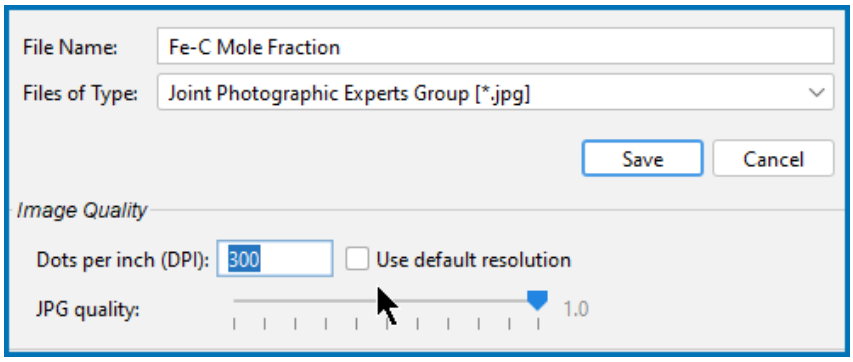
In Graphical Mode, the diagram is output to the **Visualizations** window after performing a tree that includes a Plot Renderer.

In the **Visualizations** window, right-click the diagram and select **Save as**.

In the Graphical Mode **Configuration** window you can also click the **Save Diagram** (or **Save table**) buttons to open the **Save** window.

Then in the **Save** window:

1. Navigate to where you want to save the diagram.
2. Enter a **File name**.
3. From the **Files of type** list choose **png** (the default), **jpg**, **ps**, **pdf**, **gif**, **svg**, or **emf**.
4. For PNG and JPG files only, under the **Image Quality** section, choose to improve the resolution of the image. For JPG files you can also adjust the file size.
    - To change the resolution of a PNG or JPG image, click to clear the **Use screen resolution** checkbox. Then enter a numerical value in the **Dots per inch (DPI)** field.
    - For JPEG files, you can also use the slider to choose a number between 0 and 1 for the **JPG quality**. The default is 0.9. The lower the number, the smaller the file.



5. When you are ready, click **Save**.

Saving (Exporting) Tables

You can save the table output in different file formats from the Table Renderer and Plot Renderer**Configuration** and **Visualizations** windows.

In Graphical Mode, a table is output to the **Visualizations** window after performing a tree that includes a Table Renderer. It is also output using the **Table View** button located on the Plot Renderer **Configuration** window.

Generate a table. Then depending on which window you are in:

- In the **Visualizations** window, right-click the table and select **Save as**, or
- In the **Configuration** window click the **Save table** button.

Then in the **Save As** window:

1. Navigate to where you want to save the table.
2. Enter a **File Name**.
3. From the **Files of Type** list choose **Text [*.txt]**(the default), **Hyper Text Markup [*.html]**, or **Excel [*.xls]**.
4. When you are ready, click **Save**.

Printing Output

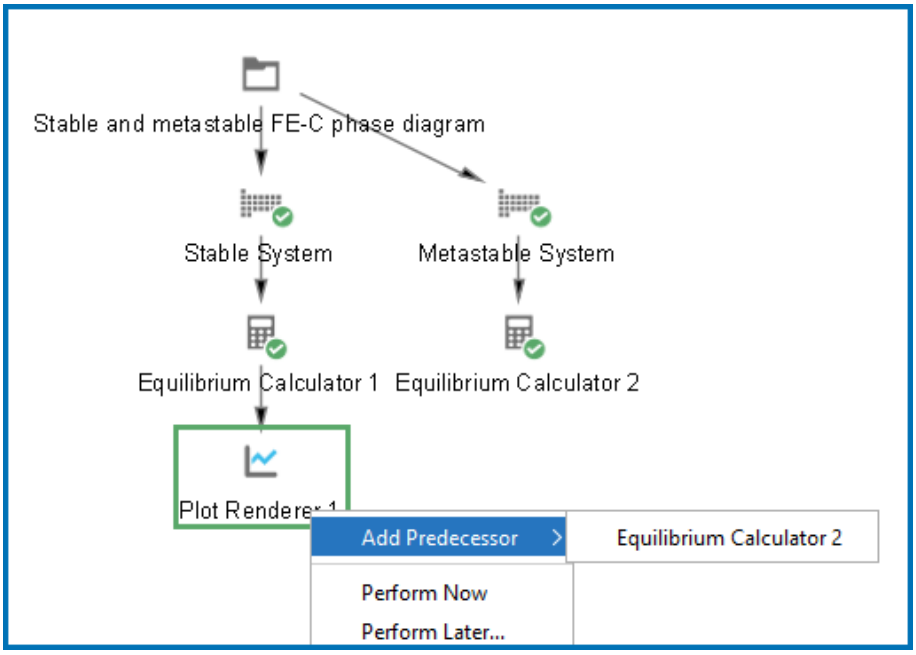
In the **Visualizations** window, right-click the table or diagram and choose **Print**. Select additional settings as required on the **Print** window.

Plotting Several Calculations in One Diagram

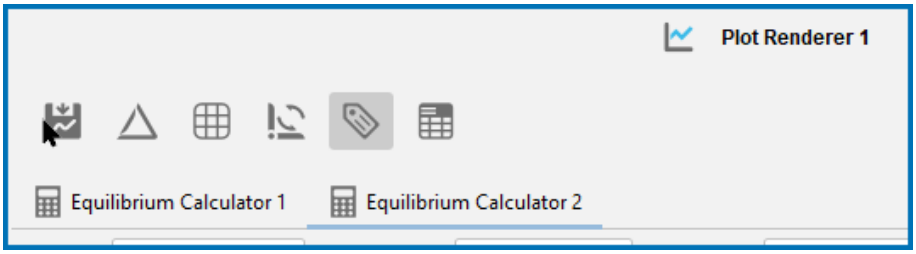
To plot several calculations in one diagram, you must have, in addition to the Plot Renderer's original predecessor, at least one available Plot Renderer predecessor in your project, for example, the additional predecessor can be an Equilibrium Calculator, Binary Calculator, Ternary Calculator, Scheil Calculator, or Experimental File Reader.

This example is based on Thermo-Calc T_05: Stable and the Metastable Fe-C Phase Diagrams.

1. In the **Project** window click the **Plot Renderer** node.
2. In the **Configuration** window click **Add Predecessor**. Or right-click the **Plot Renderer** and choose **Add Predecessor**.

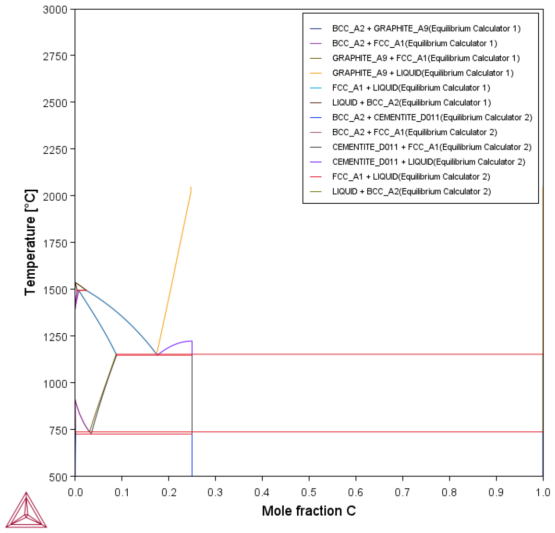


3. Select a predecessor. When added, the extra predecessor is linked to the Plot Renderer. On the **Plot Renderer Configuration** window, the predecessors are shown as two tabs:



4. Configure how you want each calculation plotted on the tabs in the **Configuration** window, then click to **Perform** the Plot Renderer activity.

   The calculations are plotted in the same diagram in a tab in the **Visualizations** window. If any of the axis variables of the plots differ, then the label and scale of all calculations are shown parallel to each other.



Zooming In and Out

In the **Visualizations** window (where the plots are):

- Use the mouse scroll wheel to zoom in and out.
- Click and drag the mouse from left to right to highlight an area of the plot to zoom into a specific point. Use the scroll wheel to continue zooming in or out.

Resetting a Plot to the Default View

- For 2D plots, click and drag the mouse from right to left.
- For 2D and 3D plots, click **Perform Tree** to regenerate the plot in the **Visualizations** window.

Rotating 3D Plots

In the **Project** window (where the activity nodes are):

- Right-click and select **Zoom In** or **Zoom Out**.
- To go back to the default zoom, select **Reset Zoom**.

Rotating 3D Plots

When you use a *Grid* calculation type you can plot the diagram in 3D. In the **Visualizations** window after you create the 3D plot:

- Rotate the diagram automatically. Double-click in the **Visualizations** window and the diagram rotates clockwise. Left-click once to stop the automatic rotation.
- Rotate the diagram manually. Left-click and hold the mouse and move it around the **Visualizations** window.
- Scroll the mouse wheel/use your fingers on a trackpad to zoom on the Z-axis values.
- Right-click and move the mouse to shift the surface up or down without zooming.
- To reset the plot to its default view click **Perform Tree** to regenerate the plot.

Learn More

Plot Type: Heat Map, Contour, and 3D and Calculation Types in Graphical Mode

3D Plots with additional functionality are also available with the Add-on Additive Manufacturing (AM) Module. The information is described separately and included with the Module's documentation.

Adding Axes to a Diagram

You can add additional axes (*X*, *Y*, and *Z* for **Grid** calculations) to a plot to compare two or more variables at the same time.

- To add an axis setting section, click the **Add an axis** button.
- Once a new axis settings section is added, click **Remove this axis** button to delete it.
- Wherever you see these plus or minus buttons, click to add or remove a section then define the axis as needed.

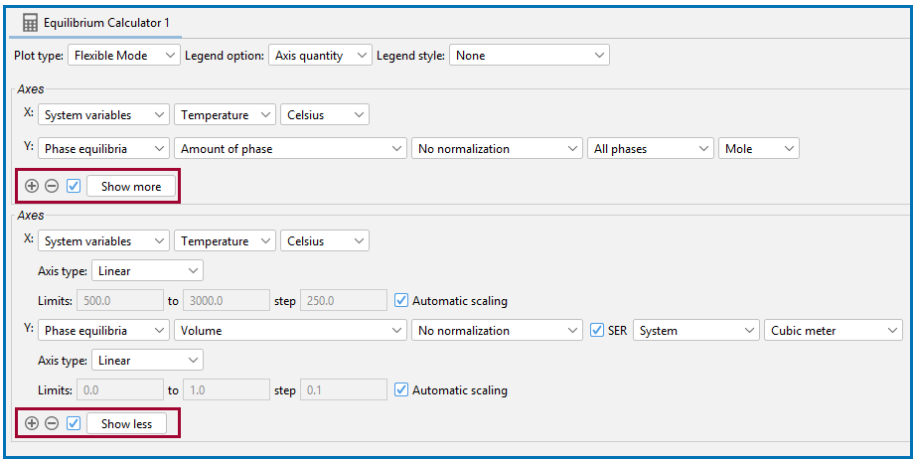
The following is based on example PM_G_03: Driving Force and Interfacial Energy.

Adding and Defining an Axis Settings Section

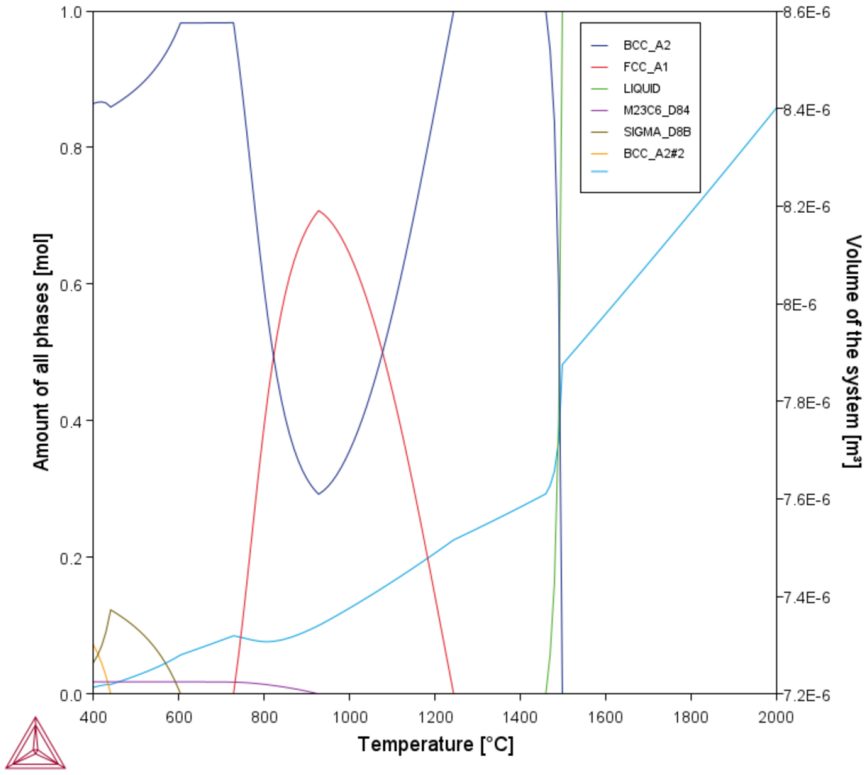
1. Open example PM_G_03. The example is the **Property Models → General** folder.
2. In the **Project** window right-click the **Equilibrium Calculator** node and add a **Plot Renderer** node from the **Create New Successor** menu. This is added to the existing tree so you can compare to the renamed **Equilibrium: Phase fractions vs T** node.
3. Click the new **Plot Renderer** node. The **Configuration** window is where you define the plot. Available settings are based on, for example, the database selected on the **System Definer** and calculation type selected on the Calculator node, in this example the **Equilibrium Calculator**.
4. For the purpose of this example, keep the default **Flexible Mode** as the *Plot type*. You can still switch between this and the **Grouped Mode** to see the differences.
5. In the *Axes* sections for each *X* and *Y* axis [and when relevant, *Z*], choose and define the variables:
    a. From the first list for each axis, select a variable group (i.e. **All variables**, **System variables**, **Physical properties**, etc.). In this example, **System variables** (X axis) and **Phase equilibria** (Y axis) are the defaults selected.
    b. From the second list, choose the axis variables, i.e. **Temperature** (X), and **Amount of phase** (Y).
    c. Based on the variable selected, from the additional lists displayed, choose the unit, i.e. for **Temperature** (X), select **Celsius**. For **Amount of phase** (Y), select **No normalization**, keep the default **All phases**, and select **Mole** as the unit. Any other relevant settings are associated specifically to the variable chosen.
6. To add additional axes, click the **Add an axis** button. A new *Axes* settings group is added. Continue to add and define the variables to plot.

7. Keep the default X axis settings, which are the same as in the first group.
8. Define the Y axis. Choose the **Phase equilibria** group and then the variable **Volume**. Keep all the defaults.

> You can toggle between **Show more** and **Show less** to discover and define additional settings i.e. choose an **Axis type**, set **Limits**, adjust the scaling and much more. In this example, no changes are needed. You might also need to expand the **Configuration** window to the right if you cannot see all the settings.



9. Click **Perform** to plot both variables on the selected axis, in this example, the *Y*-axis.



Two variables plotted on the Y-axis.

Merging Plots into One Diagram

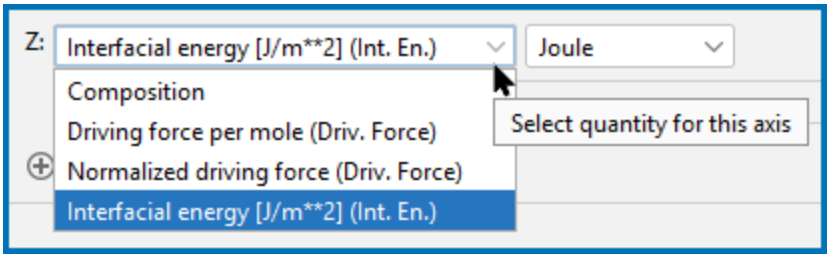
You can merge (or overlay) calculated results for several variables into one diagram. The same X and Y variables are used to compare the third variable (defined in the Plot Renderer as the *Z*-axis).

You cannot overlay heat map or frequency plots.

The following uses example PM_G_03: Driving Force and Interfacial Energy to describe the steps to overlay two plots: the driving force and interfacial energy results are combined into one diagram. The *X*- and *Y*-axis is the same for both (Mass percent Cr/Mass percent Mn).

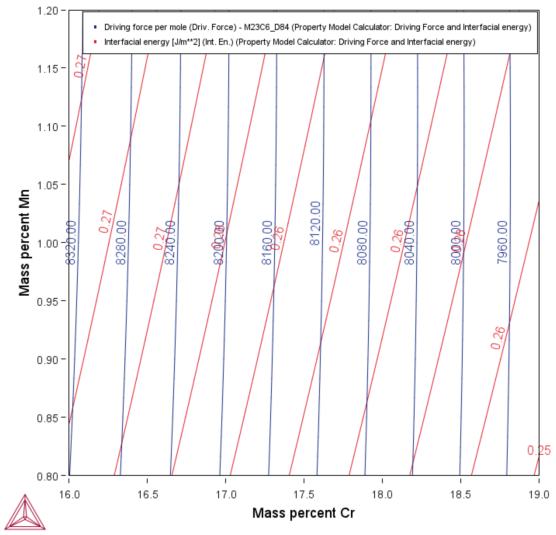
In the **Plot Renderer** settings window, click **Show more** and **Show less** to toggle between viewing all or some of the available settings.

1. In the **Project** window right-click the calculator node (e.g. Property Model Calculator) and add a **Plot Renderer** node from the **Create New Successor** menu.
2. Click the **Plot Renderer** node.
3. In the **Configuration** window, define the plot. Choose **On** for the *Legend option* and **Contour** as the *Plot type*.
4. Click the **Add an axis** button. A new axes settings section is added underneath.
5. For the *Z* axis, choose the variable. In this example, **Interfacial energy**. Select a unit or keep the default.



6. Click **Perform** to plot both on the same diagram.

   In this case, a contour plot showing both the driving force and interfacial energy calculation results comparing Mass percent Cr to Mass percent Mn.



Driving force per mole (Driv. Force) - M23C6_DB4 (Property Model Calculator: Driving Force and Interfacial energy)
Interfacial energy [J/m**2] (Int. En.) (Property Model Calculator: Driving Force and Interfacial energy)

Plot Renderer: Convert a Plot to a Table and Export the Data

For all calculation types and calculators, the associated Plot Renderer has a **Table View** button you can use to convert a plot to table data. Once the plot data is converted, you can toggle between displaying the plot or table in the **Visualizations** window as well as save the table and export to file.

For the Table Renderer only single equilibrium and property diagram (stepping) calculations are available.

Converting a Plot to a Table on the Plot Renderer

1. Set up the Plot Renderer for your particular calculation and click **Perform** to display the plot in the **Visualizations** window.
2. On the Plot Renderer **Configuration** window, click the **Table View** button (toggled ON).
3. Choose the **Decimal digits** and **Number format** (**Auto**, **Decimal**, or **Scientific**) to display in the table.
4. Click **Perform**. This converts the plot data to display table data in the **Visualizations** window.

Switching Between a Plot and a Table in the Visualizations Window

Once the plot data is converted, you can toggle between displaying the plot or table in the **Visualizations** window.

- To display the Table: On the Plot Renderer **Configuration** window, click the **Table View** button to toggle it ON and then click **Perform** to generate the table.
- To display the Plot: On the Plot Renderer **Configuration** window, click the **Table View**button to toggle it OFF and then click **Perform** to generate the plot.

Saving the Table (Exporting the Data)

Once the plot data is converted to a table, you can save/export this to file.

1. Convert the plot to a table (the **Table View** button is toggled ON).
2. Click **Save table** to export the table data.
3. In the **Save As** window navigate to where you want to save the table.
4. Enter a **File Name**.
5. From the **Files of Type** list choose **Text [*.txt]**(the default), **Hyper Text Markup [*.html]**, or **Excel [*.xls]**.
6. Click **Save**.

Saving and Printing the Output in Graphical Mode for more options.

Working with Common Phase Names

There is a **Common phase name** option available as a plotting functionality to provide flexibility and clarity for users.

CALPHAD Naming Conventions

The phase naming in Thermo-Calc stems from the use of CALPHAD, which is a proven methodology for predicting thermodynamic, kinetic, and other properties of multicomponent material systems. At Thermo-Calc Software, we use the CALPHAD methodology to develop our databases, which, when used together with our software, can predict the properties of multicomponent systems corresponding to real materials.

CALPHAD is originally an abbreviation for *CALculation of PHAse Diagrams*, but was later expanded to refer to *computer coupling of phase diagrams and thermochemistry*. More about the CALPHAD methodology, including some of its history, is available on the Thermo-Calc Software website.

Within the CALPHAD community there is a standard used where phases are named according to such things as:

- Structure (FCC, BCC, LAVES, M6C, etc.),
- Prototype (A1, B1, C14, etc.),
- Plus ordered phases are described as the disordered state (e.g. FCC_A1) with an ordered contribution (FCC_L12).

The Thermo-Calc software and databases have followed these conventions to enable consistent communication, compatibility, and clarity where necessary for research purposes, data sharing, and interoperability. However, these CALPHAD naming conventions, while standardized for developers and experts, can be confusing to many users—especially those unfamiliar with crystallography or CALPHAD modeling principles.

Availability

Common phase names are available when there is a common phase name file located in the data folders in a Thermo-Calc installation. It is applicable to Graphical Mode, Console Mode, and in TC-Python/TC-Toolbox for MATLAB®.

- Graphical Mode:
  - Use the **Legend style** setting for a **Plot Renderer**. Once plotted, common names also display in columns when you click the **Table View** button to convert a plot to a table. See About Legend Styles.
  - On the **Table Renderer** common phase names are displayed for single equilibrium calculations. See Table Renderer.
- Console Mode: Use the LIST_EQUILIBRIUM command in the POLY module or CHANGE_LEGEND in the POST module.
- TC-Python/TC-Toolbox for MATLAB®: Accessed with `set_phase_name_style()`, in the same way as other `PhaseNameStyles`. See the separate documentation.

Common Phase Name Files Included with the Installation

For selected databases and versions, there are common phase name files included with the Thermo-Calc installation data folders. When creating a custom file, there are also file naming conventions.

Databases with Common Phase Name Files

For 2026b the following databases include a common phase name file, which then is automatically referred to when plotting.

- Aluminum-based Alloys Database (TCAL8 and newer)
- Copper-based Alloys Database (TCCU7 and newer)
- High Entropy Alloys Database (TCHEA6 and newer)
- Magnesium-based Alloys Database (TCMG6 and newer)
- Metal Oxide Solutions Database (TCOX15 and newer)
- Nickel-based Superalloys Database (TCNI11 and newer)

- Steel and Fe-alloys Database (TCFE13 and newer)
- Titanium and TiAl-based Alloys Database (TCTI5 and newer)
- Ultra-high Temperature Materials Database (TCUHTM3 and newer)

File Installation Location

The location of the data folder where the files are installed is based on operating system. You can also determine the file path and location via the **Tools > Options > Database directory** field.

See the *Installation Guide* section Installation Default Directory: Databases, Database Checker, and TDB Editor. To view the current file path, see Global General Settings.

Create Your Own Common Phase Name File for Use in the Software

In addition to the ability to use common phase names set by us, you can now create your own list of phase names to use for existing and/or custom user databases. It is important to follow the syntax rules and file naming conventions as indicated.

You must remember to save a copy of any text file that contains custom user-defined phase names as these files are overwritten in future installations, i.e. you will need to copy this to the relevant data folder each time a new version of Thermo-Calc is installed.

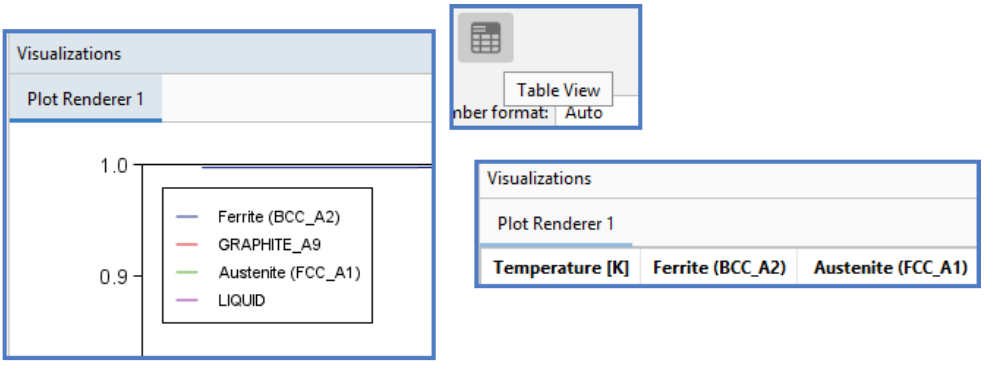
TCFE15_common_phase_names.txt

```
FCC_A1{
Austenite: y(FCC_A1,VA#2)>0.9
MC Carbide: y(FCC_A1,VA#2)<0.9 && y(fcc_a1,C#2)+y(fcc_A1,Va#2)>0.95
MN Nitride: y(FCC_A1,VA#2)<0.9 && Y(fcc_a1,N#2)+y(fcc_A1,Va#2)>0.95
MB Boride: y(FCC_A1,VA#2)<0.9 && Y(fcc_a1,B#2)+y(fcc_A1,Va#2)>0.95
MH Hydride: y(FCC_A1,VA#2)<0.9 && Y(fcc_a1,H#2)+y(fcc_A1,Va#2)>0.95
M(C,N) CarboNitride: y(FCC_A1,VA#2) < 0.9 && y(fcc_a1,C#2)+y(fcc_A1,Va#2)+Y(fcc_a1,N#2)>.95
}

BCC_A2{
Ferrite: y(BCC_A2,FE#1)>.5
Cr BCC: y(BCC_A2,Cr#1)>.95
Cu BCC: y(BCC_A2,Cu#1)>.95
Mo BCC: y(BCC_A2,Mo#1)>.95
BCC:
}

BCC_B2{
Ordered Ferrite [B2]:
}
```

Example of a file defining some common phase names. Here it shows the syntax for the steel database that displays Austenite for FCC_A1 and Ferrite for BCC_A2.



An example of common phase names used in a plot and when the Table View button converts it to a table, the headings of columns include the common phase name, i.e. Ferrite (BCC_A2) and Austenite (FCC_A1), as included in the text file saved in the data folder.

Rule Syntax for Creating a Custom Common Phase Name File

Refer to an existing file to help guide you.

- A block begins with the database phase name with curly brackets opening on the same line and closing after all common names for that phase are given, closing bracket on separate line.
- Common phase names are given each on their own line followed by a colon (`:`) and the condition(s) e.g.: `CaO: y(HALITE,CA+2#1)>0.5`.

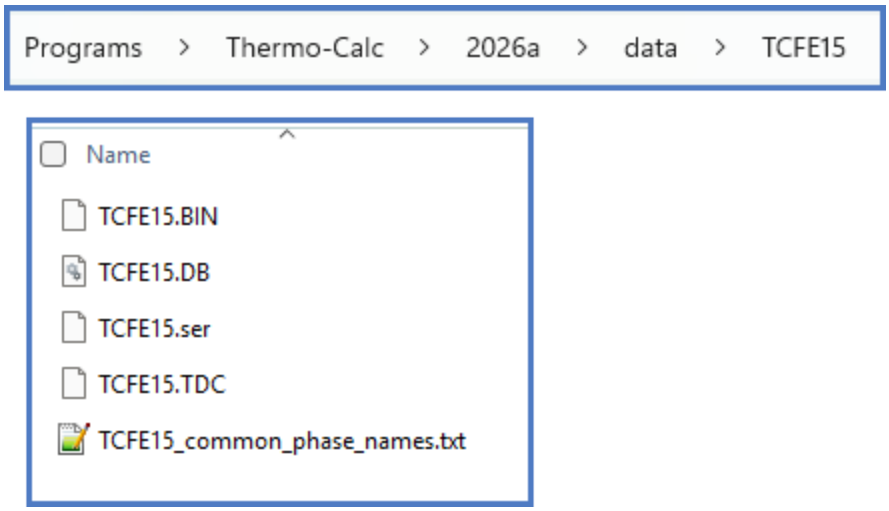
- Accepted conditions are:
  - `ORDERED` and `DISORDERED`.
  - Comparison conditions for temperature, y-fraction.
  - Empty conditions are accepted.
- The physical quantities should follow Console Mode syntax e.g.: `y(HALITE,CA+2#1)`.
- The physical quantities can be compared by `<` and `>`.
- Several conditions can be required to hold simultaneously, use `&&` to denote *and* e.g.: `FCC [A1]: y(FCC_L12,VA#3)>0.9 && DISORDERED`.
- A common name can also have alternative conditions where if any of the condition is true the common name is selected, use `||` to denote *or*.
- A condition can be for a sum of two or more quantities (i.e. y-fraction), but not mixing of different quantities in the sum. In this case use the plus sign (`+`) and write out all quantities.
- If the condition for several common names can be true at the same time, order them by priority so that highest priority is listed first.
- Empty lines are OK in the file to make it easier to read.
- For letters, do not use non-ASCII characters such as ÅÄÖ. It is recommended to use only letters in the English alphabet. Aside from letters, the common phase names can use any basic ASCII characters except the ones already used in the files for specific purpose i.e. curly brackets `{}` and the colon `:`.

File Naming Convention

When creating your own common phase name file to use in the software, it needs to be named as follows and saved in the same database directory as it is applicable to.

The basic naming is `<database_version>_common_phase_names.txt`.

If you create your own file for an existing Thermo-Calc database, then the version number of the database must be included AND it must be in the folder of the same name, i.e. `TCFE15_common_phase_names.txt` is saved in the folder of the same name, `TCFE15`.



An example in Windows of where the file is stored and how it is named. The file path varies based on operating system.

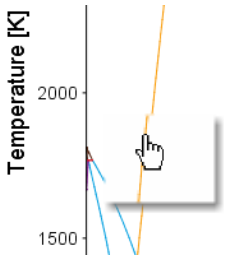
Changing the Plot Properties

To make local changes to the appearance of a specific plot, in the **Visualizations** window right-click a plot and select **Properties**. This topic includes details about features that are unique to the local plot properties options.

Edit Individual Plot Lines

You can also edit some properties for individual plot lines (the color, the line width and type, and whether data points are included).

In the **Visualizations** window, hover the mouse over a plot line. When it is over a line that can be clicked the crosshair cursor turns into a pointing finger. Click the line and then you can make changes for that specific line.



To prevent unintended edits, hold down <Ctrl> while moving the cursor around the plot to only display it as a crosshair.

Color Switching Plots Between Light and Dark Mode

Depending on whether you are using a **Light** or **Dark** look and feel for the user interface (see Global General Settings), you can also switch the default colors (lines, background, and more) of a plot using this local **Plot Properties** option. Alternatively, to set the global defaults for future project files (and plots), see Global Plot Settings: Design the Look and Feel.

Use the **Color switching** option to override the look and feel settings that may not be optimal. For example, when preparing a plot for publication, the **Dark** mode plot or line colors may not work well or do not follow a journal's guidelines. In other words, you can view and export the plot with **Light** mode color settings even though the interface is using Dark mode, and vice versa.

How to Use the Color Switching for Local Plots

Perform your calculation. Right-click in the **Visualizations** window and select **Plot Properties**. Select a **Color switching** option:

- **Switch automatically between Light mode and Dark mode**: The default, which matches the current look and feel for the GUI.
- **Always use Light mode colors**: If you are in **Dark** mode, this immediately switches the plot to **Light** default color settings.
- **Always use Dark mode colors**: If you are in **Light** mode, this immediately switches the plot to **Dark** default color settings.

Tie lines and invariant lines are the same color for both Light and Dark modes, i.e. these colors do not change.

Additional Plot Color Changes are Locked to the Original Mode

When applying any of these settings, you can make further changes to the colors for the local plot but the change is locked to the mode. For example, you are in **Dark** mode and you change the plot background color to yellow. Then you switch to a **Light** look and feel mode. The background color for that plot is the default white background that is set for Light mode. Then if you change the background to blue, but now switch to a **Dark** look and feel, the background is yellow as this is the color applied in Dark mode to this particular plot. If you switch back to Light mode then the plot background is blue again.

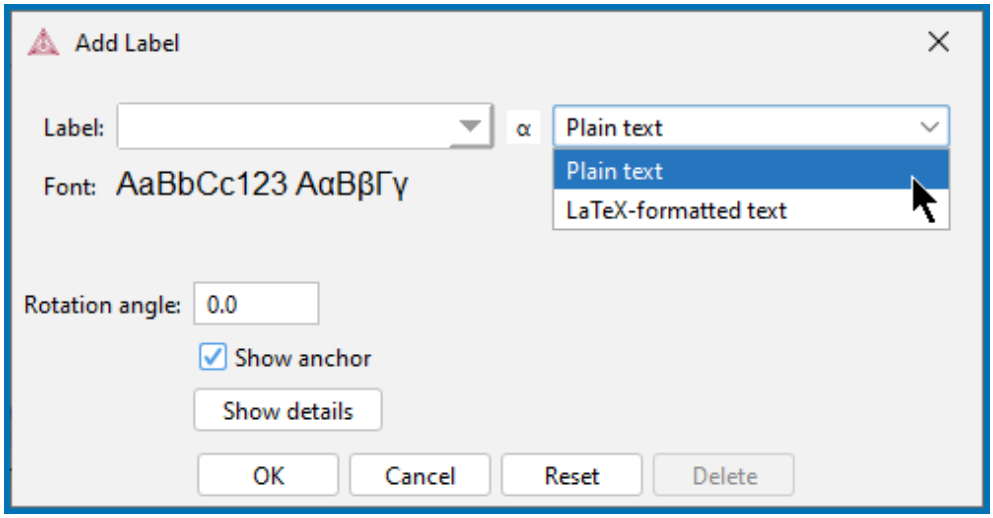
Global Settings

The available settings described in this topic are the same as what you can globally set under the **Tools** → **Options** menus but as described these are only applied to the specific plot.

To make global plot setting default changes, see the details in Global Settings: Graphical and Console Mode Plotting.

Plot Labels

To add a label text at a certain point in a plot, right-click the point, and select **Add Label**. For phase diagrams, the program suggests a label that you can keep or edit. The suggested label specifies the names of the stable phases at the coordinate where you clicked. For all other plot types, you enter your own text, which can either be Plain text or LaTeX formatted text.

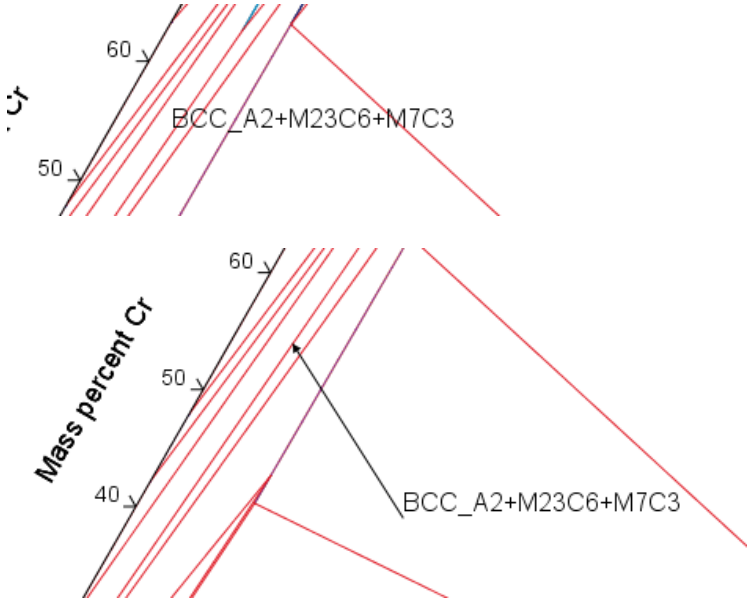


You can enter the label as **Plain text** or in **LaTeX-formatted text**. For **LaTeX-formatted text** enter or edit the text as required. For example, underscores (_) are added before the numbers to make subscripts in the label.

By default when using the LaTeX command, you are in math mode and Thermo-Calc automatically interprets the entered text as math. The above link uses the dollar sign ($) in all the examples but this is NOT required. For example, if you enter `$E=mc^2$` this is displayed including the $ instead of the equation.

Moving Plot Labels

Drag and drop labels anywhere on the plot. The anchor arrow points to the point of origin.

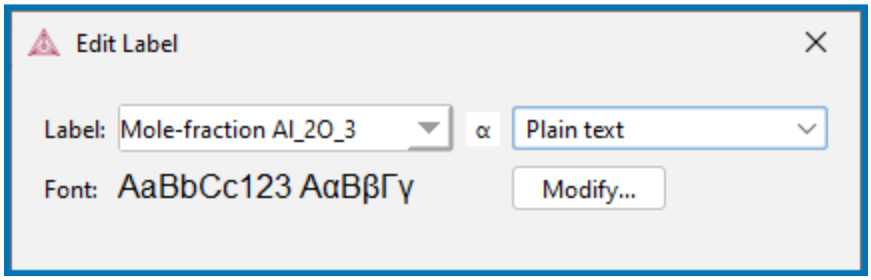


Close up of a plot label before being moved (top) and after being moved (bottom). The arrow in the lower image points to the label's original location on the plot.

Plot Labels: Entering a Mixture of Plain Text and Equations

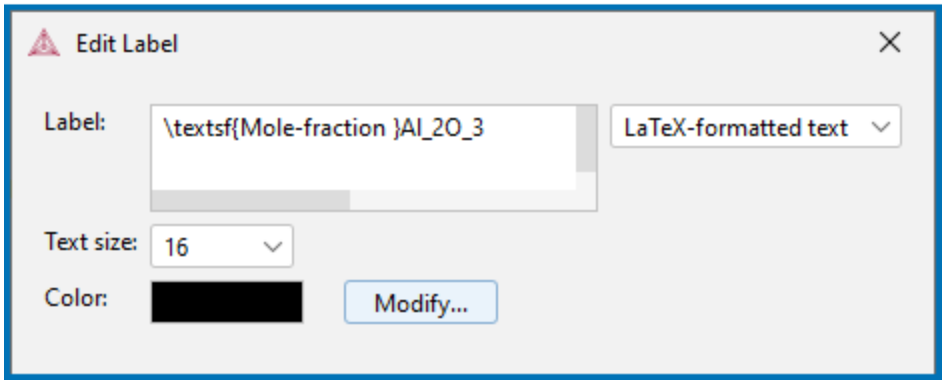
When you enter text using LaTeX formatted text it displays the text as an equation.

When using the **Plain text** format, the label does not display correctly because the label is a mixture of text (**Mole-Fraction**) and an equation needing subscripts (**Al_2O_3**).



To add a mixture of plain text and equation formatted text, exit math mode by using the string `\textsf` followed by the text to display enclosed in curly brackets `{}`.

For example `\textsf{Mole-fraction }Al_2O_3` results in this label. In this example, you need to add a space at the end of fraction in order to separate the text from the equation part of the label. You can also choose a color to apply to the label text.



When working in Console Mode, you can also use the above windows on the Console Results window to add and edit labels. In addition, you can use the command.

It is possible to change the text style used in LaTeX labels, either for a section of the text or for the whole text (unless something else is specified).

Section of Text Within Curly Brackets	*All Text After the Command*	*Resulting Text Style*
`\textsf{}`	`\sf`	Sans serif (default)
`\textrm{}`	`\rm`	Roman
`\textbf{}`	`\bf`	Bold
`\textit{}`	`\it`	Italic
`\textem{}`	`\em`	Emphasis
`\texttt{}`	`\tt`	Monospace

Plot Labels: Rotation Angle and Show Anchor

By default the **Show anchor** checkbox is selected, which includes an arrow from the label point to the coordinates.

If you do not want the label oriented horizontally in the Plot Renderer tab, then specify the number of degrees of rotation in the **Rotation angle** field.

Click **OK** to add the label to the plot. You can also move a label by clicking and dragging it. The default anchor arrow is added to indicate the point that belongs to the label.

About Legend Styles

There are a variety of legend styles you can use to display detail about the phases. The legend styles are available for both Graphical Mode and Console Mode plots.

For Console Mode, use the command . Also see LIST_EQUILIBRIUM.

In Graphical Mode the label styles are defined when using the Plot Renderer. You can select a **Legend style** for the **Stable phases** or **Axis quantity** selected for *Legend option*.

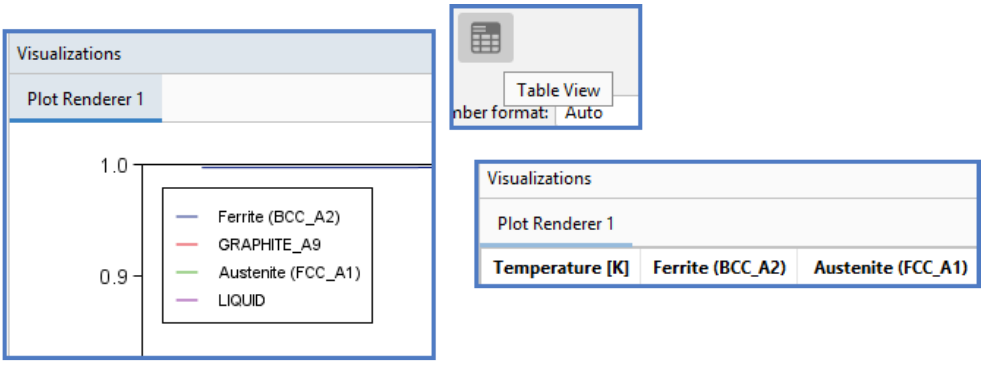
When there is a legend in the diagram you can append constitution and/or ordering descriptions to the phase name. For an example, see Legend and Label Styles. Choosing **All** in either Graphical Mode or Console Mode includes all the labels.

Common Phase Names

See Working with Common Phase Names to understand about availability by database and version as well as how to add your own common phase name files.

The option **Common phase name** (Graphical Mode), or COMMON (Console Mode), is selected by default. This includes a common phase name when a database has a file associated to it and located in the data folders in a Thermo-Calc installation. Choose **None** if you want to use the classic phase naming conventions. For example, in the steel database (TCFE), there is a phase name in the database called **BCC_A2** that is more commonly known as **Ferrite**. You can then include both names on the legend, **Ferrite (BCC_A2)**.

Once plotted, common names also display in columns when you click the **Table View** button to convert a plot to a table.



Constitution / Constituent Description

If **Constituent description** (Graphical Mode) or CONSTITUTION (Console Mode) is included in the legend, then for each equilibria along a line in the diagram, the largest constituent fractions are summed until they are equal or greater than 0.6. This is done separately for each sublattice. If the equilibria along the line gets different sets of constituents these are all appended to the list for that sublattice.

Ordering Description

The **Ordering description** (Graphical Mode) or ORDERING (Console Mode) is only printed for partitioned phases (phases that have a disordered contribution) that begins with at least two identical sublattices (sublattices where the set of constituents are identical). `DISORD` (disordered) is shown if site fractions are identical between identical constituents on all identical sub lattices (with an error margin) otherwise `ORD` (ordered) is shown in the legend.

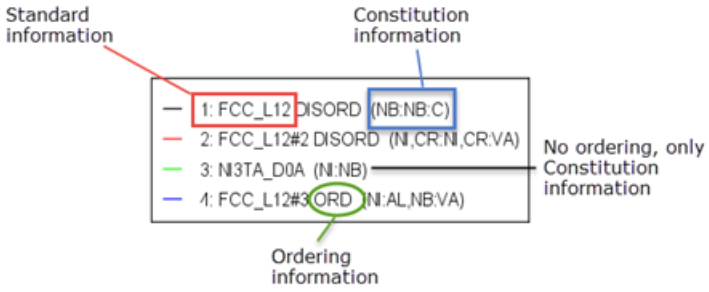
If ordering between equilibria in a line are different, then `ORD + DISORD` is shown in the legend.

Legend and Label Styles

This topic describes the variety of legend and label styles you can apply to plots such as common phase names for some databases, or ordering and constitution (constituent) descriptions.

Legend Styles

When **All** is selected for this specific example the label includes the following:



Specifically:

- There are two disordered FCC phases (matrix and carbide), one ordered FCC (gamma prime), plus a phase NI3TA_D0A (called Delta in Ni-alloys).
- **Ordering description**/ORDERING shows the different FCC phases.
- **Constitution description**/CONSTITUTION shows that FCC_L12#1 is NbC, FCC_L12#2 is matrix with Ni and Cr as major constituent, FCC_L12#3 is Ni3Al with Nb addition and NI3TA_D0A is Nb-rich (eg. Ni3Nb).
- When there is a **Common phase name**/COMMON, it is also included. See About Legend Styles and Working with Common Phase Names for details.

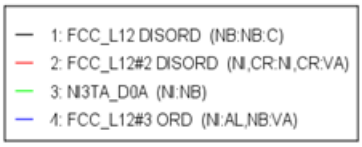
Label Styles

These examples are for each label style choice - **All**, **None**, **Common phase name**, **Constitution**, or **Ordering**. The instructions are for when you are setting the options using the Plot Renderer.

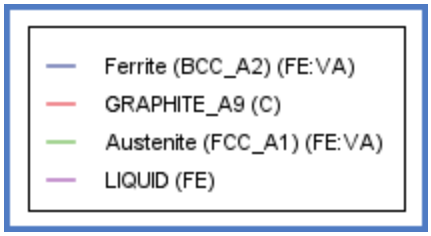
In Console Mode, you choose the options (`ALL`, `NONE`, `COMMON`, `CONSTITUTION`, or `ORDERING`) after the command CHANGE_LEGEND.

All

When you select **All** the **Constitution description** and the **Ordering description** (when there is ordering) are included. When there is a **Common phase name**, it is also included as shown in the next example.

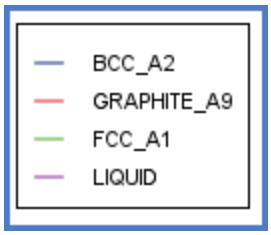


This simple label example is taken from T_02 using a licensed version of the steel database (TCFE) and shows all the available labels for that including **Common phase name** e.g. in the TCFE database, **Ferrite** and **Austenite** are the common phase names for the **BCC_A2** and **FCC_A1** phases, respectively. This simple label example is taken from T_02 using a licensed version of the database.



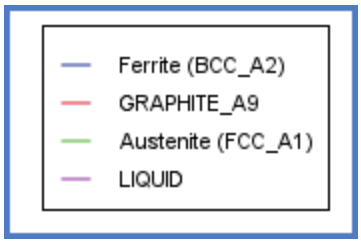
None

When **None** is selected the legend includes the standard information about the phases, which is the database phase name. This simple label example is taken from T_02 using a licensed version of the steel database (TCFE).



Common Phase Name

When you select **Common phase name** (Graphical Mode) or COMMON (Console Mode), and when it is available for the database, then the legend includes this common name e.g. in the TCFE database, **Ferrite** and **Austenite** are the common phase names for the **BCC_A2** and **FCC_A1** phases, respectively. This simple label example is taken from T_02 using a licensed version of the database.

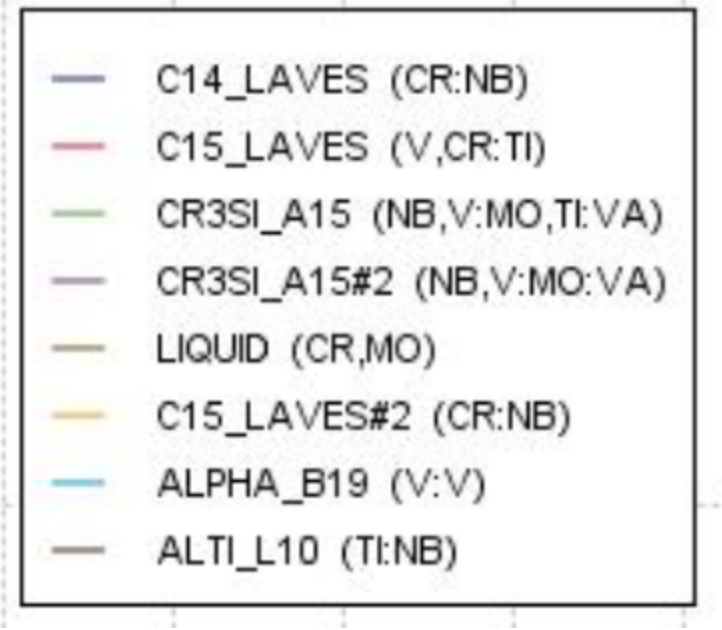


Constitution/Constituent Description

When you select **Constituent description** (Graphical Mode) or CONSTITUTION (Console Mode), this is added to the standard description.

Here is an example with a brief explanation of what you might see when choosing this option.

Only major constituents are listed.

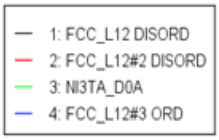


First there is the phase name then (NB, V : MO, Ti : VA) meaning the first sub-lattice contains mostly NB and V. The second sub-lattice contains mostly Mo and TI, the third sub-lattice contains mostly VA= Vacancy= No atom/molecule at all.

Mostly means Thermo-Calc sums the largest site fractions in a sub-lattice until it reaches 0.6. E.g. If sorted values are FE=0.5, AL=0.15, CR=0.15, NI=0.09 + smaller values then you will get " (Fe,AL,CR)" because FE+AL > 0.6 and then CR because it has same size as AL.

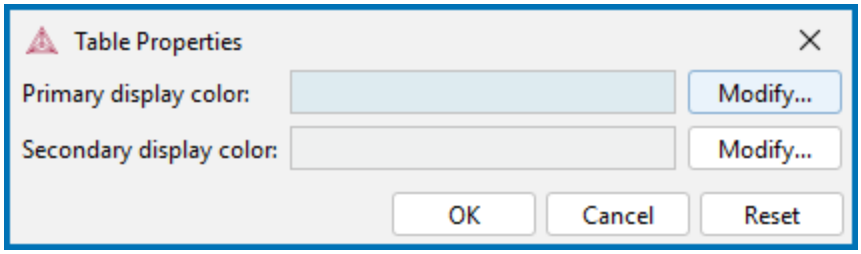
Ordering Description

When you select **Ordering description** (Graphical Mode) or ORDERING (Console Mode) and when there is ordering, this is added to the standard description.



Setting Background Colours

To change the background colours of the table, in the **Visualizations** window right-click a **Table Renderer** tab, and select **Properties**. Modify as required.



Global Settings

The defaults for these settings can be changed globally from the **Options** window.

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **Tabulation** node in the tree.

Thermo-Calc Graphical Mode Examples

There are examples available throughout the content, on the website, and included with your installation. This section contains summaries of the Graphical Mode examples that are included in the base Thermo-Calc installation.

T_01: Calculating a Single-Point Equilibrium

This example shows the result from a single-point equilibrium calculation in the Fe-C system. It demonstrates the use of the **Equilibrium Calculator** and generates a **Table Renderer** in the **Visualizations** window. The number of equilibrium conditions is C+2 where C is the number of components, meaning that four conditions are needed in this example:

- **Temperature** is 1000 K
- **Pressure** is 100000 Pa
- **System size** is 1 mole
- **Mass percent carbon** is 0.1%

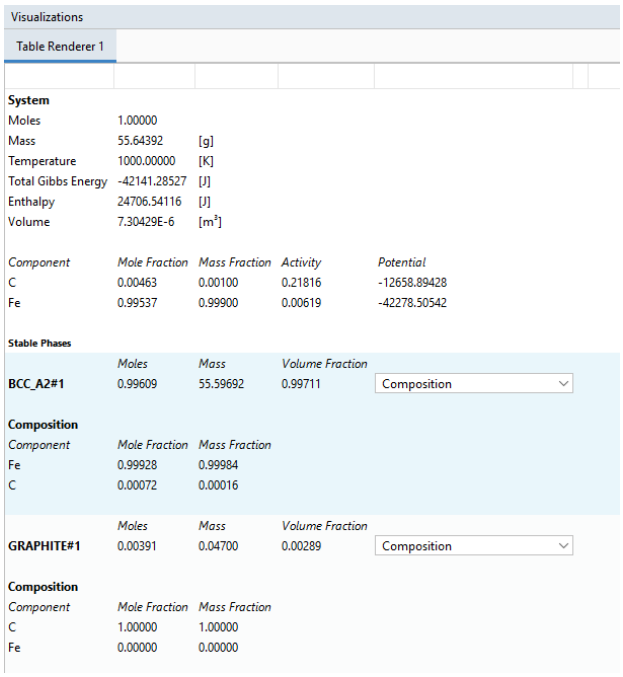
Project File Information

- Folder: **Thermo-Calc**
- File name: *T_01_Single-point_equilibrium.tcu*

Table Results

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.



Visualizations

Figure 1: The displayed results of the calculation show that the BCC_A2 (ferrite) and GRAPHITE phases are stable for this set of equilibrium conditions.

T_02: Stepping in Temperature in the Fe-C System

This example shows how the fractions of stable phases vary for an Fe-0.1 mass-% C alloy when the temperature is varied between 500 and 2000 K. It demonstrates the use of the **Equilibrium Calculator**. To allow temperature to vary, the corresponding **Axis Definition** checkbox is selected.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_02_Step_in_temperature_in_Fe-C.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

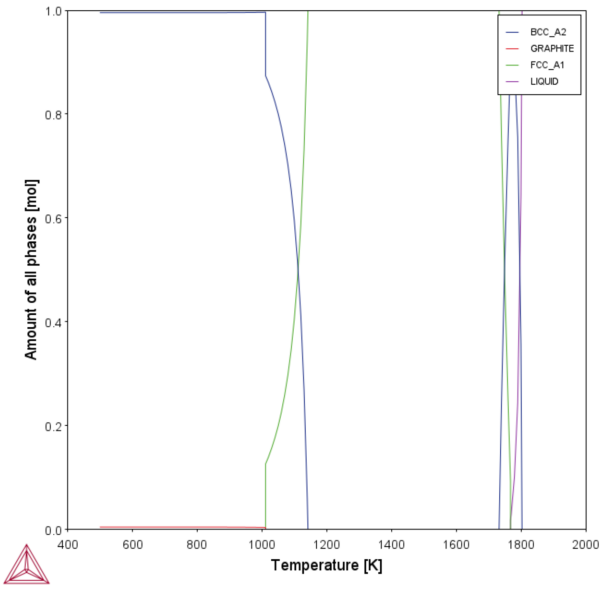

Figure 2: In this example, results are displayed graphically using a Plot Renderer activity.

For the Plot Renderer, there is an option to use the **Table View** button to convert plots to table data for all calculation types and calculators. See Plot Renderer: Convert a Plot to a Table and Export the Data.

If you want, you can also use a Table Renderer to generate text results instead, as shown in this example after adding a Table Renderer to the Equilibrium Calculator and clicking **Perform**.

Results

Plot Renderer 1 | Table Renderer 1

Temperature [K]	Volume fraction of BCC_A2	Volume fraction of FCC_A1	Volume fraction of GRAPHITE	Volume fraction of LIQUID
1000.00000	0.99711		0.00289	
1010.00000	0.99718		0.00282

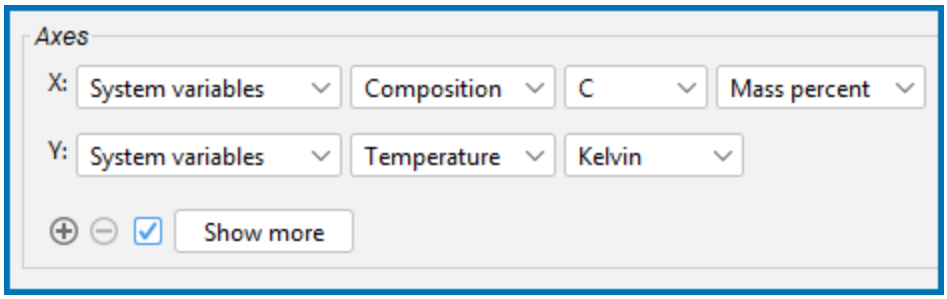
1050.00000	0.80486	0.19514		

T_03: Fe-C Phase Diagrams

This example shows the stable Fe-C phase diagram (stable meaning that the graphite phase is entered in the calculation). The same diagram is calculated using the **Binary Calculator** activity and then using a **System Definer and Equilibrium Calculator**.

In both cases, a **Plot Renderer** is used to display results. The purpose of the **Binary Calculator** is to simplify common calculations for binary systems. In the **Equilibrium Calculator** two *Axes* are defined on the **Plot Renderer**. An axis variable must be an equilibrium condition.



In the **Plot Renderer** settings window, click **Show more** and **Show less** to toggle between viewing all or some of the available settings.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_03_Fe-C_phase_diagram.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects,

you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

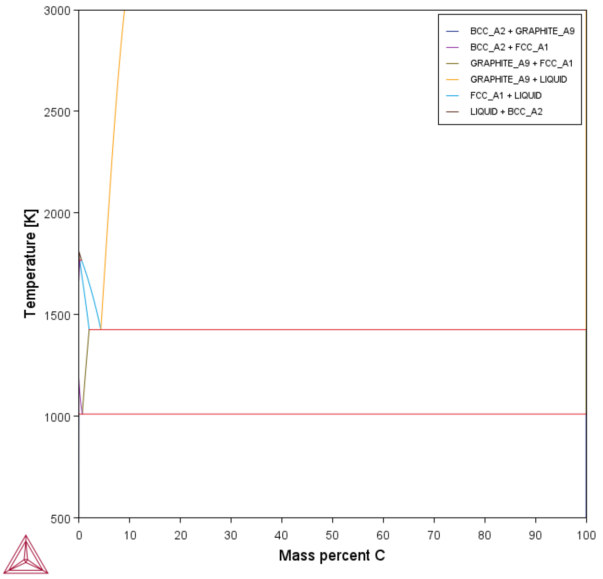


Figure 3: The plot result of the System Definer and Equilibrium Calculator.

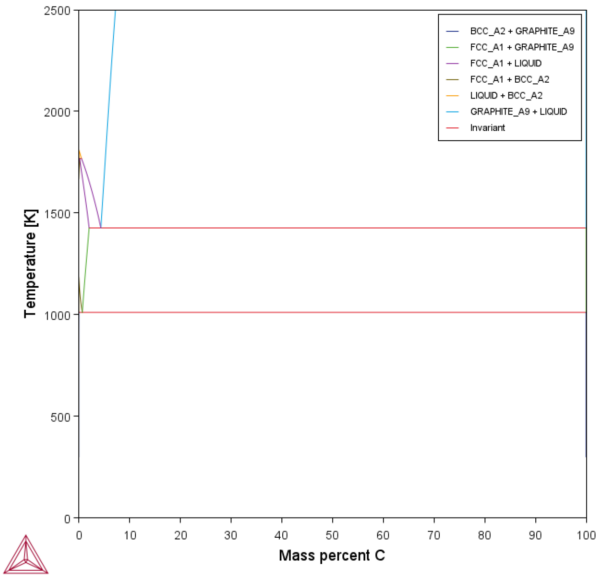

Figure 4: The plot result of the Binary Calculator simulation.

T_04: Fe-Cr-C Ternary Phase Diagram at 1000 K

This example shows a ternary phase diagram in the Fe-Cr-C system at 1000 K. Similar to example T_03: Fe-C Phase Diagrams, the same diagram is calculated using a **Ternary Calculator** and then using a **System Definer and Equilibrium Calculator**. Two **Plot Renderer** activities are added to create two plots.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_04_Fe-Cr-C_ternary_phase_diagram.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

In the **Plot Renderer** settings window, click **Show more** and **Show less** to toggle between viewing all or some of the available settings.

Try practicing with two features on the **Plot Renderer Configuration** window.

- To toggle between a triangular and a rectangular diagram, click the **Toggle Triangular/Regular Diagram** button then click **Perform** to see what happens.
- To toggle the X and Y axis variables, click the **Switch Axes** button and then click **Perform**.

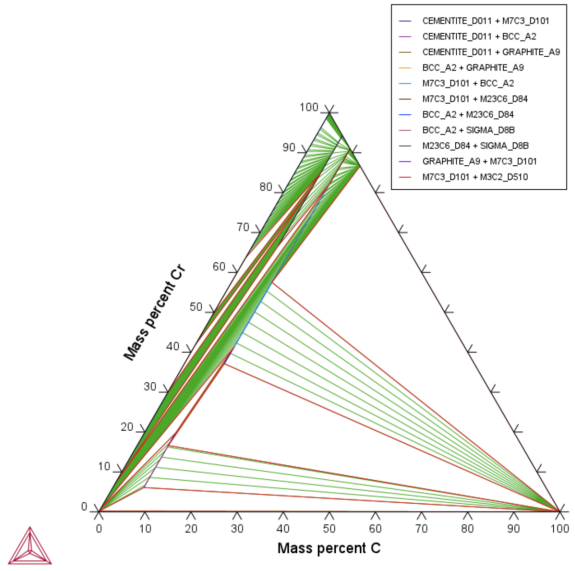

Figure 5: Ternary Calculator.

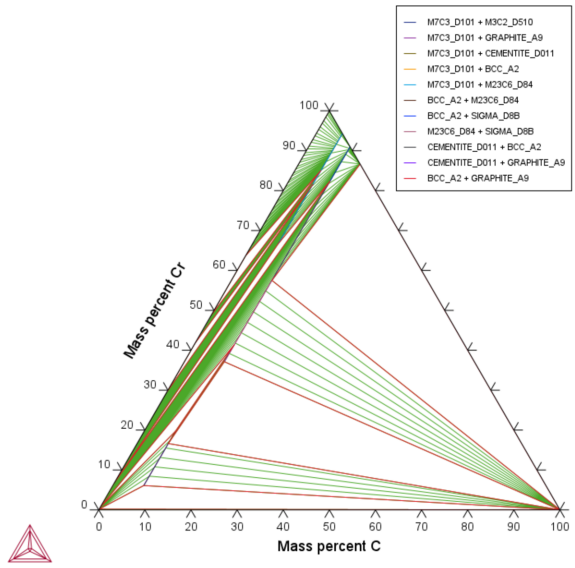

Figure 6: Equilibrium Calculator.

T_05: Stable and the Metastable Fe-C Phase Diagrams

This example shows how to overlay results from two calculations in the same plot using the **Equilibrium Calculator**.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_05_Fe-C_stable_and_metastable_phase_diagram.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

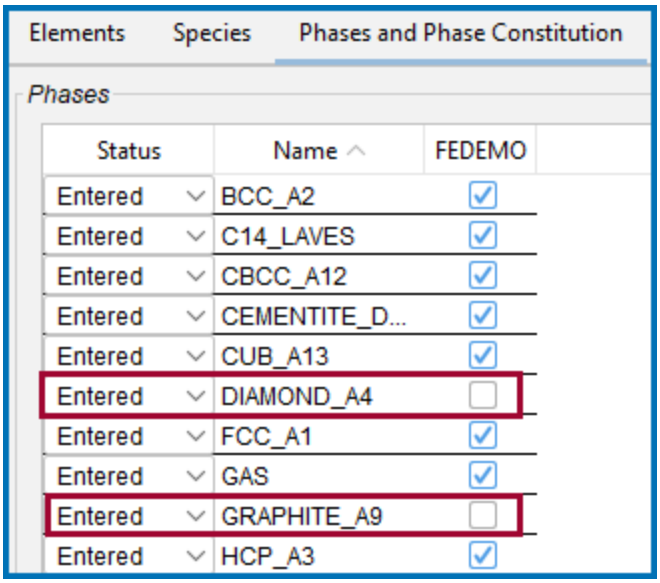
Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

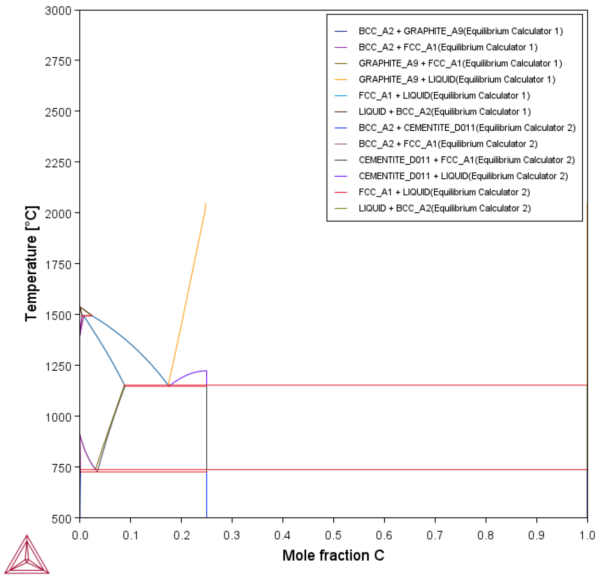
Plotting Several Calculations in One Diagram

1. The **Plot Renderer** activity is first created as a successor to Equilibrium Calculator 1.
2. Then right-click the **Plot Renderer** node and select **Add predecessor** and the results from both equilibrium calculators are in the same plot. In **Equilibrium Calculator 1** the stable phase diagram is calculated and in **Equilibrium Calculator 2** the metastable phase.

3. The metastable diagram is obtained by deselecting checkboxes for the GRAPHITE_A9 and DIAMOND_A4 phases on the **Metastable Phases** node (System Definer 2) → **Phases and Phase Constitution** tab.

To make it easier to work with your project, right-click any node and select **Rename**. In this example, System Definer 1 is renamed to **Stable System** and System Definer 2 is renamed to **Metastable System**.





T_06: Serially Coupled Equilibrium Calculators

Sometimes there are multiple solutions for a given set of equilibrium conditions. In other cases the equilibrium calculation does not converge. You can then aid the final calculation by, in effect, telling the software where it should start the search for the equilibrium.

This example shows how to serially couple two **Equilibrium Calculator** nodes together for more complex equilibrium conditions. For each calculation, the output is to a **Table Renderer**.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_06_Serial_equilibrium_calculators.tcu*

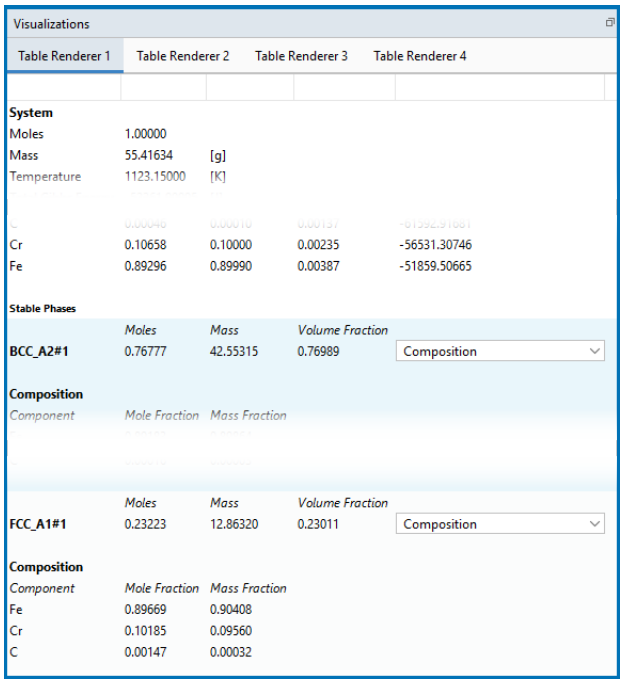
Table Renderer Results

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

Equilibrium Calculator 1

In the first example, the objective is to calculate the equilibrium at 850° C where the mole fractions of the FCC A1 and BCC A2 phases are 0.5 each for an Fe-Cr-C steel with 10% chromium. In Equilibrium Calculator 1 a simple set of equilibrium conditions (temperature, pressure, system size and composition) are used to find a carbon content where only the FCC A1 and BCC A2 phases are stable. The results from this preliminary calculation are displayed in Table Renderer 1. Open the example to see the full table.



Equilibrium Calculator 2, 3, and 4

- In Equilibrium Calculator 2 the carbon content equilibrium condition is replaced by the condition that the numbers of moles of the BCC A2 phase should be 0.5. The final result is displayed in Table Renderer 2. In this case, the final objective is to calculate the solidus temperature of an Fe-Cr-C steel with 10% Cr and 0.01% C.
- In Equilibrium Calculator 3 the state at 2000 K is calculated and the result is displayed in Table Renderer 3.
- In Equilibrium Calculator 4 the temperature equilibrium condition is replaced by the condition *Fix phase / liquid / 0.0*, meaning that liquid should be stable in an amount of zero moles, i.e. the solidus temperature. The final result is displayed in Table Renderer 4.

T_07: User-Defined Functions

This example shows how to implement user-defined functions. A series of equilibria for an Fe-Cr-C alloy are calculated by varying temperature between 500 and 3000 K. In the configuration window of the **Equilibrium Calculator** under the **Functions** tab, two identically meaning functions are defined, *fraction solid* and *f solid*, the values of which are plotted against temperature in two **Plot Renderer** activities. Functions can be entered in terms of *QuantitiesQ1*, *Q2*, *Q3* and so forth, or by using the Thermo-Calc syntax.

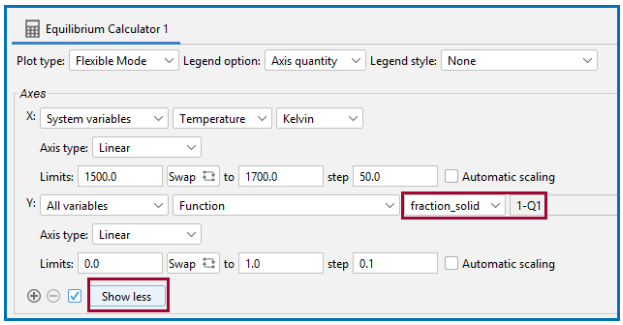
Project File Information

- Folder: **Thermo-Calc**
- File name: *T_07_User_defined_functions.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.



In the **Plot Renderer** settings window, click **Show more** and **Show less** to toggle between viewing all or some of the available settings.

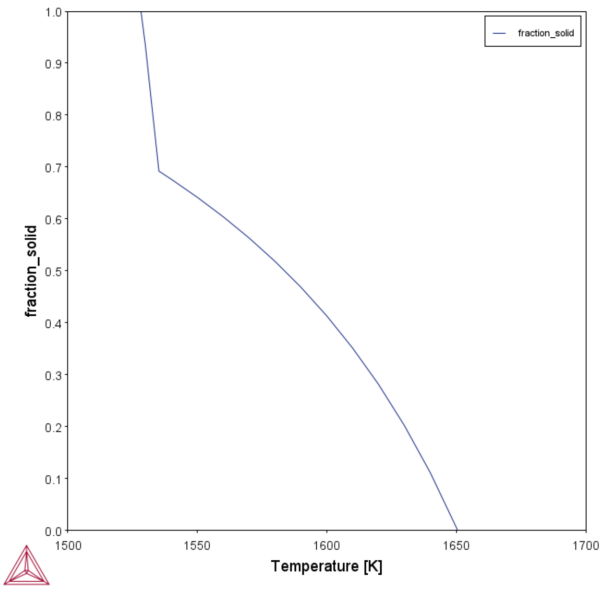


Figure 7: The result of the fraction_solid function.

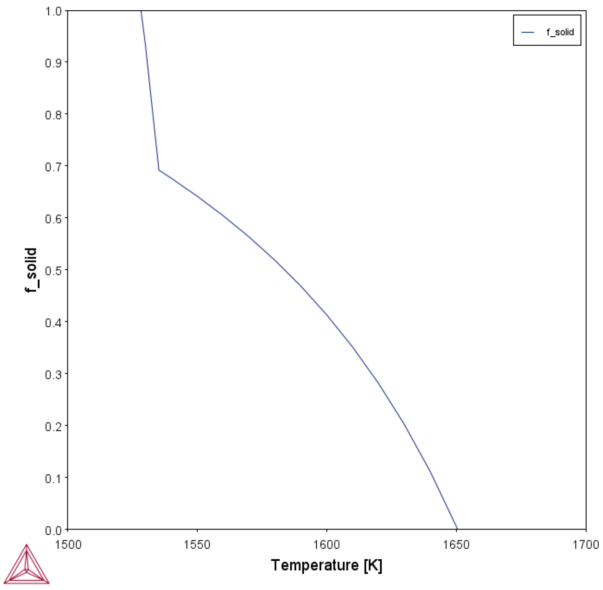

Figure 8: The result of the f_solid function.

T_08: Scheil and Equilibrium Solidification

This example shows a comparison for an Al-Si alloy solidified under full local equilibrium and under the Scheil assumptions, i.e. zero diffusion in the solidified material and infinitely fast diffusion in the liquid. The example uses the **Scheil Calculator** and adds a Plot Renderer and a Table Renderer.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_08_Scheil_and_equilibrium_solidification.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Scheil Solidification Simulations playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

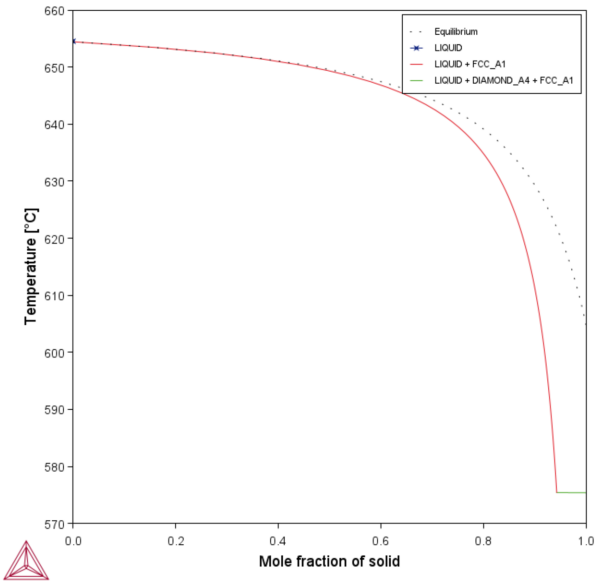

Figure 9: The plot compares the mole fraction of a solid vs temperature.

Visualizations

Plot Renderer 1 | Table Renderer 1

Mole fraction of solid	Temperature [°C]
1.00000E-30	654.52000
1.00000E-30	654.52000
1.00000E-30	654.52000
0.00105	654.42400
0.16114	653.42400
0.27839	652.42400

Figure 10: The table provides the data, which you can also export.

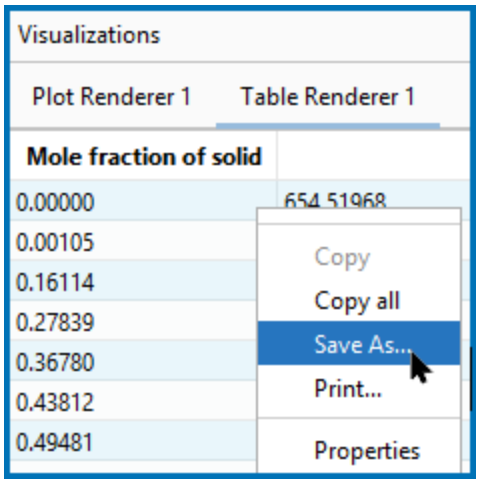
Saving the Table (via Table Renderer)

There are different ways to save the table from the Table Renderer **Visualizations** or **Configuration** windows.

For the Plot Renderer, there is an option to use the **Table View** button to convert plots to table data for all calculation types and calculators. See Plot Renderer: Convert a Plot to a Table and Export the Data.

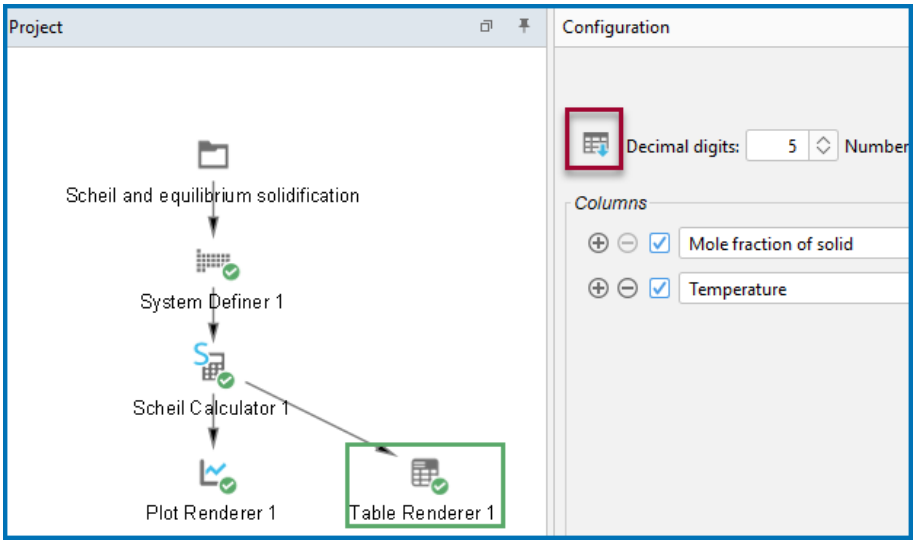
Method 1

In the **Visualizations** window, right click the table and select **Save As...**



Method 2

1. In the **Project** window, click the **Table Renderer**.
2. In the **Configuration** window, click the **Save table** button .



T_09: Carbide Driving Force Heat Map

This is an example of using **Grid** calculations to plot the driving force for a carbide as a function of two composition variables. With the **Grid** *Calculation Type*, a 2D grid is generated from the two calculation axes. After the calculation is done, an equilibrium is calculated in each grid point. A **Plot Renderer** connected to a grid calculation plots the *Z*-axis property for each equilibrium as a function of the two calculation axes. You can choose different *Plot types* such as **Heat map**, **Contour**, and **3D** to display the results.

In the **Plot Renderer** settings window, click **Show more** and **Show less** to toggle between viewing all or some of the available settings.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_09_Heat_map_of_carbide_driving_force.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

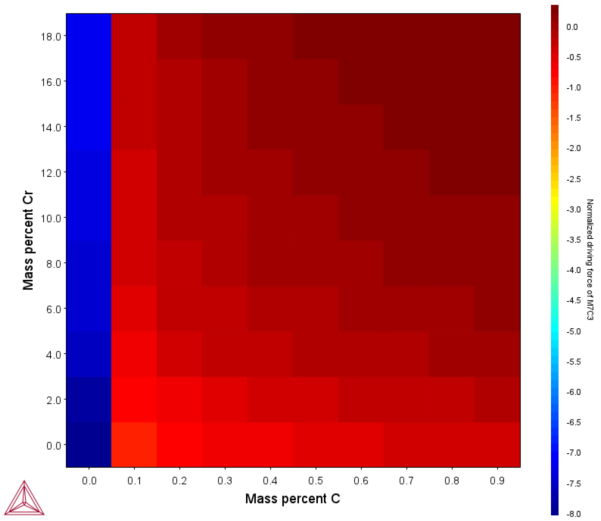


Figure 11: The results are plotted as a Heat map. Alternatively, a Contour Plot type can be selected on the Plot Renderer.

T_10: Scheil Solidification with Back Diffusion

This is an example of a Scheil solidification simulation of a Al-2.1Cu-1Si alloy including back diffusion in the primary phase.

The example uses two of the Scheil Calculator activity nodes with different cooling rates, 10 K/s and 0.005 K/s. The lower cooling rate produces a solidification curve that is closer to the equilibrium curve as shown in the plot result. Both a thermodynamic ALDEMO (aluminum demo) and mobility MALDEMO (Al-alloys mobility) database are used for this calculation.

See Scheil Calculator for an overview of the different Scheil simulation models available.

Project File and License Information

- Folder: **Thermo-Calc**
- File name: *T_10_Scheil_with_back_diffusion.tcu*

The Scheil with back diffusion feature is only available for systems with diffusion data, i.e. this model requires the use of a mobility database.

Running the example itself does not require an additional license.

Visualizations

This example is included as a tutorial on our website and as part of the Scheil Solidification Simulations playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

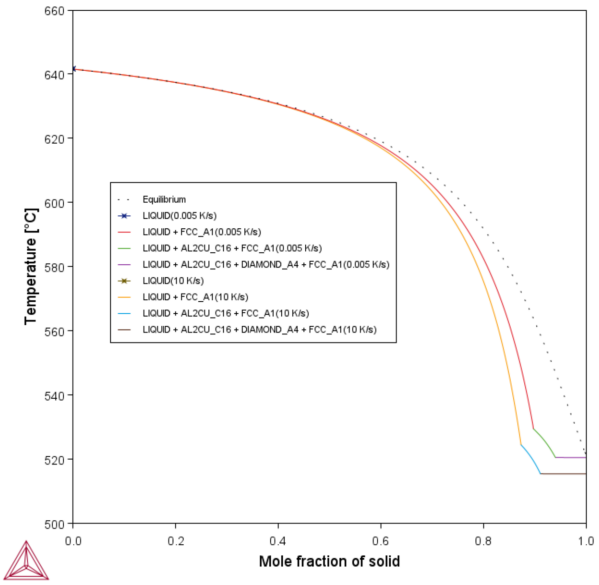

Figure 12: Scheil solidification. The lower cooling rate produces a solidification curve that is closer to the equilibrium curve.

T_11: Surface Tension in Cu-Zr

This is an example of including surface tension in the calculations.

Using the CUDEMO database, which is the free demonstration version of the TCS Cu-based Alloys Database (TCCU), the surface tension of liquid metallic is plotted at 1373 K for Cu-Zr and compared to experimental data from [2005Kra].

T_13: Scheil Solidification with Solute Trapping

In Graphical Mode, you use the **Scheil Calculator** to set up the various Scheil solidification simulations outlined in more detail in Scheil-Gulliver Solidification Calculations.

For background theory see About Scheil with Solute Trapping.

This example shows the use of the *Scheil with solute trapping* option with an Al-7.5Si-0.2Cu alloy as compared to a Classic Scheil calculation. The thermodynamic ALDEMO (Aluminum demo) database, available to all users, is selected for this calculation to simulate the effect of solute trapping in the primary phase. This type of simulation is useful for additive manufacturing applications.

This example shows how the alloy starts to solidify at a lower temperature compared to a classic Scheil simulation, an effect which increases with increasing solidification speed. The solidification speed is calculated from user supplied scanning speed and angle between the solid/liquid interface and the scanning direction.

The example uses the **Aziz** model, with an **Interface driving force** of **Migration energy** and a **Maximum velocity for infinite driving force** of 2000 m/s.

Read more about Scheil Solidification Simulations on our website, including how to select the right model for your simulation. If you are in Thermo-Calc, press F1 to search the help to learn about using Scheil.

Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

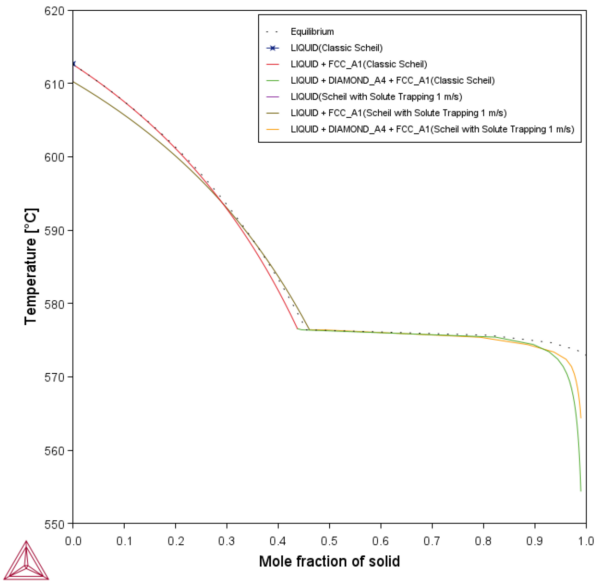

Figure 15: The effect of Scheil solidification with solute trapping of a Al-7.5Si-0.2Cu alloy compared to equilibrium and a Classic Scheil calculation.

T_14: Fe-Cr-Ni Transition Comparison Using the Material to Material Calculator

In Graphical Mode, you use the **Material to Material Calculator** to perform calculations and examine how two materials transition from one into the other. The calculations in this example search for potential deleterious phases during heat treatment of alloys joined together. In this example, the calculation steps between a model martensitic stainless steel (Fe-17Cr-2Ni) and a model Alloy 800 composition (Fe-35Ni-19Cr). Neither alloy is predicted to form the deleterious sigma phase at 600 °C. However sigma is predicted to form at a wide range of mixtures of these two materials, which could have an impact on mechanical properties if it forms.

The example, as defined when you open it, uses a **One Axis** calculation (also known as a property diagram), a temperature of 650 °C, to compare the volume fraction of all phases to the mass fraction of Alloy 800. The **Fraction of the second material** (Alloy 800) is set to 50% (0.5), which for a **One Axis** calculation is used as the start value.

As with all the examples, you can adjust the settings to plot a variety of combinations of output to see how the Material to Material Calculator works before defining your own project.

The plot for this calculation compares the volume fraction of all phases of Material 1 (martensitic stainless steel) to the mass fraction of Material 2 (Alloy 800). In the plots you can see where each phase (FCC_A1, SIGMA_D8B, and BCC_A2) evolves. As you step from Material 1 to Material 2, the FCC_A1 phase starts forming at about 5% (0.05), SIGMA-D8B phase starts to evolve at about 19% (0.19), and the BCC_A2 transitions from Material 1 to Material 2 where it stops forming at approximately 24% (0.24). The purpose of the calculation is to determine at what fraction of Alloy 800 the deleterious sigma phase forms and this is shown for these compositions.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_14_Fe-Cr-Ni_Material_to_Material.tcu*

Visualizations

This example is included as a tutorial on our website and as part of the Graphical Mode Examples playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

In the **Plot Renderer** settings window, click **Show more** and **Show less** to toggle between viewing all or some of the available settings.

The default plot shows the volume fraction of all phases as a function of the mass fraction of the second material, which in this case, is Alloy 800. You can see that the martensitic stainless composition is BCC at this temperature, and the highly alloyed stainless is FCC. Neither material is expected to form any deleterious phase on its own at 650 °C.

However, mixtures of these two materials, which could arise from a graded transition joint, weld, or potentially a diffusion couple, show some stability for the deleterious sigma phase at this temperature. You can try to make small adjustments to the initial chemistry to reduce the potential for sigma phase to form.

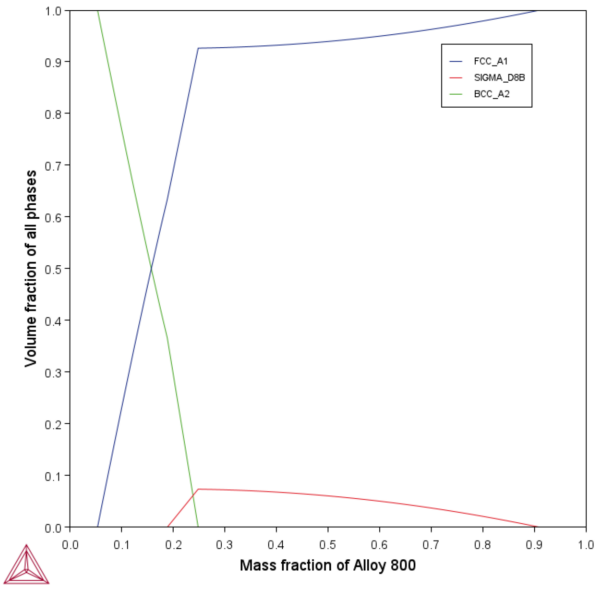

Figure 16: This plot shows the volume fraction of phases when changing composition from the Martensitic Steel (First material) to the Alloy 800 (Second material). This calculation uses the Material to Material Calculator to examine the transition of phases for two compositions of Fe-Cr-Ni. The purpose is to determine at what fraction of Alloy 800 does the deleterious sigma phase start to form. See the text for details.

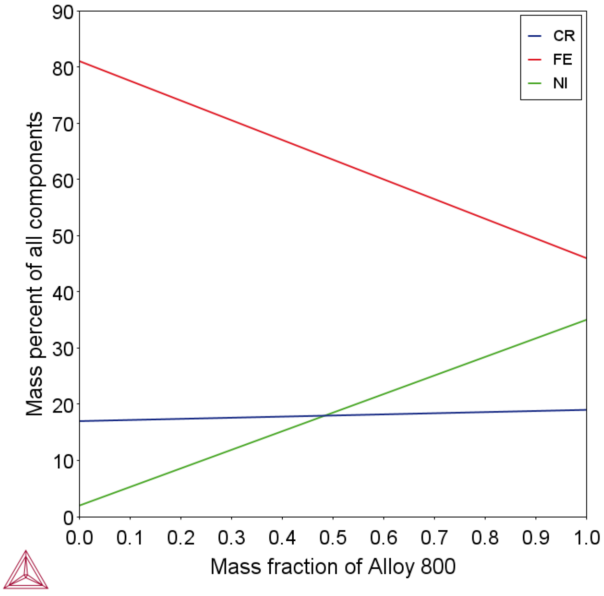

Figure 17: The composition varies linearly when the composition is changed from the Martensitic steel to the Alloy 800 using the Material to Material Calculator. See the text for details.

T_15: Molar Volume and Thermal Expansion Coefficients for L12-type Al3Sc and Al3Zr Compounds

This example calculates volumetric thermal expansion coefficients of the L12-type Al3Sc and the L12-type Al3Zr, respectively. Both Al3Zr and Al3Sc are modeled as the same phase (named as AL3SC, since Al3Sc is stable while Al3Zr is metastable).

The example uses two System Definers and Equilibrium Calculators to plot and compare the molar volume and thermal expansion coefficients of the Al3Sc and Al3Zr binary compounds. It uses the ALDEMO database, which is the free demonstration version of the TCS Al-based Alloys Database (TCAL) and an Experimental File Reader node to read the data from [2015Sah].

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_15_Molar_Volume_and_Thermal_Expansion_Coefficient.tcu*

The example includes an experimental data (*.exp) file called `Al3X.exp`.

The same example is also provided in Console Mode as two separate examples: `tcex58` and `tcex59`.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

T_16: Electrical Resistivity and Thermal Conductivity for Pure Copper

This example calculates the electrical resistivity (ELRS) and thermal conductivity (THCD) of pure Cu. It makes a *One Axis* (step) calculation over a wide temperature range, covering both the FCC_A1 state and the liquid state. It plots thermal conductivity of the system (both FCC_A1 and liquid) and that of a single phase (taking FCC_A1 as an example), respectively. Also it plots electrical resistivity of the system and that of FCC_A1.

The example set up uses an Equilibrium Calculator combined with four Experimental File Reader nodes that take data from the included 1972Ho_cu_thcd.exp and 1981Ho_cu_elrs.exp files.

The example is available to all users as it uses the ALDEMO database, which is the free demonstration version of the TCS Al-based Alloys Database (TCAL).

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_16_Electrical_Resistivity_Thermal_Conductivity_Cu.tcu*
- Experimental data files included `1972Ho_cu_thcd.exp` and `1981Ho_cu_elrs.exp`

The same example is also provided in Console Mode as `tcex60`.

T_18: Scheil with Delta Ferrite to Austenite Transition

This is a example of a Scheil solidification simulation using an Fe-0.23C-0.19Si-0.47Mn-0.92Cr-0.09Ni-0.3Mo (wt%) alloy (Steel P) [2015Sch], which is a steel that undergoes the peritectic transformation.

The result of a Scheil Calculator with the default **Classic Scheil** calculation type is compared to a the result of a calculator where the setting **Allow delta ferrite to austenite transition in steel** is selected. Carbon (C) is set as a **Fast diffuser** in both. A comparison to experimental solidus temperature from Schaffnit et al. [2015Sch] shows that for this steel, using the **Allow delta ferrite to austenite transition in steel** option gives a much better agreement with experiment than the standard **Classic Scheil**.

See Scheil Calculator for an overview of the different Scheil simulation models available.

Project File and License Information

- Folder: **Thermo-Calc**
- File name: *T_18_Scheil_with_Delta_Ferrite_to_Austenite_Transition.tcu*

This uses the TCFE database. A license is required to run the example.

T_19: Young's Modulus for Ti-O with Elastic Properties

This is an example which shows the effect of oxygen concentration at three temperatures on an elastic property, Young's modulus, for the HCP_A3 phase in a Ti-O system.

It is well established in the literature that mechanical properties of titanium and its related alloys are sensitive to the presence of even dilute concentrations of interstitial solutes such as carbon, hydrogen, nitrogen and oxygen. It is therefore important to adequately model the effects of impurities in the host lattice when calculating mechanical properties, such as the elastic constants and the corresponding moduli determined from these constants.

Only the elastic constants are assessed, and then used to derive the elastic moduli, meaning the experimental data in the plot are completely standalone from the assessment process.

In this example, three **Equilibrium Calculators** are used with **One Axis** calculations at different temperatures (298 K, 533 K, and 672 K) to show the Young's modulus of an HCP_A3 phase as a function of mole percent of O and compared to experimental data from [1957Gra; 1966Fed; 1971Hsu].

Project File and License Information

- Folder: **Thermo-Calc**
- File name: *T_19_Elastic_Properties_YoungsModulus_Ti-O.tcu*

The TCS Ti/TiAl-based Alloys Database (TCTI) is used in this example. A valid license is required to run the example.

T_20: Ternary Diagram with Clockwise Plot Axes

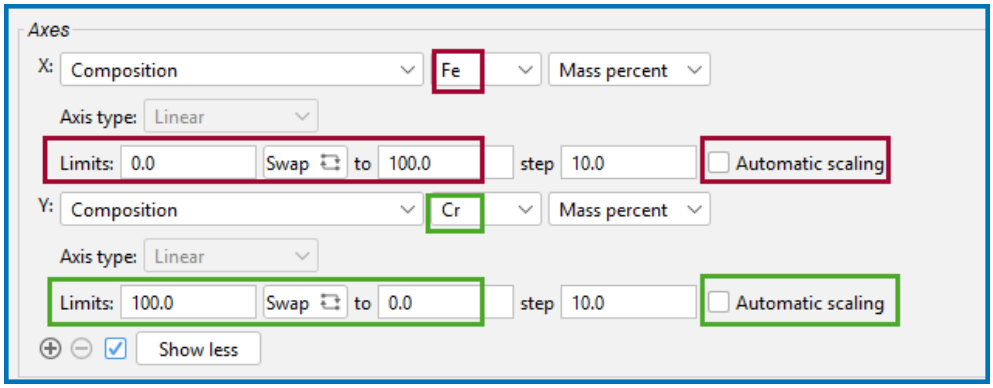
This **Ternary Calculator** example for a Cr-Fe-Ni system shows how to use different plot axis combinations on the **Plot Renderer** representing clockwise and counterclockwise axes. This example uses the FEDEMO database and is available to all users.

A ternary phase diagram is fully defined by the elements in the corners of the diagram. See Figure 27 for the Cr-Fe-Ni 1000 K isothermal section when plotted as a ternary diagram. To plot this diagram in Thermo-Calc you define the X- and Y-axes instead of the corner elements.

Define the X- and Y- Plot Axes

The same diagram can therefore be defined with different combinations of the plot axes. In this example, there is Cr in the bottom left corner and Fe in the lower right corner. Then you can define the X-axis by **Fe***increasing* from `0` to `100` (these numbers are entered in the **Limits** fields). It is also possible to define the X-axis by *decreasing***Cr** from `100` to `0`. The main reason for defining a decreasing plot axis in Thermo-Calc is when comparing with experimental diagrams that can be visualized in this way.

To define a decreasing plot axis, on the **Plot Renderer**, click to deselect the **Automatic scaling** checkbox. Then either change the limits as described above by entering `100.0` and `0.0` in the fields, or click the **Swap** button to swap the lower (0.0) and upper (100.0) limits.



The **Flexible Mode** plot type is used in this example as it allows you to individually work with the axes.

Project File Information

- Folder: **Thermo-Calc**
- File name: *T_20_Ternary_Cr-Fe-Ni_Clockwise_Axes.tcu*

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

In the installed example the Plot Renderer node is renamed to **Counterclockwise x:+Fe y:-Cr**. As above, the settings are completed on the **Configuration** window to plot the **Composition** of **Fe** on the X-axis and **Cr** decreasing on the Y-axis. Click **Perform** to display the result of Figure 27.

You can continue on the Plot Renderer to plot different combinations of axes variables in order to represent clockwise and counterclockwise plot axes.

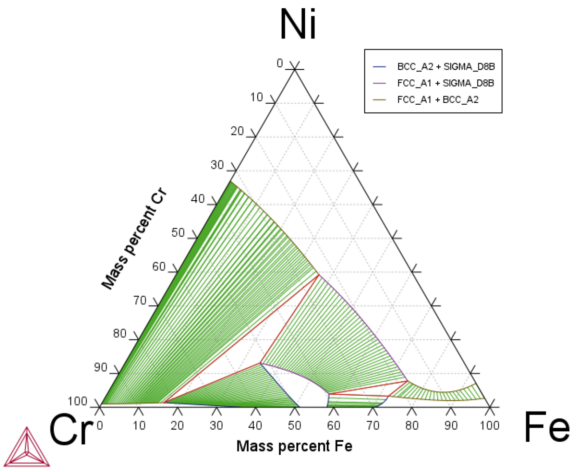


Figure 27: Counterclockwise x:+Fe y:-Cr. Increasing Mass percent Fe (X-axis). Decreasing Mass percent Cr (Y-axis).

Then for the other plot examples, the settings on each **Plot Renderer Configuration** window (for renamed nodes **Clockwise x:-Cr y:+Ni** and **Counterclockwise x:+Fe y:+Ni**) are also changed to show the different combinations of plot axes.

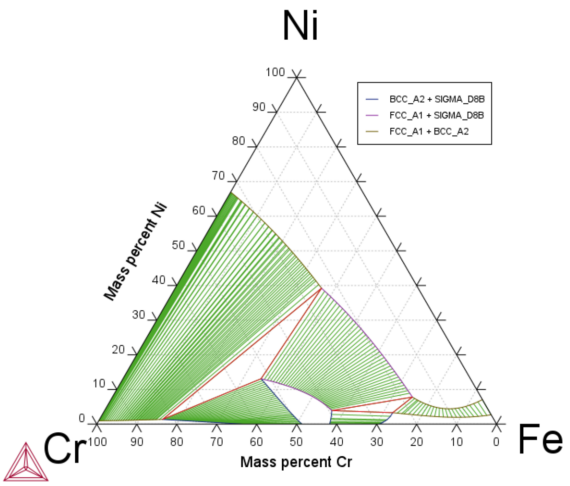

Figure 28: Clockwise x:-Cr y:+Ni: Decreasing Mass percent Cr (X-axis). Increasing Mass percent Ni (Y-axis).

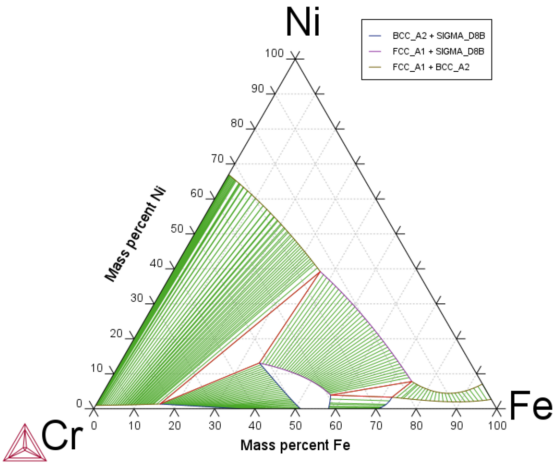

Figure 29: Counterclockwise x:+Fe y:+Ni: Increasing Mass percent Fe (X-axis). Increasing Mass percent Ni (Y-axis).

T_21: Pourbaix Diagrams of Fe with the Aqueous Calculator

In Graphical Mode, you use the **Aqueous Calculation** template in combination with an appropriate database to calculate aqueous corrosion and Pourbaix diagrams.

The aqueous template adds a **System Definer**, **Aqueous Calculator**, and **Plot Renderer** with default settings specialized for aqueous calculations.

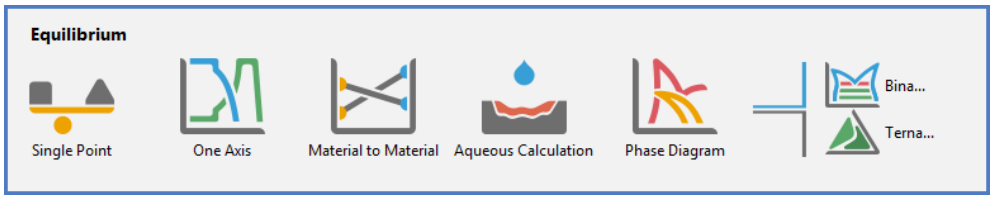

Figure 30: To add the template, click Aqueous Calculation from the My Project page in the Equilibrium group.

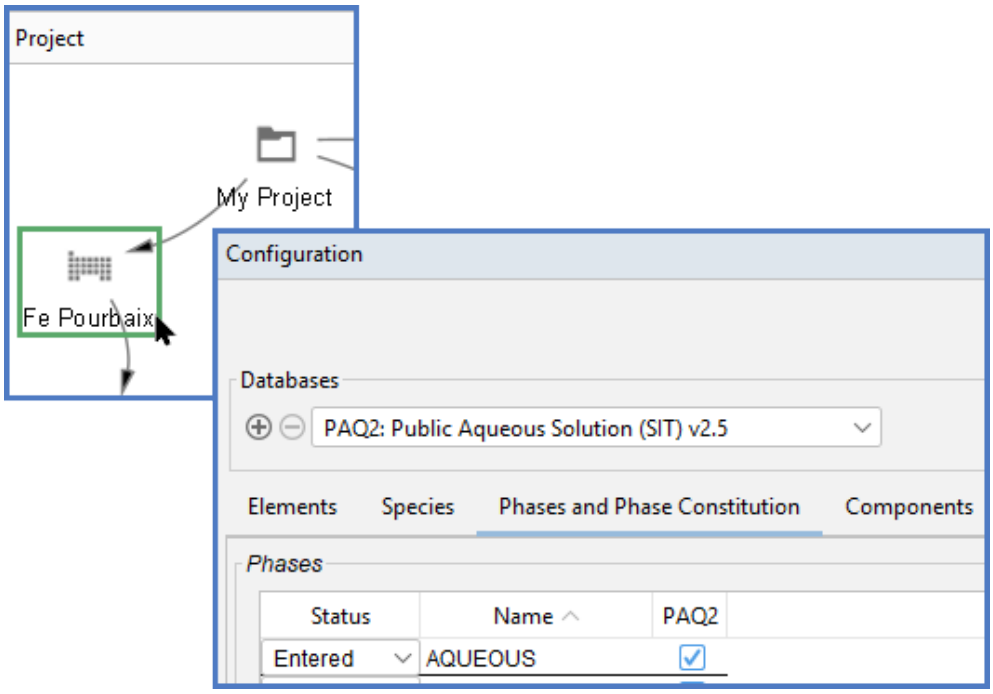
Example Overview

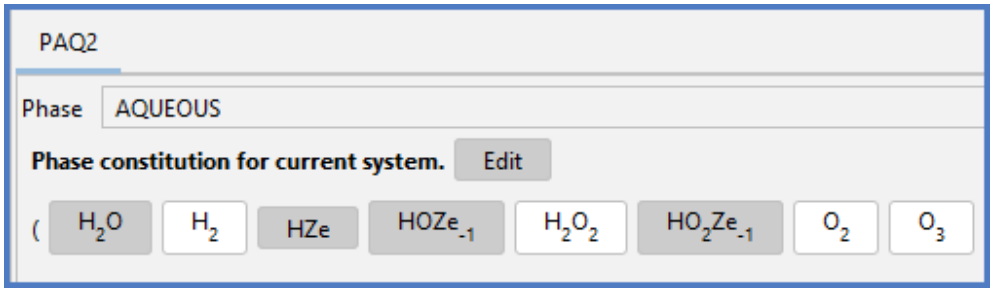
This example uses the aqueous template to plot Pourbaix diagrams of Fe under different conditions. The stability lines for H_2 and O_2 gas formation is calculated in a separate **Aqueous Calculator** (which is renamed) and overlaid to the Pourbaix diagrams.

In this example the Pourbaix diagram for Fe is calculated under normal conditions and in equilibrium with CO_2 gas. The formation of H_2 and O_2 gas is not considered in the calculations (GAS phase is set to suspended/dormant) and instead the formation lines are calculated separately and overlaid to the plot.

Since GAS is suspended from the Pourbaix calculation and we want to overlay the gas formation lines separately, you need to prevent H_2 and O_2 containing species to form in the AQUEOUS phase. This is handled on the **System Definer** window from the **Phases and Phase Constituent** tab.



On this tab, at the top under **Phases > Name**, click the AQUEOUS phase. This populates the *Constitution* details for the PAQ2 database at the bottom of the window where you next click **Edit** to add/remove species.



A similar process is done when in equilibrium with CO_2.

In a Pourbaix calculation it is not always certain that conditions can be fulfilled (eg. some pH/Eh combinations CANNOT reach equilibrium under the constraints set).

Project File and License Information

- Folder: **Thermo-Calc**
- File name: *T_21_Aqueous_Fe-Pourbaix.tcu*

The free PAQ2 database is used in this example to give all users the opportunity to experiment with these types of calculations. No additional license is required.

T_21a is available with the Educational version of Thermo-Calc. It is slightly modified from T_21 to be compatible with the free demo version of the software.

When the Aqueous Calculator is added to your project using the template, this allows for efficient setup of advanced aqueous calculations. For optimal results, the latest version (TCAQ4) of the TCS Aqueous Solutions Database (TCAQ) is recommended as it is designed specifically for this. Although other versions (TCAQ 3.1 and older) and the free PAQ2 database can be used, there are limitations and additional requirements to conduct more complex simulations.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

T_22: Aqueous pH of Solutions

In Graphical Mode, you use the **Aqueous Calculator** in combination with an appropriate database to calculate aqueous property diagrams.

This example has two calculations using the **Aqueous Calculation** template.

The aqueous template adds a **System Definer**, **Aqueous Calculator**, and **Plot Renderer** with default settings specialized for aqueous calculations.

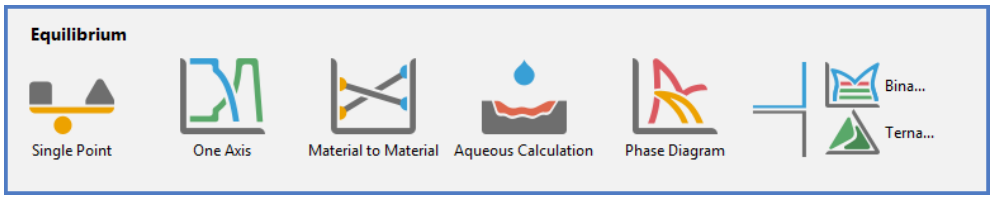

Figure 35: To add the template, click Aqueous Calculation from the My Project page in the Equilibrium group.

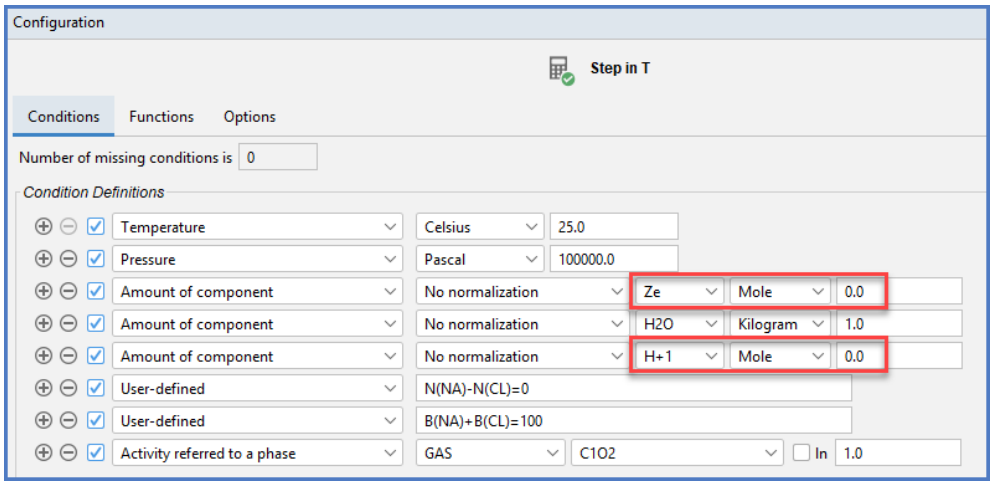
Example Overview

The first calculation shows how to calculate the pH of 1kg H2O-0.1kg NaCl solution in equilibrium with CO_2 gas. The calculation uses the template defaults set on the **System Definer** (renamed in the example to **H2O-0.1NaCl in CO2 equilibrium**) and the **Aqueous Calculator** (renamed to **Step in T**).

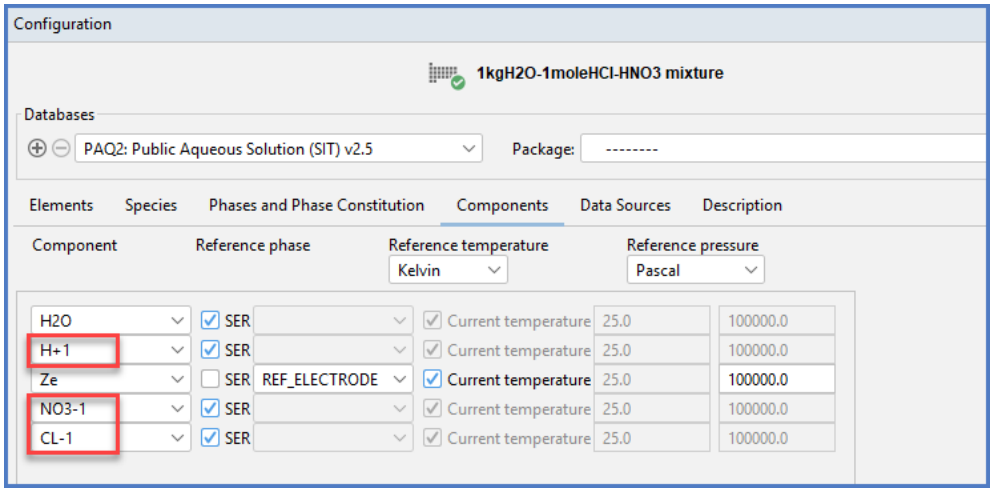
On the **Aqueous Calculator**, in the *Condition Definitions* section, you include user-defined conditions to ensure there is 0.1 kg of NaCl in the solution. Setting the amount of **Ze** and **H+1** to **0.0** also ensures there is a neutral solution. See the results when this is run in Figure 36 and Figure 37.



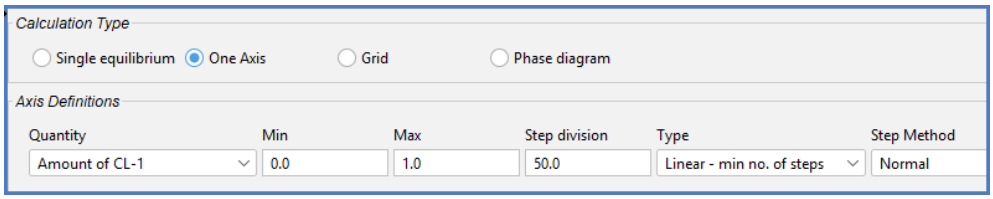
The second calculation shows how to predict pH of a solution with 1 kg H_2O with 1 mole (HCl-HNO_3) mixture.

This calculation shows how you can change the components for the calculation for an easier setup.

On the **System Definer** (renamed to **1kgH2O-1moleHCl-HNO3 mixture**) on the **Components** tab, you change the component N to **NO3-1** and Cl to **CL-1** and then you can construct the HCl-HNO_3 mixture directly in combination with the **H+1** component using user-defined conditions.



Then on the **Aqueous Calculator** (renamed to **1kg-H2O-1moleHCl-HNO3 mixture (Calc)**), with a **One Axis** step in CL-1, you can make predictions of pH for the 1 kg H_2O with 1 mole HCl-HNO_3 mixture and see how it changes with amount of HCl. See Figure 38 for the result.



Project File and License Information

- Folder: **Thermo-Calc**
- File name: *T_22_Aqueous_pH_of_Solutions.tcu*

The free PAQ2 database is used in this example to give all users the opportunity to experiment with these types of calculations. No additional license is required.

When the Aqueous Calculator is added to your project using the template, this allows for efficient setup of advanced aqueous calculations. For optimal results, the latest version (TCAQ4) of the TCS Aqueous Solutions Database (TCAQ) is recommended as it is designed specifically for this. Although other versions (TCAQ 3.1 and older) and the free PAQ2 database can be used, there are limitations and additional requirements to conduct more complex simulations.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

PM_G_01: Phase Transition

The example uses the **Property Model Calculator** and a **Phase Transition** Property Model to predict the transition temperature to the unwanted brittle sigma phase. The example shows how the temperature is influenced by changes to a steel alloy's composition using the **Uncertainty** *Calculation Type* and then you can choose to use either a **Histogram** (frequency diagram) or **Probability** plot after choosing the **Statistical** *Plot type* on the **Plot Renderer**.

Project File Information

- Folder: **Property Models → General**
- File name: *PM_G_01_Phase_Transition.tcu*

Visualizations

This example is included as a Property Model tutorial on our website and as part of the Property Model Calculator playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

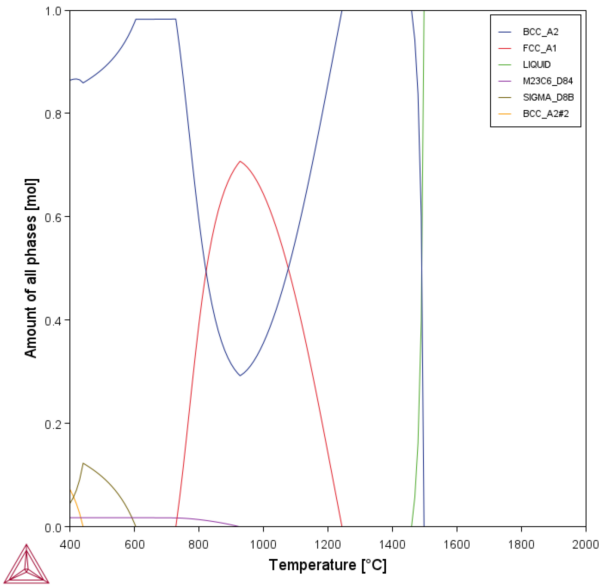

Figure 39: A property diagram as a result of using the Equilibrium Calculator with a One Axis calculation to determine a good starting temperature of the SIGMA phase.

Once you set up the Property Model Calculator, but before running a **Grid** calculation, it is recommended you run a **Single** calculation to make sure the calculation is valid.

- If the subprocess worked, it displays in the **Event Log**. The **Event Log** also has the result `Relaxed condition`, referring to the variable, which in this case is temperature.
- If the calculation did not work, `NaN` (not a number) displays instead. Check your configuration set up and run the calculation again before moving on to the more complicated calculation.

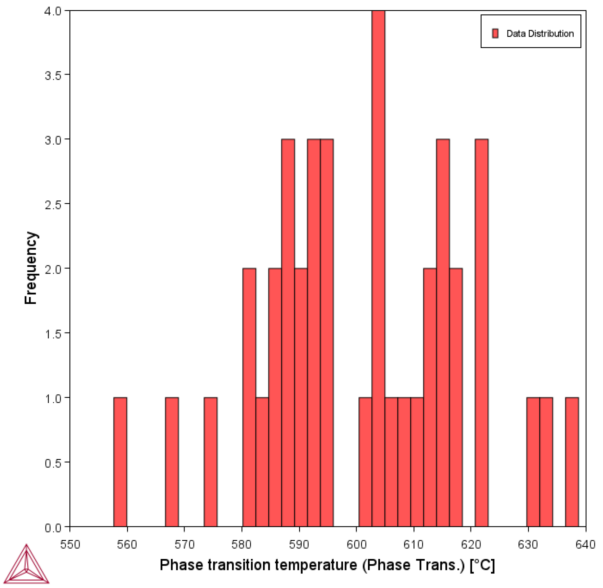

Figure 40: Using the Property Model Calculator with the Phase Transition Model to plot a histogram showing how the transition temperature of sigma varies when you vary the composition. The plot changes each time you run the calculation because it is taking a random sampling from the composition range set.

The X-axis is labeled the **Phase transition: Temperature (Phase Trans.)**, which you can see on the **Plot Renderer 1 Configuration** window. The Y-axis shows the **Frequency**, which is the number of samples out of 40 where the composition transitions at each temperature. You can see that the transitions occur more frequently near the 600 °C starting point and less frequently at the edges.

Since only one variable can serve as a **Phase transition** per calculation, the quantity that is not relaxed has a NaN result in its corresponding result quantity. The **Evaluation temperature** result quantity inherits the unit set in the conditions while the **Composition** result quantity inherits the normalization (mole or mass) but always returns a fraction.

About the Uncertainty Calculations

PM_G_02: Coarsening and Interfacial Energy

The example uses the **Property Model Calculator** and both thermodynamic (FEDEMO) and kinetic (MFEDEMO) demonstration steel databases. Using a **Grid** *Calculation Type* it produces these plot types: a **Heat map**, a **Contour plot** and an overlaid plot combining a cross plot with a contour plot (where both the interfacial energy and coarsening rate is shown). It also creates a diagram to show the phase fractions vs time and a **3D** *Plot type* comparing the coarsening rate coefficient.

Driving Force Property Model Settings and Interfacial Energy Property Model Settings

PM_G_04: Yield Strength

The example uses the **Property Model Calculator** and the **Yield strength** Property Model with a thermodynamic demonstration aluminum database (ALDEMO).

Using default options for the precipitation strengthening models, this example compares the **Simplified model (general)**, **Seidman model (Al-base)** and **Deschamps model (Al-base)** yield strength versus precipitate radius to experimental data for an Al-0.3wt%Sc alloy homogenized at 648 °C for 24 hours and subsequently aged at 350 °C.

Example Overview

The Seidman model [2002Sei] considers a combination of a shearing mechanism and Orowan dislocation bypass mechanism. For the shearing mechanism, the increase in yield strength results from the contributions of ordering strengthening, coherency strengthening, and modulus mismatch strengthening.

When **Seidman model (Al-base)** is selected as the *Precipitation strengthening model*, the setting for α is a constant related to the coherency strengthening of precipitates, which usually varies from 2 to 3. In this example, the default α is 2.6 [1985Ard]. The *m* setting is the parameter that relates to the modulus mismatch strengthening and the default is set as 0.85 [1985Ard]. This model is applied in the study of precipitation hardening in dilute Al(Sc) alloys containing coherent Al_3Sc precipitates. The model parameters described above can be adjusted to work for hardenable aluminum alloy calculations from the 2000 (Al–Cu and Al–Cu–Mg), 6000 (Al–Mg–Si), and 7000 (Al–Zn–Mg) series.

As a comparison, the **Simplified model** [2008Zan] only considers the general mechanisms of cutting and looping (Orowan mechanism) without regard to any detailed dislocation mechanisms.

When **Simplified model (general)** is selected as the *Precipitation strengthening model*, the default *Critical radius* (the critical size r_c) is optimized against experimental results for dilute Al-Sc. If the precipitates are smaller than a critical size (approximately 5–10 nm) the dislocations cut the precipitates. The strength of the obstacle is then proportional to the square root of the average radius. If the particles are larger than the critical size, r_c, it is less costly for the dislocations to bow round the particles and the strengthening contribution is inversely proportional to r. Since the **Simplified model (general)** only depends on generic material constants (k_p and r_c) it may be applied to any precipitation strengthened material.

The **Deschamps model (Al-base)** model [1998Des], is for precipitation strengthening, mainly intended for use with Al-base alloys. The Deschamps model includes use of Friedel or Kock's statistics for particle size distribution. Default parameters are used to match a dilute Al-Sc

alloy with Al_3Sc precipitates. As is done for the other precipitation strengthening models, a critical radius, describing the transition from cutting to looping, must be specified when you are setting up the configuration.

PM_G_05: Yield Strength NiAlCr

The example uses the **Property Model Calculator** and the **Yield strength** Property Model with a thermodynamic demonstration nickel database (NIDEMO).

The **Reppich model** is developed for calculation of precipitation strengthening in Ni-based super alloys consisting mainly of gamma prime (γ') precipitates in a gamma matrix. The example shows a calculation of the precipitation strengthening vs precipitate radius in a Ni-10at%Al-10at%Cr alloy.

Example Overview

This example uses the Reppich model [1982Rep] which is developed and rests on existing hardening models estimating the increase of the yield stress due to pairwise particle cutting and antiphase domain boundary (APB) formation. The effect of the anisotropy on the dislocation line tension of two-phase material and on the Orowan stress is taken into account. Compared to conventional APB hardening theories, this model can be applied to large volume fraction of precipitates in the anisotropic systems.

For the settings input of the **Reppich model (Ni-base)**:

- *A* is a numerical factor depending on the morphology of the precipitates. For spherical particles, *A* equals to 0.72.
- *w* represents the elastic repulsion between the strongly paired dislocations, which can be determined by the experimental data [1979Hüt].

  In this example, *A* and *w* are set by default to 0.7639 and 0.2919, respectively. The *C* factor default of 0 is not changed.

PM_G_06: Yield Strength HEA

The example uses the **Property Model Calculator** and the **Yield strength** Property Model with the thermodynamic TCS High Entropy Alloys Database (TCHEA). It is an example of solid solution strengthening, which is the contribution to total strength due to the elastic strains in the crystal lattice caused by alloying elements of a lattice parameter differing from the main constituent. The example shows the solid solution strengthening at 300 K and 411 K over the full solubility range for the Mo-Ta system as compared to experimental data [1972Ste].

Project File and License Information

- Folder: **Property Models → General**
- File name: *PM_G_06_Yield_Strength_HEA.tcu*

This example requires the use of the TCS High Entropy Alloys Database (TCHEA). A license is required to run the example.

This example is configured to run with BCC_A2 selected and BCC_B2/BCC_B2#2 deselected in the **System Definer → Phases and Phase Constitution** tab, when using version 8 (TCHEA8) or higher. If the database is changed to an earlier version, this selection is reset by the software and you need to either manually re-apply these settings on the System Definer or reopen the example.

PM_G_07: Hot Crack Susceptibility

The example uses the **Property Model Calculator** and the **Crack Susceptibility Coefficient** Model to calculate the hot tearing tendency during solidification for an Al-Si alloy. The **ALDEMO: Aluminum Demo Database** is used and this example is available to all users.

The **Crack Susceptibility Coefficient** Property Model, available as a General model with the Property Model Calculator, calculates the crack susceptibility coefficient, which describes the risk or tendency of a material to experience cracking or *hot tearing* during solidification. Cracking/hot tearing is one of the most common and serious defects encountered during the casting of, for example, aluminum alloys. In general, it is defined by the formation of a macroscopic fissure in a casting because of stress and the associated strain, generated during cooling, at a temperature above the non-equilibrium solidus. Crack susceptibility is also referred to as solidification cracking, hot cracking, hot shortness, supersolidus cracking, and shrinkage brittleness. The Crack Susceptibility Coefficient (CSC) is calculated using Scheil results with three different model options: *Clyne and Davies*, *Kou*, and *Easton*.

The Model is based on the publication by Yan and Lin [2006Yan] and uses experimental data [1955Pum; 1976Feu; 2004Bar] from this paper.

The experimental hot cracking susceptibility of an alloy is defined as the ratio between the cracking length for that alloy and the maximum cracking length in the alloy system studied. Considering the uncertainties and difficulties in hot tearing measurements, the calculated hot tearing tendencies are in excellent agreement with the experimental data. The typical L-shaped curve is well reproduced in the current prediction. It rapidly increases at a low solute content and has a maximum at a composition of around 0.5 wt pct Si.

About the Spinodal Property Model

PM_G_09: T-Zero Temperature

The example uses the **Property Model Calculator** and the **T-Zero Temperature** Property Model to calculate the so-called T_0 line for the two-phase field FCC_A1 and BCC_A2 in the Fe-Ni system. The line is plotted together with the phase diagram for the same Fe-Ni system. The **FEDEMO: Iron Demo Database** is used and this example is available to all users.

The $\mathbf{T_0}$ temperature is defined as the temperature where two phases of identical chemical composition have the same molar Gibbs free energy. This temperature is an important quantity in the field of diffusionless phase transformations, e.g. martensitic transformation, since it is the upper limit where diffusionless phase transformations can occur.

Two Property Model Calculators are used in this example. The T_0 line (a **One Axis** calculation) for the two-phase field FCC_A1 and BCC_A2 is overlaid on top of a the Fe-Ni **Phase diagram** calculation.

About the T0 Temperature Property Model

PM_G_10: Freeze-in Thermal Conductivity

The example uses the **Property Model Calculator** and the **Equilibrium with Freeze-in Temperature** Property Model to compare the use of the model with thermal conductivity with and without grain boundary (GB) phase scattering being included in the calculation.

Example Overview

The TCS Al-based Alloys Database (TCAL) is used to evaluate a 7075_T6 alloy (Al-1.6Cu-2.5Mg-5.6Zn-0.25Fe-0.15Mn-0.23Cr-0.2Ti-0.2Si) mass%. The "T6" in the alloy name means that the alloy has been artificially peak-aged, i.e. the matrix is almost depleted. The heating is assumed to be at a typical artificial aging temperature of 150 °C. The temperature has then been increased for measuring of the reported values thermal conductivity at 400, 500, and 532 °C.

The thermal conductivity due to grain boundary phase scattering is approximated as a scattering constant times the total volume fraction of the grain boundary phases. The contribution to thermal conductivity is assumed to be related to that to electrical resistivity, following the Wiedemann-Franz law.

The calculation set up assumes that the alloy reaches equilibrium at the peak-age temperature, i.e. that the amounts of phases and their composition freeze-in at 150 °C and that these do not change for the evaluation of thermal conductivity at the temperatures 400, 500, and 532 °C. Calculations are compared between accounting and ignoring contributions from grain boundary (GB) phase scattering.

As can be seen in Figure 56, the calculation including the approximate effect of grain boundary phase scattering is close to the experimentally measured values. Excluding the effect of grain boundary phase scattering slightly overestimates the thermal conductivity. Experimental data is from [2008ASM].

Project File and License Information

- Folder: **Property Models → General**
- File name: *PM_G_10_Freeze_In_Thermal_Conductivity.tcu*

The TCS Al-based Alloys Database (TCAL) is used in this example. A valid license for version 7 (TCAL7) or newer is required to run the example.

About the Equilibrium with Freeze-in Temperature Property Model

PM_G_11: Freeze-in Electrical Resistivity

The example uses the **Property Model Calculator** and the **Equilibrium with Freeze-in Temperature** Property Model to compare the use of the model for electrical resistivity with and without grain boundary (GB) scattering being included in the calculation.

Example Overview

The TCS Al-based Alloys Database (TCAL) is used to evaluate a 4032-O alloy (Al-0.9Cu-1.0Mg-0.9Ni-12.2Si) mass%. The "O" in the alloy name means that the Al alloy has been heat-treated at a typical temperature of 350 °C. The measurement of electric resistivity is usually performed at room temperature.

The electrical resistivity due to grain boundary phase scattering is approximated as a scattering constant times the total volume fraction of the grain boundary phases.

The calculation set up assumes that the alloy reaches equilibrium at the "O" heat-treated temperature, i.e. that the amounts of phases and their composition freeze-in at 350 °C and that these do not change for the evaluation of electrical resistivity at the room temperature. Calculations are compared between accounting and ignoring contributions from grain boundary (GB) scattering.

As can be seen from Figure 57, the calculated electrical resistivity at room temperature, including grain boundary phase scattering, is very close to the experimentally measured value (4.3E-8) for the alloy. Excluding the grain boundary phase scattering somewhat underestimates the electrical resistivity for the alloy. Experimental data is from [1993Dav].

Project File and License Information

About the Equilibrium with Freeze-in Temperature Property Model

PM_G_12: Solidus and Liquidus Batch Calculation

The example uses the **Property Model Calculator** and the **Liquidus and Solidus Temperature** Property Model to demonstrate the use of the **Batch** *Calculation Type*.

Example Overview

The thermodynamic demonstration steel database (FEDEMO) is used along with a randomized set of experimental data points that are shown on the **Configuration** window in a table. The data showing in this example is imported from a data file prepared with specific data entry requirements.

A variety of compositions for an Fe-Cr-Mn-Ni-C alloy is used for the calculations; these compositions are also taken from the same data file. When the heading includes `Exp`, then these columns are considered experimental data by Thermo-Calc, where in this example it is the columns titled `Exp Liq temp C` and `Exp Sol temp C`. This experimental data can then be plotted as a function of the calculated solidus/liquidus temperature and compared on the plot using a **Cross plot**, which is selected on the **Plot Renderer**. The limits are shown using the setting RMS (root mean square).

The experimental data entered into the batch data file is unitless even though the actual experimental data unit is Celsius (as written in the header text). In order for the plot and calculations to match, Celsius is chosen as the temperature unit when defining the **Solidus/Liquidus** Property Model and all the axes manually scaled to the same limits (1360 → 1520).

Working with Batch Calculations

PM_G_13: Ti Alloy Design for Additive Manufacturing

This in-depth example, which has some step-by-step instructions available on our website, uses the **Property Model Calculator** to find the optimal composition for a titanium-based alloy to be used for additive manufacturing applications.

Example Overview

Additive manufacturing provides new opportunities to fabricate complex parts. However, traditional alloys may not be readily printable using techniques such as laser powder bed fusion. As such, the development of new alloys may be necessary to fully realize the benefits of additive manufacturing technologies.

In this example, inspired by the work of Ackers et al. [2021Ack], **Batch** calculations within the Property Model Calculator are used to identify candidate titanium alloy chemistries for biomedical implant applications using the thermodynamic TCS Ti/TiAl-based Alloys Database (TCTI). To optimize printability and material weight, the liquidus temperature, solidus temperature, and density of 2000 randomized titanium alloy chemistries from the Ti-Nb-Zr-Sn-Ta-Fe-Mo system are calculated. An estimate of alloy cost is also made for each alloy. Taken together, this methodology can be used to identify compositions of interest and accelerate material development activities.

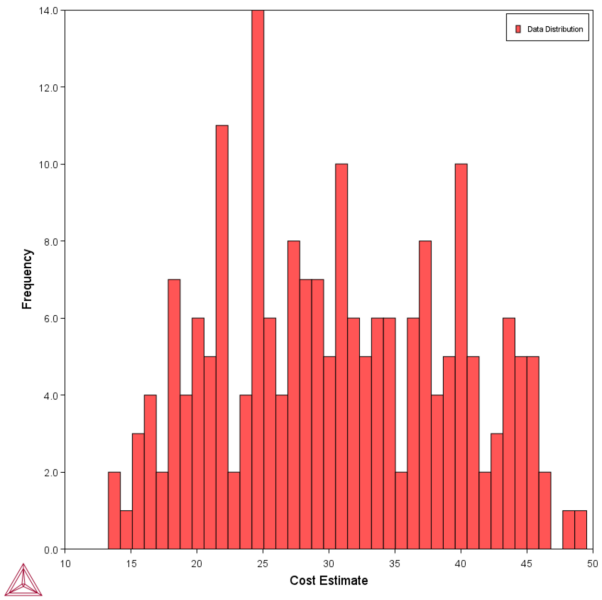

Figure 59: Cost estimate histogram for 2000 randomized chemistries from the Ti-Nb-Zr-Sn-Ta-Fe-Mo system. The cost estimate was calculated using a user-defined function in the Property Model Calculator.

About the T0 Temperature Property Model

PM_G_15: Columnar to Equiaxed Transition (CET) of a NiAlCr Alloy

This example uses the **Property Model Calculator** and the **Columnar to Equiaxed Transition** Property Model with nickel demo databases to mimic the result of CMSX-4 alloy, which compares the tip radius and undercooling with growth velocity.

Example Overview

A Ni-26Al-9Cr (at.%) alloy is used so that its calculated undercooling is close to that of a 10-component CMSX-4 alloy. A **One Axis** calculation for the FCC_L12 primary phase is done using the CET parameters entered on the **Property Model Calculator Configuration** window.

The settings used are the same as those from the literature [2001Gäu], i.e.:

- **Number of nucleation sites**: `2.0E15`/m^3
- **Equiaxed exponent**: `3.4`
- **Nucleation undercooling**: `2.5` K
- **Solve for**: **Thermal gradient**
- **Equiaxed fractions**: `0.0066 0.1`

Project File Information

- Folder: **Property Models → General**
- File name: *PM_G_15_Ni-Al-Cr_Columnar_Equiaxed_Transition.tcu*

The NIDEMO and MNIDEMO databases are used in this example and it is available to all users.

Also see these examples that use the same Property Model. However, these examples require licenses as they use the TCS Ni-based Superalloys Database (TCNI) and TCS Ni-alloys Mobility Database (MOBNI): PM_G_16: Columnar to Equiaxed Transition of a CMSX-4 Alloy and PM_G_17: Columnar to Equiaxed Transition of an IN718 Alloy.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

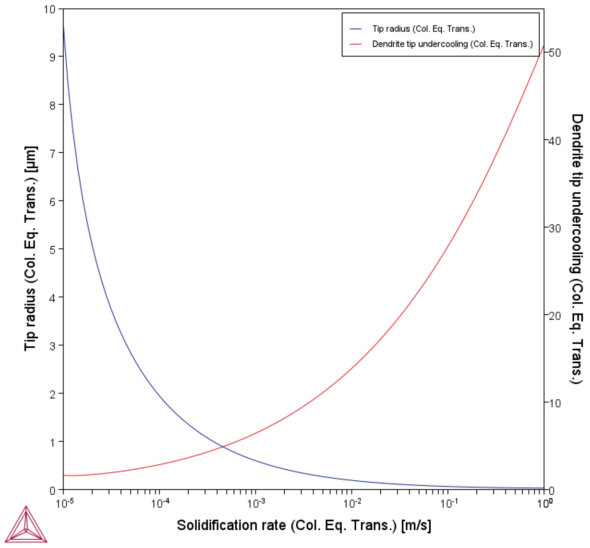

Figure 61: Tip radius and undercooling vs growth velocity for a Ni-26Al-9Cr alloy.

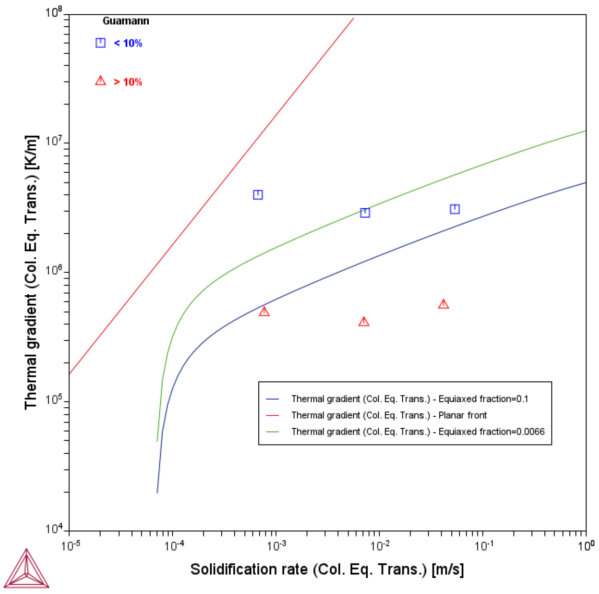

Figure 62: CET curves for a Ni-26Al-9Cr alloy using experimental data from [2001Gäu]. Also see PM_G_16 to compare the results to the CMSX-4 alloy results.

About the Columnar to Equiaxed Transition (CET) Property Model

PM_G_16: Columnar to Equiaxed Transition of a CMSX-4 Alloy

This example uses the **Property Model Calculator** and the **Columnar to Equiaxed Transition** Property Model with a CMSX-4 alloy to compare calculated CET curves to experimental data.

Example Overview

A 10-component system, with a composition from Gäumann et al. [2001Gäu], is used for this simulation of a CMSX-4 alloy.

	Co	*Cr*	*Al*	*Ti*	*W*	*Ta*	*Re*	*Hf*	*Mo*	*Ni*
wt.%	9.0	6.5	5.6	1.0	6.0	6.5	3.0	0.1	0.6	Bal
at.%	9.262	7.581	12.587	1.267	1.979	2.178	0.977	0.034	0.379	Bal

The results are compared with literature data (epitaxial laser metal forming) and the original model [1999Gäu; 2001Gäu].

A **One Axis** calculation for the FCC_L12 primary phase is done using the CET parameters entered on the **Property Model Calculator Configuration** window.

The settings entered include:

- **Interfacial energy**: `0.25` J/m^2, which gives a Gibbs-Thomson coefficient of 1.87 x 10^{-7} mK, in agreement with the literature [2001Gäu].
- **Number of nucleation sites**: `2.0E15`/m^3
- **Nucleation undercooling** : `3.0` K
- **Equiaxed exponent**: `3.4`
- **Solve for**: **Thermal gradient**
- **Equiaxed fractions**: `0.0066 0.1`

In the calculation, the nucleation undercooling is slightly larger than originally used (2.5 K) [2001Gäu], since it has been found that at a low speed limit, the Property Model gives an undercooling close to 3 K.

The original value is arbitrary and does not affect the results at a high speed range.

Project File and License Information

- Folder: **Property Models → General**
- File name: *PM_G_16_CMSX-4_Columnar_Equiaxed_Transition.tcu*

To run this example requires a license for the TCS Ni-based Superalloys Database (TCNI) version 12 (TCNI12) or newer and the TCS Ni-alloys Mobility Database (MOBNI) version 6 (MOBNI6) or newer.

Example PM_G_15: Columnar to Equiaxed Transition (CET) of a NiAlCr Alloy uses demo databases available to everyone and mimics this alloy in its results.

Visualizations

About the Columnar to Equiaxed Transition (CET) Property Model

PM_G_17: Columnar to Equiaxed Transition of an IN718 Alloy

The example uses the **Property Model Calculator** and the **Columnar to Equiaxed Transition** Property Model to compare calculated CET curves for an IN718 alloy to experimental data.

Example Overview

A **One Axis** calculation for the FCC_L12 primary phase is done using the CET parameters entered on the **Property Model Calculator Configuration** window.

The settings entered include:

- **Interfacial energy**: `0.5` J/m^2.
- **Number of nucleation sites**: `4.0E11`/m^3
- **Nucleation undercooling** : `4.0` K
- **Equiaxed exponent**: `3.13`
- **Solve for**: **Thermal gradient**
- **Equiaxed fractions**: `0.01 0.49 0.99`

The literature data from Polonsky et al. [2020Pol] are not purely experimental data, but rather combined with experimental equiaxed evidence and model calculations with numerical values of thermal gradients, growth velocity as well as tip undercooling. Polonsky et al. estimated tip undercooling based on a Scheil calculation, which smeared out the composition inhomogeneity at the dendrite front, hence underestimating the undercooling. Since both tip undercooling and nucleation site density promotes the formation of equiaxed crystals, an increase in undercooling in this example calculation leads to a decrease in nucleation site density compared to the results in [2020Pol] if one were fitting the same set of data.

About the Columnar to Equiaxed Transition (CET) Property Model

PM_G_18: Equilibrium and Annealing Heat Treatment for ASTM A29

This example uses the **Property Model Calculator** and the **Equilibrium** Property Model and calculates the equilibrium for the provided conditions. The calculation result from this model is the same as when you are using the Equilibrium Calculator with the Single Equilibrium calculation type, but this model is preferable when min/max or uncertainty calculations are required in case of compositional variations, which is true for most engineering materials.

Example Overview

An example for choosing annealing heat treatments for a medium carbon low alloyed AISI 4130 steel is shown. The alloy has the following composition, as per ASTM A29 standard:

Fe	*C*	*Mn*	*P*	*S*	*Si*	*Cr*	*Mo*
Rem.	0.28-0.33	0.40-0.60	0.035	0.040	0.15-0.35	0.80-0.10	0.15-0.25

The Equilibrium Model in this example is calculated for uncertainty in chemical compositions and annealing temperatures (820-900 °C) to optimize for formation of austenite phase (FCC_A1). This is done to achieve a microstructure suitable for machining. It is seen that best probabilistic results are achieved around 860 °C, which agrees well with the industrially applied process.

Project File Information

- Folder: **Property Models → General**
- File name: *PM_G_18_Equilibrium.tcu*

This uses the latest versions of TCS Steel and Fe-alloys Database (TCFE) (TCFE14) and TCS Steels/Fe-Alloys Mobility Database (MOBFE) (MOBFE8). Valid licenses are required to run the example. Earlier versions can be used but there will be slight differences to the results.

About the Equilibrium Property Model

PM_G_19: Thermal Conductivity for an AM Cu-Alloy

This example uses the **Property Model Calculator** and the **Equilibrium with Freeze-in Temperature**. The Equilibrium with Freeze-in Temperature Model calculates equilibrium at the freeze-in temperature and evaluates the properties at a different temperature. This model is particularly relevant for estimating thermophysical properties such as thermal or electrical conductivities. The assumption in this model is that diffusion and phase transformations are negligible when changing from the freeze-in-temperature and, therefore, that the phase amounts and compositions of phases are kept at all other temperatures.

Project File and License Information

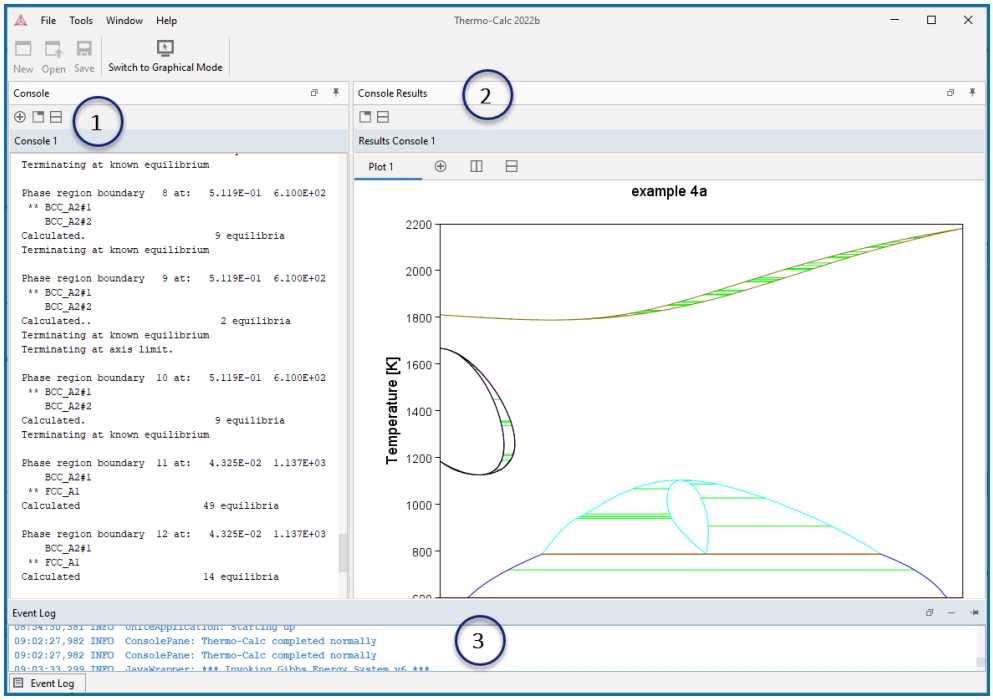
Console Mode Layout

By default the first time you launch Thermo-Calc it opens in Graphical Mode. After this, the mode defaults to the most recent one. You can switch back and forth between modes. To open the Console Mode interface, click **Switch to Console Mode** on the toolbar.

Keyboard Shortcuts to Navigate Between Tabs

The Console Mode User Interface



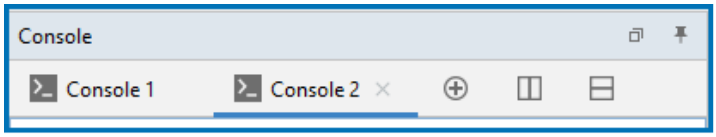
The currently selected window is called the *active* window. This has a darker title bar than the other windows. The windows are:

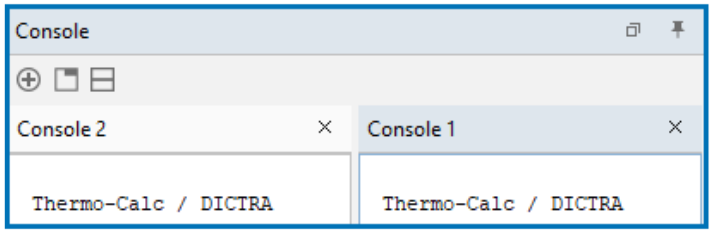
1. **Console**, with a **Console 1** tab.
2. **Console Results**, with a **Results Console 1** tab as well as a sub-tab (**Plot 1**), which is what is displayed in the window in the figure.
3. **Event Log**.

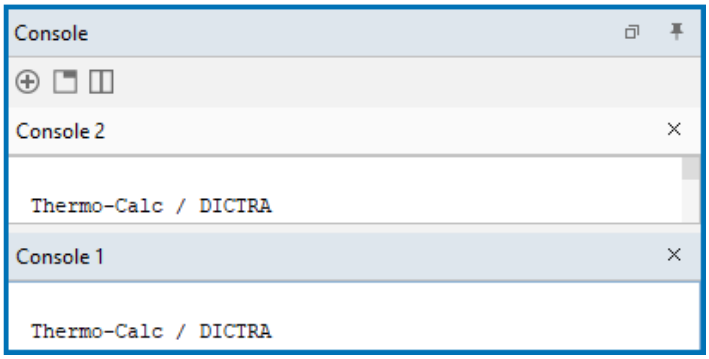
Console Tabs

By default, the tabs are side-by-side. You can toggle to view the tabs

- Click the button to display both windows side by side where you can see the information in all windows at the same time.
- Click the button to stack the windows top to bottom where you can see the information in all windows at the same time.
- Click the button to return to the default layout with tabs side by side and the focus on one window at a time.







Opening Console Windows

Open a specific window from the **Window** main menu, or select **Reset Windows** to return to the default window layout.

Console Window and Tabs

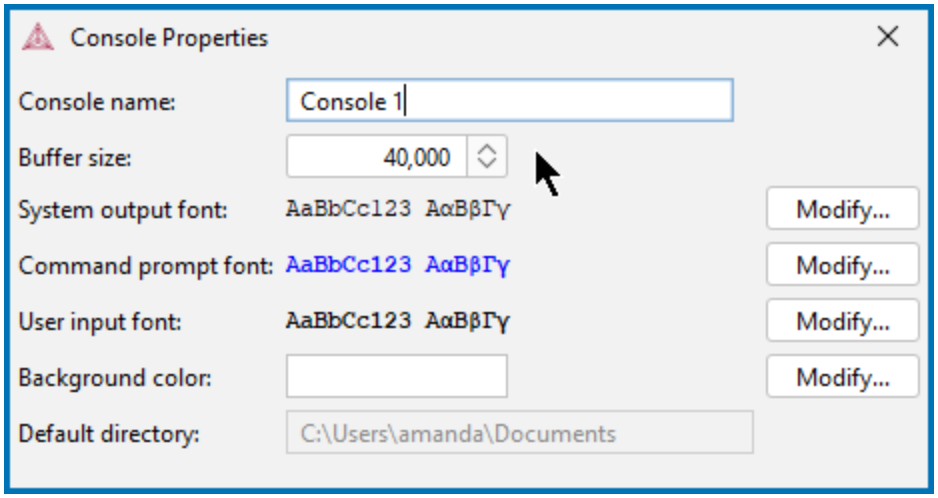
By default the Console window is on the left-hand side of the console. This is where you enter commands and within the window there can be several Console tabs open at a time. When you right-click the tab, there are options available from the menu to edit the tab properties, open and close tabs, and view, copy, and save a command history.

Keyboard Shortcuts to Navigate Between Tabs

Edit the Console Tab Properties

Right-click any tab and select **Properties** from the menu to edit the Console tab properties.

Global Settings: Console Mode Default Appearance



- Change the tab name in the **Console name** field to make it more descriptive for the work you are doing.
- Increase or decrease the buffer size.
- Edit fonts, sizes, and colors for various Console window text. Click **Modify** next to **System output**, **Command prompt**, and **User input**.
- Click **Modify** next to **Background color** to change the color for each Console window.
- To globally set the **Default directory** file path to where the various file types are saved, go to **Tools > Options > Console Mode**.

Open and Close Console Tabs

There are options to add a **New Console** tab, **Close** one, or **Close all** tabs in the Console window.

Open One or More Console Tabs

- Click the ⊕ button.
- Press <Ctrl+T> when the Console window is active.
- Right-click a tab header and select **New Console**.

Close One or More Console Tabs

- Click the X button.
- Press <Ctrl+W> or <Ctrl+F4>.
- Right-click the tab header and select **Close**.
- To close all tabs except one, right-click the header of the tab you want to keep and select **Close Other**.
- To close all tabs and open a new one, right-click the header of any tab and select **Close All**.

Copy all Text to Clipboard

- Right-click any tab and select **Copy All Text to Clipboard** from the menu. Paste in a text editor as required.
- The shortcut for this command is to press <Ctrl+Alt+C> (Windows and Linux) or ⌥⌘C (macOS).

View, Copy, or Save a Command History

There are commands available to enter at the command line prompt as well as other ways to save or copy the full set of commands in any Console window tab.

Copy Commands to a Clipboard

- Press `CTRL + Shift + C` in the window or tab where you want to copy the command history. Paste in a text editor as required.
- Right-click any tab and select **Command History** from the menu to open the **Command History** window. Then click the **Copy** ( ) button to copy all the commands to the clipboard. Paste in a text editor as required.
- Right-click any tab and select **Copy Command History to Clipboard** from the menu. Paste in a text editor as required.
    - The shortcut for this command is to press <Ctrl+Shift+C> (Windows and Linux) or ⇧⌘C (macOS).

View or Save Commands to a Macro File

Right-click any tab and select **Command History** from the menu to open the **Command History** window. Then click the **Save** ( ) button , enter a file name and path to save all the commands in a `.TCM` file format.

Enter Commands to View the History

- To scroll through the last twenty commands used, at the command line prompt enter two exclamation marks (`!!`) and press <Enter>.
- To repeat the last *n* commands, at the command line prompt enter `!` followed by the number of previous commands to be repeated.
- `!<text>` executes the most recent command starting with `<text>`. The `< >` is not entered at the prompt.
- `!*<n>` or `!*<text>` makes the command available for editing before execution. The `< >` is not entered.
- To scroll through previous performed commands, use the Up (↑) or Down arrow (↓) keys.
- To read more information about the command history functionality in Thermo-Calc, enter `! ?` at the command line prompt.

Results Window in Console Mode

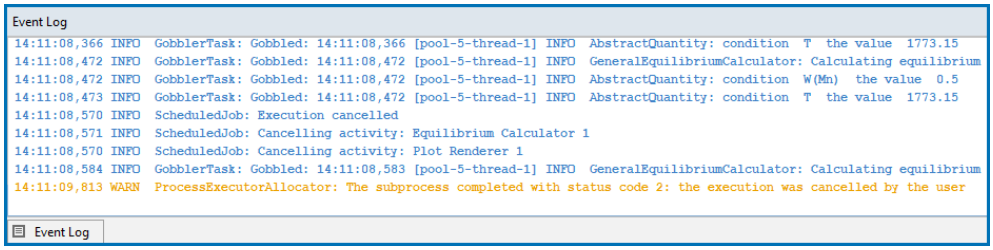
By default, the Console Results window is on the right-hand side of the screen. This is where plotted diagrams display. Each Console has its own Results tab in the Console Results window. All the plots and tables generated are presented in the Results tab.

- To open new **Plot** tabs press <Ctrl+Shift+T> or click the add ⊕ button.
- To open a new Plot tab for the currently active Console tab, press <Ctrl+Shift+T>. To close the Plot tab, press <Ctrl+Shift+W> or <Ctrl+Shift+F4>.

Keyboard Shortcuts to Navigate Between Tabs

Event Log Window

The **Event Log** window is closed by default. Information about what Thermo-Calc is processing or doing is in blue text, an error message is in red text, and caution/warning information is in yellow text.



- To open the Event Log window: Click the **Event Log** window once to expand it or select it from the **Window → Event Log** menu. Double-clicking the window maximizes it.
- To clear all messages in the window, right-click in the text area and select **Clear**.
- To specify the level of detail in the Event Log, open the **Options** window:
  - Windows: Select **Tools →** **Options**.
  - Mac: Select **Thermo-Calc** *<version>* **→ Preferences** or **Settings** or press <⌘> on the keyboard.

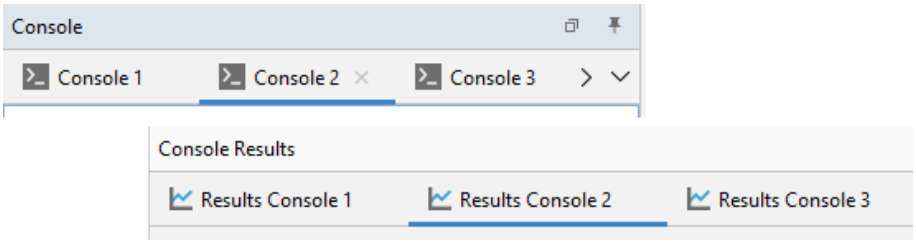
  then click the **General** tab and set the **Log level** slide bar to anything between **Debug** (most detailed) and **Error** (least detailed).

Keyboard Shortcuts to Navigate Between Tabs

Use keyboard shortcuts to move between the tabs available in the Console and Results windows.

Windows

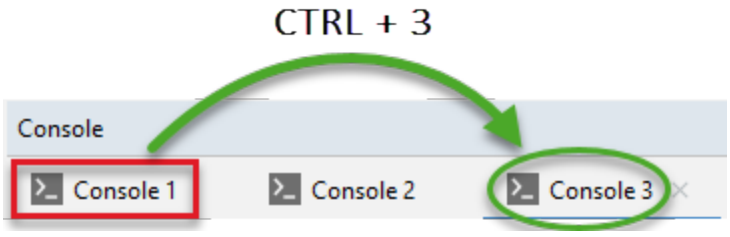
- Press CTRL + TAB to move forward sequentially through each open tab. When you are focused on the Console window, you move forward simultaneously through the Console Results tabs, e.g. If you are on Console 1 and press CTRL + TAB, you move forward to Console 2 and Results Console 2 and so forth.



- Press CTRL + SHIFT + TAB to move back through the open tabs. This is useful if you have multiple tabs open, otherwise you can use the CTRL + TAB to cycle through the windows.
- Press CTRL + [tab number 1 to 9] to move directly to the numbered tab. For example, if you are focused on Console 1 and want to move to Console 3, press CTRL+3 and the focus jumps to that tab.

> The tab number corresponds to the order of the tabs, not necessarily the name. That is, if Console 4 is first, then it is what is highlighted when CTRL + 1 is used.

For **EXAMPLE**, press CTRL + 3 on the keyboard to move focus from Console 1 to Console 3.



When you are focused on the **Console Results** window and use any of the shortcuts this only moves you through the open tabs on this window.

Linux and macOS

The same **Windows** keyboard shortcuts are used but must be pressed twice to move forward and backward.

Console Mode Workflow

Working with Thermo-Calc involves moving between different modules. The workflow differs depending on the type of calculation:

- If you want to perform a calculation using the POLY module, you typically first retrieve thermodynamic data in the DATA module, perform the calculation in POLY, and visualize the results in the POST module. It is possible to define a system directly in POLY using the DEFINE_MATERIAL and DEFINE_DIAGRAM commands.
- If you want to calculate and plot a diagram using a response-driven module, such as POTENTIAL or SCHEIL, then you can go directly to that module. Response-driven modules prompt you to go through the steps to do the calculation and the required post-processing. These modules include BIN, TERN, POTENTIAL, POURBAIX, and SCHEIL. You typically end up in the POST module after having used a response-driven module. In the POST module you can modify the plots and save the diagram.
- If you want to tabulate a chemical substance, phase, or reaction, go directly to the TAB module.

The basic workflow is:

1. You are in the **SYS** module when you start Thermo-Calc in Console Mode.
2. In the **DATA** module define the system. Before performing a calculation, you must define the system and retrieve thermodynamic data. The data is retrieved from a database file (*.TDB or *.TDC).
3. The data needed to describe a system is then sent to the **GIBBS** module. This data is accessed by the **POLY** module when you instruct it to perform calculations.
4. In the **POLY** module, perform the calculations.
    - In POLY, the conditions are set for an equilibrium calculation (temperature, pressure, system composition, etc.), then an equilibrium calculation is done.
    - If you want to make a property or phase diagram, you set the conditions for a stepping or mapping operation and perform that operation.
    - This generates data that can be used to plot a property diagram (if a stepping operation is performed) or a phase diagram (if a mapping operation is performed).

5. In the **POST** module plot and visualize your data.
    - If a stepping or mapping operation is performed, then you can go to the POST module and plot a property or phase diagram.
    - The diagram can be plotted quickly using default settings, but you can also modify which variables to plot of the diagram axes and change the appearance of the diagram.
    - You can save the diagram either as a plain text file with data about all the coordinates or as an image file.

Defining a System in Console Mode

Defining a system means to select the chemical components and to retrieve thermodynamic data about those components from an appropriate database in order to do the calculations. You use database(s) with thermodynamic data and then define what system elements as components. Once the system is defined, you retrieve the system's thermodynamic data from the database(s).

- If you use a *response-driven module* to perform your calculation, such as BIN or POURBAIX, then the module prompts you to select database(s) and define the system.
- When doing calculations in the POLY module, you typically have to manually select databases and define the system in the DATA module. However, it is also possible to define the system directly in POLY using the DEFINE_MATERIAL and DEFINE_DIAGRAM commands.

How to Define a System in Console Mode

1. Go to the DATA (TDB) module. At the `SYS` prompt, use GOTO_MODULE and enter `Data`.
2. Change the default database unless you directly specify the name of the database as a parameter to the command. Type `SWITCH_DATABASE` and follow the prompts.

   The second part of the command prompt indicates the current default database. For example, if the prompt is `TDB_TCFE10`, then the current database is TCFE10.

3. Use DEFINE_ELEMENTS followed by a list of the elements that you want in your system. (To list the elements that are available in your current database, use LIST_DATABASE and choose `Elements`). For example, if you want to have Fe and C in your system, type:

   ```
   DEFINE_ELEMENTS Fe C
   ```

4. Use REJECT and choose `Phases` if you want to avoid retrieving any phases from the database. (To list the phases that are available in your current database, use LIST_DATABASE and choose `Phases`. To list the phases that can form in the defined system, use LIST_SYSTEM and choose `Constituent`.) For example, if you do not want the graphite phase to be retrieved, you type:

   ```
   REJECT PHASES GRAPHITE
   ```

   If the number of phases to include is much lower than the total number of phases, then it can be convenient to first `Reject Phases *` and then restore the phases to include using `Restore Phases`.

5. Use GET_DATA to search the database and send the thermodynamic data about your system to the GIBBS workspace.

   At this point you can proceed to the POLY module (with GOTO_MODULE POLY). However, you may want to add elements, phases and species to the GIBBS workspace from other databases. If so, then proceed to the next step.

6. Use APPEND_DATABASE to select the (additional) database from which you want to retrieve data. This command works exactly in the same way as the SWITCH_DATABASE command, with the exception that it does not reinitialize the DATA module and the GIBBS workspace, but instead appends or replaces the data that has already been retrieved with new data from the additional database.
7. Define your elements and specify whether to reject and restore any phases. Do this in exactly the same way when using the SWITCH_DATABASE command (see steps 2 and 3).
8. Use GET_DATA to search the database and add the thermodynamic data to the data that already exists in the GIBBS workspace.
9. Use APPEND_DATABASE again if you want to add data from yet another database. When you have retrieved all the data you need, you can proceed to the POLY module.

Console Mode Modules

Graphical Mode Activities vs Console Mode Modules

Below are each of the available modules you access in Console Mode. Most of the modules have commands, some are the same no matter what module you are in (e.g. general commands like BACK. GO TO MODULE, EXIT, HELP and so forth). Other commands have different prompts based on the module you are in how you define the system and so forth.

Most modules have several commands available. The exceptions are the BINARY, TERNARY, SCHEIL, POURBAIX and POTENTIAL modules which do not have any additional commands once you access the modules. These are response-driven modules that prompt you with a series of questions and then build the diagram automatically based on your responses.

System Utilities (SYS)

This is the module where you start. It also has several commands. Throughout the other modules there are some general commands, both of which are listed together.

System Utilities (SYS) Commands

Gibbs Energy System (GES)

The Gibbs Energy System (GES) module is an important Thermo-Calc Console Mode module and consists of a comprehensive subroutine package for various thermochemical calculations. The module is interactively connected with all basic and advanced modules in Thermo-Calc and the add-on Diffusion Module (DICTRA). Most users will not directly use the GES module and commands unless you perform assessments.

The GES module is in essence the Thermo-Calc calculation engine, sometimes referred to as the *calculation core*. When working in Graphical Mode you are using the GES calculation engine behind the scenes, whereas in Console Mode, and if you are performing assessments, you are directly interacting with the module. This is also applicable if you are working with any of the software development kits (SDKs).

About the Gibbs Energy System (GES) Module

Gibbs Energy System (GES) Commands

POLY3 (POLY) (Equilibrium)

With the equilibrium calculation module, POLY3, it is possible to calculate many different kinds of equilibria and diagrams, in particular multicomponent phase diagrams.

The Equilibrium Calculation Module (POLY3)

POLY Module Commands

Database (TDB)

The Database module (full name is Database Retrieval) is where you select and retrieve various types of thermodynamic and kinetic information from the selected databases you are going to use for your system. Once you enter the module the short name is `TDB`.

Database (TDB) Module Commands

Defining a System in Console Mode

Also see the Database Manager User Guide and the available information for the specific databases.

POST - A POLY3 Submodule

The POST module (post-processor) is a submodule to the POLY module and has its own set of commands. The TAB, BIN, TERN, POT, SCHEIL and POURBAIX modules use the POST module features as part of the automatic generation of the plots.

Using the POST Module

POST Module Commands

Scheil (SCHEIL) Simulations

The available Scheil-Gulliver solidification simulations are *classic* Scheil, Scheil with *back diffusion* in the primary phase, or Scheil with *solute trapping*. There are also configuration options available with *fast diffusers* for the classic and back diffusion models.

There is also connectivity to the Diffusion Module (DICTRA) and *homogenization* where you collect data from a Scheil solidification calculation, which is then used as part of the kinetic homogenization simulation of segregated composition profiles.

Scheil in Graphical Mode vs Console Mode

The Scheil with back diffusion feature is only available for systems with diffusion data, i.e. this model requires the use of a mobility database.

In Thermo-Calc, the Scheil calculation allows the calculation of:

- The solidification range of an alloy.
- Depression of the solidus temperature due to segregation.
- Composition of the last liquid to disappear in segregation pockets.
- Phases formed on final solidification in segregation pockets.
- The composition gradient in the primary solid phase(s) (segregation profile).
- Solute trapping to simulate deviation from local equilibrium for the primary phase
- Kinetic homogenization simulation of segregated composition profile (diffusion calculations)

About the Scheil-Gulliver Solidification Simulations

SCHEIL Module Commands

Pourbaix Diagram (POURBAIX)

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

The POURBAIX module lets you construct Pourbaix diagrams and other types of property diagrams for heterogeneous interaction systems with aqueous solution phases. Once you have calculated the Pourbaix diagram, you can also use the saved results of the calculation (the POLY3-file), and make a property diagram based on stepping calculation. You can also plot additional diagrams based on the results of the same calculation, but with different axis variables than Ph and Eh.

Search the help (press F1 when in Thermo-Calc) for information about the Graphical Mode **Aqueous Calculator**, its template with predefined settings, and the aqueous properties. The help also has detailed information about the compatible and recommended database for use with all aqueous calculations.

Potential Diagram (POT)

The POTENTIAL_DIAGRAM module (short name, the POTENTIAL module) is a potential phase diagram calculation module. A potential diagram uses the activities of two major species in the gaseous mixture phase as mapping variables.

About Potential Diagrams

Binary Diagram (BIN)

The BINARY_DIAGRAM module (short name, the BIN module) enables you to quickly calculate a simple binary phase diagram. Binary phase diagrams are by far the most common found in the literature and calculated by computers. However, most real systems have more than two components and thus binary diagrams are more a kind of exercise in order to calculate more realistic phase diagrams.

About Binary Phase Diagrams

Ternary Diagram (TERN)

The TERNARY_DIAGRAM module (short name, the TERN module) enables you to quickly calculate a simple ternary phase diagram. There are many types of ternary phase diagrams but perhaps the most common is the isothermal section. In this case, the temperature is constant, which means that the tie-lines are in the plane of the calculation.

About Ternary Phase Diagrams

PARROT (Optimization)

The PARROT module makes use of the GES module to handle the models of the various phases that might form in a multicomponent system, as well as of the POLY module to store and calculate complex heterogeneous equilibria.

PARROT Module Commands

Also see Data Optimization (PARROT).

Tabulation Reaction (TAB)

The TABULATION_REACTION (TAB) module can be used to tabulate thermodynamic functions of any type of substance, stoichiometric phase or solution phase, or reaction. The module can tabulate thermodynamic functions of pure stoichiometric phases or solution phases at fixed composition, as well as various kinds of partial derivatives for a pure stoichiometric phase or solution phase at a given composition.

About the Tabulation Reaction Module

Tabulation Reaction (TAB) Commands

Reactor Simulator (REACTOR)

Simulate chemical reaction processes in several feed-forward steady-state stages or in several dynamic stages.

REACTOR (REACTOR_SIMULATOR) Commands

DICTRA Monitor (DICTRA)

DICTRA Monitor (DICTRA) and DIC Parrot (optimization for DICTRA): These are available with the add-on Diffusion Module.

Moving Between Modules and Submodules

To go to a specific module, you typically use GOTO_MODULE (or just GOTO) followed by the name of the module. For example, to go to the DATA module, type `GOTO DATA`.

The exceptions are the submodules POST and ED-EXP:

- To go to the POST module, you must enter the POST command from within the POLY module or DICTRA module (if you have the add-on license).
- To go to the Edit Experiments module you must enter the ED-EXP command from within the PARROT module.

To go back to the previous module type `Back`. For example, if you are in the DATA module and entered it from the SYS module, when you type `Back`, you return to the SYS prompt. This command is also available to exit from the submodules POST and ED-EXP.

Without a valid Thermo-Calc license, you cannot leave the SYS module. To enter the DICTRA and DIC_PARROT modules, you also need a valid Diffusion Module (DICTRA) license key.

Entering Command Names or Abbreviations

The name of a command typically consists of terms linked with underscores, for example, LIST_EQUILIBRIUM. Note the following:

- UPPER or lower case letters are OK.
- Hyphens (-) instead of underscores (_) are OK, e.g. LIST-EQUILIBRIUM.
- You can abbreviate commands as long as it is unambiguous, e.g. when more than one command begins with LIST_, you need to type the next letter or word to distinguish between the commands.
- Each word can be abbreviated e.g., L_E for LIST_EQUILIBRIUM.

Examples

These are examples of how to abbreviate commands at the command line prompt in Console Mode.

Command Name	*Abbreviation*
CALCULATE_EQUILIBRIUM	C-E
CALCULATE_ALL_EQUILIBRIA	C-A
LIST_EQUILIBRIUM	L-E
LIST_INITIAL_EQUILBRIUM	LI-I-E
LOAD_INITIAL_EQUILBRIUM	LO-I-E
LIST_PHASE_DATA CBCC	L-P-D CBC
LIST_PHASE_DATA CEMENTITE	L-P-D CEM
SET_ALL_START_VALUES	S-A-SS-AL
SET_AXIS_VARIABLE 1 X(FCC,FE) 0 0.89 0.025	S-A-V 1 X(F,FE) 0 .89 .025
SET_START_CONSTITUENT	S-S-C

Command Name	*Abbreviation*
SET_START_VALUE	S-S-V
SET_AXIS_PLOT_STATUS	S-A-P
SET_AXIS_TEXT_STATUS	S-A-T-SS-A-TE
SET_AXIS_TYPE	S-A-TY
SET_OPTIMIZING_CONDITION	S-O-C
SET_OPTIMIZING_VARIABLE	S-O-V
SET_OUTPUT_LEVEL	S-O-LS-OU

Using the Command Line Prompt

The command line prompt in the Console window tells you which module you are currently in. When Thermo-Calc is first opened in Console Mode, you are in the SYS module, which is indicated with the command line prompt `SYS`.

To use Console Mode, you type in commands at the command line prompt. The available commands depend on which module you are in. You can list the commands by typing `?` at the prompt and then press <Enter>.

Console Window and Tabs also includes information about saving or copying the Command history.

- Moving Between Modules and Submodules
- Entering Command Names or Abbreviations
- Specifying Parameters
- Wild Card Characters
- Keyboard Shortcuts to Navigate Between Tabs
- Working with the Console Mode Output

Main Menu Commands

In Console Mode you use commands to access these menu options. If there is an equivalent command, it is listed below.

The **File** menu and toolbar are reserved for Graphical Mode. The **Tools**, **Window** and **Help** menus are described in Menu, Toolbar, and Keyboard Shortcuts.

Opening Console Mode Files

- In the SYS module: MACRO_FILE_OPEN
- In the SYS module: OPEN_FILE

Opening Console Mode Macro Files

Drag and drop files into the Console window to open or run a macro, for example. File types that can be opened this way are macro files (*.TCM and *.DCM), database files (*.TDB), and workspace files (*.POLY3, *.GES5,*.PAR, and *.DIC). Note that *.DCM and *.DIC file extensions are applicable to the Diffusion Module (DICTRA).

Save (Workspace)

This command depends on the module you are in. Type ? at the prompt to look for a command such as SAVE_GES_WORKSPACE (GIBBS module).

Exit

In any module: EXIT

Close

In the SYS module: CLOSE_FILE

Display License Info

In the SYS module: DISPLAY_LICENSE_INFO

Wild Card Characters

You can sometimes use the asterisk (*) as a wild card character to, for example, refer to all components, phases, or species, when showing calculated properties in the POLY module, or when you set axis variables for plotting diagrams in the POST module.

When showing calculated properties in the POLY module, you can also use the dollar sign ($) to refer to all stable phases.

For activity and/or chemical potential properties, the * and $ normally do not work properly as wild card characters.

Examples of Wild Card Characters

These are examples of the wild card characters you can use to search commands at the command line prompt.

Command	*Action*
SHOW_VALUE B(*)	Lists mass (gram) of all components in the system.
SET_AXIS_VAR Y B(*) *	Sets mass (gram) of all components in the system as Y-axis variable.
SHOW_VALUE MUR(*)	Lists chemical potentials of all components in the system.
SET_AXIS_VAR Y ACR(*) *	Sets activities of all components in the system as Y-axis variable.
SHOW_VALUE HM(*).T	Lists heat capacities of all phases.
SET_AXIS_VAR Y GM(*) *	Sets molar Gibbs free energies of all phases as Y-axis variable.
SHOW_VALUE TC($)	Lists curie temperature of all stable phases.
SHOW_VALUE W(*,*)	Lists mass fractions of all components in all phases.
SHOW_VALUE W($,*)	Lists mass fractions of all components in all stable phases.

Command	*Action*
SHOW_VALUE W(FCC,*)	Lists mass fractions of all components in the FCC phase.
SHOW_VALUE W(*,FE)	Lists mass fractions of the Fe component in all phases.
SHOW_VALUE W($,FE)	Lists mass fractions of the Fe component in all stable phases.
SHOW_VALUE Y(*,*)	Lists site fractions of all species in all sublattices of all phases.
SHOW_VALUE Y($,*)	Lists site fractions of all species in all sublattices of all stable phases.
SHOW_VALUE Y(*,*)	Lists site fractions of all species in all sublattices of all phases.

Optimization File Types **764**

Working with the Console Mode File Types

For DICTRA Console Mode see About the Console Mode File Formats.

In Console Mode, Thermo-Calc uses different types of files, including:

- Macro Files and Log Files both with the file extension *.TCM. Log files are created using the SET_LOG_FILE command.
- Workspace Files in POLY (*.POLY3), GIBBS module (*.GES5), and the PARROT module (*.PAR). (For the GIBBS module, this cannot currently be done with GES6).
- Experimental Data Files (*.POP, *.DOP) are a type of workspace file available with the PARROT module and have the file extension of *.POP. In the Diffusion Module (DICTRA), you work with .DOP files instead of .POP. These .POP and .DOP files are referred to as experimental data files.

Another type of experimental data file with the *.EXP file extension are also generated when working with DATAPLOT. See About the DATAPLOT Graphical Language.

A reminder that Linux and Mac are case sensitive; when applicable ensure you enter file extensions with capital letters.

Drag and drop files into the Console window to open or run a macro, for example. File types that can be opened this way are macro files (*.TCM and *.DCM), database files (*.TDB), and workspace files (*.POLY3, *.GES5,*.PAR, and *.DIC). Note that *.DCM and *.DIC file extensions are applicable to the Diffusion Module (DICTRA).

Opening Console Mode Macro Files

The macro files (with the extension *.TCM) include comments, which you can either run in Thermo-Calc or open and read in a text editor.

Options To Open Macro Files

You can open the macro files (*.TCM or *.DCM files) in different ways.

- From the main menu,
- Using a command,
- By dragging and dropping the file into the Console window, or
- Navigate to the file location on your computer and double-click to open it. If you already have Thermo-Calc open, the macro opens in a new tab. Otherwise a new instance of Thermo-Calc is launched.

  If you are using the advanced pipe or redirect option (Technical Note: Pipe or Redirect Output Data from Console Mode) then a new instance of Thermo-Calc is always started.

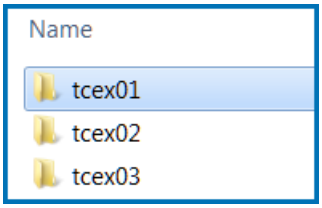
- You can also read the commands listed in the macro file using a text editor.

If you only open and read the macro file in a text editor, you do not see the output that Thermo-Calc gives in response to the commands stored in the macro file.

Opening a Macro from the Main Menu

To open a Thermo-Calc example macro file:

1. Open Thermo-Calc.
2. Confirm you are in Console Mode. If not, click the **Switch to Console Mode** button.
3. From the main menu, select **File →** or **Help → Examples Files**. The Console Mode folder opens.
4. Open the **Thermo-Calc** folder to see the available examples contained in separate folders.



For the Diffusion Module (DICTRA) examples (*.DCM macro files), open the **Diffusion Module - DICTRA** folder.

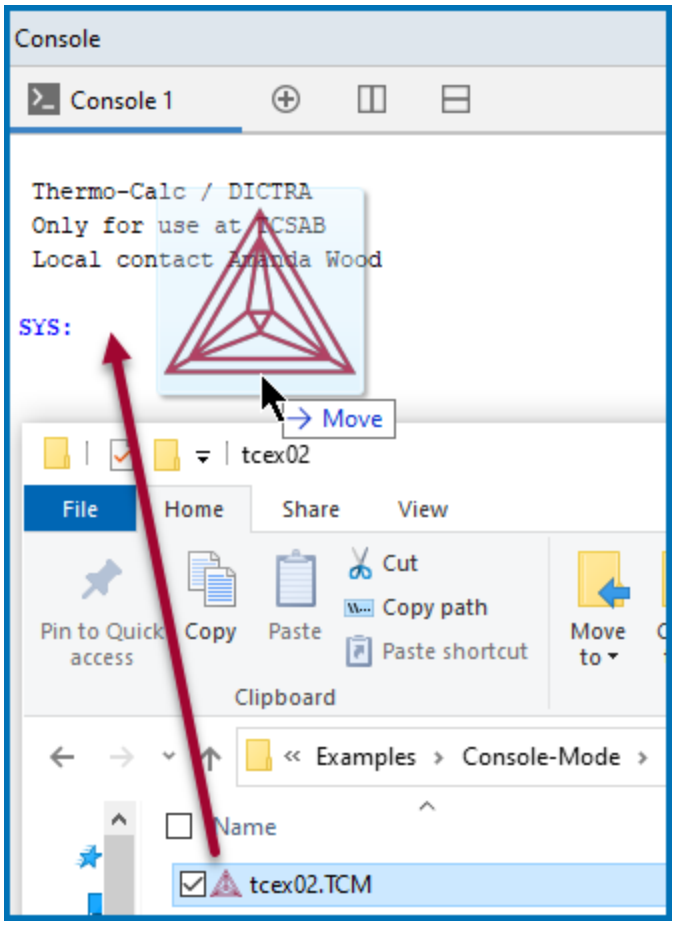
5. In the folder, double-click the *.TCM file or click **Open**.
6. Follow the prompts in the Console window i.e. keep pressing <Enter> to run the macro and produce a plot in the **Console Results** window.

Opening a Macro Using a Command

At the SYS prompt, type MACRO_FILE_OPEN and press <Enter>. In the file dialogue window that opens, navigate to and select the macro file to open.

Dragging and Dropping a Macro File into the Console Window

For example, on your computer, navigate to the examples folder. Drag the file from its location into the Thermo-Calc Console window. When you release (drop) the file, the macro starts running. Follow the prompts in the Console window i.e. keep pressing <Enter> to run the macro and produce a plot in the **Console Results** window.



```

Drag and drop files into the Console window to open or run a macro, for example. File types that can be opened this way are macro files (*.TCM and *.DCM), database files (*.TDB), and workspace files (*.POLY3, *.GES5,*.PAR, and *.DIC). Note that *.DCM and *.DIC file extensions are applicable to the Diffusion Module (DICTRA).

Log Files

Log files with the file extension *.TCM are plain text files used to save a sequence of commands. Log files can be edited in a text editor.

- To start saving your input into such a file, use SET_LOG_FILE in the SYS module, followed by the name of the file that you want to save your command sequence to.
- If you want to save the output in the log file as well, use SET_ECHO before the SET_ LOG_FILE command. Doing this is useful if you want use the log file later as a macro file.

Macro Files

Macro files (with the file extension of either *.TCM or *.LOG) are plain text files used to save a sequence of commands that can be loaded and executed. Macro files can be edited in a text editor. When creating a command sequence, you add comments to the file by starting a line with @@.

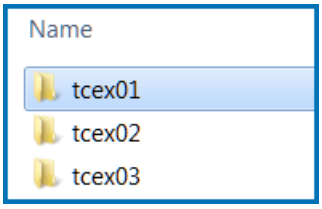
Macro files include comments, which you can either run in Thermo-Calc or open and read in a text editor.

If you only open and read the macro file in a text editor, you do not see the output that Thermo-Calc gives in response to the commands stored in the macro file. It is recommended you run the macro to view all the details.

Opening Console Mode Example Macro Files

To open a Thermo-Calc example macro file:

1. Open Thermo-Calc.
2. Confirm you are in Console Mode. If not, click the **Switch to Console Mode** button.
3. From the main menu, select **File →** or **Help → Examples Files**. The Console Mode folder opens.
4. Open the **Thermo-Calc** folder to see the available examples contained in separate folders.



For the Diffusion Module (DICTRA) examples (*.DCM macro files), open the **Diffusion Module - DICTRA** folder.

5. In the folder, double-click the *.TCM file or click **Open**.
6. Follow the prompts in the Console window i.e. keep pressing <Enter> to run the macro and produce a plot in the **Console Results** window.

Macro File Commands

Action	*Command*	*Description and Comments*
To load a macro file	In the SYS module, MACRO_FILE_OPEN followed by the name of the macro file.	Thermo-Calc starts the command sequence that the file contains.
Regain control of the console	SET_INTERACTIVE	End a macro file with this command to have control of the Console returned to you.
Add comments to a macro file	Start a line with @@, or enclose it between an @ (-line and a @)-line.	When lines are enclosed the software ignores them when running the macro.
Open a macro file	MACRO_FILE_OPEN	When creating the log file, you can make a macro file load up to five other macro files.
Nest macro files inside of each other	MACRO_FILE_OPEN SET_INTERACTIVE	If a nested macro file ends with SET_INTERACTIVE, then Thermo-Calc resumes with the higher-level macro file at the command immediately following the MACRO_FILE_OPEN command that loaded and executed macro file that has just been terminated. If a nested macro file doesn't end with SET_ INTERACTIVE (but with an end-of-file character), then the console shuts down and the macro is stopped.

Macro File Control Characters

The `@?` character allows you to make a macro interactive by allowing input. At the @? character, which is placed where a parameter value or argument is normally put, Thermo-Calc prompts to input the value of a parameter or argument. You can enter a string immediately following the @? character. This string is presented to the user when prompted to enter the parameter value or argument. The entered value is used by Thermo-Calc as input to the command in question. For example, you can request the user to specify the temperature range of a stepping calculation by entering the following in a macro file:

```
SET_AXIS_VARIABLE 1 T @?Low-temperature-limit: @?High-temperature-
limit:
```

You can also use up to nine variables in your macro file and prompt the user to enter values that can be assigned to these variables. Use the `@#n` character when you want to prompt the user to provide a value to the variable, where the n is a digit between `1` and `9`. You can then use this value by with the `##n` character. For example, you can request the user to provide the first element of a system by entering the following in the macro file:

```
@#3First-element?
```

You can then use this variable with the entering the character ##3 later in the macro file. For example, you can write:

```
SET_AXIS_VARIABLE 1 x(##3) 0 1,,,
```

Finally, there is the `@&` pause character. Thermo-Calc pauses and waits for input from the user when this pause character is read from a macro file. Inserting pause characters is useful if you want to allow the user to monitor what is happening when Thermo-Calc is running the macro.

Response-Driven Modules and Macros

Macro files that are created while you use a *response-driven module* begin with the module-entering command (for example, `Goto_Module Scheil)` followed by a number of lines with responses to the module's questions and requests. The file terminates with the commands POST or SET_INTERACTIVE (this command gives you back control of the Console). An empty line cannot be edited with any input rather than the default answer (to a specific question). Comment lines, commands to open other macro files, pause characters or input-controlling characters cannot be inserted between these empty lines (otherwise the response-driven module cannot be executed properly).

Workspace Files

Workspaces files allow you to save all the data in your current workspace. A workspace contains all the data, specified settings and the result of any calculations performed. The saved data includes original and modified thermodynamic data, the last set of conditions and options, and the results of any simulations. You use the command SAVE_WORKSPACES to create this file type, which is available in the POLY, GIBBS, and PARROT modules.

The workspace has all the settings specified and the result of any stepping or mapping operations performed after using SAVE_WORKSPACES. Consequently, the command opens a workspace in which all data is saved which is generated after the SAVE_WORKSPACE command is executed. The saved data includes original and modified thermodynamic data, the last set of conditions and options, and calculation results.

To load the data and calculation results of a workspace file, use the READ_WORKSPACES command available in the POLY module. The file can be used for calculation in POLY, visualization in POST, or data manipulation in GES. You are also given the option in the POURBAIX and SCHEIL modules to open a previously saved workspace file. This allows you to make new POURBAIX or SCHEIL calculations on the same chemical system as before but with different temperature, pressure, and composition conditions, or to plot new property diagrams based on the previous calculations.

File Extension Details

When in Thermo-Calc Console Mode these are the workspace file extensions:

- POLY module (*.POLY3)
- GIBBS (GES) module (*.GES5)
- PARROT module (*.PAR and *.POP)

A reminder that Linux and macOS are case sensitive; when applicable ensure you enter file extensions with capital letters.

Drag and drop files into the Console window to open or run a macro, for example. File types that can be opened this way are macro files (*.TCM and *.DCM), database files (*.TDB), and workspace files (*.POLY3, *.GES5,*.PAR, and *.DIC). Note that *.DCM and *.DIC file extensions are applicable to the Diffusion Module (DICTRA).

For DICTRA in Console Mode, the PARROT module file extension is *.DOP. Also see About the Console Mode File Formats.

POLY Module

- READ_WORKSPACES
- SAVE_WORKSPACES

Gibbs (GES) Module

- READ_GES_WORKSPACE
- READ_WORKSPACES
- SAVE_GES_WORKSPACE
- SAVE_WORKSPACES

PARROT Module

- READ_PARROT_WORKSPACES
- SAVE_PARROT_WORKSPACES

ED-EXP Module (Submodule to PARROT)

- READ_WORKSPACES
- SAVE_WORKSPACES

Reactor Module

- READ_WORKSPACE
- SAVE_WORKSPACES

Important: Map and Step Commands and the Save_Workspaces Command

A STEP or MAP command automatically saves the workspace with the most recently specified name. Do not use the SAVE_WORKSPACES command after a MAP or STEP command.

The results from the STEP or MAP commands are destroyed by the SAVE_WORKSPACE command. You can append several results obtained by sequential STEP or MAP calculations without destroying the previous results, whilst SAVE_WORKSPACE erases them all. Keeping this in mind is important and useful particularly for calculating various isothermal (or isoplethal) sections and plotting them on the same diagram in a single Thermo-Calc run.

To suspend some of the STEP or MAP results, use the AMEND_STORED_EQUILIBRIA command.

Editing the Default Console Directory

You can add a startup parameter to a shortcut when launching Thermo-Calc on any of the platforms. When you launch the revised shortcut, the file path is set to a user-defined default directory. An example of why you might want to have a custom directory path is if you use batch projects or if you have macro files for batch jobs. The custom directory file path can also be viewed from within Console Mode.

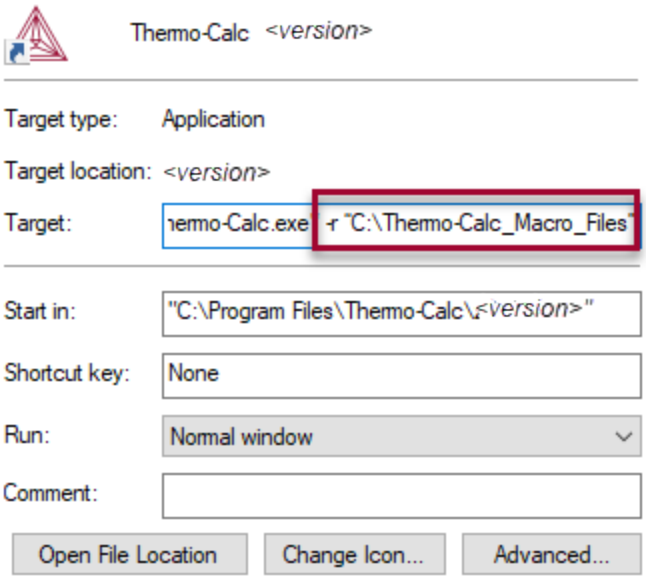
The shortcut is only valid throughout the existing session; it is not saved as a default. Each time you want to use this file path you must launch Thermo-Calc from the customized shortcut.

Setting up the Default Console Directory

The following uses Windows for the example.

1. Right-click a shortcut to Thermo-Calc and click **Properties**.
2. In the **Thermo-Calc 2026b Properties** dialog, **Target** field, add the following to the end of the string: **–r** plus the *"path to the default directory"*. Include a space between the –r and path, and use quotation marks around the full file path. A simple example:

   -r "C:\Thermo-Calc_Macro_Files"

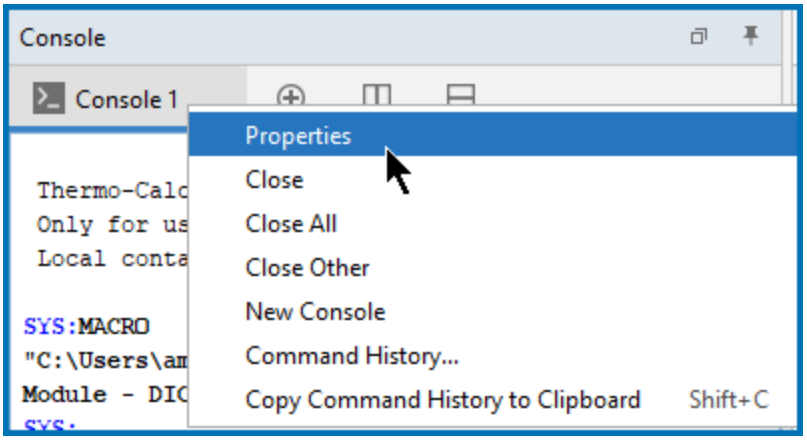


3. Click **Apply** and **OK**.
4. Launch Thermo-Calc from the shortcut where you added the parameter. You can confirm that it is set correctly from within Thermo-Calc.

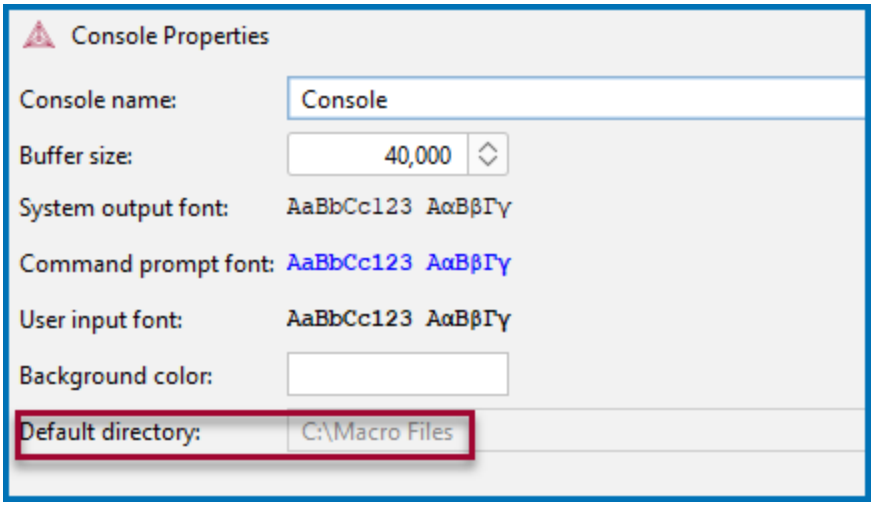
Viewing the File Path in Thermo-Calc

The following uses Windows for the example.

1. Launch Thermo-Calc from the short cut where you added the parameter.
2. In Console Mode, right click the **Console** window and choose **Properties**.



3. In the **Console Properties** window the **Default directory** section displays the custom file path. This default is set in the **Options** window, Console Mode section.



To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

Experimental Data Files (*.POP, *.DOP)

In order to conduct an assessment for a system, the experimental data is described with a syntax, which is similar to the way that one calculates an equilibrium in the POLY module or you edit an experimental point in the ED_EXP module. Similar to a Thermo-Calc macro file (*.TCM), an experimental data file (i.e. the *.POP or *.DOP file) is a basic text file and can be opened and edited by any text editor. For this reason, a *.POP or *.DOP file is not hardware dependent.

About the POP and DOP Files

A POP or DOP file consists of various commands from the POLY and ED_EXP modules, as well some special commands which can only be used in such experimental data files. Various experimental information can be inputted in an *.POP or *.DOP file as different tables; the same type of experimental data are usually documented in the same table (see below).

A *.POP or *.DOP file is used in the PARROT module to provide experimental information for the optimization process, and is checked by a *syntax checker* when the PARROT command COMPILE_EXPERIMENTS is proceeded.

The special commenting identifier, i.e. a dollar sign $ which starts a line, is used to document comment lines at any position in a *.POP or *.DOP file. You may remember that this feature is universally the same as in almost all kinds of text files in Thermo-Calc software, e.g. in *.TDB, *.DAT, *.TCM, *.POP/*.DOP and *.EXP files. Such a sign and all information afterwards in the same comment line is skipped and ignored by the syntax checker.

Many POLY and ED_EXP commands can be directly used in a POP or DOP file. But there are some differences with the set of POLY or ED_EXP commands, and some specially designed commands as described in this topic can only be used in the *.POP or *.DOP files.

Frequently Used POLY Commands

Most of the commands in the experimental data file are the same as in the POLY module. The most frequently used are listed below:

The last command in an *.POP or *.DOP file must always be the SAVE command.

- CREATE_NEW_EQUILIBRIUM
- CHANGE_STATUS
- SET_CONDITION
- SET_REFERENCE_STATE
- ENTER_SYMBOL
- SAVE_WORKSPACES

Less Often Used POLY Commands

Other legal commands from the POLY module that are used less often are:

> The DEFINE-COMPONENTS command must be always used as the first command in an *.POP or *.DOP file, as it automatically reinitiates the whole workspace.

- DEFINE_COMPONENTS
- EVALUATE_FUNCTIONS
- SET_ALL_START_VALUES
- SET_NUMERICAL_LIMITS
- SET_START_VALUE
- ADVANCED_OPTIONS

Frequently Used Edit Experiments (ED_EXP) Commands

Most of the special commands for the ED_EXP module are also often used in an *.POP or *.DOP file. For example:

- EXPERIMENT
- EXPORT
- IMPORT
- LABEL_DATA
- SET_ALTERNATE_CONDITION
- SET_WEIGHT

Do NOT Use these Edit Experiment (ED_EXP) Commands

The following special ED_EXP commands are illegal and should not be used in any *.POP or *.DOP file:

- COMPUTE-ALL-EQUILIBRIA
- MAKE-POP-FILE
- READ (READ-BLOCK OR READ-WORKSPACE)
- TRANSFER-START-VALUES

Learn More

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

There is also another type of experimental data file (*.EXP) generated when working with DATAPLOT. See About the DATAPLOT Graphical Language.

If you are using Graphical Mode, the Experimental File Reader activity node is used to plot experimental data on one or more plots.

Optimization File Types

These are the important files you work with when optimizing.

File type	*Description*
POP file	The POP file (Parrot OPtimization file) is the file that contains all the experimental data that you use for optimizing Gibbs energy values for your system. The POP file is a plain text file that contains ED_EXP commands. By default, the file has the filename extension *.POP in Thermo-Calc.
Setup file	The setup file is a Thermo-Calc macro file (*.TCM). This file typically contains commands that define your system, opens the PARROT workspace (and associated GIBBS and POLY workspaces) and sets optimizing variables.
Other macro files	It is often useful to have other macro files than the setup file at hand while you are doing your optimization. For example, it is convenient to have a macro file that automatically plots phase diagrams or other diagrams based on the latest values of your optimizing variables. An optimization process typically involves many optimization cycles, so this operation needs to be done many times during a typical optimization.
Workspace files	The PARROT module has its own workspace with dynamic memories, similar to the workspaces of POLY and GIBBS. It is stored and updated in a PARROT workspace file with the filename extension *.PAR. The workspace file is a binary file whose format is hardware dependent. This means that the format is unique for each type of CPU. Hence, a workspace file saved on a computer with one type of CPU cannot be used on a computer with another type of CPU.
EXP-file	The EXP-file is a plain text file with information in the form of DATAPLOT Graphical Language commands. These commands can specify some or all of the data points in your POP file. This allows you to plot these data points on top of your plotted optimization results (with the POST commands APPEND_EXPERIMENTAL_DATA or QUICK_EXPERIMENTAL_PLOT). You can then visually assess the fit between these results and the experimental data. The PARROT workspace is not influenced in any way by the creation or use of EXP-files.

Equilibrium Calculations

Topics to Explore >

The Equilibrium Calculation Module (POLY3) **766**

Setting Conditions for Equilibrium Calculations **768**

State Variables *769*

Calculating an Equilibrium **770**

Calculating an Equilibrium with a Fixed Phase **771**

Calculating an Equilibrium with Suspended or Dormant Phases **772**

The Equilibrium Calculation Module (POLY3)

An equilibrium describes what the composition of the end state of a system is, given a full specification of state variables such as temperature, pressure, initial composition, system size, etc. An equilibrium calculation is normally done in POLY-3 according to the *Global Minimization Technique*, which ensures that the most stable minimum under the specified conditions is computed.

For an equilibrium calculation to be performed, the state variables must all be set as conditions for the calculations. Such conditions include, for example, temperature, pressure, and system composition. When you calculate an equilibrium in the POLY module, you have to set these conditions manually.

Knowledge of the thermodynamic equilibrium is an important factor for understanding properties of materials and processes. With a database of thermodynamic model parameters, it is possible to predict such properties and also to obtain driving forces for diffusion-controlled phase transformations and other dynamic processes.

With the equilibrium calculation module, POLY3, it is possible to calculate many different kinds of equilibria and diagrams, in particular multicomponent phase diagrams.

Different types of databases can be used with the POLY module, and it can be used for alloys or ceramic systems, as well as gaseous equilibria, aqueous solution involved heterogeneous interaction systems. Up to 40 elements and 1000 species can be defined into a single system for equilibrium calculations.

All normal thermodynamic state variables can be used to set as conditions in calculating equilibria, and as axes in plotting diagrams. You can set the composition or any property of an individual phase as a condition. Any state variable can be varied along an axis in order to generate a diagram. During calculations of a diagram, complete descriptions of all calculated equilibria are stored, and in the diagram any state variable can be used as an axis.

The *Global Minimization Technique* is used to ensure that the present minimum in an equilibrium calculation is the most stable minima for the specified conditions. This is based on the traditional GEM (Gibbs Energy Minimization) technique.

A direct global minimization can be performed on conditions: N, n(comp), B, b(comp), w (comp), x(comp), T, and P, but not when combined conditions as e.g. w(a)-3*w(b)=1 are used or when an activity or potential condition is used. For all other types of conditions where regular minimization converges, Indirect Global Minimization, i.e. global test and corrections, if necessary, are performed until the lowest minimum is found.

- Direct Global Minimization: From the mesh of Gibbs energy, find the set of grid points that gives the lowest energy solution under the specified conditions. This set of grid points provides starting combination of phases and their constitutions for regular minimization to find the exact equilibrium solution. This solution is then subject to a global test as described below.
- Indirect Global Minimization: Under certain conditions, a direct approach is impossible. In this case, regular minimization is performed first and then a check is performed in order to see if the found local minimum is a global one by checking if all grid points are above the equilibrium Gibbs energy plane. If not, then recalculate by including these grid points until no grid point is above the equilibrium Gibbs energy plane from the previous step.

The full-scale and full-scope usage of the *Global Minimization Technique* has been extended from for only single-point calculations for all types of calculations (of single-points, property diagram stepping and phase diagram mapping)in Thermo-Calc.

The use of *Global Minimization Technique* may increase the computation time. The main cost in time comes from the calculation of Gibbs energy at each grid point generated by properly meshing the composition space for each entered phase. An additional (but much smaller) cost in time comes from finding the set of grid points in the above mesh that give the lowest energy solution. This solution is where POLY starts its ordinary minimization. When POLY has found an equilibrium, the equilibrium Gibbs energy surface is compared to the mesh to assure that no grid point is below the surface, i.e. a global minimization has been reached.

Global minimization is performed by default in single-point or stepping or mapping equilibrium calculations.

Together with the PARROT module, the POLY module is also used for critical assessment of experimental data in order to develop thermodynamic databases. The POLY module uses the Gibbs Energy System (GES) for modeling and data manipulations of the thermodynamic properties of each phase.

Setting Conditions for Equilibrium Calculations

Setting a condition normally involves giving a single state variable a specific value. For example, you can set the temperature to 1273.5 Kelvin (T=1273.5). Alternatively, setting a condition can involve giving a linear expression with more than one state variable a specific value. For example, you can set the mole fraction of the S component to be the same in the liquid and the pyrrohotite phases (`X(LIQ,S)-X(PYRR,S)=0`).

```

```

The number of state variables that need to set is determined by the *Gibbs Phase Rule*. Typically, the state variables to give values to are:

- temperature (in K)
- pressure (in Pascal)
- system size in number of moles (in mole) or mass (in grams)
- the fraction of each component (in number of moles or mass)

If you fix the phase of the equilibrium and all but one of the state variables, you can discover the value of the other state variable at equilibrium.

It is possible to specify a set of conditions that does not have any equilibrium and the program detects this by failing to reach equilibrium during the calculation.

State Variables

The table lists some of the available state variables you can use to set conditions.

State Variable	SET_CONDITION Parameter
temperature in the system (in K)	T
pressure in the system (in Pascal)	P
system size (mole number in moles)	N
system size (mass in grams)	B
number of moles of a component in the system	N(<component>)
mole fraction of a component in the system	X(<component>)
mass fraction of a component in the system	W(<component>)
activity of a component in the system	ACR(<component>)
chemical potential of a component in the system	MUR(<component>)
mole fraction of a component in a phase	X(<phase>,<component>)
mass fraction of a component in a phase	W(<phase>,<component>)
activity of a species referred to a phase at ambient temperature and pressure	ACR(<species>,<phase>)
chemical potential of a species referred to a phase at ambient temperature and pressure	MUR(<species>,<phase>)
enthalpy in the system (in J)	H
enthalpy of a phase (in J/mol)	HM(<phase>)

Calculating an Equilibrium

This topic explains how to calculate an equilibrium in POLY. To calculate an equilibrium means to calculate the equilibrium composition of your system, given a full specification of conditions that reduce the degrees of freedom of the calculation to zero.

1. Define your system. See Defining a System in Console Mode.

2. Go to the POLY module. At the SYS prompt, type `GOTO_MODULE` and enter `POLY`.

   > If you are running a network client installation of Thermo-Calc and cannot enter the POLY module, this may be because all the license instances on that the license server makes available have been checked out.

3. Use SET_CONDITION followed by conditions and value assignments to set the conditions of your calculation. For example, to set temperature, pressure, initial composition and system size for a Fe-Cr-C system, you might enter the following:

   ```
   SET_CONDITION T=1200 P=1E5 W(CR)=0.18 W(C)=0.0013 N=1
   ```

   This sets the temperature (T) to 1200 K, the pressure to 1 bar (100,000 Pascal), the mass fraction of Cr to 18 mole percent, the mass fraction of C to 0.13 weight percent, and the total amount of material to 1 mole. The fraction of Fe in the system is calculated from the fractions of Cr and C. You have to set the fraction of all the components in your system except one.

4. Use COMPUTE_EQUILIBRIUM to run the calculation.
5. Use LIST_EQUILIBRIUM to see the results of the calculation.

Calculating an Equilibrium with a Fixed Phase

There are many ways to calculate equilibriums in Thermo-Calc. The following is one example.

You can calculate an equilibrium that has a certain amount of a certain stable phase. Use CHANGE_STATUS and choose `Phase` to specify the phase and the amount of that phase (in normalized mole number) that you want to set as fixed. For example, if you want to find out at what temperature a system starts to melt, enter the following:

```
CHANGE_STATUS PHASE LIQUID=FIX 0
```

You must leave the state variable whose equilibrium value you are interested in unspecified. However, if you have already specified that state variable, you can make it unspecified again by using SET_CONDITION and set that state variable to `NONE`. For example, if you have given temperature a value, you can type:

```
SET_CONDITION T=NONE
```

The calculated equilibrium includes the value of the unspecified variable at which the equilibrium enters the phase that is fixed.

For an example where an equilibrium is calculated with a fixed phase, see Console Mode example tcex07 via Single Equilibrium Calculation Examples.

Calculating an Equilibrium with Suspended or Dormant Phases

You can calculate an equilibrium under the assumption that one or several phases are `SUSPENDED` or `DORMANT` using CHANGE_STATUS and choose `Phase`. For example, to specify that all phases except one should be suspended, you can first suspend all phases and then enter a single phase in the following way:

```
CHANGE_STATUS PHASE *=SUSPENDED
CHANGE_STATUS PHASE FE_LIQUID=ENTERED
```

For an example where this is done, as well as where the status of phases is set to be dormant, see the Single Equilibrium Calculation Examples.

Gibbs Energy System (GES)

Topics to Explore >

About the Gibbs Energy System (GES) Module **774**

Calculation Engine: GES5 vs GES6 ..... *775*

About the Gibbs Energy System (GES) Module

The Gibbs Energy System (GES) module is an important Thermo-Calc Console Mode module and consists of a comprehensive subroutine package for various thermochemical calculations. The module is interactively connected with all basic and advanced modules in Thermo-Calc and the add-on Diffusion Module (DICTRA). Most users will not directly use the GES module and commands unless you perform assessments.

The GES module is in essence the Thermo-Calc calculation engine, sometimes referred to as the *calculation core*. When working in Graphical Mode you are using the GES calculation engine behind the scenes, whereas in Console Mode, and if you are performing assessments, you are directly interacting with the module. This is also applicable if you are working with any of the software development kits (SDKs).

The objective of the GES module is to provide a unified set of subroutines to be used in any application program that needs thermochemical data. All kinds of thermodynamic models for various types of substances are implemented. However, most model-dependent features are hidden inside the module, and the application programmer can use a standardized set of subroutines, i.e. using the Thermo-Calc SDKs such as TC-Python, TQ-Interface, and TC-Toolbox for MATLAB® to calculate the integral Gibbs energy or any partial derivative thereof for each phase at any composition, temperature and pressure.

There are subroutines to analytically calculate the first and second partial derivatives of integral Gibbs energy with respect to any variable. You can enter and modify phase descriptions, model connections, basic thermodynamic parameters, and so on.

POLY and all other basic and special modules, as well as the add-on Diffusion Module (DICTRA), interactively call the subroutines within the GES module to calculate any thermodynamic quantities.

Calculation Engine: GES5 vs GES6

GES6 is a re-write and new implementation of the Gibbs Energy System module of Thermo-Calc and it is the default engine in Thermo-Calc. As of 2026b, TQ-Interface has access to it but GES5 is the default. GES5 continues to be available and works in the background of the program where necessary. The main purpose of GES6 is to support faster development of new features. However, not all GES5 functionality is implemented in GES6. In such cases (except for the POURBAIX module), GES6 falls back silently and uses functionality from GES5 in the background.

To globally set the default from GES6 back to GES5, go to the **Tools → Options →** Global General Settings tab and click **Version 5** for the *Preferred Gibbs Energy System* setting. This is useful if you are using the POURBAIX module in Console Mode only (aqueous solutions), or if you have a custom database that is not compatible with GES6. The SET_GES_VERSION Console Mode command can also be used to change GES versions for a single Thermo-Calc session.

Contact Thermo-Calc Software AB at info@thermocalc.com for more information about the changes or if you encounter any issues you think are related to the new version of the calculation engine.

Property Diagrams

About Property Diagrams **777**

Calculating and Plotting a Property Diagram **778**

Calculating a Property Diagram One Phase at a Time **780**

Calculating Several Properties in the Same Diagram **781**

About Property Diagrams

When you calculate and plot a property diagram, there is only one independent state variable. Many different properties can be plotted as a function of this independent variable. For example, if the independent state variable is temperature, then the mole fractions of all phases can be plotted as a function of temperature. Or the composition of a specific phase may be plotted relative to temperature, or the activity of a component in the system as a whole or in a specific phase may be plotted relative to it.

A property diagram is plotted based on a series of equilibria that is computed while the value of one state variable is varied between a minimum and a maximum value. This variable is referred to as the stepping axis variable. In Thermo-Calc, first calculate one initial equilibrium, and then new equilibria are calculated at incremental steps in both directions on the stepping axis from the initial equilibrium. This continues until the stepping operation has covered the length of the axis between a minimum and a maximum value that is specified.

For an example of the calculation of a property diagram, see tcex08.

Calculating and Plotting a Property Diagram

This topic explains how to calculate a property diagram in POLY. To calculate a property diagram means to calculate a series of equilibria while the value of the stepping axis variable varies between a minimum and a maximum value. With the exception of the stepping axis variable, all the state variables that you set when you calculate the initial equilibrium retain the values when the new equilibria are calculated.

1. Calculate an initial equilibrium in the POLY module.

2. Use SET_AXIS_VARIABLE to set the axis variable, the minimum and the maximum stepping variable values and the step length. The first parameter of SET_AXIS_VARIABLE is the axis number. Since a property diagram only has one axis variable, this is set to 1. For example, if you want to set the axis variable to temperature, and calculate an equilibrium at every 50 K between a minimum temperature of 100 K and a maximum temperature of 2000 K, enter

   ```
   SET_AXIS_VARIABLE 1 T 100 2000 50
   ```

   An axis variable must be a state variable that is set when you calculated the initial equilibrium. For example, if you set the fraction of a component in number of moles, then you cannot set the mass fraction of this component as an axis variable. Also, the minimum stepping variable value must be smaller than, and the maximum value larger than, the value that you set the state variable to when calculating the initial equilibrium.

3. Use STEP_WITH_OPTIONS and choose `Normal` to perform the stepping operation.

   The phase regions are listed along the stepping axis, the phases contained in each region, and the number of equilibria calculated in that region. Each region is defined by the phases it contains.

   The number of equilibria calculated is not just the number of steps that are performed according to the step length and the minimum and maximum values on the axis variable. This is because Thermo-Calc calculates extra equilibria when a new phase is discovered in order to determine the phase region boundary more precisely.

```
POLY_3:s-a-v 1 T 1000 2000 100
POLY_3:step
Option? /NORMAL/:
 No initial equilibrium, using default
 Step will start from axis value    1000.00
...OK

 Phase Region from    1000.00     for:
     BCC_A2
     GRAPHITE
 Global check of adding phase at  1.01118E+03
 Calculated     4 equilibria

 Phase Region from    1011.18     for:
     BCC_A2
     FCC_A1
     GRAPHITE
 Calculated     2 equilibria

 Phase Region from    1011.18     for:
     FCC_A1
     GRAPHITE
 Global test at  1.09000E+03 .... OK
 Global check of removing phase at  1.15727E+03
 Calculated    17 equilibria
```

4. To plot the diagram, open the POST module and then use PLOT_DIAGRAM. By default, the X-axis represents the stepping axis variable and Y-axis represents the sum of the mole fractions of all phases (NP(*)).

Calculating a Property Diagram One Phase at a Time

There are many ways to calculate property diagrams in Thermo-Calc. One example is where you can calculate a property diagram with a separate stepping operation being performed for each phase at a time in its default most stable composition (the major constitution). This is useful if you want to create a property diagram for a heterogeneous system with both ordered phases and their disordered pairs.

To calculate a property diagram one phase at a time, use STEP_WITH_OPTIONS and when prompted choose `One_phase_at_time` to perform the stepping operation.

Calculating Several Properties in the Same Diagram

There are many ways to calculate property diagrams in Thermo-Calc. The following is another example. If you perform several stepping calculations after each other, the results of these calculations are all saved in your workspace file. This allows you to the following:

- Calculate (and then plot) missing parts of a specific property inside the first property diagram. These parts are calculated inside the range of the stepping variable with a different control condition.
- Calculate (and then plot) two or more sets of a specific property on the same property diagram for the same system. These can be calculated under different control conditions with stepping operations being performed across the same stepping axis variable range.
- Calculate phase boundary lines and then plot them in a corresponding phase diagram for the same system. This can be especially useful for some defined secondary phase-transformations. For example, if you want to find the phase boundary between BCC_A1 and BCC_B2, or the equal-Gm for two specific phases, or the equal-fraction or equal-activity for two specific phases of a certain species, then this can be useful.

Unless you have opened a new workspace file previously using SAVE_WORKSPACES , the results of the stepping calculations are saved in a RESULT.POLY3 file. To save the results of several stepping calculations in a file different from the workspace file that your results are currently saved to, then use SAVE_WORKSPACES before you perform the first stepping calculation.

SAVE_WORKSPACES overwrites and deletes the results of all previous stepping calculations.

A reminder that Linux and Mac are case sensitive; when applicable ensure you enter file extensions with capital letters.

About Phase Diagrams

Phase diagrams have two or more independent axis variables. Any state variable that has already been set can be used as the mapping variable for a mapping calculation and then as the axis variable for a phase diagram. From a mapping calculation, many types of phase diagrams can be plotted, with one of the mapped variables as one axis variable, and with other mapped variables or any varied property (state or derived variables) or entered symbol (variables, functions or table values) as the other axis variables.

All phase diagrams consist of zero phase fraction lines. There are two distinct types of phase diagrams: those with the tie-lines in the plane of the diagram and those where the tie-lines are not in the plane. The former includes binary phase diagrams and ternary isotherms. The latter includes more general isopleth diagrams with one or more fixed extensive variables (normally, this is a composition).

- The BIN and TERN modules calculate binary and ternary phase diagrams.
- The POTENTIAL and POURABIX modules calculate the more general isopleth diagrams and other related diagrams.

The following topics describe how to calculate the types of phase diagrams in the POLY_3 module. In POLY, you can calculate phase diagram for systems with up to 40 components and with thousands of phases. You can combine activity conditions and fixed phase status and fraction conditions in any way. Thermo-Calc can calculate any arbitrary 2D section through composition space.

There is no guarantee that the conditions set will result in a calculation that reaches an equilibrium.

Pourbaix Diagram Examples

Calculating and Plotting a Phase Diagram

This topic describes how to calculate a phase diagram in the POLY module.

1. Calculate an initial equilibrium in the POLY module.

2. Use SET_AXIS_VARIABLE to set the first axis variable, its minimum and maximum mapping value and the length of each incremental step on this axis. The first parameter of SET_AXIS_VARIABLE is the axis number and is set to 1. For example, suppose you want the mass fraction of C as your first axis variable. You want it to vary between 0 and 0.1, with the length of each incremental step being no more than 0.002. Then enter:

   ```
   SET_AXIS_VARIABLE 1 W(C) 0 .1 0.002
   ```

   An axis variable must be a state variable that is set when you calculated the initial equilibrium. For example, if you set the fraction of a component in number of moles, then you cannot set the mass fraction of this component as an axis variable.

3. Use SET_AXIS_VARIABLE to set the second axis variable and specify its minimum, maximum, and step length values. The axis number is set to 2. For example, suppose you want temperature as your second axis variable and you want it to vary between 900 K and 1900 K, with an incremental step of 25 K. Then enter:

   ```
   SET_AXIS_VARIABLE 2 T 900 1900 25
   ```

4. If you want more than two axis variables, then use SET_AXIS_VARIABLE until you have set all the axis variables. You can set up to five axis variables. Axis variables 3, 4 and 5 must be set temperature, pressure or to the chemical potentials of components.

   You may want to save your workspace with SAVE_WORKSPACES before you perform the mapping calculation. This saves the axis variables you have set. However, it overwrites the results of any previous stepping or mapping calculations done.

5. Use MAP to perform the mapping calculation. The console lists the phase region boundaries and the phases contained on one side of each boundary.

```
Phase region boundary  30 at:   1.363E+03  2.012E-01
    FCC_A1
 ** GRAPHITE
Calculated.                      3  equilibria
Terminating at known equilibrium

Phase region boundary  31 at:   1.990E+03  2.526E-01
    LIQUID
 ** GRAPHITE
Calculated.                     13  equilibria
Terminating at known equilibrium
```

6. To plot the diagram, use POST to open the POST module and then use PLOT_DIAGRAM. By default, the X-axis represents mapping axis variable 1 and the Y-axis represents mapping axis variable 2.

About Binary Phase Diagrams

Binary phase diagrams are by far the most common found in the literature and calculated by computers. However, most real systems have more than two components and thus binary diagrams are more a kind of exercise in order to calculate more realistic phase diagrams.

You can calculate many types of binary phase diagrams with POLY, but the traditional one has one composition axis and the temperature on the other axis. This is calculated by first specifying a single equilibrium by setting conditions such as

```
SET_CONDITION T=1200, P=1E5, W(C)=.02, N=1
```

This means that the temperature should be 1200 K, pressure 1 bar, mass fraction of C is 0.02 (i.e., 2 weight percent) and the system contains one mole of atoms. Note that one does not set a condition on the amount of the second component. This is simply taken to be the rest of the system.

After setting these conditions one can calculate the equilibrium by giving the command:

```
CALCULATE_EQUILIBRIUM
```

When the calculation has converged, one continues by setting the axes for the diagram calculation. In most cases, one is interested in the complete composition range but the temperature range may vary.

```
SET_AXIS_VARIABLE 1 W(C) 0 .1 0.002
SET_AXIS_VARIABLE 2 T 900 1900 25
```

This means that the axis number 1 is taken to be the mass fraction of C which may vary between 0 and 0.1 with a maximum increment of 0.002. The axis number 2 is the temperature varied between a minimum 900 and maximum 1900 K with a maximum increment of 25.

Before starting the mapping, it is a good rule to SAVE the workspaces. If this is done just before the MAP command, and the MAP command fails for some reason, the user can restart from the situation just before mapping and try to find a better start point.

```
SAVE
MAP
```

The diagram is plotted in the post-processor. The post-processor will automatically set the same axes for plotting as used for mapping.

```
POST
PLOT
```

BINARY_DIAGRAM

The BINARY_DIAGRAM module (short name, the BIN module) enables you to quickly calculate a simple binary phase diagram. Access to specific databases designed for BIN, such as TCBIN, is required.

To enter the module, at the SYS prompt type `GOTO_MODULE BINARY`. There are no other commands for this module. Follow the prompts to plot a diagram.

Syntax	BINARY_DIAGRAM
Prompts	`Database: /TCBIN/`
	`First element` `Second element`
	`Phase diagram, Phase fraction (FE), G- OR A-curves (G/A): /Phase_Diagram/`

About Ternary Phase Diagrams

There are many types of ternary phase diagrams but perhaps the most common is the isothermal section. In this case, the temperature is constant, which means that the tie-lines are in the plane of the calculation. Isothermal sections and monovariant lines on the liquidus surface can be calculated in traditional way. They can also be calculated in the TERN module, but this requires a special database (such as PTERN).

In order to set up calculation of a ternary isothermal section in the system Al-Mg-Si, do the following (after retrieving the data from the database (TDB) module):

```
SET_CONDITION T=823,P=1E5,N=1,X(MG)=.01,X(SI)=.01
C_E
```

Note that there is no condition on the amount of Al as that is the "rest". N=1 specifies that the system is closed. This calculation gives one point inside the system. Now define the axis:

```
S-A-V 1 X(MG) 0 1 0.01
S-A-V 2 X(SI) 0 1 0.01
```

Of course, you might not be interested in the whole section, and in such cases specify different lower and upper limits for the axes. Then give a SAVE command before the MAP command:

```
SAVE almgsi-823
MAP
```

The result can be plotted in the POST module. Ternary isopleths are equally simple to calculate. Use the same conditions as above if you are interested in a section of Al-Si at 1 mole percent of Mg, just define a different set of axis:

```
S-A-V 1 X(SI) 0 1 .01
S-A-V 2 T 500 2000 25
SAVE almgsi-1mg
MAP
```

In the resulting diagrams, the tie-lines are not in the plane of the diagram, thus the lever rule etc. cannot be applied. But you can calculate more elaborate sections. An interesting diagram is the section from pure Al to Mg2Si, which is almost a quasi-binary section. In order to calculate this, set up the conditions differently:

```
SET-CONDITION T=823, P=1e5, N=1, X(MG)-2*X(SI)=0, W(MG)=.01
C-E
```

Note that there is no condition on the amount of Si as this is given by the relation X(MG)-2*X(SI)=0. Also note that you can mix conditions in X and in W. Then set the axis, save the workspace and map.

```
S-A-V 1 W(MG) 0 .1 .01
S-A-V 2 T 500 1500 10
SAVE al-mg2si
MAP
```

A special type of ternary phase diagrams is liquidus surfaces. This is still not simple to calculate as a separate start point is needed for each separate line at each temperature.

However, you can easily calculate the monovariant lines where the liquid is stable together with two condensed phases:

```
SET-CONDITION T=800, P=1e5, N=1, X(MG)=0.01, X(SI)=.01
C-E
C-S P LIQ=FIX 0.3
S-C T=NONE
C-E
```

Now there should be an equilibrium where liquid is just stable. Set the axis to be the compositions.

```
S-A-V 1 X(MG) 0 1 .01
S-A-V 2 X(SI) 0 1 .01
SAVE almgsi-luni
MAP
```

TERNARY_DIAGRAM

The TERNARY_DIAGRAM module (short name, the TERN module) enables you to quickly calculate a simple ternary phase diagram.

To enter the module, at the SYS prompt type GOTO_MODULE TERNARY. There are no other commands for this module. Follow the prompts to plot a diagram.

Syntax	TERNARY_DIAGRAM
Prompts	`Database: /FEDEMO/`

	`First element:`
	`Second element:`
	`Third element:`

	`Phase diagram, Monovariants, or Liquidus Surface: /Phase_Diagram/`
	`Temperture (C) /1000/`
	`Global minimization on: /Y/`

About Quasi-Binary and Quasi-Ternary Phase Diagrams

Quasi-binary diagrams, as well as quasi-ternary diagrams and so forth, have often been misunderstood and misused. A real quasi-binary phase diagram is for a ternary system where one component has a fixed activity or chemical potential, and a real quasi-ternary phase diagram is for a quaternary system where one component has a fixed activity or chemical potential.

A typical example of quasi-ternary system is a quaternary system Fe-Cr-Ni-C calculated at fixed carbon activity. The condition can be set as follows:

```
SET-REF-STATE C GRAPH ,,,,
SET-CONDITION T=1273, P=1e5, N=1, X(CR)=.1, X(NI)=.1, ACR(C)=.002
```

In some cases, the activity may vary in a quasi-binary section if one has a phase fixed instead (and where the phase may vary in composition). The advantage with the quasi-binary section is that the tie-lines will be in the plane of the diagram and thus the lever rule etc is obeyed.

A quasi-binary section in Ca-Fe-O when the liquid oxide is in equilibrium with liquid Fe can be specified as follows:

```
DEFINE-COMPONENTS CAO FE FEO
SET-CONDITION T=1850, P=1e5, N=1, X(CAO)=.1
CHANGE-STATUS PHASE FE-LIQ=FIX 0
```

and the mapping can be done with the following axis

```
S-A-V 1 X(CAO) 0 1 .01
S-A-V 2 T 1500 2000 25
```

However, it is a problem as FE-LIQ is not the stable phase for pure iron below 1811. One will have to calculate separate sections depending on the stable modification of Fe.

Calculating a Quasi-Binary Phase Diagram

There are many ways to calculate phase diagrams in Thermo-Calc. The following is an example where a quasi-binary phase diagram is used for calculations on a ternary system in which one component has an activity or chemical potential that is fixed (although if you have fixed a phase and the phase composition varies, then the activity or chemical potential may also vary). The tie-lines in a quasi-binary diagram are in the diagram's plane of the diagram. This means that the calculation follows the lever rule as well as other rules.

When calculating a quasi-binary phase diagram it is necessary to set a condition on either activity or chemical potential of the third component. To specify a meaningful value it is

recommended that you first change the component's reference state using SET_REFERENCE_STATE. For example, to calculate a phase diagram for a quasi-binary Fe-Cr-O system with fixed oxygen activity, you can enter the following:

```
SET_REFERENCE_STATE O GAS ,,
```

You must also use SET_CONDITION to set the activity of the component whose activity or chemical potential you have fixed. Do this by assigning a value to the ACR state variable. For example, if the component is oxygen, you might enter

```
SET_CONDITION ACR(O)=0.2
```

Alternative Way to Set the Component Activity

As an alternative to set the activity of the component, you can Use CHANGE_STATUS to set a phase to fixed. For example, suppose you want to compute the iron-saturated section in "FeO"-SiO2. You then enter:

```
CHANGE-STATUS FCC=FIX 0
```

Calculating a Quasi-Ternary Phase Diagram

There are many ways to calculate phase diagrams in Thermo-Calc. The following is an example of a quasi-ternary phase diagram used for calculations on a quaternary system where one component has a fixed activity or fixed chemical potential.

When calculating a quasi-ternary phase diagram it is necessary to set a condition on either activity or chemical potential of the fourth component. To specify a meaningful value it is recommended that you first change the component's reference state using SET_REFERENCE_STATE. For example, to calculate a phase diagram for a quasi-ternary Fe-Cr-Ni-C system with fixed carbon activity, you can enter the following:

```
SET_REFERENCE_STATE C GRAPH ,,
```

You must also use SET_CONDITION to set the activity of the component whose activity or chemical potential you have fixed. Do this by assigning a value to the ACR state variable. For example, if the component is carbon, you might enter

```
SET_CONDITION ACR(C)=0.002
```

T0 Temperature Simulations

Topics to Explore >

About T0 Temperature Simulations **793**

Making a T0 Temperature Simulation **794**

About T0 Temperature Simulations

The T0-temperature is the temperature at which two phases have the same Gibbs energy for a certain composition in a multicomponent system. The T_0-temperature is located within the two-phase field between the phases and it is the theoretical limit for a transformation without diffusion. T0 temperatures are often of interest if you want to understand how diffusionless transformations work. The T0 temperature in a multicomponent system with a fixed composition is temperature at which the tangent lines of the Gibbs energies of the two target phases are the same.

If the composition of one or two components varies, the common Gibbs energy for the two phases in partial equilibrium of a diffusionless transformation becomes a plane or surface, and the T0 temperature becomes a line or plane.

See Console Mode examples tcex 23 and tcex41.

Also see Making a T0 Temperature Simulation for step-by-step instructions.

Making a T_0 Temperature Simulation

This describes how to perform a T_0 temperature simulation and apply a stepping calculation to its initial result.

Before you perform a T_0 temperature calculation, you must have defined your initial system and be in POLY. The initial overall composition must have appropriate settings for the desired T0 temperature calculation for the two target phases.

1. Use SET_CONDITION to set the conditions of your calculation in the same way as when you calculate an ordinary equilibrium.
2. Use COMPUTE_EQUILIBRIUM to run the calculation. The calculation does not need to reach an equilibrium in which any of the target phases is stable.
3. When you have calculated your initial equilibrium, use ADVANCED_OPTIONS and choose `T-zero`.
4. When prompted, specify the names of the two target phases for which the T_0 temperature (where the phases' Gibbs energies are equal) is to be calculated.
5. If the T_0 temperature between the two target phases is calculated, this temperature (in Kelvin) is shown in the Console window.
6. If you want to do a stepping calculation based on this initial T_0 temperature calculation, then use SET_AXIS_VARIABLE to specify which state variable to use as the stepping variable. This is done the same way as when you calculate a normal property diagram.

When a T_0 temperature simulation is run, you cannot set temperature as the stepping variable.

7. Use STEP_WITH_OPTIONS and choose `T-zero` to initiate the stepping calculation. You are prompted to specify the names of the target phases for which the T0 temperature is calculated.

   During the STEP T-ZERO calculation procedure, the calculated T0 values are presented next to the stepping variable.

   For example, part of the output might look like this:

```
Phase Region from  1.000000E-01 for:
BCC_A2
FCC_A1

```

When the stepping calculation has finished, you can move to the POST module and plot the T0 line against the stepping composition variable or another varying axis value. Or you can impose the calculated T0 line onto a normal phase diagram.

Paraequilibrium

Topics to Explore >

About Paraequilibrium **797**

Calculating a Paraequilibrium **798**

About Paraequilibrium

A paraequilibrium is a partial equilibrium where one interstitial component (such as carbon C and nitrogen N) in a multicomponent alloy can diffuse much faster than the other components (the substitutional elements, including the matrix element and alloying elements). The chemical potential for the interstitial component in two partially equilibrated phases is equal in such a case, but this is not true for the other components. In such a paraequilibrium state, it is possible to have a transformation that is partly without partitions, where a new phase of the mobile component can form with different content but where the slowly diffusing components retain their compositions.

A paraequilibrium calculation is useful when, for example, you want to study phase transformations in systems with large differences in the diffusivities of different elements. Transformations occurring under paraequilibrium states can be much more rapid than if full local equilibrium holds at the phase interface.

Calculating a Paraequilibrium

Calculating a Paraequilibrium

This topic describes both how to calculate an initial paraequilibrium with two target phases, and how to base a stepping calculation on this initial calculation.

Before you do any paraequilibrium calculations, you must have defined your initial alloy system and be in POLY. The initial overall composition must have appropriate settings for the desired paraequilibrium calculation for the two target phases.

1. Use SET_CONDITION to set the conditions of your calculation just like when you calculate an ordinary equilibrium.

2. Use CHANGE_STATUS to set the status of the chosen interstitial components to SPECIAL. For example, if C is an interstitial component, enter:

   ```
   CHANGE_STATUS COMPONENTS C=SPECIAL
   ```

   This gives you a clear picture on u-fractions of the substitutional and interstitial components, which are different from the overall composition in the system. The SPECIAL status means that the specified components are not included in summations for mole or mass fractions. Therefore, all the composition variables plotted from paraequilibrium calculations are u-fraction related quantities.

3. Use COMPUTE_EQUILIBRIUM to run the calculation.
4. When you have calculated your initial equilibrium, use ADVANCED_OPTIONS `Paraequilibrium` to perform the paraequilibrium calculation.

5. Specify the names of the target phases of the paraequilibrium state. For example, `FCC#1 BCC` and `FCC#2 M23C6`.

   Both phases must have similar interstitial/vacancy sublattices that the fast-diffusion interstitial components occupy. Both target phases should have phase constitution definitions that cover all the defined substitutional and interstitial components of the current alloy system.

6. Specify the names of one or more fast-diffusing components. These components must be located on the interstitial/vacancy sublattices in both of the chosen phases.

Interstitial components (for instance C and N combined) may have significantly different behaviours depending on how they are partitioned in different structured phases.

If the paraequilibrium between the two specified phases is successfully calculated, then a message is displayed, for example:

```
NP(FCC) = 0.3586 with U-fractions C = 2.71821E-02 N =
4.1548129E-03

NP(BCC) = 0.6414 with U-fractions C = 7.10061E-04 N =
2.3781027E-04

All other compositions are the same in both phases
```

The first two lines show the phase amounts expressed in mole-percent [NP(phase)] and the contents of the interstitial components C and N in each phase. These contents are expressed in u-fractions. The third line states that the compositions of the matrix component and all the remaining compositions (regarding substitutional components) are equal in the two target phases at the paraequilibrium state.

7. If you want to do a stepping calculation based on this initial paraequilibrium, then use SET_AXIS_VARIABLE to specify which state variable to use as the stepping variable. This is done exactly in the same way as when you calculate a normal property diagram.

8. Use STEP_WITH_OPTIONS → `Paraequilibrium` to initiate the stepping calculation. You are prompted to specify the names of the target phases of the paraequilibrium states as well as the fast-diffusing components.

   The stepping calculation is performed, and the different phase regions are listed with columns for the value of the stepping variable, the amounts of the two target phases, the u-fractions of interstitial(s) in each of the two phases, and the LNACR value(s) of the interstitial component(s).

```
This command calculates a paraequilibrium between two phases.
You must calculate an equilibrium with the overall composition first.
Name of first phase: fcc_a1
Name of second phase: bcc_a2
Fast diffusing component: /C/: C
Fast diffusing component: /NONE/:
 Output during stepping is:
 axis value, phase amounts, u-fractions of interstitial(s) in phase 1 and 2,
 and LNACR value(s) of interstitial(s)

 Phase Region from    900.000     for:
     BCC_A2
     FCC_A1
  9.000000E+02    0.176    0.824   4.977501E-02   6.609390E-04  -2.303643E-01

  8.800000E+02    0.148    0.852   5.872152E-02   7.140931E-04   1.943989E-01
  8.700000E+02    0.137    0.863   6.329608E-02   7.362105E-04   4.040959E-01
  8.600000E+02    0.127    0.873   6.792661E-02   7.552871E-04   6.126989E-01
  8.500000E+02    0.119    0.881   7.260558E-02   7.713010E-04   8.206607E-01
  8.400000E+02    0.111    0.889   7.732629E-02   7.842505E-04   1.028392E+00
  8.300000E+02    0.105    0.895   8.208278E-02   7.941530E-04   1.236267E+00
  8.200000E+02    0.099    0.901   8.686971E-02   8.010431E-04   1.444633E+00
  8.100000E+02    0.093    0.907   9.168236E-02   8.049714E-04   1.653814E+00
  8.000000E+02    0.089    0.911   9.651648E-02   8.060032E-04   1.864114E+00
```

It is possible to now move to the POST module and plot some of the results of the calculation. For an example of a paraequilibrium calculation and how it can be plotted, see Console Mode example tcex23.

Potential Diagrams

Topics to Explore >

About Potential Diagrams **802**

POTENTIAL_DIAGRAM **803**

Calculating a Potential Diagram **804**

Calculating a Potential Diagram with Different Pressure **806**

About Potential Diagrams

If you have a metal-oxide/sulphide-gas interaction system, you might want to calculate a so-called potential phase diagram given certain temperature and pressure. A potential diagram uses the activities of two major species in the gaseous mixture phase as mapping variables. The activities (that is, the fugacities at 1 bar) of these two species are typically set as the X- and Y-axis when the diagram is plotted. The phase relations between the gaseous mixture and various metal forms, metal-oxides, metal-sulphides, or other metal-bearing solids, are represented by different fields controlled by these two potential quantities.

This topic describes how to calculate such potential diagrams with the POTENTIAL module, and how to later modify the pressure of such a calculation in POLY. The calculation done by the POTENTIAL module always assumes a pressure of 1 bar.

POTENTIAL_DIAGRAM

The POTENTIAL_DIAGRAM (POT or POTENTIAL) module is a potential phase diagram calculation module.

If you have a metal-oxide/sulphide-gas interaction system, you might want to calculate a so-called potential phase diagram given certain temperature and pressure. A potential diagram uses the activities of two major species in the gaseous mixture phase as mapping variables. The activities (that is, the fugacities at 1 bar) of these two species are typically set as the X- and Y-axis when the diagram is plotted. The phase relations between the gaseous mixture and various metal forms, metal-oxides, metal-sulphides, or other metal-bearing solids, are represented by different fields controlled by these two potential quantities.

To enter the module, at the SYS prompt type `GOTO_MODULE POTENTIAL`.

There are no commands for this module. Follow the prompts and see About Potential Diagrams for details about how to calculate using potential diagrams.

Syntax	POTENTIAL_DIAGRAM
Prompts	`Database: /POT/` Press <Enter> and the program lists the available databases. Type one of the database names and press <Enter> to select. The following default elements are then based on the chosen database.
	`Matrix element: /Fe/`
	`First potential species: /S1O2/`
	`Second potential species: /O2/`
	`Temperature: /1000/`

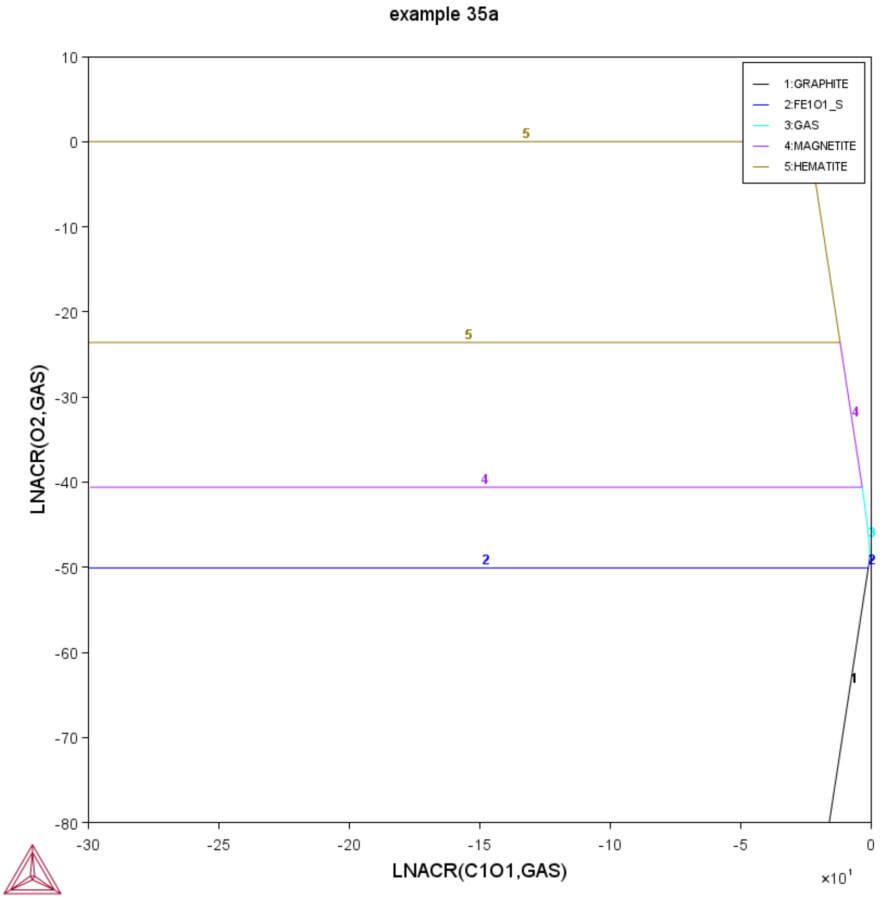
Calculating a Potential Diagram

You need access to a substance or solution database that contains a gaseous mixture phase, metals (or alloys), and solids such as metal-oxides, sulphides, sulphates, carbonates, silicates, nitrides or nitrates (stoichiometric or solution phases).

1. Use GOTO_MODULE and enter `POTENTIAL`.
2. Specify which substance or solution database to use. Any substance or solution database can be used that has a gaseous mixture phase, metals (or alloys), and solids such as metalxides, sulphides, sulphates, carbonates, silicates, nitrides, and nitrates (stoichiometric or solution phases).
3. Specify the matrix element (a metal) and the two gaseous species that define you metal-gas interaction system. The names of these components must be available in the database you are using.
4. Set the temperature (in Kelvin). (The pressure is always 1 bar.)

   A potential diagram with the activities of the two gaseous species as mapping variables is calculated. These mapping variables are also set as the axis variables in the plotted diagram.

   An example diagram (Console Mode example 35).



A POLY3 file is also automatically saved in the current working directory with the default name POT.POLY3.

5. When the diagram is plotted, it opens the POST module where you can modify the plotted diagram in any way you like.

Calculating a Potential Diagram with Different Pressure

It is possible to modify both the calculation and the plotted diagram that the POTENTIAL module generates in the POLY and POST modules. You can do this by opening a POLY3-file with the results from a POTENTIAL module calculation in either POLY or POST. You can modify the calculation in the same way that you can modify any ordinary mapping calculation or phase diagram. For example, this is useful for calculating a potential diagram at a pressure other than 1 bar.

You must have calculated a potential diagram already, and have the saved POLY3-file available.

1. Use GOTO_MODULE and enter `POLY`.

2. Use READ followed by the name of the POLY3 file that contains the results of the potential diagram calculation that you want to modify.

   A reminder that Linux and Mac are case sensitive; when applicable ensure you enter file extensions with capital letters.

3. This opens the workspace file and loads the previous settings and results. The activities of the two gaseous species is now part of the conditions, and these conditions are set as the mapping variables.

4. Use SET_CONDITION to specify the pressure under which you want the potential diagram to be calculated. For example, to set the pressure to 1000 bar, enter:

   ```
   SET_CONDITION P=1e8
   ```

5. Use COMPUTE_EQUILIBRIUM to compute the initial equilibrium.

   You may also want to use ADD_INITIAL_EQUILIBRIUM to calculate some additional equilibria that the mapping calculations are based on.

6. Use MAP to perform the mapping calculations.
7. Use GOTO_MODULE and enter `POST` to set conditions for visualization and to plot the diagram.

About the Scheil-Gulliver Solidification Simulations

In Console Mode most of the set up for the Scheil module is via the START_WIZARD command where you are prompted to answer a series of questions. You can also perform Scheil calculations in Graphical Mode using the Scheil Calculator, which is recommended for most users. See Scheil in Graphical Mode vs Console Mode to compare.

Thermo-Calc is often used to perform equilibrium calculations, but some non-equilibrium transformations or partial-equilibrium transformations can also be simulated.

A well-known example of a non-equilibrium calculation is the *Scheil-Gulliver solidification simulation*. In Thermo-Calc, the available Scheil-Gulliver solidification simulations are *classic* Scheil, Scheil with *back diffusion* in the primary phase, or Scheil with *solute trapping*. There are also configuration options available with *fast diffusers* for the classic and back diffusion models. Also learn about Homogenization, Segregation Profiles, and the Diffusion Module.

Classic Scheil Simulation

This is a Scheil simulation based on the well-known *Scheil-Gulliver* model. If this model is used without "fast diffusers" it is *Classic Scheil* simulation with the following assumptions:

- Diffusion in the liquid phase is assumed to be very fast, that is, infinitely fast.
- Diffusion in the solid phases is so slow that it can be ignored, that is, diffusion is assumed to be zero.
- The liquid/solid interface is in thermodynamic equilibrium.

In this Classic Scheil simulation the temperature is decreased step-by-step. When the temperature drops below the liquidus temperature the equilibrium amount and composition of solid and liquid phase is calculated. The solid phase is removed from the system and only the amount and composition of the liquid phase is used for the next calculation step at a lower temperature. Again, the equilibrium amount and composition of solid and liquid phase is calculated and again the solid phase is removed from the system for the next step. This procedure is repeated until the last liquid disappears.

This calculation procedure is equivalent to assuming that there is no diffusion in the solid phase and infinitely fast diffusion of all elements in the liquid phase. It has been shown to be a good approximation of the solidification of most alloys such as Ni-superalloys, Cu alloys, Al alloys, Mg alloys, and others. However, in materials with interstitial elements, such as carbon, ignoring diffusion in the solid causes discrepancies with experimental results. Interstitial elements have much faster diffusion rates. The assumption of no diffusion in the solid phase during solidification is thus not correct at most industrial or lab-scale solidification rates.

For this reason, a variant of the Scheil simulation was developed and implemented in Thermo-Calc, where one or more elements can be defined as *fast diffusers*. See Other Options: Fast Diffusers and Scheil Simulations.

Scheil Simulation with Back Diffusion in Primary Phase

The *Scheil simulation with back diffusion in primary phase* kinetic model quantitatively takes into account the real back diffusion of all elements in the primary solid phase (typically the FCC or BCC phase). This model requires the use of both a thermodynamic and mobility database. The calculation also requires the cooling rate to be specified; a fast cooling rate allows for less time for back diffusion and the simulation result is similar to the classic Scheil-Gulliver solidification simulation. A very slow cooling rate allows for almost complete back diffusion, the solidification simulation is then close to an equilibrium calculation. It also requires that the size of the solidification domain is specified. In most cases this domain size corresponds to the secondary arm spacing, as this is where typically the liquid is trapped during solidification.

The secondary arm spacing also depends on the cooling rate. For this reason, a simple empirical relation between cooling rate and secondary arm spacing is predefined in Thermo-Calc.

For the *Scheil simulation with back diffusion in primary phase* model the following assumptions are made.

- Diffusion of all elements in the liquid phase is infinitely fast.
- Diffusion of all elements in the primary solid phase are quantitatively calculated using mobility data, a cooling rate and a domain size (typically this is the secondary arm spacing).
- The liquid/solid interface is in thermodynamic equilibrium.

Also see Other Options: Fast Diffusers and Scheil Simulations.

Scheil with Solute Trapping

The *Scheil with solute trapping* model simulates deviation from local equilibrium for the primary phase. It is useful for high solidification speeds, such as those seen in additive manufacturing applications.

For equilibrium- and classical Scheil-type solidification simulations thermodynamic equilibrium is established at the solid-liquid interface. This means that solutes are partitioned between the solid and liquid phases according to solidus and liquidus lines of the phase diagram. The assumption of thermodynamic equilibrium at the solid-liquid interface however, is invalid for very fast solidification rates, as encountered for example during additive manufacturing. The faster the solidification rate, the less the partitioning at the interface, which can be perceived as that solutes in the liquid are trapped in the advancing solid phase, hence the term *solute trapping*.

The *Scheil with solute trapping* model calculates the solute partitioning between liquid and primary solid that deviates from thermodynamic equilibrium due to solidification speed.

The following assumptions are made:

- Only one primary solid phase forms dendrite, NOT necessarily the first solid phase.
- Solute trapping in primary solid phase only. Other solid phases have equilibrium compositions following Scheil model.
- Dynamic liquidus for primary solid phases is dependent on solute trapping and solidification speed.
- Amounts of solid phases are dependent on solute trapping and solidification.

More theory details are in About Scheil with Solute Trapping.

Other Options: Fast Diffusers and Scheil Simulations

If a *Classic Scheil* or *Scheil simulation with back diffusion in primary phase* model is selected plus one or more *Fast diffuser* checkboxes selected, then Thermo-Calc takes into account the concept of the *fast diffuser*. Typically, C is defined as a fast diffuser, but also other elements such as N, O, or others can also be defined.

Fast diffuser does not quite define this since diffusion is not actually simulated. It is simply assumed that the "fast diffusers" distribute throughout the solid and liquid phase according to thermodynamic equilibrium. This corresponds to *infinitely fast diffusion* for the selected elements.

For a *Classic Scheil* model with the compositions defined with *Fast diffuser* the following assumptions are made.

- Diffusion of all elements in the liquid phase is infinitely fast.
- Diffusion of all elements in the solid phases, except the ones defined as "fast diffusers", is zero.
- Diffusion of the elements defined as "fast diffusers" is infinitely fast in the solid phase.
- The liquid/solid interface is in thermodynamic equilibrium.

For a *Scheil simulation with back diffusion in primary phase* model with the compositions defined with *Fast diffuser* the following assumptions are made.

- Diffusion of all elements in the liquid phase is infinitely fast.
- Diffusion of all elements in the primary solid phase are quantitatively calculated using mobility data, a cooling rate and a domain size (typically this is the secondary arm spacing).
- Diffusion of the elements defined as "fast diffusers" is infinitely fast in the solid phase.
- The liquid/solid interface is in thermodynamic equilibrium.

The Classic Scheil simulation and Classic Scheil simulation with fast diffuser models can be considered *thermodynamic* models. There are clear limitations as a certain amount of back diffusion always takes place in the solid phase at real solidification.

You can also use the more sophisticated *Scheil simulation with back diffusion in primary phase* kinetic model. Adding the fast diffuser option to this can be useful, for example for interstitials like C in steels where these then equilibrate in all phases and not just the primary phase.

Homogenization, Segregation Profiles, and the Diffusion Module

Scheil calculations can be used in diffusion simulations with the Diffusion Module (DICTRA).

Homogenization is a process were you want to get rid of the composition segregation from solidification with a homogenization heat treatment. This composition segregation can be simulated with Scheil. Then with the Diffusion Module (DICTRA), you input the secondary dendrite arm spacing to get the right diffusion distances. With composition profile from file the idea is that you should be able to input for example a measured composition profile (from EDS/WDS, micro-probe etc). This could also be a segregation profile but also composition profiles over a weld, substrate/coating, diffusion couple, and so forth.

Summary

The available Scheil-Gulliver solidification simulations are *classic* Scheil, Scheil with *back diffusion* in the primary phase, or Scheil with *solute trapping*. There are also configuration options available with *fast diffusers* for the classic and back diffusion models.

There is also connectivity to the Diffusion Module (DICTRA) and *homogenization* where you collect data from a Scheil solidification calculation, which is then used as part of the kinetic homogenization simulation of segregated composition profiles.

Scheil in Graphical Mode vs Console Mode

The Scheil with back diffusion feature is only available for systems with diffusion data, i.e. this model requires the use of a mobility database.

In Thermo-Calc, the Scheil calculation allows the calculation of:

- The solidification range of an alloy.
- Depression of the solidus temperature due to segregation.
- Composition of the last liquid to disappear in segregation pockets.
- Phases formed on final solidification in segregation pockets.
- The composition gradient in the primary solid phase(s) (segregation profile).
- Solute trapping to simulate deviation from local equilibrium for the primary phase
- Kinetic homogenization simulation of segregated composition profile (diffusion calculations)

Scheil in Graphical Mode vs Console Mode

Type of Calculation	*Console Mode*	*Graphical Mode*
Classic Scheil	Use the START_WIZARD command to answer prompts	Scheil Calculator > click the **Classic Scheil** button on the Configuration window. On the My Project Configuration window under Getting Started, click **Quick Start** and select **Scheil solidification simulation**.
Scheil with back diffusion in the primary phase	USE_BACK DIFFUSION command (turn on) then use the START_WIZARD command to answer prompts	Scheil Calculator > click the **Scheil with back diffusion in the primary phase** button on the Configuration window then enter the settings as needed. A mobility database is required.
Scheil with solute trapping	SOLUTE_TRAPPING command (turn on) then use the START_WIZARD command to answer prompts	Scheil Calculator > click the **Scheil with solute trapping** button on the Configuration window then enter the settings as needed.
Fast diffusers and Classic Scheil	Use the START_WIZARD command to answer the prompt`Fast diffusing components`where you enter the elements that diffuse fast in solid phases and can assume to be in equilibrium in the whole phase. E.g. C in a steel.	Scheil Calculator > click the **Classic Scheil** button plus one or more of the **Fast diffuser** checkboxes next to the composition(s) on the Configuration window then enter the settings as needed.
Fast diffusers and Scheil with back diffusion in the primary phase	USE_BACK DIFFUSION command (turn on) then use the START_WIZARD command to answer the prompt `Fast diffusing components`where you enter the elements that diffuse fast in solid phases and can assume to be in equilibrium in the whole phase. E.g. C in a steel.	Scheil Calculator > click the **Scheil with back diffusion in the primary phase** button plus one or more of the **Fast diffuser** checkboxes next to the composition(s) on the Configuration window then enter the settings as needed. A mobility database is required.

Type of Calculation	*Console Mode*	*Graphical Mode*
Homogenization	Use the EVALUATE_SEGREGATION_PROFILE command before START_WIZARD to generate the segregation profile to file. In DICTRA_MONITOR use INPUT_SCHEIL_ PROFILE for use of segregated profile in simulation. An additional license to the Diffusion Module (DICTRA) is needed to work with more than three components.	Use the **Homogenization** template under **Non-Equilibrium** to automatically set up the project tree with the defaults needed to work with this. An additional license to the Diffusion Module (DICTRA) is needed to work with more than three components.

Scheil-Gulliver Examples

About the Scheil-Gulliver Solidification Simulations

tcex15 - Simulating the Solidification of a Cr-Ni Alloy

This is an example of a solidification simulation of a Cr-Ni alloy. There is no back diffusion in the solid, i.e. this is a classic Scheil-Gulliver simulation. The FEDMO database is used and included with your installation.

These commands are of note and used in this example:

- START_WIZARD
- COMPUTE_TRANSITION
- ADD_INITIAL_EQUILIBRIUM
- ENTER_SYMBOL
- ADVANCED_OPTIONS
- STEP_WITH_OPTIONS
- MAKE_EXPERIMENTAL_DATAFILE
- CHANGE_STATUS

tcex30a and 30b - Scheil Calculation for an Al-4Mg-2Si-2Cu Alloy

The Equilibrium Calculation Module (POLY3) and About the Scheil-Gulliver Solidification Simulations

These examples show two ways to do a Scheil calculation for an Al-4Mg-2Si-2Cu alloy. In part A, you use the POLY3 module and the STEP_WITH_OPTIONS command with an EVALUATE option. Then in part B you use the SCHEIL module commands to do the same thing. Data from the COST2 database is used and included with the example in the file named *tcex30_cost2.TDB*.

tcex48 - Scheil Solidification with C Back Diffusion

The FEDEMO database is used and the example is available to all users.

This is an example of Scheil solidification with simulated back diffusion of carbon in solid phases. The results are compared between a simple Scheil and equilibrium calculation. First perform a Partial Equilibrium Scheil by assigning carbon as a fast diffusing element. Plot solidification curve and a microsegregation diagram and save to file (so called .exp files). The "back diffusion" of C in solid phases is not from any calculation involving kinetics, but comes from the equilibration of chemical potential of C at each step in temperature, thus allowing each already solidified part of the system to change its C concentration.

See tcex54 for an example that calculates "real" back diffusion. This model requires a kinetic (mobility) database in addition to the thermodynamic one. Also see About the Scheil-Gulliver Solidification Simulations for details about the different Scheil options.

tcex54 - Scheil Solidification of an Al-2.1Cu-1Si Alloy including Back Diffusion

This is an example of a solidification simulation of a Al-2.1Cu-1Si alloy. The back diffusion option in the Scheil module is used, i.e. there is back diffusion in the primary phase. The example uses both the thermodynamic ALDEMO and mobility MALDEMO demo databases included with your installation.

tcex57 - Scheil Solidification with Solute Trapping

This is an example of a solidification simulation of a Al-7.5Si-0.2Cu system. The solute trapping option in the Scheil module is used. The example uses the thermodynamic ALDEMO demo database included with your installation.

See the Graphical Mode example T_13: Scheil Solidification with Solute Trapping for an additional comparison to Classic Scheil.

Simulating a Scheil Solidification Process

About the Scheil-Gulliver Solidification Simulations

Simulating a Scheil-Gulliver solidification process involves calculating the liquid composition of a higher-order multicomponent system at each step of a cooling process, and resetting the liquid composition as the composition of the entire system (after having removed all amount of solid phase).

The step-by-step instructions below are intended as a simple example of setting up a calculation using the wizard in Console Mode. You can also use the macros available and briefly described in Scheil-Gulliver Examples.

The following does not include any prompts related to using back diffusion or solute trapping. See START_WIZARD for additional details about when these options are enabled with the USE_BACK_DIFFUSION and SOLUTE_TRAPPING commands.

1. At the prompt type GOTO_MODULE SCHEIL.
2. Type START-WIZARD and press <Enter>.
3. Specify which `Database` to use. Type `?` for a list of available databases based on your license.
   - Type `FEDEMO` for this example.
4. Specify the `Major element or alloy` in your system. For example, enter `Fe` (steel/Fe-alloy), `Al` (Al-based alloy), or `Ni` (Ni-based super alloy).
   - Type `Fe` for this example.
5. Set whether to specify the `Composition input in mass (weight) percent` (the default) or in `Mole percent`. Press <Enter> to keep the default for mass (weight) percent or type `N` to use mole percent.
   - Keep the default for this example (press <Enter>).
6. Specify the name of the `1st alloying element`. You can directly specify mass or mole percent after the name. If this is not specified, then you are prompted to enter it separately.
   - Type `Cr 5` for this example.

7. Specify the other alloying elements in the same way as you specify the first.
    - Type `C 1` for this example.
8. After you have specified your last alloying element, press <Enter>. This ends the process of defining the bulk composition of the alloy system.

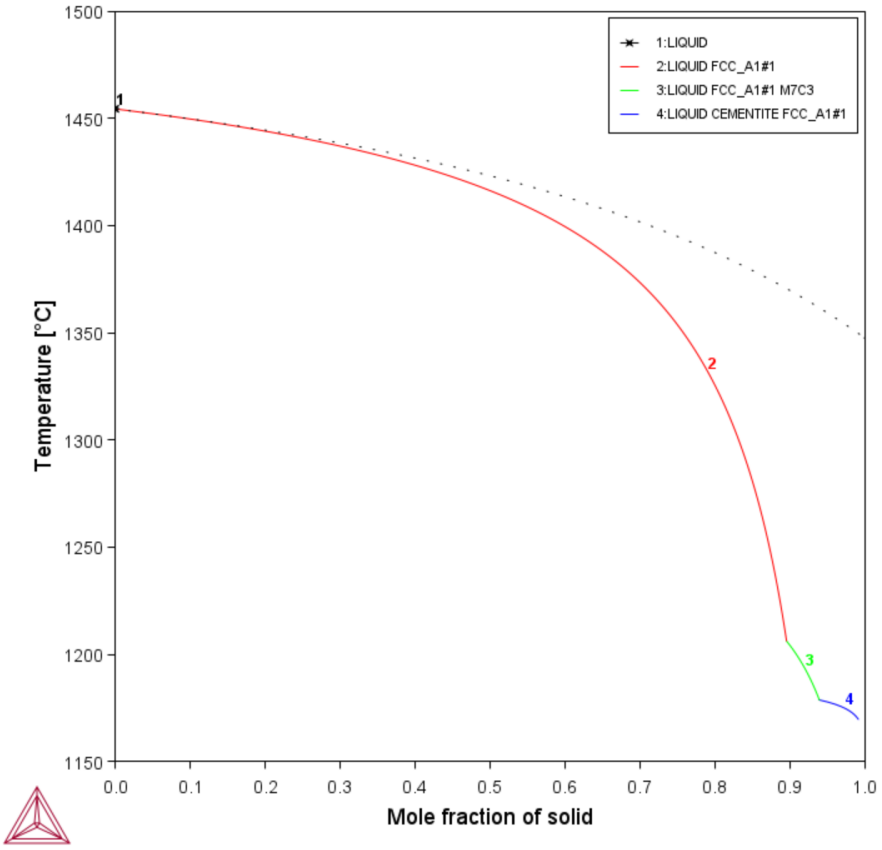
You can also specify all the alloying elements and their corresponding compositions on the same line when you are prompted to specify your first alloying element. As a general example, you can enter `Cr 5 Ni 1 Mo 0.5 C 0.01 N 0.02`.

    - Press <Enter> for this example.
9. Specify the starting `Temperature (C)` in Celsius. The default is `2000`.

    This value should be sufficiently high so that the solidification simulation starts with the alloy system in the liquid single-phase region.

    - Keep the default for this example (press <Enter>).
10. At the `Reject phase(s)` prompt enter the name of the phases to reject or press <Enter> for the default `NONE`.
    - Keep the default s for this example (press <Enter>).
11. At the `Restore phase(s)` prompt you may want to restore a phase that you rejected when you ran the simulation earlier, or you may want to restore a phase that is rejected by default in your database. Enter the name of the phases to restore or press <Enter> for the default `NONE`.
    - Keep the default for this example (press <Enter>).
12. When prompted `OK?` type `N` to go back to reconsider which phases to reject or restore. Type `Y` to continue. The thermodynamic data about the alloy system you defined is retrieved from the database.
    - Keep the default for this example (press <Enter>).
13. At the `Should any phase have a miscibility gap check` prompt, press <Enter> for the default `N` or type `Y` then specify the `Phase with miscibility gap`.
    - For this example, type `Y` then enter `FCC` as the `Phase with miscibility gap`.

14. If you answer `Y` to the miscibility gap check, then next enter the following for `Major constituent(s) for sublattice 1` and `Major constituent(s) for sublattice 2`.
    - Enter `Cr` for sublattice 1 and `C` for sublattice 2 in this example. Then at the `Phase with miscibility gap` prompt press <Enter>. The system responds with `LIQUID PHASE NAME: LIQUID`.
15. Specify the names of any `Fast-diffusing components`. Press <Enter> for `NONE` or type all the names on the same line then press <Enter>. Keep the default for this example (press <Enter>).



After the Scheil-Gulliver solidification simulation runs, the diagram Temperature versus Mole Fraction of Solid is plotted in the Console Results window.

State Variables for Scheil

Post processing is done the same way as POLY-3: specific variables for plotting in the Scheil module are listed.

For a comparable list in Graphical Mode, see Scheil Calculator Available Plot Variables.

The variables can be plotted along the X- and Y-axes. In the table, *ph* is an abbreviation of *phase*, and *el* is an abbreviation of *element*. An asterisk (*) can be used as a wild character for *el* and *ph*. Use the abbreviations of the variables when you specify what the X- and Y-axes represent in a diagram.

Abbreviation	*State Variable*
T	Temperature in Celsius
NL/BL/VL	Mole/mass fraction of liquid
NS/BS/VS	Mole/mass fraction of all solid phases
NS(ph)/BS(ph)	Mole/mass fraction of a solid phase
VS(ph)	Volume fraction of a solid phase
W(ph,el)	Weight fraction of an element in a phase
X(ph,el)	Mole fraction of an element in a phase
Y(ph,el)	Site fraction of an element in a phase
NN(ph,el)	Distribution of an element in a phase
NH/BH	Total heat per mole/gram (top curve) and Latent heat per mole/gram (bottom curve)
CP/BCP	Apparent heat capacity per mole/gram
NV/NV(ph)	Molar volume of the system or a phase
DS/DS(ph)	Average density of the system or a phase
BT	Apparent volumetric CTE of the system

Abbreviation	*State Variable*
DVIS(ph)	Dynamic viscosity of a phase
KVIS(ph)	Kinematic viscosity of a phase
SURF(ph)	Surface tension of a liquid phase
ELRS/ELRS(ph)	Electrical resistivity of the system or a phase
ELCD/ELCD(ph)	Electrical conductivity of the system or a phase
THCD/THCD(ph)	Thermal conductivity of the system or a phase
THRS/THRS(ph)	Thermal resistivity of the system or a phase
THDF/THDF(ph)	Thermal diffusivity of the system or a phase
DGV	Driving force for evaporation
DHV	Evaporation enthalpy
MMG	Molar mass of gas
XAVG(el)	Mole fraction of an element in solid phases
WAVG(el)	Mass fraction of an element in solid phases

Pourbaix Diagrams

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

Search the help (press F1 when in Thermo-Calc) for information about the Graphical Mode **Aqueous Calculator**, its template with predefined settings, and the aqueous properties. The help also has detailed information about the compatible and recommended database for use with all aqueous calculations.

About Aqueous Solutions and Pourbaix Diagrams in Console Mode

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

For background information relevant to both Graphical and Console Mode, start with the topic Introduction to Aqueous Solutions and Pourbaix Diagrams.

General Information about the POURBAIX Module in Console Mode

The POURBAIX module lets you construct Pourbaix diagrams and other types of property diagrams for heterogeneous interaction systems with aqueous solution phases. The compositional definition and variations and the basic solvent and electron components H_2O, H^{+1} and ZE are automatically determined by the aqueous solution phase in the Pourbaix module.

Besides the aqueous solution phase, your system may also contain a gaseous mixture phase. Other neutral and charged gaseous species may also be constituents. For multicomponent systems there are normally also some interacting solid phases (stoichiometric or solution) as the so-called secondary phases. These are typically the matrix and/or precipitate phases in the alloys of interest.

In Console Mode, diagrams can be calculated and plotted either using the response-driven POURBAIX module or directly using the DATA, GIBBS, POLY, and POST modules. However, it is recommended that you use the Graphical Mode Aqueous Calculator and template if you are new to these calculations.

Database Compatibility

When using the TCS Aqueous Solutions Database (TCAQ) version 4 (TCAQ4) and newer, the database is optimized to be used with the Graphical Mode Aqueous Calculator in Thermo-Calc (version 2026a and newer). The Aqueous Calculator, and associated Aqueous Calculation template that has many predefined settings, are designed to more easily set up aqueous calculations (including Pourbaix diagrams). When TCAQ4 is used, there is no need to append the gas solution phase, the metallic solid solutions or any oxide phases. This is applicable to both Graphical Mode and Console Mode.

If you are working with the TCS Aqueous Solutions Database (TCAQ) version 3 (TCAQ3.1 and older) in Console Mode or with the classic POURBAIX_DIAGRAM module, then the aqueous solutions database requires appended gas and solid metallic and oxide phases from other compatible databases, for example, SGTE Substances Database (SSUB), SGTE Solutions Database (SSOL), or TCS Steel and Fe-alloys Database (TCFE).

GES5 and GES6 Calculation Engine Version

This section is applicable to the Console Mode POURBAIX diagram module only.

As of Thermo-Calc version 2019b, the default calculation engine is set to GES6. For POURBAIX module users, you need to use GES5. When you try to enter this module, you are instructed to switch to GES5 using the SET_GES_VERSION command.

To globally set the default from GES6 back to GES5, go to the **Options** window **General** tab and click **Version 5** for the *Preferred Gibbs Energy System* setting. The SET_GES_VERSION Console Mode command is used to change GES versions for a single Thermo-Calc session.

GES6 is a re-write and new implementation of the Gibbs Energy System module of Thermo-Calc and it is the default engine in Thermo-Calc. As of 2026b, TQ-Interface has access to it but GES5 is the default. GES5 continues to be available and works in the background of the program where necessary. The main purpose of GES6 is to support faster development of new features. However, not all GES5 functionality is implemented in GES6. In such cases (except for the POURBAIX module), GES6 falls back silently and uses functionality from GES5 in the background.

Aqueous Properties for Plotting

There are some differences between Console Mode and Graphical Mode. Additional details are provided throughout the content.

In Console Mode you can set aqueous properties other than pH and Eh as axis variables. For example, the following properties can also be set as axis variables: `Ah` (electronic affinity), `pe` (electronic activity log10ACRe), `IS` (ionic strength), `TM` (total aqueous concentration, in molality), `OC` (Osmotic coefficient), activity or activity coefficient of solvent H_2O, and activities or activity coefficients or concentrations in m (molality) of charged or neutral solute species.

In Graphical Mode you can select various **Aqueous properties** as *Quantities* (on the Aqueous Calculator) and *Axis Variables* (on the Plot Renderer).

Search the help (press F1 when in Thermo-Calc) for information about the Graphical Mode **Aqueous Calculator**, its template with predefined settings, and the aqueous properties. The help also has detailed information about the compatible and recommended database for use with all aqueous calculations.

Key Components in Console Mode

These key components are defined as follows:

Component	Component Status	Reference State	Ref-T(K)	Ref-P(Pa)
H2O	ENTERED	AQUEOUS	*	100000
H+1	ENTERED	SER		
ZE	ENTERED	REFERENCE_ELECTRODE	*	100000

POURBAIX_DIAGRAM Module

This section is applicable to the Console Mode POURBAIX diagram module only.

The **Aqueous Calculator** and a predefined template is available in Graphical Mode and recommended for aqueous calculations (including Pourbaix diagrams).

Getting Started with the Pourbaix Module

After you enter the POURBAIX_DIAGRAM module, you are asked if you want to have step-by-step instructions to help walk you through the module. If you answer `Y` a series of notes are displayed.

The Console Mode help is only relevant to the historical use of the POURBAIX module. As of 2026a, it is recommended you use the Graphical Mode Aqueous Calculator and template instead. Also refer to such topics as About Pourbaix Diagrams and About the Thermodynamic Database Requirements.

Choosing a Custom Aqueous Solution Database

You can also use a custom database but it must be in the Thermo-Calc TDB format. Due to the restrictions of aqueous solution models used within Thermo-Calc, such a database must be designed in the same format as in the default TCAQ (PAQ2) for aqueous solution phases. Among other things, keep the following requirements in mind:

- The ELECTRON is defined as an special element (ZE) and as the only constituent in its reference phase REFERENCE_ELECTRODE (for determining the electro-potential that is defined as Eh with the standard hydrogen electrode as the reference), but it is not defined as an aqueous species;
- The vacancy (VA) is unnecessary for AQUEOUS solution phase and it should be avoided in the definition of phase-constituents in the AQUEOUS phase;
- The AQUEOUS solution phase should always be defined as a constitutional solution phase, implying that all the aqueous solution species must be included in a single site, rather than in two or multiple sublattices.

Beside the AQUEOUS solution phase, there shall exist a GAS mixture phase containing at least H2O1, O_2 and H_2; and for multicomponent systems, normally there shall also contain some solid (stoichiometric or solution) phases. Of course, if desired, you could also choose to calculate and generate a Pourbaix diagram without considering the GAS mixture phase entirely; however, such a plot is not really a complete Pourbaix diagram, due to the fact that thermodynamically-stable phase boundaries between the AQUEOUS solution phase and GAS mixture phase will then not be calculated at all.

As of 2026a, information about appending databases or retrieving thermodynamic data is only applicable if you are using TCAQ version 3.1 and older or one of the free databases. Otherwise it is recommended you upgrade to TCAQ version 4.0, which has access to many new phases and there is no need to append the gas solution phase, the metallic solid solutions, or any oxide phases. This is applicable to both Graphical Mode and Console Mode.

All the required thermodynamic data for calculations of Pourbaix diagrams or other diagrams must be retrieved either from one (single) database which consists of an AQUEOUS solution phase, a GASeous mixture phase, a REF_ELECTRODE phase, and some SOLID phases (being solutions and/or stoichiometric compounds; for primary metals/alloys and for secondary products formed from heterogeneous chemical/electrochemical interactions, or from several (multiple) databases that respectively contain various solutions/compounds (as listed above).

Copy and Rename the POLY3 file

At the end of a Pourbaix module calculation, a new POLY3 file is automatically saved.

A reminder that Linux and Mac are case sensitive; when applicable ensure you enter file extensions with capital letters.

If you are using a POLY3 file more than once (as is done in the extended examples), it is recommended that you copy and rename the previously-generated POLY3 file. This is so that the required POLY3 file structure and Pourbaix results are not lost. Do this outside of Thermo-Calc i.e. do not save from within Thermo-Calc.

The reason you do not save from within Thermo-Calc is because of how the file is saved. When the command sequence (GO POLY3>SAVE <*FILE NAME*>.POLY3>Y) is used, the POLY3 workspace of the POURBAIX calculation results in the POLY3 module monitor and all the initial equilibrium points and the mapping/stepping calculation results are lost as well as parts of the POLY3 file structure (e.g., some definitions of the previously defined POURBAIX-type calculation system).

Enforce a Pause

After the initial set of information is displayed, you are asked:

```
Enforce a PAUSE after plotting when running a MACRO? /N/
```

- If you choose `Y` a pause is always enforced after each diagram is plotted;
- If you choose `N`, all the command-lines (answers) for the session continue without stopping or until the SET_INTERACTIVE_MODE line in the macro file is reached.

Whenever running a Thermo-Calc macro (TCM) file, you may want to pause after a specific diagram is plotted on screen. This gives you the flexibility to:

- Print it (of EMF/PS format) to a printer
- Convert it (of EMF format) to (PDF) graphical files;
- Save it as an EMF graphical file;
- Dump it as a PNG or BMP graphical file;
- Set background colour for the current diagram
- You can also set the default font/size and change plot layers for sequential plots.

Pourbaix Main Options

If you answer `Y` to the Pause prompt above, these options are displayed:

1. Start a completely new Pourbaix diagram calculation.
2. Open an old file and plot other property diagrams.
3. Open an old file and make another Pourbaix calculation.
4. Open an old file and make another stepping calculation.

Calculating a Pourbaix Diagram

This section is applicable to the Console Mode POURBAIX diagram module only.

As of Thermo-Calc 2026a, there is a Graphical Mode **Aqueous Calculator** and template to work more efficiently with advanced aqueous and Pourbaix diagram calculations. Explore your options on our website about what the Aqueous Calculator can do. You can also learn more about the latest compatible and recommended TCS Aqueous Solutions Database (TCAQ) database on the Aqueous Solutions Databases webpage.

About the Thermodynamic Database Requirements

With the POURBAIX module in Console Mode you construct Pourbaix diagrams and other types of property diagrams for heterogeneous interaction systems with aqueous solution phases.

How to Calculate a Pourbaix Diagram (Console Mode)

1. At the `SYS` prompt, enter GOTO_MODULE POURBAIX.

2. At the `Need any instruction on the POURBAIX module?` prompt, press <Enter> to skip or enter `Y` to learn more.

   The Console Mode help is only relevant to the historical use of the POURBAIX module. As of 2026a, it is recommended you use the Graphical Mode Aqueous Calculator and template instead. Also refer to such topics as About Pourbaix Diagrams and About the Thermodynamic Database Requirements.

3. Press <Enter> at the prompt `Enforce a PAUSE after plotting when running a MACRO?`.

4. Press <Enter> to accept the default `1` to `Start a completely new POURBAIX diagram calculation` or enter `3` to `Open an old file and make another POURBAIX calculation`.

   To choose `3`, you must have already done a Pourbaix calculation and have it saved in a POLY3 file. The new calculation uses the same system definition as the previous calculation, but the other conditions, such as the bulk composition, temperature and pressure, can be modified in the next step.

5. Type `Y` or `N` to set whether to `Consider the GAS phase` (gaseous mixture phase) in the calculation.

   > As of 2026a, information about appending databases or retrieving thermodynamic data is only applicable if you are using TCAQ version 3.1 and older or one of the free databases. Otherwise it is recommended you upgrade to TCAQ version 4.0, which has access to many new phases and there is no need to append the gas solution phase, the metallic solid solutions, or any oxide phases. This is applicable to both Graphical Mode and Console Mode.

   The gaseous mixture phase should at least contain H_2O, O_2, and H_2. If a GAS phase is not considered, then only the interactions between the aqueous solution phase and various solid phases (alloy phases and secondary phases) are calculated. Such a calculation may not accurately present all the heterogeneous interactions. Some secondary phases are therefore usually needed. Such phases exist in the PAQ or PAQS Public Aqueous Solution Databases. They can also be appended from the SSUB/SSOL/TCFE or other appropriate substances/solutions databases.

6. Type `Y` or `N` to set whether to `Use single database` (`Y`) or a multiple database (`N`).

   If you choose to use a single database, at the `Combined Database: /PAQ2/` prompt specify a database that is specially developed for the Pourbaix module's diagram calculations.

   If you choose to use a multiple database, then you are prompted to specify an aqueous solution database and to append any additional required data and select necessary phases, such as various interacting alloy (solid) solution phases, and secondary (solid and liquid) phases, for example.

7. Specify all your solutes and the molality of each solute when prompted to do so. This can be done in terms of elements (such as Fe, Ni, Na, Cl, C or S) or arbitrary complex species (such as NaCl, CO2, CoCl3, Fe0.93S, NaSO4-1, or H2SO4). You can enter the element/species and the molarity on one line (for an example, NaCl 2.5).

   The definition of your system and its initial bulk composition is now presented.

   > The first letter of the element abbreviation must always be upper case. Any second letters must be lower case. When you have finished your specification, press <Enter> when asked to specify `Next solute`.

8. Type `Y` to confirm the defined system and its bulk composition.

   The thermodynamic data for your system is now retrieved from the database(s) chosen.

9. Answer the questions that you are prompted regarding various parameters of your calculation. You are asked to do any of the following:

   - `Rejectphase(s)` or `Restore phases(s)`
   - Check for miscibility gaps on any phase (`Should any phase have a miscibility gap check?`)
   - `Enforce the Global Minimization Technique in calculations?`
   - Save all functions, variables and tables in POLY3 file?
   - `Set numerical limits` on the calculation
   - Confirm defined conditions?
   - Accept the default settings for two mapping variables

10. The Pourbaix calculation starts. Answer the question `Any missing phase boundary you could possibly think of?` Type `Y` or `N` to set whether you want to add starting points to the calculation. If you suspect that the calculation has missed some phase boundaries, this may help the program to detect them.

11. Answer questions about how the diagram is plotted and how to save the results of your calculation. You are asked to do any of the following:

- Change the pH/Eh steps for smoother curves?
- `Zoom in` on a specific region of the diagram
- `Change the curve-label option for the diagram`
- `Add label-texts onto the Pourbaix diagram`
- `Change the subtitle of the diagram`
- `Change the axis-texts`
- `Further refine the diagram in the POST Module`
- Print the diagram (save a `Hard copy of the diagram`)
- `Save the X-Y coordinates of curve on a text file`
- `Modify the diagram`
- Calculate and plot another Pourbaix diagram (`Any more diagram?`)

Basic Settings and Definitions

This section is applicable to the Console Mode POURBAIX diagram module only.

As of 2026a, information about appending databases or retrieving thermodynamic data is only applicable if you are using TCAQ version 3.1 and older or one of the free databases. Otherwise it is recommended you upgrade to TCAQ version 4.0, which has access to many new phases and there is no need to append the gas solution phase, the metallic solid solutions, or any oxide phases. This is applicable to both Graphical Mode and Console Mode.

Go to the Aqueous Solutions Databases page on our website where you can access the latest TCAQ *Examples Collection* and the *Technical Information*. Also explore further options to work with aqueous solutions and this database using the Aqueous Calculator.

Basic Settings and Definitions

In a homogeneous aqueous solution or an aqueous-bearing heterogeneous interaction system, the most essential definition is for system-components there must be `H2O`, `H+1` and `ZE` (electron) plus those for elements dissolved in aqueous solution (such as `Na`, `Cl`, `S`) and associated in interacting metals/alloys (such as `Fe`, `Cr`, `Mn`, `Mg`, `Ni`, `Al`, `Si`, `Zn`).

Three fundamental phases in a system are the `AQUEOUS` solution, the `GAS` mixture and the `REF_ELECTRODE`. The `REF_ELECTRODE` phase is used for setting the reference state for electrostatic potential in the system and for calculating the Eh condition (defined as `MUR(ZE)/RNF`).

Other phases should be appropriately selected and retrieved from critically-assessed databases that cover not only the target phases (solution or stoichiometric) in interacting metals/alloys but also the secondary phases (solution or stoichiometric). The two public databases PAQ and PAQS are specially designed as single-database choices that cover all kinds of phases necessary for calculations. However, these databases are each limited to a framework of a very small number of elements.

When it comes to simulations of complex multicomponent systems with a wide variety of elements and phases, the thermodynamic data must be selected and retrieved from several databases: AQUEOUS solution and REF_ELCTRODE phases must be retrieved from TCAQ (for TCAQ3.1 and older) or AQS; alloy phases (such as FCC_A1, BCC_A2, HCP_A3, CEMENTITE) from alloy solution databases (such as SSOL for general alloy phases, TCFE for steel/Fe-alloy phases, TCAL for Al-based alloy phases; TCMG for Mg-based alloy phases, and TCNI for Ni-based superalloy phases); gaseous mixture phase and secondary phases from specific substance or solution databases (such as SSUB for GAS phase and various solid compound phases or TCOX for oxide solution phases).

The REF_ELECTRODE phase should always be suspended in equilibrium calculations, while GAS phase could be set as ENTERED, SUSPENDED or DORMANT, depending on the purpose of the calculation.

When defining an interaction system, the initial condition for the H2O component is always set as 1 kg of water. The initial composition conditions for dissolving and interacting elements are normally defined in moles (such as n(Fe)=0.009, n(Cr)=5E-4, n(Ni)=3E-4, n(Mn)=5E-5, n(S)=5E-5, n(Na)=3, n(Cl)=3). This makes it straightforward and convenient to count various related aqueous solution properties based on molality. The initial conditions for the H+1 and ZE components can be given as molar compositions (such as n(H+1)=0, n(ZE)=0) or their activities or potentials (such as lnACR(H+1)=-9.21, MUR(ZE)=8400).

The pH and Eh properties of the aqueous solution in the interacting system are always defined in the following way:

```
pH = -log10[ACR(H+1,AQUEOUS)*AH2O]]Eh = MUR(ZE)/RNF
```

The symbol AH2O is the molecular weight of solvent H_2O (equals 55.508435) and RNF is the Faraday constant (equals 96485.309).

The activity of the solvent water (ACRH2O, Aw), the osmatic coefficient of aqueous solution (OSMC, Os), electronic affinity (Ah), electronic activity log10ACRe (pe), ionic strength (IS), total aqueous concentration, in molality (TM) and total alkaline concentrations under two definitions (At1/AT2) are calculated and listed for each equilibrium state.

POLY3 calculations for mass balances in Thermo-Calc are always based on site-fractions. Consequently, when functions for describing various properties of aqueous solutes are defined, such as molality (MLi), activity coefficient (RCi) and activity (AIi), they should be converted to molality-based quantities:

```
MLi = Y(AQUEOUS,i)*AH2O/YH2O
RCi = ACR(i,AQUEOUS)*YH2O/Y(AQUEOUS,i)
AIi = ACR(i,AQUEOUS)*AH2O
```

Here, `YH2O` is the site-fraction of solvent H_2O and `AH2O` equals `55.508435`.

Many more variables, functions and tables can be entered for various purposes. For instance, an equilibrium constant for a homogeneous reaction or a solubility product for a solid dissolution reaction can be entered.

Plotting More Pourbaix Diagrams

This section is applicable to the Console Mode POURBAIX diagram module only.

When you have calculated a Pourbaix diagram, you can plot additional diagrams based on the results of the same calculation, but with different axis variables than Ph and Eh.

The variables can be plotted along the X- and Y-axes. Use the abbreviations of the variables when you specify what the X- and Y-axes represent in a diagram. In the table, *AQsp* refers to the name of a specific aqueous species. The asterisk (*) can be used as a wild card character for all such species. If neither *AQsp* nor * is entered in parenthesis, then all species are searched.

You must have plotted a Pourbaix diagram to plot a diagram with other variables than Ph and Eh on the Y-axis and the X-axis. You can either plot such additional diagrams directly after having finished the plotting and saving/printing of a Poubaix Ph-Eh diagram or by choosing option 2 (Open an old file and plot other property diagrams) when you enter the POURBAIX module and opening a POLY3 workspace file.

Abbreviations for Aqueous Solution Variables (Console Mode)

For Graphical Mode, see Quantities Groups Available for Plots and Tables.

Abbreviation	Variable
pH	Acidity
Eh	Electronic Potential (V)
Ah	Electronic Affinity (kJ)
Pe	Electronic Activity (log10ACRe)
IS	Ionic Strength
TM	Total Concentration
Aw	Activity of Water
Oc	Osmotic Coefficient

Abbreviation	Variable
MF(AQsp)	Mole Fractions of Aqueous Species
ML(AQsp)	Molalities of Aqueous Species
AI(AQsp)	Activities of Aqueous Species
RC(AQsp)	Activity Coefficients of Aqueous Species

Plotting an Aqueous Solution Diagram

The **Aqueous Calculator** and a predefined template is available in Graphical Mode and recommended for aqueous calculations (including Pourbaix diagrams).

1. Type `Y` when prompted whether to plot any more diagrams, or select option 2 when you enter the POURBAIX module.
2. Specify which variable you want the X-axis to represent. Use the abbreviation specified in the preceding table. When you specify the name of an aqueous species, you can use the asterisk (*) to select all species.
3. Specify which variable you want the Y-axis to represent. The diagram is then automatically plotted.
4. Answer questions about how the diagram is plotted and how to save it. You are asked to do any of the following:
    a. change the axis-type (linear, logarithmic or inverse) on the X-axis or Y-axis
    b. zoom in on a specific region of the diagram
    c. change the curve-label option for the diagram
    d. add label-texts onto the Pourbaix diagram
    e. change the subtitle of the diagram
    f. change the axis-texts
    g. refine the diagram in the POST Module
    h. print the diagram (save a hard copy)

i. save the X-Y coordinates of curve on a text file
j. modify the plotted diagram
k. calculate and plot another aqueous solution diagram

Stepping Calculations in an Aqueous Solution

This section is applicable to the Console Mode POURBAIX diagram module only.

Performing the stepping calculation overwrites all the previous settings and stepping results on the POLY3-file. To avoid this, use SAVE_WORKSPACES to create a new workspace.

When you have calculated a Pourbaix diagram in Console Mode, you can use the saved results of the calculation (the POLY3 file), and make a property diagram based on stepping calculation.

Since the program normally sets the calculated initial equilibrium point as the starting point, the minimum value for the stepping variable must be specified as smaller or equal to the specific initial condition, and the maximum value as larger or equal to that condition. If pH is set as the stepping variable, the program automatically calculates the equilibrium constant in logarithmic (log10Ka) of the electrolysis reaction H2O (water) = H+ + OH- for the real aqueous solution under the current temperature-pressure-composition conditions, and thus this constant log10Ka value is considered as the highest pH in specifying the maximum value along stepping. Subsequently, confirm or modify an increment factor with a default value; for pressure and mole of a component, specify the step in logarithmic (log10P or log10N).

State Variable Abbreviations

You can use any of these state variables as a stepping variable.

For Graphical Mode, see Quantities Groups Available for Plots and Tables.

State Variable	Abbreviation
Temperature (K)	T
Pressure (bar)	P
Acidity	pH
Electronic potential (V)	Eh

State Variable	Abbreviation
Mole number of a dissolving component (such as Fe, Na, Cl, or NaCl) in 1 kg of water.	N(Comp) (for example, `N(Fe)`)

How to Do a Stepping Calculation

The **Aqueous Calculator** and a predefined template is available in Graphical Mode and recommended for aqueous calculations (including Pourbaix diagrams).

You must have plotted a Pourbaix diagram before making a stepping calculation on an aqueous solution.

1. Use GOTO_MODULE POURBAIX to enter the POURBAIX module.
2. Type `4` to open an old file and make another STEPPING calculation.
3. Choose which POLY3 file to load.
4. Specify the conditions of the calculation by answering the questions that follows.

   The system definition is the same as in the previous Pourbaix calculation, but you can modify conditions such as bulk composition, temperature and pressure, and change some component definitions if necessary.

5. Specify which variable to use as the stepping variable (see the preceding table), its minimum and maximum value, and the length of each incremental step.

   The settings and stepping results are written to the opened POLY3 file, and a first default property diagram is plotted.

Including or Excluding the Gas Phase

This section is applicable to the Console Mode POURBAIX diagram module only.

Under defined pressure and temperature conditions, the solvent water's thermodynamic stability limits are determined by the following two electrochemical reactions:

```
H2O(water) + 2e- = H2(gas) + 2OH-1
2H2O(water) = O2(gas) + 4H+1 + 4e-
```

The first reaction describes the formation of H_2-dominated gaseous mixture, under reducing conditions. The second reaction describes the formation of O_2-dominated gaseous mixture, under oxidizing conditions.

If the system reaches global equilibrium, then the water component is electrolyzed to H^+ and O^{-2} at all pH conditions. The degree of electrolysis depends on the pH value in the aqueous solution phase. If Eh gets high enough, then the O^{-2} anion is oxidized to O_2 (aqs). On the other hand, if Eh gets low enough, then the H^+ cation is reduced to H_2 (aqs). The major electrolysis and redox reactions are the following:

```
H2O (water) = H+ + OH- → Electrolysis of water at all pH.
H2O (water) = 2H+ + O-2 → Electrolysis of water at all pH.
O-2 - 2e- = 0.5O2 (aqs) → Oxidation or de-electronization of O-2 at high
Eh.
2H+ + 2e- = H2 (aqs) → Reduction or electronization of H+ at low Eh.
```

At a critically high Eh value under a given pH condition, an aqueous solution phase with a high enough O_2 activity becomes less stable than an O_2-dominated gaseous mixture phase. At this point, the gas phase replaces the aqueous solution phase in the system. The replacement process can be characterized by the following phase-transformation on the aqueous-gas phase boundary and oxidation of remaining water:

```
O2 (aqs) = O2 (gas)
H2O (water) - 2e- = 2H+(gas) + 0.5O2 (gas)
```

Similarly, at a critically low Eh value under a given pH condition, an aqueous solution phase with a high enough H_2 activity becomes less stable than a H_2-dominated gaseous mixture phase. At this point, the gas phase replaces the aqueous solution phase in the system, through the following phase-transformation on the aqueous-gas phase boundary and reduction of remaining water:

```
H2 (aqs) = H2 (gas)
H2O (water) + 2e- = O-2 (gas) + H2 (gas)
```

The phase transformation from an aqueous solution phase to an O_2- or H_2-dominated gaseous mixture phase also depends on the total molar Gibbs energies of the phases (which are complex functions of the phase constituents, the temperature and the pressure). The Gibbs energy minimization technique used in Thermo-Calc ensures that the phase transformation is accurately simulated.

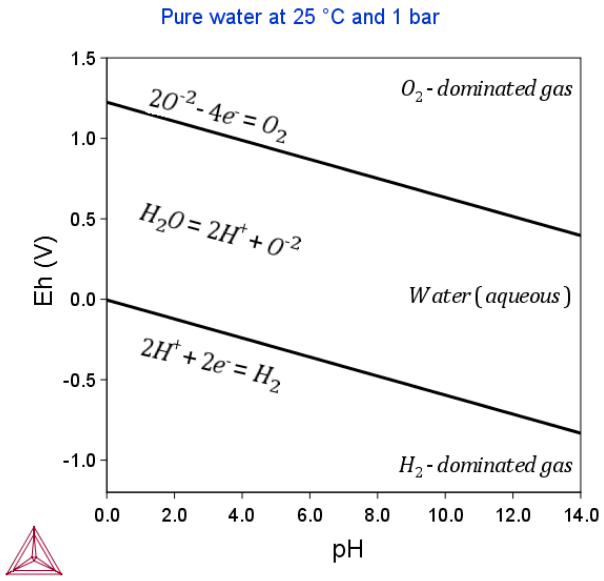
The following Pourbaix diagrams show the result of a calculation where the gaseous mixture phase was included. In the upper region (high Eh) and lower region (low Eh), the aqueous solution phase has been oxidized and reduced, respectively, to an O_2- or H_2-dominated gaseous mixture phase.

The two example diagrams show that the upper and lower boundaries between the aqueous phase (water) and the gas phase (dominated by either O_2 or H_2) can shift when solutes dissolve or when the temperature and pressure change.

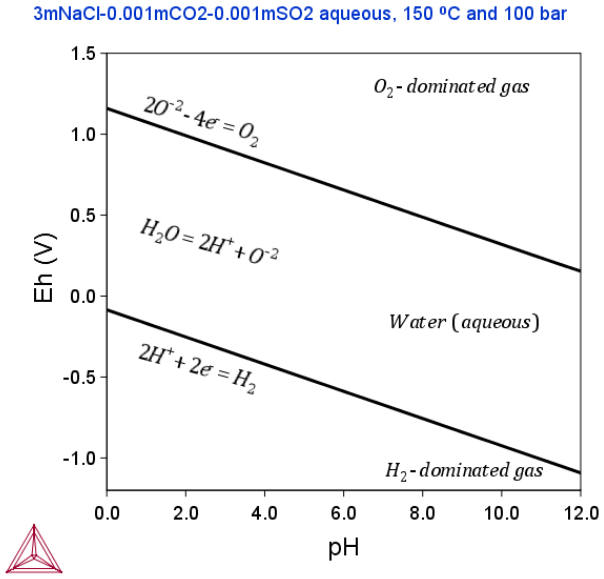
Accordingly, if one does not take a gaseous mixture phase into account when performing a calculation of Pourbaix diagram (as above), then the aqueous solution phase may end up with an extremely high O_2 (aqs) concentration at high Eh condition, or an extremely high H_2 (aqs) concentration at low Eh condition. Under either of these two extreme circumstances, the concept of “aqueous solution phase” is no longer valid and consequently no proper aqueous solution model can actually be applied. Therefore, from a restrictive thermodynamic equilibrium point of view, one shall normally include a gaseous mixture phase in an aqueous-bearing heterogeneous interaction system. This is true for all types of equilibrium calculations for an aqueous-bearing heterogeneous interaction system, not only of Pourbaix diagram calculations.

Hence, to perform a completely accurate Pourbaix diagram calculation, the gaseous mixture phase must be taken into account. However, since these electrochemical reactions normally have much higher kinetic barriers and are slower than other electrochemical and chemical reactions in the interaction system, one can sometimes ignore the gaseous mixture phase in the calculation.

If the gaseous mixture phase is ignored in this way, then the Pourbaix diagram does not show the H_2O-stability limiting lines.



A pH-Eh diagram for pure water at 25 °C and 1 bar.



A pH-Eh diagram for 3mNaCl-0.001mCO2-0.001mSO2 aqueous solution at 150 °C and 100 bar.

Pourbaix Diagram Examples: Gas Phase Excluded or Included for Fe

This section is applicable to the Console Mode POURBAIX diagram module only.

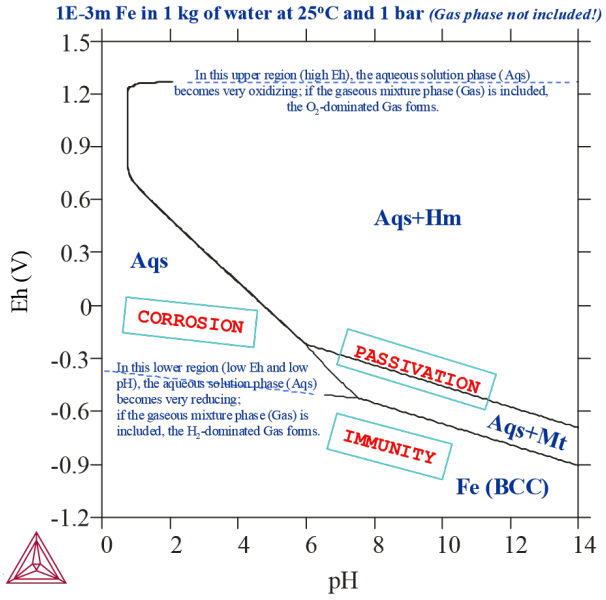
The Console Mode POURBAIX diagram module was used to generate these example plots as well as using the TCAQ database version 3.1 and older. In Graphical Mode, with the TCAQ4 database and newer for best results, you can use the **Aqueous Calculator** with a **Phase diagram** *Calculation Type* to plot Pourbaix diagrams.

The following are examples of Pourbaix diagrams for Fe. For the first example, the calculations on which the diagrams are based have not taken the gas phase into account. The diagrams in the second example are based on calculations that have taken the gas phase into account.

Pourbaix Diagrams with Gas Phase Excluded

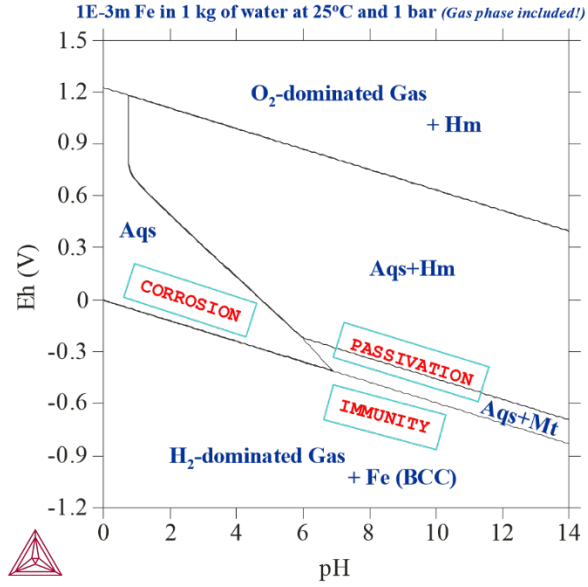
This is an example of a Pourbaix diagram of Fe, in which the gas phase has not been considered in the calculation. The system has 0.001 mole of Fe in 1 kg of pure water at a temperature of 25 °C and a pressure of 1 bar. Magnetite (Mt, Fe_3O_4) and hematite (Hm, Fe_2O_3) co-exist with the Fe-containing dilute aqueous solution. The formation of magnetite and hematite represent the passivation of iron in the upper right pH-Eh field.

If pH is low and Eh is relatively high, then Fe eventually completely dissolves into the aqueous solution phase. Under conditions of low Eh, Fe remains in its stable solid state, the BCC phase, and neither dissolves into water nor into alternates to Fe (the immunity of Fe).



Pourbaix Diagrams with Gas Phase Included

With all the possible redox reactions involving the aqueous solution phase and gaseous mixture phase being considered in the equilibrium system, that is, the gaseous mixture phase is included in the calculation, the Pourbaix diagram of Fe in a system with 0.001 mole of Fe in 1 kg of pure water at 25 °C and 1 bar.



Comparing this Pourbaix diagram with that from Basic Settings and Definitions , you can see that both diagrams are for the same interaction system under the same temperature-pressure condition, but the present diagram shows the results of calculations where the gaseous mixture phase has been included. It presents the complete Pourbaix diagram for the defined interaction system, in a full thermodynamic equilibrium. In the upper region (high Eh) and lower region (low Eh), the aqueous solution phase is oxidized and reduced to the O_2- or H_2-dominated gas phase. Hematite coexists with the O_2-dominated gas, while Fe-BCC is stable with the H_2-dominated gas. The stability field of magnetite may extend slightly into the H_2-dominated gas region, where it coexists with the gaseous mixture instead of the aqueous solution. Its boundary with Fe (BCC) cannot be drawn due to the absence of aqueous solution phase.

It is not possible to calculate the pH value in both the O_2- and H_2-dominated gaseous mixture phase stability regions where the aqueous solution phase is absent. Hence, in a normal Pourbaix diagram, no line is drawn that indicates a phase boundary between the gas phase and the metallic phases or secondary phases (that is, metal-oxides).

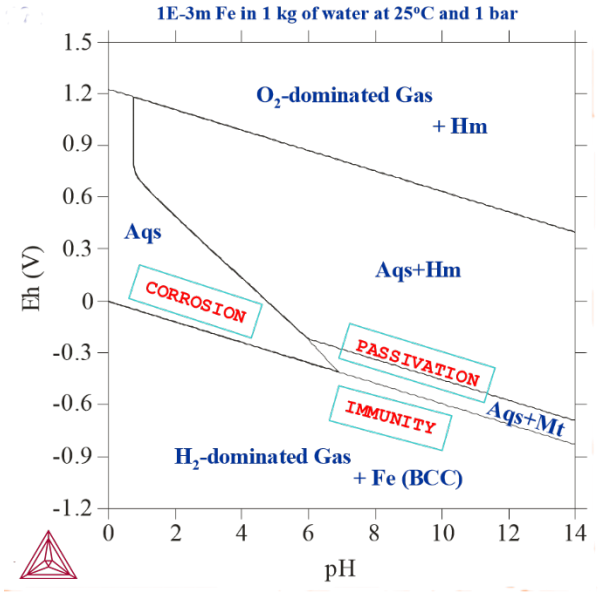
Variations of Pourbaix Diagrams

The Console Mode POURBAIX diagram module was used to generate these example plots as well as using the TCAQ database version 3.1 and older. In Graphical Mode, with the TCAQ4 database and newer for best results, you can use the **Aqueous Calculator** with a **Phase diagram** *Calculation Type* to plot Pourbaix diagrams.

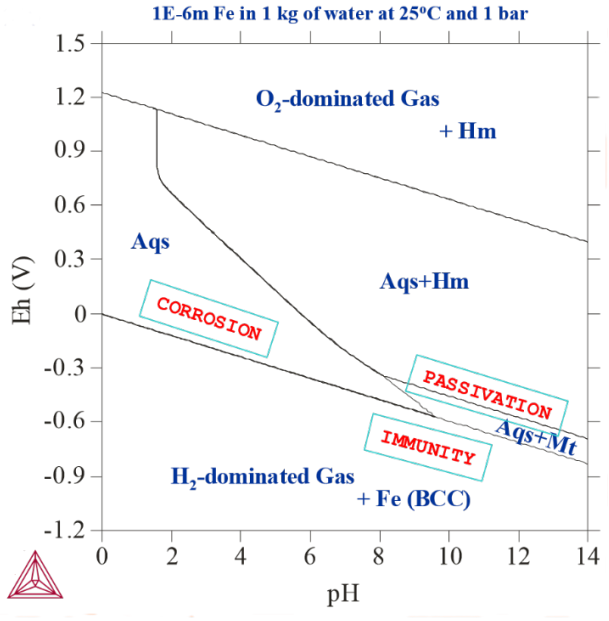
The shape of a Pourbaix diagram of an alloy or condensed material and the stability relations of various secondary phases depend upon the following system factors:

- Initial amount of the alloy or other condensed materials
- Initial composition of the alloy or other condensed materials
- Initial amount of the interacting aqueous solution phase
- Initial composition of the interacting aqueous solution phase
- Temperature and pressure conditions

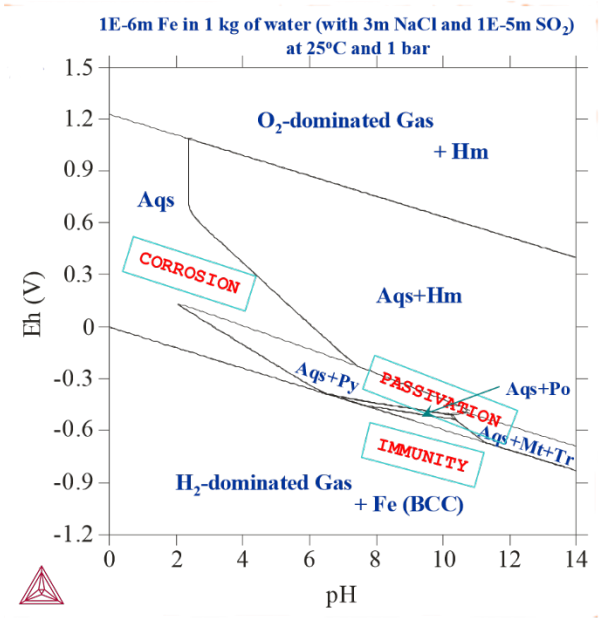
In the interaction system that the diagrams in Pourbaix Diagram Examples: Gas Phase Excluded or Included for Fe are based on, the initial amount of pure Fe that was taken to have effectively reacted with 1 kg of pure water at 25 °C and 1 bar was 0.001 m. The following diagrams are Pourbaix diagrams of Fe where other initial amounts of pure Fe have been used, or where the interacting aqueous solution compositions have been alternated, or the temperature and/or pressure have been changed. Gaseous mixture phases have been included in all the calculations that these diagrams are based on.



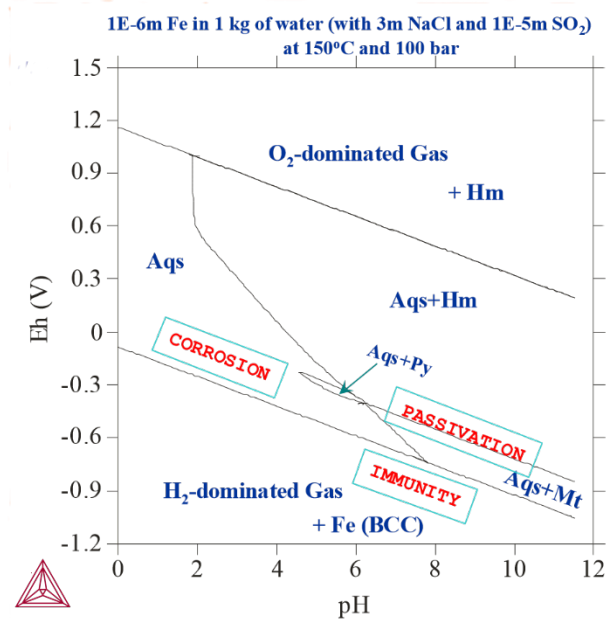
1E-3 m Fe actively reacted with 1 kg of pure water at 25 °C and 1 bar (as in the calculation in Pourbaix Diagrams with Gas Phase Included).



1E-6 m Fe actively reacted with 1 kg of pure water at 25 °C and 1 bar. Note that the active metal corrosion region gets enlarged as the initial Fe amount decreases from 1E-3m to 1E-6m.



1E-6 m Fe actively reacted with 1 kg of water, 3 m NaCl and 1E-5 m SO_2 at 25° C and 1 bar. Introducing SO_2 into the system leads to the formation of various metal-sulphides (Py-pyrite, Popyrrhotite, Tr-troilite). In addition, the passivation region becomes larger.



1E-6 m Fe actively reacted with 1 kg of water, 3 m NaCl and 1E-5 m SO_2 at 150° C and 100 bar. Here, changing the temperature and pressure affects the stability fields of various Fe-oxides/sulphides.

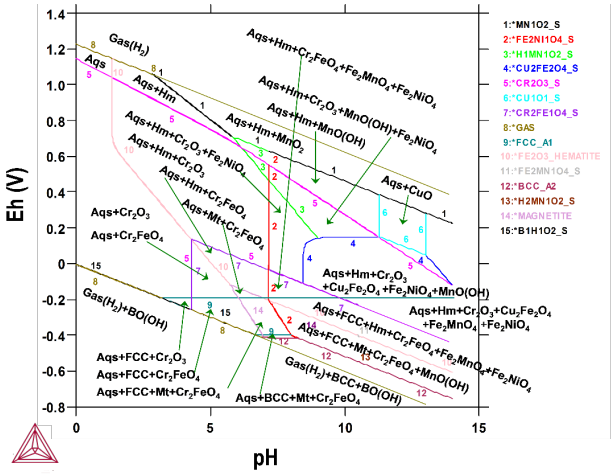
As you can see from the figures, the aqueous-gas phase boundaries shift as the initial bulk compositions, pressure and temperature conditions in the interaction system change.

Pourbaix Diagrams for Complex Alloys

The Console Mode POURBAIX diagram module was used to generate these example plots as well as using the TCAQ database version 3.1 and older. In Graphical Mode, with the TCAQ4 database and newer for best results, you can use the **Aqueous Calculator** with a **Phase diagram** *Calculation Type* to plot Pourbaix diagrams.

Thermo-Calc can not only be used to simulate how pure metals interact with pure water or simple aqueous solutions under normal pressure and temperature conditions. It can also be used to calculate how complex alloys and concentrated aqueous solutions interact over a very wide pressure, temperature and composition ranges. This is shown with the two examples.

The first example is a Pourbaix diagram calculated for the heterogeneous interaction between 0.001 mole of steel (Fe-7.676Cr-5.0Ni-2.1887Mn-1.0Cu [at%]) and 1 kg of water (and with 1.2 m H_3BO_3, 0.022 m Li and 0.001 m NH_3), at 25 °C and 1 bar. This application is particularly useful for safety assessments of nuclear reactors and nuclear waste repositories.



The next example is a Pourbaix diagram calculated for the heterogeneous interaction systems between 0.1 mole of AISI4340 stainless steel (Fe-0.80Cr-1.85Ni-0.70Mn-0.25Mo-0.25Si-0.40C [wt%]) and 1 kg of seawater (with the equivalent of 0.6054 m NaCl), at 25 °C and 1 bar. This application is particularly useful for failure analysis of petroleum exploitation industry.

Tabulating a Reaction **859**

Tabulating a Substance or Solution Phase at Fixed Composition **860**

About the Tabulation Reaction Module

The TABULATION_REACTION (TAB) module can be used to tabulate thermodynamic functions of any type of substance, stoichiometric phase or solution phase, or reaction. The module can tabulate thermodynamic functions of pure stoichiometric phases or solution phases at fixed composition, as well as various kinds of partial derivatives for a pure stoichiometric phase or solution phase at a given composition.

The TAB module begins by evaluating the most stable species of a substance in either a homogeneous state or in a reaction. Results are presented in a table or plotted as a graph.

A reaction tabulation presents you with the following properties, on rows representing different temperature levels:

- Heat capacity change / Delta-Cp (Joule/K) in column 2.
- Enthalpy change / Delta-H (Joule) in column 3.
- Entropy change / Delta-S (Joule/K) in column 4.
- Gibbs energy change / Delta-G (Joule) in column 5.

In the case of a tabulation of a substance or solution phase at a fixed composition, the properties presented are the heat capacity, enthalpy, entropy and Gibbs energy, rather than the degree of change in those properties.

You can add a 6th column to the table that shows the values of a property or user-defined function of your choice.

- Tabulating a Reaction
- Tabulating a Substance or Solution Phase at Fixed Composition

Tabulating a Reaction

A tabulation of a given chemical reaction provides you with data about the rate of change of the standard tabulation properties at various levels of temperature. You can also add a column for a property of your choice to the table.

1. Use GOTO_MODULE TAB to enter the TAB module.

2. If you want to add one thermodynamic functions to the tabulation calculation, which is present in a sixth column in the table, use ENTER_FUNCTION.

   You are prompted to enter the name of the column that is given at its head, and the function itself. The following state variables can be used to define the function: G, H, S, T, P, V and H298.

3. Use TABULATE_REACTION followed by a formula that specifies of the reacting species and products to perform the tabulation calculation. The name of the elements must be entered in upper case letters only. Terminate the chemical reaction with a semi-colon. For example, you can enter:

   ```
   TABULATE_REACTION 3H2+N2=2N1H3;
   ```

   Elements that are designated with a single letter must be followed by a stoichiometry factor, even if this factor is 1. `CO` hence be interpreted as Cobalt rather than as carbon monoxide. Carbon monoxide is entered as `C1O1` or `O1C1`.

4. Set the pressure, the range of temperature that you want the tabulation to cover, and change in temperature between each row in the table. You can also specify if you want to output the calculation results to an EXP-file and whether you want any graphical output, and if so, which column you want to be plotted against temperature.

   The tabulation calculation is performed and you are given a table that shows the various properties at each temperature level within the range defined.

   If you have chosen to receive graphical output, then the Console Results window presents a graph that plots the column of you chose (on the Y-axis) against temperature (on the X-axis). When this graph is plotted, you are now in the POST module, where you can modify the graph in various ways.

Tabulating a Substance or Solution Phase at Fixed Composition

A tabulation of a substance or solution phase at fixed composition provides you with data about the standard tabulation properties at various levels of temperature for a given chemical reaction. You can also add one extra property column of your choice to the table.

It is important to have already defined the system and retrieved thermodynamic data from a database before using the TAB command.

1. Use GOTO_MODULE TAB to enter the TAB module.
2. Use SWITCH_DATABASE to switch to a database that contains solution-based data, such as TCFE for example.

   You cannot use the default SSUB database when tabulating solution phases at a fixed composition.

3. If you want to add one thermodynamic function to the tabulation calculation, which is present in a sixth column in the table, use ENTER_FUNCTION.

   You are prompted to specify the column header and the function itself. The following state variables can be used to define the function: G, H, S, T, P, V and H298.

4. Use TABULATE_SUBSTANCE followed by the name of the substance or solution phase to perform the tabulation calculation.
5. Set the pressure, the range of temperature that you want the tabulation to cover, and change in temperature between each row in the table. You can also specify if you want to output the calculation results to an EXP-file and whether you want any graphical output, and if so, which column you want to be plotted against temperature.

The tabulation calculation is performed and a table shows the various properties at each temperature level within the defined range.

If you have chosen to receive graphical output, then the Console Results window presents a graph that plots the column you chose (on the Y-axis) against temperature (on the X-axis).). When this graph is plotted, you end up in the POST module, where you can modify the graph in other ways.

Commands by Module

All the commands for each Thermo-Calc Console Mode Module are listed and described in the following sections.

- System Utilities (SYS) Commands
- Database (TDB) Module Commands
- POLY Module Commands
- Gibbs Energy System (GES) Commands
- SCHEIL Module Commands
- PARROT Module Commands
- EDIT_EXPERIMENTS (ED_EXP) Submodule Commands
- Tabulation Reaction (TAB) Commands
- REACTOR (REACTOR_SIMULATOR) Commands
- POST Module Commands

System Utilities (SYS) Commands

ABOUT

The ABOUT command lists basic information about the development history and ownership of the Thermo-Calc software as well as version information.

BACK

GOTO_MODULE

Use the BACK command to switch control back to the most recent module. Going from the POST module, BACK goes only to the TAB or POLY module (from where the POST module is entered).

CLOSE_FILE

Close an opened text file.

Syntax	CLOSE_FILE
Prompt	`Unit number: <Unit number>` A unit number given in an OPEN_FILE command must be specified.

DISPLAY_LICENSE_INFO

You can also access this same information from the top menu. Choose **Help → Show License Info**.

Use this command to launch a license diagnostics program implemented in the SYS module. It detects the license information for the Thermo-Calc installations on the current client computer (and on the connected license server), and lists the details, including the current status of available license file and all its included license features for the current installation(s), as well as the Safenet Environment Variables and detailed Local (Client) Information, on screen or into a textual file (*.TXT).

This is useful for a list of license details, and to obtain basic technical support by sending the *.TXT file to support@thermocalc.com. If you are running a network client installation of Thermo-Calc, you can see how many of the client example licenses that are currently checked out and how many of them are left. You can also see which clients computers it is that have checked these client example licenses out.

Syntax	**DISPLAY_LICENSE_INFO**
Prompt	`Output to screen or file /Screen/: <Mylicenseinfo.txt>` Press <Enter> to display a list of license information or into a *.TXT file under a specific file name which can later on be opened and edited by any basic text editor.

EXIT

Use the EXIT command to leave the program and return to the operating system. Use a SAVE command before exiting otherwise all data and results are lost (in either the GIBBS, POLY, PARROT or REACTOR module).

GOTO_MODULE

Switch between modules. The name of the module must be typed. To get a list of available modules, press the <Enter> key.

Syntax	GOTO_MODULE
Prompt	`Module name: <Module name>`
	If the <Enter> key is pressed without typing a unique module name (or typing a ? mark) it prompts for the `MODULE NAME` and lists the available modules.

HELP (? and ??)

Enter ? or ?? to get text help about the current prompt (whether this is the prompt of a module, or a prompt that requests you to specify the value of some parameter).

For some commands and prompts, more detailed help is given when two ?? are entered.

HELP

Lists the available commands or explains a specified command. Specifying a unique command displays an explanation on screen. Typing a command abbreviation that is not unique lists all matching commands. Get the command information by typing a unique abbreviation or the complete command name.

Syntax	HELP
Prompt	`Command: <Command name>` *Command name* is the name of the command (one of the-module commands) to get help. If the <Enter> key is pressed without typing a command name, then all the available commands are listed.

HP_CALCULATOR

The HP-CALCULATOR commend is the QBA simple interactive calculator using reverse Polish notations.

Available OPCODEs (HPC codes) are listed by entering the command HELP.

Use the BACK command to quit and go back to the SYS module.

Input are numbers, + - * / and ^ and OPCODEs. Several numbers an operations can be given on one line. The content of the X register is displayed after each operation.

For example, to compute 2*EXP(1.5**3-30000/(8*1273)), you should input the following:

```
30000 8/1273/chs 1.5 3 ^ + exp 2 *
```

INFORMATION

Get basic information about topics related to the module you are in.

Syntax	INFORMATION
Prompt	`Which subject /Purpose/: <Topic name>` Specify a subject (or its abbreviation as long as it is unique). Enter a question mark `?` for a list of topics.

MACRO_FILE_OPEN

Some of the information in this topic is related to the add-on Diffusion Module (DICTRA).

The macro file functionality is a way to predefine sequences of Thermo-Calc commands stored in a macro file (a basic text file usually with the default extension *.TCM or*.DCM for DICTRA) and then executing all of the sequences using this command (preceded by the macro file name). This command can be used within various modules (i.e. SYS, POLY, PARROT, TAB and DICTRA_Monitor).

Syntax	MACRO_FILE_OPEN
	`<Name of a macro file *.tcm>` An **Open** window displays to specify the filename of the macro file (*.TCM) with the macro command, so that the path (in the **Look in** field) and **File name** can be specified. The **Files of type** *.TCM for Thermo-Calc (Console Mode) calculations and *.DCM for DICTRA simulations, cannot be changed. Click **Open** or **Cancel** to continue. A window such as **Save**, **Open**, or **Print** opens if the macro file contains commands to: • set log files (these have a file extension .TCM) • save or read GIBBS, POLY or PARROT workspaces • switch user databases • compile experiments (from existing *.POP files) • create new *.PAR files • append *.EXP files • plot diagrams, etc. If required, opening these windows can be avoided by issuing the file names (preferably with file-type extensions; if the files are not in the current working area where the macro is located, the appropriate and complete paths of the files should also be specified) and sometimes with the required options after the corresponding commands or parameters/options. For details, see the related commands and modules. When using a macro file that intended to plot graphs on screen, but the command SET_PLOT_FORMAT is used to alter the plotting environment from the default value, it is important to first use the command SET_PLOT_FORMAT again to change back to the default value.

This is useful when the same or similar calculations are made frequently with small changes [in terms of system definitions, data manipulations, conditions (for single points, stepping or mapping calculations), plotting settings, etc.). For example, use this feature when calculating phase/property diagrams during an assessment of thermodynamic data.

A macro file can be automatically generated in Console Mode if in the SYS module the SET_LOG_FILE command is used and a log file name (with a file extension *.TCM) is given before any other SYS, DATA, TAB, GIBBS, POLY, POST, PARROT, or ED-EXP command or any special-module command (e.g. BIN, TERN, POTENTIAL, SCHEIL, POURBAIX, or REACTION). Such a log file generated in Console Mode is a text file. You can use a text editor (such as Notepad++) to remove unnecessary command lines, modify some commands, settings and definitions, add some pause points, add comment lines that start with `@@`, and so forth. Then save it as a macro file with the standard file extension TCM.

Experienced users can also write/edit an appropriate macro file for calculations/simulations, using any basic textual editor outside the Thermo-Calc program.

All commands can be used in a macro file.

The file can be terminated with EXIT or interrupted with SET_INTERACTIVE.

Within a macro file you can use comment-lines (for describing the problems and for explaining commands and inputs/outputs), which should always start with the @@ signs in the beginning of each comment-line. Such comment-lines help to document the macro file, while these are not considered as command lines and thus do not affect the proceeding of all the normal commands in modules when the file is called by Thermo-Calc.

You can put multiple-line comment-blocks in a macro file between the @(and @) signs. The former sign indicates where the comment begins and the latter sign indicates where the comment ends. A comment-block begins from a line started with the *begin comment* sign @ (and ends with the *finish comment* sign @) where all the lines written in between are ignored, and the line started with @) is also ignored.

Make sure to put the comment block end command @) on its own line.

An example of the block end command on its own line:

```
@(
Comment 1
Comment 2
@)
```

Another use for a macro file is to allow you to interact at some specific points, using the @? sign starting a text line (note that the text describing the expected user-specification/input should be written as a continuous string without any empty space), for user's on-time

specifications of arguments/parameters or inputs of parameter-values that are requested by a certain command. The macro temporally stops at the @? sign, prompt on screen the text given after @?, and waits for the specified argument/parameter/value. Thermo-Calc then uses specified argument/parameter/value as the input(s) for the associated command. For example, you can input the values of lower and higher temperature limits for the second axis-variable as follows:

```
GO POLY-3
SET-AXIS-VAR 2 T @?Low-temperature-limit:
@?High-temperature-limit:
```

You can have macro-variables denoted by the signs of @#n (for definition) and ##n (for usage); and up to nine variables inside a single macro file. Such a macro-variable can be assigned with its desired value, as for example:

```
@#3First-element?
```

This writes the text (note that the text describing the expected user specification/input is written as a continuous string without any empty spaces) after the @#3 sign as prompted on screen and then wait for a specification. The input is assigned to the macro-variable ##3, which is directly called in different parts within the current macro file.

For example, the content of the macro-variable `##3` is inserted in the command:

```
DEFINE-SYSTEM ##3
```

It is also useful in more complicated commands, such as:

```
SET AXIS VAR 1 x(##3) 0 1,,,
```

This command sets the mole fraction of macro variable 3 as axis 1.

A macro file can have any number of pauses at the `@&` signs, for the purpose of checking the details/results of executing certain commands when running the macro file. However, you can also prevent the software from temporarily stopping at any pause by typing any character (except for the `Y` character for confirming a Yes answer to a command prompt) after specifying the name of a macro file.

A macro file can have a maximum of five nested levels, i.e. a macro file can call another macro file, and if one sub-level macro is terminated by the command it resumes at the next command in the previous macro. If it is terminated by `end-of-file`, the Thermo-Calc (Console Mode) software stops.

This feature is especially useful for alloy design that requires many (hundreds) of calculations/simulations on similar material system/processes (specified in many different but appropriately-documented macro files that are organized in up to five levels) during a certain period of time (e.g. in an evening), you can run the main macro (on the top level) at a certain

time (e.g. before leaving the office) and afterwards (e.g. next morning) you can systematically and efficiently check/compare/analyse the results (saved as graphical files, and/or EXP, TXT, XLS… files).

By adding the SYS command SET_ECHO at the beginning of a macro file (or in the primary macro file on the top level if any sub-level(s) of macro files are used), it is useful to automatically display the complete/detailed meaning of various commands in all the sequential operations in the software, all enforced according to the macro file(s).

OPEN_FILE

A text file is opened for use in other commands where a unit number is necessary. The program automatically assigns a unit number.

Syntax	OPEN_FILE
Prompt	`File name: <File name>` A legal file name must be specified.

SET_COMMAND_UNITS

This command is useful for reading inputs already prepared by a textual editor on a file. Such inputs can be a table of values or a large number of parameters. The file must be opened with OPEN_FILE.

The first two lines of an input file are skipped before any input is read.

Syntax	SET_COMMAND_UNIT
Prompt	`Input unit number /5/: <Input unit number>` Specify the input unit number returned from an OPEN_FILE command. The next command is taken from the file connected to this unit number. The last command on such a file must be EXIT or SET_INTERACTIVE when you are in POLY, POST or SYS module, in order to go back to read input from the keyboard. The default value is the current input unit.
	`Output unit number /6/: <Output unit name>` Specify the output unit number returned from an OPEN_FILE command.

SET_ECHO

This command is only applicable to use with macro files, i.e. it does not work to enter this command directly into the Console.

Add the SET_ECHO command at the beginning of a macro *.TCM file (or to the primary macro file on the top level if any sub-level(s) of macro files are used).

Automatically displays on screen the complete details of various commands in all the sequential operations in the software, that are enforced according to the macro file(s).

SET_GES_VERSION

This command enables switching between the two versions of the Gibbs Energy System (GES) calculation engine. As of Thermo-Calc version 2019b, GES6 is the default. Also see About the Gibbs Energy System (GES) Module.

GES6 is a re-write and new implementation of the Gibbs Energy System module of Thermo-Calc and it is the default engine in Thermo-Calc. As of 2026b, TQ-Interface has access to it but GES5 is the default. GES5 continues to be available and works in the background of the program where necessary. The main purpose of GES6 is to support faster development of new features. However, not all GES5 functionality is implemented in GES6. In such cases (except for the POURBAIX module), GES6 falls back silently and uses functionality from GES5 in the background.

Syntax	SET_GES_VERSION
Prompt	`USE GES VERSION 5 OR 6 /6/:` The default is version 6. If you change the version to GES5, it is set for the current session of Thermo-Calc only. If you launch a new Console window, the version resets to GES6.
	To globally set the default from GES6 back to GES5, go to the **Tools → Options →** Global General Settings tab and click **Version 5** for the *Preferred Gibbs Energy System* setting. This is useful if you are using the PARROT module (optimization) or if you have a custom database that is not compatible with GES6.

Contact Thermo-Calc Software AB at info@thermocalc.com for more information about the changes or if you encounter any issues you think are related to the new version of the calculation engine.

SET_INTERACTIVE

Use the SET_INTERACTIVE command to reset the input and output units to the initial values, i.e. keyboard and screen. Add this as the last command to the macro files.

SET_INTERACTIVE_MODE

Use the SET_INTERACTIVE_MODE command to reset the input and output units to the initial values, i.e. keyboard and screen.

Remember to add this as the last command to your macro files, in order to stop execution of the command file in the POST module. It has no meaning in interactive mode.

SET_LOG_FILE

Use it to save, in a basic text file, everything typed into Thermo-Calc. When having problems executing a command sequence, this command can be used to save the command typed onto a log file with the file extension *.TCM.

This command also makes the system echo the full command for all commands typed. This feature is useful when demonstrating the system since the abbreviated commands are often difficult.

The saved log file can then be edited as a macro file by using a basic text editor. This is useful to run the macro file(s) for similar calculations (the same system but slightly varied temperature-pressure-composition conditions), or run the example macro files.

Macro Files

Syntax	SET_LOG_FILE
Prompt	A **Save** window opens to specify a file name for the *.TCM file, so that the path (in the **Save in** field) and **File name** can be specified. If a log file with the same name exists in the current working directory, it is overwritten. The **Files of type** (i.e. TCM) cannot be changed. Click **Save** or **Cancel** as applicable.

SET_PLOT_ENVIRONMENT

Use this command to set the plot devices to save or print plots to, which varies for by installation type.

This command must be terminated with an empty line or two commas.

Syntax	SET_PLOT_ENVIRONMENT
Prompts	`Default plot device number /Default number/: <Device number>` The number given is unique for each type of graphical device. The default graphical device number should normally be selected. A question mark `?` gives you a list of all available graphical devices used.
	`Pseudo file name: <Pseudo-file name>` The name given here is a symbol which can be used to refer to a physical graphics device when asked for graphical output file.
	`Plot device number /1/: <Device number>` The number that specifies the type of graphical device.

	`Plot file name: <File name or printer name>`
	The name of the graphical device on system level (name of file or printer).
	
	Example
	`SET_PLOT_ENVIRONMENT 1 lasp 5 a0tr,,`
	This example sets the default plot device number to `1`, and defines an alias named `lasp` with plot device `5` and connected to a printer named `a0tr`.

SET_TC_OPTIONS

Predefine the default values of three general options for performing all the sequential single-points, stepping and mapping calculations.

Syntax	SET_TC_OPTIONS
Prompts	`Use_global_minimization /Y/:` By default it global minimization is used where possible (depending on the conditions setting). A global minimization test is performed when an equilibrium is reached. This costs more computer time but the calculations are more robust. Enter N to prevent global minimization being used to reach the equilibrium.
	`Global_test_interval /0/: <An integer value>` The integer number determines how often the global minimization should be used during calculations with STEP_WITH_OPTIONS and MAP. If it is set to 0 (zero), the recommended global test interval is used: i.e. every tenth step and at each phase change during step calculations, and only at node points during map calculations. Any other positive integer number, n, suggests it performs global minimization tests at every n^{th} step during step and map calculations. Of course, the Global Minimization test is always carried out at a phase change or a node point. The software is initially configured with 0 (zero) as the default value, but such a configuration for the default value can be changed by this option.
	`Automatically_add_initial_equilibria /Y/:` When ADD_INITIAL_EQUILIBRIUM is not used before a map calculation, a mesh of INITIAL_EQUILIBRIUM is automatically added before the mapping procedure itself takes place. This mesh is only available when the two independent axis-variables have already been defined by the POLY command.
	`Set_axis_variable` If Y is entered, the POLY module always enforces the automatic procedures for adding initial equilibrium points during mapping. For N, no initial equilibrium points are then added during mapping.

STOP_ON_ERROR

Useful for batch jobs in order to prevent that an erroneous sequence of commands to the program causes waste of computer activity.

Syntax	STOP_ON_ERROR
	Give the preferred argument (ON or OFF) after the STOP command. If the default argument ON is given, the program terminates after an illegal or ambiguous command. It is possible to reset the effect of this command by giving the argument OFF.

Database (TDB) Module Commands

These commands are related to the DATABASE_RETRIEVAL module, which is also known as the TDB module.

Also see Defining a System in Console Mode for step-by-step instructions.

RESTORE **899**

SET_AUTO_APPEND_DATABASE **900**

SWITCH_DATABASE **901**

AMEND_SELECTION

This command is for the DATABASE_RETRIEVAL (TDB) module.

Use this command after defining the elements, species or the system (with the commands DEFINE_ELEMENTS, DEFINE_SPECIES, or DEFINE_SYSTEM). The prompts allow changes to the predefined system. By answering Y or N, each of the selected elements, species or phases can be accepted or rejected (although this is not the case for the constituents or the entire system).

Syntax	AMEND_SELECTION
Prompt	`Keep <Name1> No/Quit/Yes/` `Keep <Name2> No/Quit/Yes/`
Options	`Keyword-- Elements/Species/Phases name&` Names of the pre-defined or pre-selected elements/species/phases

APPEND_DATABASE

This command is for the DATABASE_RETRIEVAL (TDB) module.

Appends data to the current set of data already read from another database. The syntax is the same as for the SWITCH_DATABASE command.

This command enters all additional functions and parameters to already existing phases, e.g atomic mobilities, phase constituents, excess models, G0 and interaction parameters.

This command is most commonly used to read mobility data from stand-alone mobility databases.

This command should be used with some caution if thermodynamic data is appended and the application is run with Gibbs Energy System version 5 (see SET_GES_VERSION in the SYS module). It can change calculated values in an unexpected way. This can happen e.g. if the appended database has the same function name as a function in the data retrieved from a database opened with SWITCH_DATABASE.

Syntax	APPEND_DATABASE
Prompt	`New database name /XYZ/:` The name of either an existing database (e.g. FEDEMO) or USER.

DATABASE_INFORMATION

This command is for the DATABASE_RETRIEVAL (TDB) module.

Use the DATABASE_INFORMATION command to obtain a short description of the current database. This can include information on covered systems, used models, valid ranges for parameters in temperature and composition, major applications, and so on.

DEFINE_ELEMENTS

This command is for the DATABASE_RETRIEVAL (TDB) module.

Define the system in terms of elements. All possible species that can be formed by the given elements are retrieved from the database. The names of elements must be separated with a space or comma. It is possible to use a wildcard * after a common part of element names so that all the elements, which start with that common part and are available in the currently switched or appending database, are defined in the system. Up to 40 elements can be defined into a single system.

Also see Defining a System in Console Mode for step-by-step instructions to define a system with this command.

Syntax	DEFINE_ELEMENTS
Prompt	`Element& <Element1, Element2, …>` A list of elements to be defined into the system.
	When appending database(s), this command, or DEFINE_SPECIES or DEFINE_SYSTEM must be repeated with the same or similar elements as defined in the first switched database.

DEFINE_SPECIES

This command is for the DATABASE_RETRIEVAL (TDB) module.

Define the system in terms of species. Only those species given are retrieved. The different names of species must be separated with a space or comma. It is possible to use a wildcard * after a common part of species names so that all the species, which start with that common part and are available in the currently switched or appending database, are defined in the system. Up to 1000 species can be defined in a single system.

Defining a System in Console Mode

Syntax	DEFINE_SPECIES
Prompt	`Species& <Species1, Species2, …>` A list of species to be defined in the system.
	When appending database(s), this command, DEFINE_ELEMENTS or DEFINE_SYSTEM must be repeated with the same or similar elements as defined in the first switched database.

DEFINE_SYSTEM

This command is for the DATABASE_RETRIEVAL (TDB) module.

Define the system in terms of either elements (equivalent to DEFINE_ELEMENTS) or species (equivalent to DEFINE_SPECIES). Certain databases have a default value of the keyword (as either ELEMENTS or SPECIES) reflecting what is most appropriate when defining a system.

The different names of elements or species must be separated with a space or comma. It is possible to use a wildcard * after a common part of elements or species names so that all the elements or species, which start with that common part and are available in the currently switched or appending database, are defined in the system.

When appending database(s), this command (or DEFINE_ELEMENTS or DEFINE_SPECIES) must be repeated with the same or similar elements as defined in the first switched database. Different databases might contain different elements and have different species definitions: avoid defining elements/species that are missing in the appending database(s). Otherwise, the program indicates these missing elements/species, and ignores them in subsequent steps. But additional elements/species, and additional phases not available in the first switched database can be defined and retrieved from the appending database(s). Up to 40 elements and 1000 species can be defined in a single system.

Also see Defining a System in Console Mode for step-by-step instructions to define a system with this command.

Syntax	DEFINE_SYSTEM
Prompt	`Elements: <Element1, Element2, …>, or Species: <Species1, Species2, …>`
Options	**Description**
`Species or Elements`	Default keyword.
`Element&`	Specify a list of elements for the defining system.
`Species&`	Specify a list of species for the defining system.

GET_DATA

This command is for the DATABASE_RETRIEVAL (TDB) module.

Enter the defined system's elements, species, phases, and the connected parameters obtained from either the primary switched or additionally appending database(s) to the GIBBS and/or DICTRA workspace. Then use the GET_DATA command to get all information concerning a defined system from the databank.

Only after executing this command can you go to any of the application programs such as GES, POLY or DICTRA and use the retrieved data. When appending database(s), this command must be repeated in order to obtain the additional system definitions, parameters and functions.

LIST_DATABASE

This command is for the DATABASE_RETRIEVAL (TDB) module.

List all elements, species, phases or phase constituents in the database.

Syntax	**LIST_DATABASE**
Options	**Description**
`Keyword`	One of the keywords Elements, Species, Phases or Constituent must be used to indicate what to list
`Elements`	All available elements, the reference state, atomic mass, H298-H0 and S298. Some elements have spaces in the column for the reference state. This implies that there are no parameters stored for this element.
`Species`	All available species together with the stoichiometric factors.
`Phases`	All available phases together with the number of sublattices and the number of sites in each sublattice.
`Constituent`	All available phases, the number of sublattices, the number of sites in each sublattice and the species dissolved in each phase. Species in different sublattices are separated with a colon (:). It is important to realize, for example, a phase can consist of Fe, Mo, V, and Cr, and its thermodynamic parameters can come from the binary systems Fe-Mo, Fe-V, Fe-Cr, and Mo-Cr. These data can give a relatively good description of the corners of the Fe-Cr-Mo system, but would most certainly give a bad one for the system Mo-Cr-V, due to the fact that the interaction parameters are, by default, set to zero, which originates from binary systems not included in the database.

LIST_REFERENCES

This command is for the DATABASE_RETRIEVAL (TDB) module.

Use the LIST_REFERENCES command to list the relevant literature references for the assessed data for the present system. The command is used after the GET_DATA command.

Syntax	LIST_REFERNCES
`Prompt`	There is no prompt after entering the command. The list of references is shown in the Console Window.

You can highlight the list of references to copy to another program. Or if the reference list is very long, right-click the Console tab and select **Copy Command History to Clipboard** or **Copy All Text to Clipboard** (or use the keyboard shortcuts).

LIST_SYSTEM

This command is for the DATABASE_RETRIEVAL (TDB) module.

List all elements, species, phases or phase constituents in the defined system. It works only after a system is defined.

Syntax	LIST_SYSTEM
Keyword	One of the keywords `Elements`, `Species`, `Phases` or `Constituent` must be used to indicate what to list. LIST_DATABASE

REJECT

This command is for the DATABASE_RETRIEVAL (TDB) module.

Reject elements, species, phases or phase constituents that can form from the defined elements and species. Phases/species/constituents that are possible to form in the defined system are removed from the list of system phases/species/constituents (shown by the command LIST_SYSTEM). Phases/species/constituents that are not included in the list cannot be entered without first being restored. The different names must be separated with a space or comma. You can use a wildcard * after a common part of names so that all the elements/species/phases/constituents that start with that common part and are available in the currently switched or appending database, are rejected from the defined system.

This command can also reject a defined system, and thus reinitiate the entire DATA module memory and GES workspace.

Syntax	**REJECT**
Prompt 1	(Keyword = Elements or Species or Phases) `If keyword: <Name1, Name2, …>`

Prompt 2	(if keyword = Constituent)
	`Phase: <Phase name>`
	`Sublattice number: <Sublattice number in the phase>`
	`Constituent: <Constituent(s) in the sublattice of the phase>`

Prompt 3	If keyword = SYSTEM the DATA module is reset to its initial state; GIBBS is reinitiated and data already entered to GES is lost.
Options	**Description and additional information**
`Keyword`	One of the keywords `Elements`, `Species`, `Phases`, `Constituent` or `System` must be used to indicate what is rejected.
`Name&`	Names of the pre-defined elements/species/phases/constituents/system
`Elements`	The given elements are rejected.
`Species`	The given species are rejected, making it impossible to form them from the defined elements.
`Phases`	The given phases are rejected, making it impossible to form them from the defined elements or species.
`Constituent`	The given constituent in one phase are rejected. Add the following when prompted: `Phase`: The name of the phase containing the constituent to be rejected. `Sublattice number`: The sublattice where the constituent enters (the first sublattice is 1). The question is omitted if there exists only one possible sublattice. `Constituent`: The name(s) of the constituent(s) to be rejected.

RESTORE

This command is for the DATABASE_RETRIEVAL (TDB) module.

Restore already explicitly rejected elements, species, phases or constituents; it is the opposite of the command REJECT although it does not restore a completely rejected system.

Phases/species/constituents that are possible to form from the defined elements or species are entered to the list of system phases/species/constituents (shown by the command LIST_SYSTEM). Phases/species/constituents that are not included on the list can now be added to the list. The different names must be separated with a space or comma. It is possible to use a wildcard * after a common part of names so that all the elements/species/phases/constituents, which start with that common part and are available in the currently switched or appending database, are restored in the defined system.

Syntax	**RESTORE**
Prompt1	(if keyword = ELEMENTS or SPECIES or PHASES) `Keyword: <Name1, Name2, …>`

Prompt2	(if keyword = CONSTITUENT)
	`Phase: <Phase name>`
	`Sublattice number: <Sublattice number in the phase>`
	`Constituent: <Constituent(s) in the sublattice of the phase>`

Options	**Description and Information**
`Keyword`	One of the keywords `Elements`, `Species`, `Phases` or `Constituent` must be used to indicate what is rejected.
`Name&`	Names of the pre-defined elements, species, phases, and constituents
`Elements`	The given elements are restored.
`Species`	The given species are restored and thus possible to form from the defined elements.
`Phases`	The given phases are restored and thus possible to form from the defined elements or species.
`Constituent`	The given constituent in one phase are restored. Add the following when prompted: `Phase`: The name of the phase containing the constituent to be restored. `Sublattice number`: The sublattice where the constituent enters (the first sublattice is 1). `Constituent`: The name(s) of the constituent(s) to be restored.

SET_AUTO_APPEND_DATABASE

This command is for the DATABASE_RETRIEVAL (TDB) module.

Enforce an automatic action that appends thermodynamic data from a chosen database regarding the system to the data you already have about the system from the current database (that is, the default database or the database last chosen with SWITCH_DATABASE or APPEND_DATABASE).

This is useful to simultaneously retrieve both thermodynamic and mobility data for a defined system when performing a DICTRA module simulation.

This command should be used before defining a system (with the commands DEFINE_ELEMENTS, DEFINE_SPECIES, or DEFINE_SYSTEM) and retrieving the data with the GET_DATA command from the primary switched database.

Syntax	SET_AUTO_APPEND_DATABASE
Prompt	`Database name /XYZ/: <Additional database name>`
Option	`Additional database name` The name of an existing database or a User database that corresponds to the automatically-appending database.

It works in a way that is similar to the APPEND_DATABASE<DATABASE-NAME> command sequence, but only the phases that are also available in the primary switched database are appended. There is no possibility to manually list, reject and/or restore any phase that is available in the appending database. When retrieving data with GET_DATA afterwards, all the phases that exist in the appending database but not in the primary switched database are automatically rejected. The prompt is kept as for the primary switched database, `TDB_XYZ`: (where `XYZ` stands for the name of the primary switched database) until the execution of GET_DATA.

Therefore, to selectively append more phases from a secondary database to a system that is defined and retrieved from a primary switched database, then APPEND_DATABASE and sequential commands (such as DATABASE_INFORMATION, DEFINE_SYSTEM, DEFINE_ELEMENT, DEFINE_SPECIES, LIST_SYSTEM, REJECT, RESTORE and GET_DATA) should be used instead, before this command.

Although it is impossible to manually list, reject and restore any phase from the appending database, the DATA module automatically ignores all the phases that do not exist in both the primary switched database and the appending database, and append the data for the phases (that are also available in the primary switched database) from the appending database, as informed on screen when executing GET_DATA afterwards.

SWITCH_DATABASE

This command is for the DATABASE_RETRIEVAL (TDB) module.

Switch (or change) from the current database to a new one. It also reinitializes the entire module.

The database can be either a standard database (the ones in `tc_initd.tdb`) or a so-called user database. To open your own (user) database, type `USER` followed by the path to the user `.TDB` file or press <Enter> and select it in the window that opens.

Syntax	SWITCH_DATABASE
Prompt	`New database name /XYZ/:` The name of either an existing database (e.g. FEDEMO) or USER.

ADD_INITIAL_EQUILIBRIUM

This command is for the POLY module.

Add initial equilibrium points from which a phase diagram is calculated (through the MAP command).

For each initial equilibrium the first stage of the mapping varies the value of the given axis variable condition, changing it in the given direction. When a phase change is found it is saved as a start equilibrium, and if the symbol ">" was used, it continues the search until the end of the axis variable.

If no axis variable conditions differ between initial equilibria then the map results in several overlaid diagrams, in accordance with the selected conditions and the values.

The ADD_INITIAL_EQUILIBRIUM default command implicitly makes the MAP command search for phase changes according to settings set by ADVANCED_OPTIONS STEP_AND_MAP command. Default for STEP_AND_MAP are three initial equilibrium equidistantly along each axis variable, along the edge of the axis variable rectangle.

By default these default start points are used in MAP. If any ADD_INITIAL_EQUILIBRIUM is used these default start points are not used. They are again used if the command ADD default is used together with another ADD_INITIAL_EQUILIBRIUM command.

The ADD command with the default direction scans along the axis variables and generates start points each time the scan procedure crosses a phase boundary. In addition, it generates four start points, scanning cross the middle of each axis, if there is any solubility line that does not reach the axes. At the MAP command, a search for lines in the diagram is made along each direction of the axis variables in the diagram.

In this way, it should guarantee that all possible phase boundary lines in a phase diagram are found. It may take a little longer to execute than using the minimum number of start points, as some lines may be calculated more than once. But the POLY module remembers all node points and subsequently stops calculations along a line when it finds a known node point.

It is also possible to create a sequence of start points from one initial equilibria by appending a > after the direction at the ADD command. For example:

```
Direction /Default/: 2>
Direction /Default/: -2>
```

This generates one start point for each set of phase change in the positive direction of the axis 2 (or negative direction of the axis 2); this ensures finding all possible phase boundary lines (not just the first one) along such an axis direction.

This is particularly useful when you have a phase diagram with several lines with no intersection. It is thus possible to calculate e.g. an isopleth for a much more limited composition range. It is also useful for calculating CVD diagrams and Pourbaix diagrams.

Syntax	**ADD_INITIAL_EQUILIBRIUM**
Prompt	`Direction /Default/: <Direction code>` Direction code(s): • `1` or `2` for positive direction of axis 1 or 2, respectively. • `-1` or `-2` for negative direction of axis 1 or 2, respectively. • `Default` for MAP to start looking for phase changes from each corner of the axis variable rectangle. The direction is important when the initial equilibrium point is in a single-phase region or when the diagram is an isopleth (tie-lines not in the plane of calculation). In such cases, the program will search for a line in the diagram (i.e., a line where the amount of a phase is zero) in the given direction.

Normally, this command is not needed to calculate a property diagram (with the STEP_WITH_OPTIONS → `NORMAL` command-sequence), as the STEP procedure starts from the current equilibrium state already calculated. In many cases, the ADD_INITIAL_EQUILIBRIUM command is not required for MAP commands either.

In order to calculate a simple property diagram, set the equilibrium conditions and the stepping axis variable, and then give a STEP command. But if a phase diagram has disconnected lines, ADD_INITIAL_EQUILIBRIUM may still be needed to add two or more initial equilibria so that the MAP calculation starts from such initial equilibria at the specified directions to find all phase boundary lines.

This command becomes unnecessary in most cases, as the MAP routines that by default use the Global Minimization Technique handles all the initial equilibrium points in a robust and automatic way. Therefore, you do not need to have a good guess of the starting point and to add any initial equilibrium point prior to the calculations of various types of phase diagrams. However, if preferred, use this command to add any initial equilibrium points in certain directions, the POLY module uses the specified starting point(s) and corresponding user-added initial equilibrium point(s) for a mapping calculation; in such a case, the automatic procedure in the rewritten MAP routines are not enforced while the Global Minimization Technique can still be applied. Similar situations occur when a specific database, in which there are some definitions of initial-equilibrium adding direction(s) for accessed binary and/or ternary subsystems in its ACCESSED_SYSTEM section, is used in the BINARY or TERNARY module for calculating a binary or ternary phase diagram.

All the initial equilibrium points generated by ADD_INITIAL_EQUILIBRIUM (previously and presently; saved in the current POLY workspace) can be easily listed on screen with LIST_INITIAL_EQUILIBRIA. A certain initial equilibrium point (including its conditions and equilibrium results) can be loaded into the current equilibrium, if needed, with LOAD_INITIAL_EQUILIBRIUM. Any specific or all of the initial equilibrium points can be deleted from current POLY workspace, if desired, with DELETE_INITIAL_EQUILIBRIUM.

ADVANCED_OPTIONS

This command is available with the POLY and ED-EXP modules.

Syntax	ADVANCED_OPTIONS
Prompt	`Which option? /Step_and_Map/: <Option>`

Several options are available after you enter this command at the prompt. The default is STEP_AND_MAP.

```
POLY:advanced-options
Which option? /STEP_AND_MAP/:?
 EQUILIBRIUM_CALCUL       NEW_COMPOSITION_SET      STABILITY_CHECK
 GLOBAL_MINIMIZATION      OUTPUT_FILE_FOR_SHOW     STEP_AND_MAP
 IGNORE_COMPOSI_SET_ORDER PARAEQUILIBRIUM          T-ZERO TEMPERATURE
 KEEP_COMP_SET_NUMBERS    PHASE_ADDITION           TOGGLE_ALTERNATE_MODE
 LIST_PHASE_ADDITION      PRESENT_PHASE
 MAJOR_CONSTITUENTS       SHOW_FOR_T=
Which option? /STEP_AND_MAP/:
```

- EQUILIBRIUM_CALCUL
- GLOBAL_MINIMIZATION
- KEEP_COMP_SET_NUMBERS
- LIST_PHASE_ADDITION
- MAJOR_CONSTITUENTS
- NEW_COMPOSITION_SET
- OUTPUT_FILE_FOR_SHOW
- PARAEQUILIBRIUM
- PHASE_ADDITION
- PRESENT_PHASE
- SHOW_FOR_T=
- STABILITY_CHECK
- STEP_AND_MAP
- TOGGLE_ALTERNATE_MODE
- T-ZERO_TEMPERATURE

STEP_AND_MAP

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

STEP_AND_MAP is the default ADVANCED_OPTIONS choice and is used to determine how to perform Global Minimization test and how to handle initial equilibrium points.

Settings for MAP and STEP:

```
Global test interval /0/: <Integer number>
```

Settings for MAP:

```
Automatically add initial equilibria /Y/:
Number of mesh along an axis /3/: <Integer number>
Use inside meshing points /N/:
Global test interval /0/: <Integer number>
```

The integer number determines how often the Global Minimization should be used during STEP_WITH_OPTIONS and MAP calculations. If it is set to 0 (zero), the recommended global test interval is used: i.e. every tenth step and at each phase change during STEP calculations, and only at node points during MAP calculations. Any other positive integer number, n, suggests it performs a Global Minimization test at every n-th step during STEP and MAP calculations. Of course, the Global Minimization test is always carried out at a phase change or a node point. The Thermo-Calc software is installed with 0 (zero) as the default value, but such a configuration for the default value can be changed by using SET_TC_OPTIONS in the SYS module.

```
Automatically add initial equilibria /Y/:
```

When ADD_INITIAL_EQUILIBRIUM is not used before MAP, a mesh of initial equilibrium points are added before the mapping itself takes place. This mesh is only available when two (2) axes are already defined. The default on start-up may be changed by SET_TC_OPTIONS in the SYS monitor.

```
Number of mesh along an axis /3/: <Integer number>
```

An integer for how many intervals of initial equilibrium points to be added along an edge in the diagram. For example, if set to 2 (two), initial equilibrium points are added at the beginning, center, and end of each axis-variable forming 2 intervals.

```
Use inside meshing points /N/:
```

If N the INITIAL_EQUILIBRIUM mesh consists of initial equilibrium points added only along the edge/border of the diagram defined by the axis-variables. If Y, the initial equilibrium points added are also added to the inside edge.

EQUILIBRIUM_CALCUL

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

Use this command to decide how to perform the POLY minimization (i.e. the traditional Gibbs energy minimization). The *Global Minimization Technique* is used by default for various single point equilibrium calculations and for stepping or mapping calculations.

To permanently turn off the Global Minimization Technique (for all sequential calculations throughout the current run), use the GLOBAL_MINIMIZATION command and set the options to use only the local POLY minimization. You can also make other adjustments to control the steps in reaching Gibbs energy minima in an equilibrium state, for example.

When enforcing the Global Minimization Technique in the equilibrium calculations, you can further adjust how to assign grid points and to handle compositional set(s) for solution phases during stepping/mapping. In order to improve convergence, and because the Global Minimization Technique uses the normal POLY optimization routine for some calculations, you can also change how to control the steps in reaching Gibbs energy minima in an equilibrium state.

Settings for the Minimization of an Equilibria

The following prompts show how the POLY optimization does the local POLY minimization to reach the minimum of an equilibrium state.

```
Force positive definite phase Hessian /Y/:
```

Choose `Y` or `N` to determine how to reach the minimum of an equilibrium state in a normal POLY optimization procedure. This is related to the special quantity, the phase stability function `QF (phase)`, for all kinds of phases in an equilibrium state [a phase stability function for a phase is negative when the phase composition is inside a spinodal, and positive everywhere else].

If the composition of a solution phase is inside its spinodal, the enforcement of positive definite eigenvalues of a Hessian matrix (i.e. when `Y` is selected) makes the step be taken towards the minima rather than the local maxima. Furthermore, if an eigenvalue (for a phase) of the Hessian matrix is near `0.0`, the step size is large this sets a lower limit to this eigenvalue, reducing the step-size and improving the convergence.

The POLY command sequence SHOW_VALUE`QF(phase)` shows the size of the lowest eigenvalue of a phase in an equilibrium state.

If you answer:

- `Y` , it helps the local POLY minimization to converge (if there is a problem), especially if `QF(phase)=0` for phases.
- `N` the local POLY minimization routine is applied.

For each phase in a defined system, the molar Gibbs energy of the phase is a function of the temperature-pressure condition and its composition:

$$G_m(X) = G_m(T, P; y_1, y_2, \ldots, y_n)$$

Compute a Hessian matrix, which describes the curvature of the Gibbs energy curve of this phase at the defined composition X:

$$\partial^2 G_m / \partial y_i \partial y_j$$

Diagonalize this matrix and call the Eigenvalues as `e1,e2,...,en` . The `QF(phase)` quantity for this phase is the lowest of these eigenvalues divided by the same values for a corresponding ideal phase:

$$QF(ph) = \min(\{e_1, e_2, \ldots, e_n\}) / \min(\{se_1, se_2, \ldots, se_n\})$$

Here, `se1,se2,...,sen` are the Eigenvalues for the ideal phase. Therefore, for an ideal phase, the `QF(phase)` should always be `1.0`.

```
Control stepsize during minimization /Y/:
```

Choose `Y` or `N` to determine whether to introduce a control of step size while reaching the minimum of an equilibrium state in a normal POLY optimization procedure. If you choose `Y` it might help the POLY optimization to converge, especially if some site fractions are less than `1E-4`.

GLOBAL_MINIMIZATION

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

Designed to decide how to perform the so-called Global Minimization in the POLY module. By default, the POLY module uses the Global Minimization technique for various single-point equilibrium calculations and for stepping or mapping calculations. You can use this to permanently (for all sequential calculations throughout the current software run) turn off the Global Minimization technique and consequently use only the Ordinary POLY Minimization, and additionally adjust the ways to proceed the normal minimization (mainly in terms of how to control the steps in reaching Gibbs energy minima in an equilibrium state). When enforcing the Global Minimization technique in the equilibrium calculations, you can adjust the manners for assigning grid-points and for handling new possible compositional set(s) for solution phases during stepping/mapping; since the Global Minimization technique also uses the normal POLY optimization routine for some calculations, it is also possible to change the ways on how to control the steps in reach Gibbs energy minima in an equilibrium state, in order to improve convergence.

The following prompts affect how the Global Minimization is done. Settings for global minimization:

```
Use global minimization as much as possible /Y/:
Use global minimization for test only? /N/:
Maximum number of gridpoints per phase /2000/: <Integer number>
Use global minimization as much as possible /Y/:
```

Choose Y or N to decide if using the Global Minimization Technique from start of calculation or not. The default value on start-up may be changed by SET_TC_OPTIONS in the SYS module.

If Y the calculation is done when possible (depending on the condition settings), and a Global Minimization test is always performed when an equilibrium is reached. This costs more computer time but the calculations are more accurate.

If N the calculation is not used to reach the equilibrium state. Use global minimization for test only? determines if the Global Minimization test is made against the calculated equilibrium states obtained by the Ordinary POLY Minimization calculation.

```
Use global minimization for test only? /N/:
```

If Y a calculated equilibrium state obtained by the Ordinary POLY Minimization calculation is tested against the Global Minimization Technique after it is reached; and if found it as unstable, there is an error message.

If N the Global Minimization Technique is never tested for or done for all sequential calculations throughout the current TCC run. This implies that Global Minimization Technique is permanently turned off, and that consequently only the Ordinary POLY Minimization routine is used.

```
Maximum number of gridpoints per phase /2000/: <Integer number>
```

Specify the maximum number of grid points that are computed for each of the phases in the currently defined system, during the calculations enforced by the global minimization. More grid points give a higher robustness and take more computation time. The total number of computed grid points in all phases is limited to 2E6.

KEEP_COMP_SET_NUMBERS

This is available with the ADVANCED_OPTIONS command in the POLY module.

ADVANCED_OPTIONS

COMPUTE_EQUILIBRIUM

This setting affects the COMPUTE_EQUILIBRIUM command and turns on/off the functionality to keep the composition set numbers from the previous equilibrium calculation. The setting is on by default.

To turn the setting on or off enter the ADVANCED_OPTIONS command in POLY, then enter this option and either press `<Enter>` to keep the default `Y` or enter `N` at the prompt:

```
Keep composition set numbers /Y/:
```

If this setting is on, performing the COMPUTE_EQUILIBRIUM command keeps the composition set number for any phases that were also present in the last result from COMPUTE_EQUILIBRIUM.

The composition set numbers are kept when the constitution of a phase in the new equilibrium result is similar to the constitution of one of the composition sets of that phase in the previous result. Making major changes to the conditions between calculations makes it therefore less likely that the composition set numbers are kept. The major constituents, given in the thermodynamic database, are used if no previous result exists.

LIST_PHASE_ADDITION

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

The values set as additional contributions (given by PHASE_ADDITION) to Gibbs energy *G*m (J/mol formula unit) to all the phases (stoichiometric or solution) are listed at the current calculated equilibrium.

LIST_PHASE_ADDITION has no additional prompt.

NEW_COMPOSITION_SET

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

A solution phase that can exist with two (or more) different compositions simultaneously must have two (or more) composition sets in its phase descriptions. Normally the database creates as many composition sets as is necessary but use this command to add or delete more composition sets. A complex solution phase in a defined multicomponent system can have up to 9 different composition sets for the purpose of appropriately handling its possible miscibility gap(s) under various temperature-pressure-composition conditions.

This option is unnecessary if the Global Minimization Technique is in use, as it can automatically detect all possible miscibility gap(s) for complex solution phases (normal or disordered/ordered phases) and then automatically add required composition sets for such phases in the defined system.

This option can automatically create composition sets also for disordered phase when it is executed for the ordered phase.

If you have your own data file, this option must be used to indicate that a solution phase can have a miscibility gap (or may exhibit some complex phase separations as to more than two composition sets), unless that the possibly-additional composition set(s) for the solution phase must have already been added inside the TDB file (through a TYPE_DEFINITION command to amend composition-set) or been manipulated through the GIBBS module (using the AMEND_

PHASE_DESCRIPTION COMPOSITION_SET command-sequence). This option asks for default major constituents for the new sets and it is important that this is set correctly, otherwise the test for miscibility gaps may fail.

The following prompts are to specify the additional composition set(s) to handle possible miscibility gap(s) of a certain solution phase:

```
Phase with miscibility gap: <Name of a phase>
```

Specify the name of the phase with miscibility gap.

```
New highest composition set number /2/: <#>
```

The default value is usually one higher than the current value. Each phase has initially one composition set. If a lower value is given, composition sets are deleted. You cannot take away the first composition set.

A message displays to show that you need to specify the composition for the composition set # (2,3,…).

```
Major constituent(s) for sublattice 1: /XX/: <YY>
```

The major constituents (YY) in each sublattice can be given. This may simplify giving start values when calculating the equilibrium as phases with miscibility gaps should have different major constituents for each composition set.

This prompt is repeated for each sublattice in the phase, sometimes even for all sublattices in the first composition set if such major constituents have not been specified.

MAJOR_CONSTITUENTS

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

Use this to set the major constituent(s) of a composition sets in a miscibility gap of a solution phase. Normally, the major constituents are specified when a new composition set is created by the NEW_COMPOSITION_SET option; but for the first composition set, this option may be needed before using NEW_COMPOSITION_SET.

The following prompts are to specify the major constituent(s) on each of the sublattice sites for a composition set of a certain solution phase:

```
Phase name: <name of a phase>
```

Specify the name of the solution phase with a new set of major constituents.

```
Composition set number /1/: <#>
```

The default value for the composition set number (#) is usually /1/ as the other composition sets are given major constituents when creating them. Each phase has initially one composition set.

```
Major constituent(s) for sublattice 1: /XX/: <YY>
```

The major constituents (YY) on each sublattice of a solution phase can be given. This may simplify giving start values when calculating the equilibrium as phases with miscibility gaps should have different major constituents for each composition set.

This question is repeated for each sublattice in the phase.

NEW_COMPOSITION_SET

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

A solution phase that can exist with two (or more) different compositions simultaneously must have two (or more) composition sets in its phase descriptions. Normally the database creates as many composition sets as is necessary but use this command to add or delete more composition sets. A complex solution phase in a defined multicomponent system can have up to 9 different composition sets for the purpose of appropriately handling its possible miscibility gap(s) under various temperature-pressure-composition conditions.

This option is unnecessary if the Global Minimization Technique is in use, as it can automatically detect all possible miscibility gap(s) for complex solution phases (normal or disordered/ordered phases) and then automatically add required composition sets for such phases in the defined system.

This option can automatically create composition sets also for disordered phase when it is executed for the ordered phase.

If you have your own data file, this option must be used to indicate that a solution phase can have a miscibility gap (or may exhibit some complex phase separations as to more than two composition sets), unless that the possibly-additional composition set(s) for the solution phase must have already been added inside the TDB file (through a TYPE_DEFINITION command to amend composition-set) or been manipulated through the GIBBS module (using the AMEND_PHASE_DESCRIPTION COMPOSITION_SET command-sequence). This option asks for default major constituents for the new sets and it is important that this is set correctly, otherwise the test for miscibility gaps may fail.

The following prompts are to specify the additional composition set(s) to handle possible miscibility gap(s) of a certain solution phase:

```
Phase with miscibility gap: <Name of a phase>
```

Specify the name of the phase with miscibility gap.

```
New highest composition set number /2/: <#>
```

The default value is usually one higher than the current value. Each phase has initially one composition set. If a lower value is given, composition sets are deleted. You cannot take away the first composition set.

A message displays to show that you need to specify the composition for the composition set # (2,3,…).

```
Major constituent(s) for sublattice 1: /XX/: <YY>
```

The major constituents (`YY`) in each sublattice can be given. This may simplify giving start values when calculating the equilibrium as phases with miscibility gaps should have different major constituents for each composition set.

This prompt is repeated for each sublattice in the phase, sometimes even for all sublattices in the first composition set if such major constituents have not been specified.

OUTPUT_FILE_FOR_SHOW

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

The name of a text file is asked for and all the results output from the command SHOW_VALUE is written to this file.

When you use this command, a window opens with a default name for the file `tc_show.dat`. Choose a location to save the file and click **Open**.

PARAEQUILIBRIUM

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

This calculates a paraequilibrium between two specific phases in an alloy system with one or more interstitial component(s) as fast diffusion species. Under the paraequilibrium state, two partially-equilibrated phases have the same chemical potential (but different contents) for one

or more interstitial components (such as C, N, O, S, etc., as individual or combined)], along varied temperature or along a composition variable (of the matrix or one substitutional component) which has already set as the stepping variable with SET_AXIS_VARIABLE.

To ensure a successful point calculation of paraequilibrium state between two specific phases in a defined alloy system, it is important that you first have made a single-point equilibrium calculation with an initial overall composition in the current system before performing this advanced-option calculation; however, it is unnecessary to obtain an equilibrium in which either one or both of the target phases is stable. The initial overall composition must have a reasonable setting for the desired paraequilibrium calculation for the two target phases. This is especially true for cases where there are more than one interstitial components to be considered in the paraequilibrium state, because different interstitial components (for example C and N combined) may have significant different behaviors as partitioning into different structured phases; otherwise, for one chosen interstitial component the initial overall composition is OK for the paraequilibrium calculation between the specified two phases, but for other chosen interstitial component(s) it might be impossible to calculate the paraequilibrium state.

Note the following:

- Always check if the chosen phases A and B have the exactly same definition of elements and if the chosen interstitial components are all in the vacancy sublattice sites of the two phases; otherwise the program cannot find the paraequilibrium state (as it is impossible to correctly calculate u-fractions).
- Always have a comprehensive understanding of the normal phase diagram for the currently investigated system, so that you make the appropriate choice of the phase pair and staring bulk composition for the system.
- Always set the status of the chosen interstitial components as SPECIAL using the POLY command: CHANGE_STATUS`Component <interstitial component> = SPECIAL`. By doing this, you get a clear picture of u-fractions of various substitutional and interstitial components, which are different from the overall composition in the system. The SPECIAL status means that specified component(s) are not included in summations for mole or mass fractions. Therefore, all the composition variables plotted from paraequilibrium calculations are u-fraction related quantities.

Settings

```
Name of first phase: <Phase A>
Name of second phase: <Phase B>
```

The names of the two target phases A and B, between which the paraequilibrium state is to be calculated, must be entered subsequently or on the same (first) line at once then separated by an empty space, e.g. `FCC#1 BCC` or `FCC#2 M23C6`.

You need to understand what you are dealing with in terms of calculating a paraequilibrium state between the two specified phases.

Specifically, there are four distinguished cases to understand: (1) both chosen phases must have similar interstitial/vacancy sublattices where the fast-diffusion interstitial component(s) occupy; (2) the choice on the target phase pair must be reasonable for the defined system and specified initial overall composition; (3) both target phases should have phase constitution definitions that cover all the defined substitutional and interstitial components of the current alloy system; or (4) it is impossible to calculate the paraequilibrium state between the target phase pairs with given interstitial component(s) in the currently defined system.

```
Fast diffusing component: /c/: <interstitial component(s)>
Fast diffusing component: /none/: <interstitial component(s)>
```

The name(s) of the fast-diffusing component(s) (C as the default single component) must be given at the above prompts subsequently or at the same (first) prompt. It is possible to specify more than one interstitial component as fast diffusion species.

Note the following:

Such specified interstitial component(s) must be appropriately defined according to the phase constitution definitions of the two selected phases: these must be located on the interstitial/vacancy sublattices in both chosen phases;

If there is only one fast-diffusing component which is carbon, press the <Enter> key to accept the default input at the first prompt; if the single fast-diffusing component is another element (e.g. N), type its name at the first prompt;

If there are two or more fast-diffusing components (e.g. `C` and `N`), type their names at the above prompts subsequently or at the same (first) prompt (separated by an empty space, such as `C N`);

To finish the input of fast-diffusing elements, accept NONE at a repeated prompt, i.e. by pressing <Enter> key to start the paraequilibrium point calculation;

If NONE or a non-existing component name is typed at the first prompt, it means no back diffusion is to be considered, and the para-equilibrium calculation is thus canceled entirely.

If the paraequilibrium state between the two specified phases is successfully calculated, the messages displays e.g.

```
   NP(FCC) = 0.3586 with U-fractions C = 2.71821E-02 N = 4.1548129E-03
   NP(BCC) = 0.6414 with U-fractions C = 7.10061E-04 N = 2.3781027E-04
   All other compositions the same in both phases
  Note: LIST-EQUILIBRIUM is not relevant
```

The first and second lines list the phase amounts expressed in mole-percent [NP(phase)] and the contents of the interstitial components C and N in a specific phase expressed in the so-called u-fractions [u-f(phase,C) and u-f(phase,N)], for the phase A (in this case as FCC) and phase B (in this case as BCC), respectively. The third line states that the compositions of the matrix component and all the remaining compositions (regarding substitutional components) in both the target phase A and target phase B are the same at the current paraequilibrium state, while these are not shown on screen. The last line indicates that after this advanced-option calculation the LIST_EQUILIBRIUM command is irrelevant and does not list the paraequilibrium state for the system at the current condition.

However, if the single-point calculation of the paraequilibrium state between the two specified phases has failed, these messages display:

```
*** Error 4 in ns01ad
*** Numerical error
```

This implies that the chosen target phase pair may be unreasonable for the defined alloy system or for the defined initial overall composition, or one or both phases may have inappropriate phase constitution definitions regarding the specified interstitial component(s). Then, you must either modify the settings of initial overall composition or specify the reasonable target phase pair with an appropriate choice of the fast diffusion interstitials in the defined alloy system.

PHASE_ADDITION

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

Sometimes it is interesting to add a constant contribution to the Gibbs energy of a phase (stoichiometric or solution). This can be done in the Database module (DATA) or Gibbs Energy module (GIBBS), for a stoichiometric phase, or for a pure end-member in a solution phase. However, if the addition is related to the equilibrium state, for example, strain energies or surface energies, interfacial energies, or deformation energies, it may be more convenient to have this quantity related to the equilibrium state rather than the thermodynamic data.

Give a value of an addition to the Gibbs energy of a phase. The value should always be constant (implying that the addition is not a function of phase composition or temperature-pressure conditions in the equilibrium state) and always be given in the unit of J/mol formula unit of the phase.

The following prompts are to specify the additional energy term (always being a constant) of a given phase.

```
Phase name: <Name of a phase>
```

Specify the name of the (stoichiometric or solution) phase with the addition.

```
Addition to G per mole formula unit: <xxxxx>
```

The value (`xxxxx`) given is added to the Gibbs energy of the (stoichiometric or solution) phase. It can represent a nucleation barrier, surface tension, elastic energy, etc.

It is not composition-, temperature-, or pressure-dependent.

PRESENT_PHASE

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

Specify the name of the present phase a the name of the phase that should be present at all calculated equilibria:

```
Present phase:
Phase name: <Name of a phase>
```

SHOW_FOR_T=

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

Display various thermodynamic properties (state variables, derived/partial variables or entered symbols) of the currently calculated (stable/meta-stable) equilibrium state but under a different temperature condition. This is useful for knowing, for example, a volume-related

property of a frozen (stable/meta-stable) equilibrium state at a certain temperature, where the equilibrated phase assemblage and all the phase compositions are not adjusted while only the temperature condition is changed.

Use this option carefully. You must have successfully calculated a real equilibrium state under one temperature condition (normally the temperature for the last heat treatment). This can then be used to obtain the value(s) of any specified state variable(s) or derived/partial variable (s) or defined symbol(s) for thermodynamic properties of the entire system, of components, or of phases for the currently-defined system (being in a frozen state) under another temperature (normally at room temperature). No real equilibrium is re-calculated through this option, and thus the phase amounts and compositions in the system are the same as at the last real equilibrium calculation.

Settings

```
Temperature (K) /298.15/: <temperature_in_K>
```

Specify the new temperature condition (in K) under which the values of some specific state variable(s) or derived/partial variable(s) or defined symbol(s) for various thermodynamic properties of the entire system, of components, or of phases) in the currently-defined system (being in a *frozen* state) is shown on screen.

```
State Variable or symbol /VM/: <State variable or symbol name(s)>
```

Specify the name(s) of the desired state variable(s) or derived/partial variable(s) or defined symbol(s) for various thermodynamic properties of the entire system, of components, or of phases) in the currently-defined system. More than one state variable or symbol of interest can be simultaneously specified on the same line. For example, you can choose to show the values of VM or GM (i.e. molar volume or molar Gibbs energy of the entire system), or of VM (*) or HM(*).T (i.e. molar volumes or isobaric heat capacity of all phases), or of ACR(*), DGM(*) and LNACR(*,FCC) [i.e. activities of all system components, driving forces for all phases, and activities (in logarithm) of all system components in the FCC solution phase], under the new temperature condition (being in a frozen state).

STABILITY_CHECK

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

In some composition ranges of a multicomponent system, it often happens that an unstable solution phase region locates inside a miscibility gap, and the stability limit (the *spinodal curve* or *spinodal*) may be not easy to find. A system inside a spinodal is thermodynamically unstable

with respect to compositional fluctuations, and the system may experience the *spinodal decomposition* (i.e. decomposing to a mixture of regions with the two stable compositions, one on each side of the miscibility gap).

This option makes it possible to automatically check internal stability of both stable and unstable phases in all subsequent single-point equilibrium and MAP/STEP calculations. It can find out if any phase is subject to spinodal decomposition during the subsequent calculations. If there is an unstable phase located inside a miscibility gap in a calculation, it gives a warning so that you suspend the unstable phase, or use FORCED automatic start values for phase constituents (i.e. SET_ALL_START_VALUES → `FORCE` command-sequence), or create other composition sets; you can also ignore the warning message if you know that the unstable phase is not formed in the current calculations.

Settings

```
Stability check on? /Y/:
Check also for unstable phases? /Y/:
```

If the automatic stability-check option is switched on choose to also check the stability for unstable phases. The default is Y and if an unstable phase is found to be located in a miscibility gas during a subsequent single-point equilibrium or MAP/STEP calculation, a warning message informs you to selectively make adjustments in the calculation settings [e.g. suspending the unstable phase, or using FORCED automatic start values for phase constituents by the S_A_S_V F command-sequence, or creating other composition sets, etc.]. By answering N the stability check is enforced only to stable phases in the system.

TOGGLE_ALTERNATE_MODE

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

Toggle the ALTERNATE mode for experimental equilibrium calculation between DEFAULT, ALWAYS and NEVER, during data-assessments using the PARROT optimization.

```
Set alternate toggle to DEFAULT, ALWAYS, or NEVER?
Set global toggle to DEFAULT, ALWAYS, or NEVER?
```

- `DEFAULT`: the experiment points are calculated according to the Alternate Technique depending on the SET_ALTERNATE command.
- `ALWAYS`: the experiment points are always calculated according to the Alternate

Technique even if the Alternate Mode is switched off in the PARROT module.

- NEVER: the experiment points are calculated as normal equilibria even if you SET_ ALTERNATE in the PARROT module.

T-ZERO_TEMPERATURE

This is an option that is available with the ADVANCED_OPTIONS command with the POLY and ED-EXP modules.

ADVANCED_OPTIONS

This calculates the temperature when two specific phases have the same Gibbs energy, i.e. the so-called T0 temperature. You must calculate an equilibrium state at an estimated temperature before performing this advanced-option calculation; however, it is unnecessary to obtain an equilibrium state in which either one or both of the target phases is stable.

The following prompts are shown.

```
Name of first phase: <Phase A>
Name of second phase: <Phase B>
```

The names of phases A and B must be given, for which the T0 temperature (where the Gibbs energies are equal) is to be calculated.

If the T0 temperature between the two specified phases is successfully calculated, a message displays, e.g.

```
The T0 temperature is 840.82 K. Note: LIST-EQUILIBRIUM is not relevant
```

The first message shows the calculated T0 temperature between the two specified phases.

The second message indicates that after this option calculation with LIST_EQUILIBRIUM is irrelevant and does not list the equilibrium for the system at the T0-temperature.

AMEND_STORED_EQUILIBRIA

This command is for the POLY module.

This command gives information about the calculated blocks (and phase regions included in blocks) after the STEP or MAP calculation(s). It allows you to list all or part of the calculation results, to suspend all or parts of the calculation results that are redundant or where metastable equilibria are calculated, and to restore all or parts of the calculation results (if having been suspended by another AMEND_STORED_EQUILIBRIA command).

The workspace for storing equilibria may overflow during stepping or mapping, and is then written to a file as blocks. Each block usually contains one or more ranges of equilibrium regions.

Use one these options:

- `L` to list the calculated equilibria (all or a specified block)
- `S` to suspend everything (all blocks and their regions)
- `Q` to suspend each set of equilibria individually (specified blocks and/or regions)
- `R` to restore everything (all blocks and their regions)

Syntax	AMEND_STORED_EQUILIBRIA
Prompts	`Name: <Name of a defined table>` List (`L`) the calculated equilibria, suspend everything (`S`) or suspend each set of equilibria individually (`Q`), or restore everything (`R`).
	`Block /*/: <Block number>` Specify a block number in the option `L`, `S`, `Q` or `R`. Or include all the blocks in the amending option, by accepting the wildcard * (press <Enter>). For `L`, a block (if a block number is specified) or all the blocks (if the wildcard * is accepted/used), with the regions and the equilibrium details, that are calculated during stepping or mapping is listed on screen or in a textual file. For `Q`, each ranger in a block (if a block number is specified) or in all blocks (if the wildcard * is accepted/used) then choose:

	`S(uspend) K(eep) /K/: <S or K>`
	For `S` or `R`, if a block is specified, you are asked what region in the block should be suspended or restored. However, if the wildcard * is accepted/used, you are asked the following:
	`Really suspend all /N/:`
	`Really restore all /N/:`
	In both cases the default is N and you are prompted for which block(s) and which region(s) in a certain block to execute the `S` or `R` action.
	`Really suspend all /N/:`

Syntax	AMEND_STORED_EQUILIBRIA
	Y suspends everything. `Really restore all /N/:` Y restores everything.
	`Range: <Range(s) of region>` Specify one or more ranges to be suspended (the `S` option) or restored (the `R` option). The wildcard * suspends or restores all ranges in the specified block. In order to know the ranges the LIST command must first be used.
	`S(uspend) K(eep) /K/: <S or K>` The Query suspend option (`Q`) asks for each region in a certain block if it should be suspended or kept. Suspended regions are not included on sequentially generated plots.
	`Output file: /Screen/: <File name>` This prompt is only for listing (the `L` option), and after it the command is terminated. The file name must be given here; or accept the default Screen (terminal) by pressing <Enter>. A list of stored equilibria as various blocks (with all their ranges) are shown out on screen or the file.

CHANGE_STATUS

This command is available with the POLY and ED-EXP modules.

In the POLY module, use the CHANGE_STATUS command to set the status for components, species and phases in the defined system for all the sequential calculations (single-point, stepping, and mapping) in equilibrium or local/partial equilibrium state. Each component, species and phase has a status. The default status is `ENTERED`.

The most important use is to calculate metastable equilibria and metastable phase diagrams by setting some phases (that would otherwise be stable) to the SUSPENDED or DORMANT phase-status. Another important applications is to calculate paraequilibria by setting some components to the SPECIAL component-status.

For a component and for a species, the status can be one of the following:

- `ENTERED`: the component(s) or species are included in the calculation. This is the default status.
- `SUSPENDED`: the component(s) or species are not considered in the calculation.
- `SPECIAL`: the specified component(s) are not included in summations for mole or mass fractions. It only works for component(s).

Only component(s) can have the status SPECIAL, which implies that these are not included in summations for mole or mass fractions.

For example, for the *u-fractions* or other normalized fractions, when one or more of the components are excluded from the summation, you must specify which component(s) should be excluded from the calculation of mole or mass fraction. This component status is particularly useful when calculating paraequilibrium states. Such component(s) are normally interstitial component, and must have the status SPECIAL. This is assigned by the CHANGE_STATUS command.

Syntax	CHANGE_STATUS
Prompts	`For phases, species or components? /Phases/: <Keyword>` *Keyword* = phase or species or components
	`Phase name(s): <Name(s) of the phase(s)>` For `phase` as the keyword, the names of the phases that have their status changed must be given (all on one line). A comma or space must be used as separator. The status to be assigned to the phases can also be given on the same line if preceded with an equal sign (=).

Syntax	CHANGE_STATUS

An asterisk, *, can be used to denote all phases. The special notations `*S`, i.e. a wildcard * directly followed by an `S`, sign, means all suspended phases. In the same way, `*D` means all dormant phases, and `*E` means all entered phases.

`Name(s): <Name(s) of the Species or Component(s)>`

For species or components as the keyword, the names of the species or components that have their status changed must be given (all on one line). A comma or space must be used as separator. Similarly to the case of phase as the keyword, the status to be assigned to the species or components can also be given on the same line if preceded with an equal sign =.

An asterisk, *, can be used to denote all species or components. The special notations `*S`, i.e. a wildcard * directly followed by an `S`, sign, means all suspended species or components. In the same way, `*E` means all entered species or components.

`Status /Entered/: <New status>`

The `new` status to be assigned must be given.

For species, the values `ENTERED` or `SUSPENDED` can be used.

For the POLY module, using the `Entered` or `Suspended` status here has the same result as using the commands MAKE_COMPONENT_ENTERED and MAKE_COMPONENT_SUSPENDED. The exception is that any existing conditions that depend on a suspended component are removed when using the MAKE_COMPONENT_SUSPENDED command.

For components, the status `ENTERED`, `SUSPENDED` or `SPECIAL` can be given. SPECIAL means that this component is excluded from sums for mole fractions and mass fractions, which is useful when calculating the *ufractions* or other normalized fractions of system components.

For phases, the status `ENTERED`, `SUSPENDED`, `DORMANT` or `FIXED` can be given. DORMANT means the same as suspended but the driving force is calculated. FIXED means that it is a condition that the phase is stable at a certain amount.

For example, for the ufractions, when one or more of the components are excluded from the summation, you must specify which component should be excluded from the calculation of the mole fraction. This component must have the status SPECIAL. This is assigned by the CHANGE_STATUS command: `Change_Status comp C=special`.

`Start value, number of mole formula units /0/: <Initial amount>`

For ENTERED phases, an `initial amount` of the phase can be given. Normally, 0 is given if the phase is not likely to be stable, and 0.5 or 1 or any positive number if the phase could be stable, but such an initial amount is only used as the rough starting estimation in the equilibrium calculations.

`Number of mole formula units /0/: <Equilibrium amount>`

Syntax	CHANGE_STATUS
	For FIXED phases, the `equilibrium amount` of the phase [always using an initial estimation being the `NPF(phase)` value which it is the normalized mole number of components (per mole formula unit) of the specific status-fixed phase] must be given. If the equilibrium amount is zero, then the phase is at its stability limit. See Note About Specifying a FIXED Phase Status for more details.

Note About Specifying a FIXED Phase Status

Special attention should be paid when specifying a FIXED phase status in equilibrium calculations (for single points, stepping or mapping calculations), as described below.

The phase amount variables, NP(phase), BP(phase) and VP(phase), as well as all their M/W/V-suffixed quantities, should not be used as conditions. Instead, use the CHANGE_STATUS command to set a relevant condition, e.g. `CHANGE_STATUS phase <phase>=fix <amount>` where the fixed <amount> is roughly the same as the F-suffixed quantity `NPF(phase)`.

The `NPF(phase)` quantity is the normalized mole number of components (per mole formula unit) of the specific phase in the defined system, which unlike other `F`-suffixed state variables [e.g. GF(phase), HF(phase) and DGF(phase)] cannot be directly applied in any POLY command, implying that it cannot be directly evaluated or listed/shown. If intended to shown such a normalized phase amount value in an equilibrium state, you should use a properly-entered symbol (function or variable), for example: `NPFabc = NP(abc)/NA` or `NPFabc = NPM(abc)/NA*N`. N is the total system size (in mole). The NA value is a quantity that is phase-dependent (and sometimes also equilibrium-dependent for ionic solution phases), and is the total atomic number in a mole-formula-unit of the specific phase abc (excluding interstitial component and, of course, vacancy). For example, the SIGMA, FCC, BCC and LIQUID phases (among others) in a defined Fe-Cr-Ni-C-N-O system (retrieved from a specific database) may be modeled by certain models, and their NA values must be evaluated in different ways, as described below:

```
LIQUID (C,Cr,CrO3/2,Fe,FeO,FEO3/2,N,Ni,NiO)1 NA = 1
FCC_A1 (Cr,Fe,Ni)1(Va,C,N,O)1 NA = 1
BCC_A2 (Cr,Fe,Ni)1(Va,C,N,O)3 NA = 1
SIGMA (Fe,Ni)8(Cr)4(Cr,Fe,Ni)18 NA = 30
```

If in the same Fe-Cr-Ni-C-N-O system the liquid solution phase is modeled by the Two-Sublattice Ionic Liquid Model, i.e.:

```
IONIC_LIQ (Cr+3,Fe+2,Ni+2)p(VA,C,N,O-2,FEO3/2)q,7
```

then the evaluation of its NA value becomes even more complicated:

```
NA = p + q*yC2 + q*yN2 + q*yO2 2 + q*yFeO2 3/ 2
```

where the stoichiometric coefficients *p* and *q* are also dependent upon the real equilibrium state (rather than having fixed values in the system). Similar situations occur for other (solid) phases which are described by a multiple sublattice model with ionic constituents, such as SPINEL and HALITE phases in some databases.

There is no strange thing when using a zero value [i.e. `0`] in a FIXED phase-status, since it means the specified phase is stable in equilibrium state but has a zero-amount of mass in the equilibrium calculations; in other words, on a phase diagram, the specific phase is on a zero-fraction line (ZFL), i.e. it starts becoming stable on one side of a corresponding phase-boundary line or unstable on the other side of the same boundary. It is often and efficient to do so when calculating e.g. solidus equilibrium states.

However, when a non-zero value [it must always be positive; e.g. 1 or 0.5 or 0.3 or 1.5] is to be specified in a FIXED phase-status, it is unnecessarily the exactly same stable amount of the specific FIXED-status phase in a calculated equilibrium state any longer; instead, the <equilibrium amount> value is the NPF(phase) value that is only roughly used as the estimated starting-value of the FIXED-status phase in the equilibrium calculations.

Therefore, a FIXED-status for a liquid phase being unity does not necessarily imply that it is a liquidus equilibrium state (where the liquid phase is in equilibrium with some solid phases but the liquid phase takes all the mass in the defined system). A unity value for setting the liquid phase status in calculating liquidus equilibrium state can only be used when the liquid mixture phase is predefined as a single-sublattice solution phase (such as metallic liquid phase in multicomponent alloy systems) and the total system size as one mole (i.e. N=1).

When a phase is described by a solution model in which two or more sublattices are considered and these sublattice sites may also have different stoichiometric coefficients [meaning that the mixture phase could have more than one atom in formula [NA>1; see some examples above], the unity value should not be used when setting the FIXED status for the phase; instead, you should use an appropriate value that ranges from 0 to a NPF(phase) value that equals to or is smaller than 1/NA (if the total system size N=1) or 1/NA*N (if N differs from unity). For this reason, if a multicomponent system bears an IONIC_LIQUID phase that is described by the Two-Sublattice Ionic Liquid Model (or any other multiple-sublattice ionic solution phases), it is difficult to use a proper `NPF(ION_LIQ)` value in setting its FIXED phase-status, because that should be less than (or equal to) the complex value of

N/[$p + q^{*}y_{C}2 + q^{*}y_{N}2 + q^{*}y_{O}22 + q^{*}y_{FeO}2\ 3/\ 2$].

Examples

For example, to obtain the metallic fraction in a system with carbon as an interstitial component, you can set the component status for carbon as SPECIAL:

```
Change_Status comp C=special
```

The SUSPENDED status for components and species does not always work as expected.

For a phase, it may have one of these statues:

- ENTERED: the phase(s) are included in the equilibrium calculations and these are stable if that minimizes the total Gibbs energy in the defined system. This is the default status for all phases already retrieved from the chosen database(s). An ENTERED phase-status is always associated with an initially-estimated amount [in mole number; normally, as 0 if the phase is not likely to be stable, and as 0.5 or 1 or any positive number if the phase could be stable] but it is only used as the rough starting value in the equilibrium calculations.
- SUSPENDED: the phase(s) are not considered in the equilibrium calculations.
- DORMANT: the phase(s) are not considered in the equilibrium calculations but their driving forces for precipitation are calculated.
- FIXED: it is an equilibrium condition that the status-fixed phase must be stable, and be in equilibrium at a specified amount [always using an initial estimation being the NPF (phase) value which it is the normalized mole number of components (per mole formula unit) of the specific status-fixed phase]. See more descriptions at the end of this command.

COMPUTE_EQUILIBRIUM

This command is for the POLY module.

The full equilibrium state is calculated for the given set of conditions. The Global Minimization Technique is by default enforced in this command (C_E), while it can be disabled temporarily (for the current single-point equilibrium calculation) if using C_E – or C_E * command-combination, or permanently (for all the sub sequential single-point calculations or stepping/mapping calculations within the current TCC run) if having decisively switched it off by a user (or possibly in some special modules) through changing the minimization option using the ADVANCED_OPTIONS → `MINIMIZATION_OPTION` command-sequence.

Syntax	COMPUTE_EQUILIBRIUM
Prompt	The C_E command can be used, in order to enforce the ordinary POLY minimization routines in an equilibrium calculation; this is because of that the ordinary C_E command is now associated with the Global Minimization Technique, and only after the Global Minimization If technique is permanently switched off the C_E command makes no difference from the C_E – command-combination. Only certain types of equilibrium conditions [e.g. `T`, `P`, `N`, `N`(`<component>`), `X`(`<component>`), `B`, `B`(`<component>`), and `W`(`<component>`)] are fully supported in the Global Minimization mode (called *Direct Global Minimization*); and when other types of equilibrium conditions are used, after the initial POLY, a Global Minimization test and corrections are performed until the lowest minimum is found (called *Indirect Global Minimization*). If there is any problem with convergence, you may try the C_E * command-combination. The character * enforces the command to use an advanced technique to obtain a complex equilibrium. However, after a successful C_E *calculation, you may repeat the C_E command and can check the status of phases, species or components (with LIST_STATUS → CPS command-sequence) and equilibrium conditions (with LIST_CONDITIONS) and list out the calculation results (with LIST_EQUILIBRIUM), because such actions may tell you how to further modify various settings for your current calculation. This command-combination is not that useful anymore, because the Global Minimization Technique that is always associated with the C_E command is even more powerful and more precise in finding the most-stable equilibrium state in a complex heterogeneous interaction system; therefore, the C_E * command-combination is functional and can be used only after the Global Minimization mode has already been disabled temporarily or permanently. Some phases that are not stable in the current equilibrium state may not have their most favorable composition after this command, and thus their driving forces may not be correct. You can force the program to correctly calculate the driving forces of metastable phases, by giving repeated C_E commands until the number of iterations (that is shown on screen after this command) is reduced to 2. Also see the POLY command SET_NUMERICAL_LIMITS which can set the approximate driving force for metastable phases option on or off in all the subsequent POLY calculations within the current TCC run.

Syntax	COMPUTE_EQUILIBRIUM

If an equilibrium state for the defined system is not found, an error message is given.

You can try repeating this command a few times, or change some of settings for the numerical limits, for starting variables and starting values, for starting constitutions of certain phases and for reference states of certain components, or to verify some of the defined conditions.

COMPUTE_TRANSITION

This command is for the POLY module.

This command is a combination of the CHANGE_STATUS, SET_CONDITION and COMPUTE_EQUILIBRIUM commands. It allows a direct calculation when a new phase may form by varying one of the already-set conditions. It can be used only after at least one equilibrium is calculated successfully; otherwise, you are informed on the necessity of first making an equilibrium calculation to find out the stable phases under the current conditions.

When this command is used, the program calls the command CHANGE_STATUS to temporarily change the phase status of a specified phase as FIXED at the *zero* amount, and at the same time to temporarily release one of the existing equilibrium conditions (which is chosen by you). The program calculates a new equilibrium in which that specific phase is stable but its equilibrium amount in the system is zero. The released condition is then assigned with a calculated value that ensures the calculated equilibrium. After wards, the program automatically changes the phase status of that specific phase back to ENTERED, and resets the temporarily released condition as one of the conditions and assigns it with the value that is calculated to ensure the zero-amount formation of that specific phase.

This command is useful to find melting temperature, boiling temperature, or solubility limits, and generally when you want to set the most optimal conditions for calculating an equilibrium where a specific phase becomes stable. It can also be used when you want to know exactly how far away the defined conditions are from the value that can ensure a zero-amount of a specific phase in the system when other conditions remain the same.

After a successful calculation, you can issue a COMPUTE_EQUILIBRIUM calculation to assure the calculated transitional equilibrium is a really stable one, and can also use LIST_EQUILIBRIUM to see the details of transitional equilibrium state.

Syntax	COMPUTE_TRANSITION

Prompts	`Phase to form: <Phase name>`
	
	A new `phase name`, e.g. `BCC` that is expected to form, is specified here. This changes the status of this new phase to be `FIXED` as `0` amount, and the program shows the information such as:
	
	`You must remove one of the these conditions`
	
	`P=100000, T=800, N=1, X(FE)=.5  DEGREE OF FREEDOM 0`
	
	If the key word `ANY` is used when prompted for `Phase to form` (instead of a specific phase name), it is possible to find out any new phase to be formed, in a given varying direction sign and at an estimated change of the released condition: a negative sign means at a lower value of the released condition any new phase is to be found, and a positive sign at a higher value; an estimated change of the released condition implies where any new phase is expected (but it is only estimated value, so any value within its reasonable scale would be enough). Such calculations can be repeated if required. This feature is useful to find out all possible phase transformations along a certain released condition.

	`Give the state variable to be removed /T/: <One condition>`

Syntax	COMPUTE_TRANSITION
	`One condition` must be removed, in order to calculate the transition equilibrium where the specified (or any) new phase to be formed at a calculated value of this released variable.

	Therefore, the message may display (after a successful calculation) if, for example, `X(Fe)` is entered:
	`To form BCC the condition is set to X(FE)=.48605791769`
	This calculated value is assigned as the parameter of that removed condition, in this case, the `X(FE)` variable. If the LIST_CONDITIONS command is typed this message displays:
	`P=100000, T=800, N=1, X(FE)=4.86057918E-1`
	`DEGREES OF FREEDOM 0`
	If the key word `ANY` (instead of a specific phase) is given as the phase name when it is prompted for Phase to form, the line is prompted for a given varying direction sign and an estimated change of the released condition before the calculation of transition equilibrium:

	`Estimated change (with sign) /1/: <+/-#>`
	A given varying direction sign and an estimated change of the released condition, in this case as `X(FE)`, must be given here: a negative sign means at a lower value of the released condition any new phase is to be found, and a positive sign at a higher value; an estimated change of the released condition implies where any new phase is expected (but it is only estimated value, so any value within its reasonable scale would be enough). For example, if a combination of -0.02 is input, this message may display (after a successful calculation):
	`To form BCC_A2#1 the condition is set to X(FE)=.493708756187`
	This calculated value is then assigned as the parameter of that removed condition, in this case, the `X(FE)` variable. The message is shown if the LIST_CONDITIONS command is typed:
	`P=100000, T=800, N=1, X(FE)=4.93708756E-1`
	`DEGREES OF FREEDOM 0`

CREATE_NEW_EQUILIBRIUM

This command is available with the POLY and ED-EXP modules.

During data-assessments using the ED_EXP module (a submodule of PARROT), you can, in the POLY module, create several equilibria with different sets of conditions and phases (but normally with the same set of components). By default, there is one equilibrium. To keep the set of conditions and phase for this equilibrium, create another one using this command, and use another set of conditions for that. Two equilibria may be useful to calculate easily the enthalpy difference between two states. In the PARROT module, the experimental information is stored as a sequence of equilibria.

Syntax	CREATE_NEW_EQUILIBRIUM
Prompts	`Equilibrium number /2/: <A new equilibrium number>` Each equilibrium in the POLY workspace is identified by a unique integer number. Such an equilibrium number can be recalled with SELECT_EQUILIBRIUM.
	`Initiation code /2/:` When an equilibrium is created, you can choose to `ENTER` all components and phases (initiation code 2), `ENTER` the components only (initiation code 1) or `SUSPEND` everything (initiation code 0). No other values are legal. The entered components and phases can later be changed with CHANGE_STATUS.

DEFINE_COMPONENTS

This command is available with the POLY and ED-EXP modules.

Use the DEFINE_COMPONENTS command to change the set of components. By default, the elements are used as components. The set of components can be important because some conditions are set using components, for example, the amounts, activities or chemical potentials.

For example, in the system Fe-Si-O, you can define FEO, FE2O3, and SIO2 as components, thus replacing the default FE, SI and O.

This implies a command REINITIATE_MODULE and it should be given as the first command in the POLY module.

Syntax	DEFINE_COMPONENTS
Prompt	`Give all new components / existing components/: <New components>` The `new components` must be specified all on one line. These replace the existing component definitions. The number of components cannot be changed with this command. Use CHANGE_STATUS instead.
	To keep some existing components, it is recommended that you also enter these on the line. Otherwise, the added new components may not be defined correctly. This is especially important if some components are built out of several elements. The new components do not have to be present as species.

DEFINE_DIAGRAM

This allows automatic calculation and plotting of a diagram with a single command. It is the same as the DEFINE_MATERIAL command up to when the first equilibrium is calculated. The alloy OPTION feature is also available in this command to specify alloying compositions for a special alloy predefined by the OPTION keyword in a selected database (e.g. the TCNI Ni-based Superalloys Database).

Use this command to calculate all types of phase diagrams after specifying all composition value and an initial temperature (if temperature is used as an axis). However, for binary and ternary diagrams, the special BIN and TERN modules may be preferred.

It then lists all the independent variables for the defined system (i.e. temperature and the components) and asks for a variable as the X-axis. You must also specify a maximum and minimum for the X-axis. The second axis (Y-axis) can be another composition (or the temperature if that is not on the X-axis) from the independent variable list. The program then calculates and plots a *phase diagram*, as there are two independent quantities on the axes.

Alternatively, select a dependent quantity as the Y-axis variable from the second list on screen (e.g. the amount of all phases, composition of a specific phase, or fractions of a component in all phases), and the program calculates and plots how this quantity depends on the condition on the X-axis. This is a *property diagram*.

This command ends up within the POST module monitor. You can refine the calculated phase diagram or property diagram.

Moreover, many more property diagrams with axes other than compositions can also be plotted (after the calculation), using SET_AXIS_VARIABLE in the sequent POST monitor.

Syntax	DEFINE_DIAGRAM

Prompts	These prompts are given:
	`Same elements as before /Y/?`
	`Mole percent of <Element> /##/: <Value>`
	or
	`Mass percent of <Element> /##/: <Value>`
	`Database /ABCDE/: <Database name>`
	`Major element or alloy: <Element name>`
	`Composition in mass (weight) percent? /Y/:`
	`1st alloying element: <Element name>`
	`Mass (weight) percent: <Amount of the above specified element>`
	`2nd alloying element: <Element name>`
	`Next alloying element: <Element name>`
	`Mass (weight) percent: <Amount of the above specified element>`
	`Temperature (c) /1000/: <Temperature of interest in oc>`

Syntax	DEFINE_DIAGRAM

	`Reject phase(s) /none/: <List of phase(s) to be rejected>`
	`Restore phase(s) /none/: <List of phase(s) to be restored>`
	`OK? /Y/: <Y or N>`
	`Should any phase have a miscibility gap check? /N/:`
	`Phase with miscibility gap: <phase name>`
	`Major constituent(s) for sublattice #: /aa/: <Constituent(s)>`
	`Phase with miscibility gap: <Phase name>`
	The first equilibrium is calculated, as with DEFINE_MATERIAL. Then a list of all independent conditions suitable to be chosen as X/Y-axis variables is given by the program.

	`Quit? /Y/: <Y or N>` This question is asked only when the axis variables are already defined, or if DEFINE_DIAGRAM is used. It then offers an opportunity to quit (Y) the calculation or to continue (N) the calculation but by defining other axes.
	`Give the number of the condition to vary /1/: <A condition index>` Select one of the independent conditions by giving its index on the condition list as the X-axis variable.
	`Minimum value /XXX/: <minimum value for X-axis>` Specify the minimum value of the chosen X-axis variable. A default value is shown automatically by the program; press <Enter> to accept it or input another value.
	`Maximum value /YYY/: <maximum value for X-axis>` Specify the maximum value of the chosen X-axis variable. A default value is shown automatically by the program; press <Enter> to accept it or input another value. Then another list with some dependent quantities is given by the program, which can be selected as the Y-axis variable.
	`Give the number of the quantity on the second axis /#/: <##>` Select one of the independent conditions or dependent quantities as the Y-axis variable, by giving its corresponding index given on the condition lists. It must be different from the X-axis variable already selected. If selecting one of dependent quantities (by giving the corresponding number from the second list) as the Y-axis, then a property diagram is to be automatically calculated (through a normal stepping procedure) and generated. For `composition of a phase` the phase name is asked for further specification subsequently. If selecting any of the other independent variables (conditions) on the first list as the Y-axis, then a phase diagram is automatically calculated (through a mapping procedure) and plotted.
	`Name of phase: /ABC/: <phase name>` This is prompted only in case of that the `composition of a phase` is selected as the Y-axis variable. The phase name for which the composition varied along with X-axis variable should be specified.
	`Multiple start points? /Y/:`

Syntax	DEFINE_DIAGRAM
	By default, the program automatically generates and uses multiple start points for mapping the defined phase diagram.
	`Save file /Result/: <File name>` The file name where the calculations are stored (saved as a *.POLY3 file) should be specified; the default file name is `RESULT.POLY3`. Linux and Mac are case sensitive so ensure you enter `.POLY3`.

DEFINE_MATERIAL

This command is for the POLY module.

Read data for a system from a database in the POLY module. It is convenient to use for alloys when there is a major component and the amount of the other elements is known in mass (weight) fraction. The command reads the system from the specified database, sets the composition and temperature (and pressure equal to 1 bar) and calculates the equilibrium state before the prompting for a new command. You can list the results with LIST_EQUILIBRIUM or set a new composition or set axis for a STEP or MAP command.

You cannot append data from different databases in this way. Use this command with data from a USER database.

Syntax	DEFINE_MATERIAL
Prompts	`Same elements as before /Y/?` This question is asked only if some data is already read from the database, or if the command DEFINE_MATERIAL or DEFINE_DIAGRAM is used. It then offers a convenient way to change the composition and temperature with one command. This command only works properly in cases where the composition of the material system is already defined as in the mole-percent or mass-percent unit.

	`Mole percent of <Element> /##/: <Value>`
	or
	`Mass percent of <Element> /##/: <Value>`
	If you have decided to use the same materials system (available in the current POLY3 workspace) by accepting the default (Y) to the previous prompt `Same elements as before /Y/?`, one of the alternative prompts display for each of the components in the defined system, depending on how the composition is defined (either in mole-percent, or in mass-percent).
	Prompts are repeated until all the defined components are completed. Then, the program prompts to specify the temperature condition.

	`Database /ABCDE/: <Database name>` The database with the description for the material must be given, or press <Enter> if using the current database. It is possible to give a USER database.
	`Major element or alloy: <Element name>` The material must have a major element, usually the element which is present in the largest amount. The fraction of this element is not set but is the rest.

Syntax	DEFINE_MATERIAL
	In some databases there are the alloys predefined. An alloy has a default major element and have limits of the amounts of the alloying elements. If you stay within these limits the calculation gives reasonable results.
	`Composition in mass (weight) percent? /Y/:` By default the input is taken as mass percent. Choose N to change to mole percent. Composition should be given in PERCENT not FRACTION, as it is required for the `W` and `X` state variables in the SET_CONDITION command.
	`1st alloying element: <Element name>` The first alloying element must be given. All alloying elements are asked for in a sequence. These can be given in any order. You must know if you are present as assessed systems in the database. There is no error or warning messages if data are missing. Check the documentation of the database selected. If an alloy is selected, a list of legal alloying elements and their maximum percent is listed on-line.
	`Mass (weight) percent: <Amount of the above specified element>` The amount of the alloying element in mass (weight) percent. Using DEFINE_MATERIAL you cannot use the normal flexibility for conditions, but all must be given in mass percent. However, you can after wards change the conditions using SET_CONDITION.
	`2nd alloying element: <Element name>` The second alloying element must be given. If only one, press <Enter>. If an element name is given then the program asks for its mass fraction.
	`Mass (weight) percent: <Amount of the above specified element>` The amount of the above specified alloying element in mass (weight) percent.
	`Next alloying element: <Element name>` Continue giving elements and mass (weight) fractions until all elements specified. When all alloying elements and their compositions (as in the above prompt) are specified, press <Enter> as answer to this question to finish the materials definition.
	`Temperature (C) /1000/: <Temperature of interest in oC>` POLY makes the first calculation after retrieving the data for this temperature. By pressing <Enter> to accept the default temperature. The value should be given in Celsius (°C). The pressure is set to 1 bar.
	`Reject phase(s) /None/: <List of phase(s) to be rejected>` This is a question generated by the database allowing you to select the phases. Normally, all phases should be included when you press <Enter>. If a phase is to be rejected, the name of the phase must be supplied. Several phase names can be specified in one line. It is possible to reject all phase by giving

Syntax	DEFINE_MATERIAL
	an asterisk *. If the number of phases to be included is much smaller than the total number of phases, it may be convenient to first reject all phases and then restore those that should be included. The question is repeated until you press <Enter> after rejecting all unwanted phases or an asterisk *.
	`Restore phase(s) /None/: <List of phase(s) to be restored>` You can restore phases that are accidentally or deliberately rejected. It may also be possible to restore some hidden phases. If phases are to be restored the name of the phases must be supplied. Several phase names can be specified in one line. It is possible to restore all phase by giving an asterisk *. The question is repeated until you press <Enter> after restoring all desired phases.
	`OK? /Y/:` By default, all phases to be selected from the database have the thermodynamic data retrieved and the references from the chosen database are listed. Enter N if there are any errors or you want to amend the selection then you are returned to the prompt about rejecting phase(s).
	`Should any phase have a miscibility gap check? /N/:` The database usually creates two or more composition sets for phases that can have miscibility gaps. However, for some phases this is not done automatically, for example the miscibility gap in the bcc phase in Fe-Cr is usually ignored. But if it is important to include a Cr-rich bcc phase, specify this here. It costs some computation time and may make the subsequent MAP or STEP more difficult to converge. If you do not want to have any phase with a miscibility gap in the calculation, press <Enter>. Then, DEFINE_MATERIAL starts calculating the equilibrium, and is terminated.
	To set such a phase with miscibility gaps in the calculation, answer Y. Then the software asks questions about the phase names and their constitutions, such as: `Phase with miscibility gap: <Phase name>` You must supply the phase name, which has a miscibility gap under the specified system and conditions.
	`Major constituent(s) for sublattice #: /AA/: <Constituent(s)>` The software shows a default constituent in the sublattice `#(1,2,3,…)`, according to the existing phase definition in the chosen database. You can specify one or more major constituents for the sublattice # in the phase. This question is repeated until all sublattices are specified.
	`Phase with miscibility gap: <Phase name>` You can supply another phase name with a miscibility gap under the specified system and conditions, and answer the questions concerning the major constituent(s) in associated sublattice(s). By pressing <Enter>, the command starts calculating the equilibrium, and then terminates.

Syntax	DEFINE_MATERIAL

It is also possible to use this command to select an alloy from a specific database (e.g. the TCNI Ni-based superalloys database). Such alloys are predefined by the OPTION keyword inside the database, and have their default major elements and composition limits of their alloy elements.

Such alloys available in the selected database (at the prompt `Database /ABCDE/` can be listed on the screen if typing a ? mark on the prompt `Major element or alloy`. When a specific predefined alloy (instead of a major element) is selected, the major element is staked from the alloy definition and shown on the screen (with a message like `Alloy found with major element NI`).

You can only specify alloying elements and the compositions (weight percent or mole percent). Typing a ? at any of the prompts for the alloying element names, e.g. `1st alloying element`, `2nd alloying element`, lists all the alloying elements and the composition limits in the alloy. If the composition of an alloying element is outside of its limit, there is a message (such as `Amount above limit: 30.0000`) and a prompt `Override limit ? /N/`. If you decide to enforce the override by answering `Y` on this prompt (i.e. accepting the over-limit alloying composition), another warning message (such as `Amount of major element below limit: 70.0000`) and prompt `Override limit ? /N/`. Then further decide if enforcing the overriding: if Y then accepting the major element's composition below the limit; if N then using the predefined major element composition limit.

DELETE_INITIAL_EQUILIBRIUM

This command is for the POLY module.

Delete ONE specific initial equilibrium point or ALL of the initial equilibria. The initial equilibria are used as starting points for all the sub-sequential MAP and STEP calculations.

ADD_INITIAL_EQUILIBRIUM.

Syntax	DELETE_INITIAL_EQUILIBRIUM
Prompt	`Number /All/: <Number of an initial equilibrium>`
	Specify the number of an initial equilibrium (as a specific numerical value e.g. 3, or ALL) to be deleted from the POLY3 workspaces. It is recommended to use LIST_INITIAL_EQUILIBRIA to figure out the numbers for all the existing initial equilibrium points that have already been added (*manually* through ADD_INITIAL_EQUILIBRIUM, or *automatically* by some other POLY commands) and stored in the current POLY3 workspace. By default, ALL the initial equilibrium points are deleted.

DELETE_SYMBOL

This command is available with the POLY and ED-EXP modules.

Use the DELETE_SYMBOL command to remove symbols i.e. constants, variables, functions or tables.

Syntax	DELETE_SYMBOL
Prompt	`Name: <Name of a symbol>` Specify the name of the symbol to be deleted. Only one symbol can be deleted each time.

ENTER_SYMBOL

This command is for the POLY module.

There are also GES and POST module commands with the same name.

Symbols are a useful feature of the POLY and POST modules to define quantities that are convenient. Symbols can be constants, variables, functions or tables.

Functions or tables (with defined functions as values) can be entered in the POST module after a stepping or mapping calculation, for purposes of plotting such entered functions or tables as axis variables.

Within the POLY module, symbols are normally defined prior to an equilibrium calculation (enforced by a C_E command), stepping calculation (enforced by the command STEP_WITH_OPTIONS) or mapping calculation (enforced by MAP). These can be entered after an equilibrium calculation; however, for defined functions, variable or tables, it requires using EVALUATE_FUNCTIONS before showing the corresponding values in the calculated equilibrium state.

The symbols entered in the POST module are not saved in the currently-loaded POLY3 workspaces. Therefore, if you want to apply such symbols in other similar calculations for the same defined system, you must use the ENTER_SYMBOL command prior to the STEPPING or MAPPING calculation in the POLY module.

See example 44 for an example of using variables and functions.

Use the ENTER_SYMBOL command to enter symbols, which can be constants, variables, functions, or tables.

Syntax	ENTER_SYMBOL
Prompt	`Constant, Variable, Function or Table? /Function/: <Keyword>` The `Keyword` can be specified as `CONSTANT`, `VARIABLE`, `FUNCTION`, or `TABLE`. • CONSTANTS can only be entered once and is a means of using a name for a numeric value. For example, the value of 1 atmosphere in Pascal can be denoted by `P0` after the command ENTER_CONSTANT `P0=101325`. Defined constants can be used as values in condition assignments, for example, `SET-COND P=P0`. • FUNCTIONS are expressions of state variables or other functions. These expressions are saved, and whenever a function value is requested all functions are evaluated. The reason for this is that they may depend on each other. • VARIABLES are similar to functions because they can also be expressions of state variables. However, contrary to functions, they are only evaluated when they are entered or if they are explicitly named in an EVALUATE_FUNCTIONS command. It is possible to enter a variable with a new expression any time. This expression is evaluated directly and its value stored as the

Syntax	ENTER_SYMBOL

value of the variable. Defined variables can be used as values in the SET_CONDITION command.

- TABLES are used for listing results from the STEP or MAP commands. A table consists of a list of any number of state variables, functions, or variables. Defined tables can also be used in the POST (post-processor) module.

There is a special connection between tables and variables. If a variable is used in a table, it is evaluated for each line of the table in the TABULATE command or when the table is used in a plot.

`Name: <Name of the symbol>`

Each symbol has a unique name that must start with a letter and can have maximum 8 characters. Legal characters include letters (either UPPER or lower case), digits and underscore _. Any other special character, such as parentheses (and), plus +, minus -, slash / or \, full stop (.), are illegal for symbol names.

You can enter the symbol name and the value or function on the same line; these must be separated with an equal sign =, for example, `TC=T-273.15` or `T_C=T273.15` which stands for a definition of temperature in Celsius. Otherwise, these questions are asked.

For different types of symbols (constant, function, variable, or table), the questions have different prompts.

`Function: <Definition for a function or variable>`

Functions and *variables* are evaluated from an expression of state variables or other functions, constants, or variables. The expression is a FORTRAN-like expression and operators +, -, *, = and ** can be used (** only with integer powers).

Unary functions like `LOG`, `LOG10`, `EXP`, `SIN`, `COS`, and `ERF` can also be used. An expression can be continued on more than one line. An expression should be terminated by a semicolon (;) or an empty line (press <Enter> at the next prompt).

Examples of function expressions:

- `GM(LIQUID)`: The Gibbs energy of liquid per mole component
- `H.T/4.184`: The heat capacity of the system in calories
- `ACR(CR)/X(FCC,CR)`: The activity coefficient for Cr in FCC
- `T-273.15`: The temperature in Celsius

`&: <Continuation of the definition for the symbol>`

The ampersand & means that you can continue to write the function on the new line if one line is not

Syntax	ENTER_SYMBOL
	enough for the function. If you finish the function press <Enter> again.
	`Value: <Value for a constant>` A *constant* can only be assigned a numeric value once.
	`Value or expression: <Value of expression for a variable>` A *variable* can be assigned a numeric value or an expression. An expression is evaluated immediately and discarded. Only the numeric value is kept. This gives a possibility to save a value between calculations with different conditions because all state variables and functions are evaluated for the new conditions.

	`Variable(s): <Variable(s) in a table>`
	A *table* consists of a list of state variables or functions. One way to obtain results from a STEP command is through a table.
	Example:
	`ENTER TABLE K=T,X(LIQ,C),X(LIQ,CR),ACR(C)`
	Which means that the table called K contains four columns, i.e. the temperature, the mole fractions of C and Cr in the LIQUID phase, and the activity of C.
	To show the temperature in Celsius in a table, give the command ENTER_FUNCTION `TC=T-273`; and then use the symbol `TC` in the table.
	`& <Continuation of the definition for the table>`
	The ampersand `&` means that you can continue to write the table on the new line if one line is not enough for the table. If you finish the table press `<Enter>` again.

EVALUATE_FUNCTIONS

This command is available with the POLY and ED-EXP modules.

Use the EVALUATE_FUNCTIONS command to evaluate and list the value of one or more, or all, entered functions or variables.

Syntax	EVALUATE_FUNCTIONS
Prompt	`Name(s): <Name(s) of defined function(s)>` The names of one or more entered functions or variables must be specified. By typing a wildcard *, all functions and variables are evaluated. Variables are evaluated only if these are explicitly named.

LIST_AXIS_VARIABLE

This command is for the POLY module.

Syntax	LIST_AXIS_VARIABLE
	Lists all the axis variables for a stepping or mapping calculation that have already been set by SET_AXIS_VARIABLE.

LIST_CONDITIONS

This command is available with the POLY and ED-EXP modules.

All the conditions that are set by the SET_CONDITION command and the command-sequence CHANGE_STATUS PHASE =FIXED <0 or 1 or alike>, are listed when you use the LIST_CONDITIONS command. The current conditions are also listed by the LIST_EQUILIBRIUM command. The degree of freedom in the defined system is also shown.

- If this is zero, you can perform a COMPUTE_EQUILIBRIUM command.
- If it is larger than zero, some more conditions are required, and you must further set additional ones, using SET_CONDITION or CHANGE_STATUS.
- If it is negative, then too many conditions are defined and the unnecessary ones conditions need to be removed using the SET_CONDITION command (with a value of NONE for the to-be-deleted condition) or the CHANGE_STATUS command (i.e. changing a FIXED status of a phase to another type of phase status, ENTERED or DORMANT or SUSPENDED).

Example of LIST_CONDITIONS

```
P=100000, T=800, N(NI)=1E-1, N=1
FIXED PHASES
FCC_A1=1 LIQUID=0  DEGREE OF FREEDO 0
```

LIST_EQUILIBRIUM

This command is available with the POLY and ED-EXP modules.

The result (always in SI units) from the last calculated equilibrium is listed on screen or in a text file when you use the LIST_EQUILIBRIUM command.

You can also execute this command if no calculation is made or if the calculation fails. Make sure to interpret the results accordingly.

Syntax	LIST_EQUILIBRIUM
Prompt	`Output to screen or file /Screen/: <File name>` The name of the text file where the list of the calculation results shall be written.
	`Options /VWCSF/: <Option(s)>` Select the output units and formats by optionally specifying a combination of these letters. • *Fraction order:* `V` means VALUE ORDER; `A` means ALPHABETICAL ORDER. • *Fraction type*: `W` means MASS FRACTION; `X` means MOLE FRACTION. • *Composition*: `C` means only COMPOSITION; `N` means CONSTITUTION and COMPOSITION. • *Phase*: `S` means including only STABLE PHASES; `P` means including ALL NON-SUSPENDED PHASES. • *Phase name*: `F` means including COMMON PHASE Name if available; `D` mean only DATABASE PHASE NAME.
	Default options are `VWCSF`. If the output fraction type should be in mole fraction (rather than mass fraction), then give `VXCSF` or type `X` (implying that in this case the options V, C, S, and F are accepted as the listing manners for fraction order, composition and phase). If accepting all the default options, or if accepting all the altered options that had already changed when using this command previously, you can type `L_E,,,` or `LIST_EQUILIBRIUM ,,,` LIST_EQUILIBRIUM displays ORD (ordered) or DISORD (disordered) (when available). See CHANGE_LEGEND for details.

LIST_INITIAL_EQUILIBRIA

This command is for the POLY module.

List all the equilibria added with ADD_INITIAL_EQUILIBRIUM.

Syntax	LIST_INITIAL EQUILIBRIA
	All the initial equilibria are used for the MAP (and STEP) calculations.

LIST_STATUS

This command is for the POLY module.

There is also an ED-EXP module command with the same name.

Use the LIST_STATUS command to list the status of components, species, or phases.

The results depend on the key word specified in the options for CHANGE_STATUS, a table with the current status of phases or species or components, or the combinations, is shown:

- For components, the statuses and reference states are listed.
- For species, only the status is listed.
- For ENTERED and FIXED phases, the status, driving forces and equilibrium amounts are listed.

The metastable phases are listed in descending order of stability. To avoid long outputs only 10 metastable phases (in ENTERED status) are listed by lines, while all other less stable phases are merged onto one line. For DORMANT phases, their phase names and driving forces are listed. For SUSPENDED phases, only the phase names are listed.

Syntax	LIST_STATUS
Prompt	Specify what to list: `Option /CPS/`:*<keyword(s)>* keyword = C or P or S, or any combination • `C`: list component status • `P`: list phase status • `S`: list species status • `CS`: list both components and species Default is `CPS`.

LIST_SYMBOLS

This command is for the POLY module.

There are also POST and ED-EXP module commands with the same name.

Use the LIST_SYMBOLS command to list the definitions for all constants, functions, variables, and tables.

In order to find the value of a function or variable, use SHOW_VALUE or EVALUATE_FUNCTIONS. A table is tabulated with the TABULATE command.

The defined variables are listed up together with the defined functions, but variable names are followed by a percentage sign %.

LOAD_INITIAL_EQUILIBRIUM

This command is for the POLY module.

Copies all conditions and calculated results from a specific added initial equilibrium to the current equilibrium. The current conditions and calculation results are lost, and the newly loaded initial equilibrium point gets into the POLY workspace.

Syntax	LOAD_INITIAL_EQUILIBRIUM
Prompt	`Number: <Number of an initial equilibrium>` Specify the number of an initial equilibrium to be loaded as current. The number can be found with LIST_INITIAL_EQUILIBRIA.

MAKE_COMPONENT_ENTERED

This command is for the POLY module.

The MAKE_COMPONENT_ENTERED command sets the status for the components to be ENTERED in the defined system for all the sequential calculations (single-point, stepping, and mapping) in equilibrium or local/partial equilibrium states. ENTERED means that the component(s) are included in the calculation and these are stable if that minimizes the total energy.

This command has the same results as when using CHANGE_STATUS `Entered` option.

Syntax	MAKE_COMPONENT_ENTERED
Prompts	`Name(s) <Name(s) of the components>` The names of the components to set to ENTERED (all on one line). A comma or space must be used as separator. An asterisk, "*", can be used to denote all components.

MAKE_COMPONENT_SUSPENDED

This command is for the POLY module.

The MAKE_COMPONENT_SUSPENDED command sets the status for the components to be SUSPENDED in the defined system for all the sequential calculations (single-point, stepping, and mapping) in equilibrium or local/partial equilibrium states. SUSPENDED means that the component(s) are not considered in the calculation. Any conditions that depend on the suspended components are automatically removed.

Removing relevant conditions is unique to this command and does not occur when suspending components with the CHANGE_STATUS command and `Suspended` option.

Syntax	MAKE_COMPONENT_SUSPENDED
Prompts	`Name(s) <Name(s) of the components>` The names of the components to set to SUSPENDED (all on one line). A comma or space must be used as separator. An asterisk, "*", can be used to denote all components.

This command is useful when an element has a very low amount because you can now ignore it in the calculation instead of reading the entire system from the database. The command is also of use when working in an API with many calculations.

MAP

This command is for the POLY module.

This command starts the mapping procedure for making a calculation of phase diagrams in a defined multicomponent heterogeneous system, from one or more initial equilibria. A phase diagram is usually mapped within a specific space that is constructed by two (or more) defined independent mapping axis-variables.

Syntax	MAP
	A phase diagram consists of mapped phase boundary lines/curves; on one side of each such phase-boundary line/curve, the amount of one specific stable phase is zero (i.e. the zero-fraction lines). From a single MAP calculation, many different types of phase diagrams in the defined multicomponent heterogeneous system can be plotted, with some desired properties (that vary along the calculated phase-region boundaries) plotted as X/Y-axis variables. All different types of phase diagrams are generated by the mapping calculations through this command.

Normally, you need to have calculated at least one initial equilibrium point and have also defined at least two independent varying variables (i.e. the controlling conditions in the system) that are set with SET_AXIS_VARIABLE. You can also have three, or four or maximum five independent varying variables that are defined by the SET_AXIS_VARIABLE command).

This lists the current values of each of the independent axis variables for each of the calculated equilibrium points along each of the mapped phase boundaries, and also lists the corresponding information when the set of stable phases changes.

The Global Minimization Technique is by default enforced in this command while it can be disabled if having decisively switched it off (or possibly in some special modules) through changing the minimization option using the ADVANCED_OPTIONS → MINIMIZATION_OPTION command-sequence. You can choose how often to do a Global Minimization test (via the Global Test Interval option) in the ADVANCED_OPTIONS STEP_AND_MAP command-sequence.

During a MAP calculation, the values of mapped axis-variables for presenting each phase boundary (lines/points) of the calculated phase-regions are listed, and the corresponding stable-phase sets are shown up.

You can terminate the mapping of a line by pressing a single <Ctrl-A> (Windows) or <Ctrl-C> (Linux). This can be useful in order to stop a longish calculation without losing what is already calculated.

If there is any convergence problem in finding a stable solution at a certain stage during a calculation procedure enforced by this command, these messages display on screen:

```
Convergence problems, increasing smallest site-fraction from 1.00E-30
to hardware precision 2.00E-14. You can restore using SET-NUMERICAL-
LIMITS
```

This implies that smallest site fraction in the current POLY3 workspace is automatically increased from the default value 1.00E-30 to the hardware-dependent precision (under Linux, as 2.00E-14). For other subsequent POLY-module calculation in the current TC run, you can use SET_NUMERICAL_LIMITS to restore or reset the smallest site fraction to the previous or another preferred value, as well as to reset other numerical limits.

In particular, for phase diagrams with tie-lines in the plane (i.e. most binary systems and ternary isotherms), there is a MAP procedure which checks for the best phase to use as axis variables in order to ensure reasonable increments between the tie-lines. This produces smoother curves and also gives a better stability in finding adjacent phase-regions.

Complex miscibility gaps of various solution phases are automatically detected during a mapping calculation, and two or more composition sets for each of such solution phases are automatically generated as well, through an automatic Global Minimization Test procedure (by specifying a Global Test Interval value and confirming the `Automatically add initial equilibria` in the ADVANCED_OPTION STEP_AND_MAP command-sequence). As a particular case, such an automatic Global Minimization Test ensures that you can start calculating from high temperatures in an austenitic steel (metallic FCC_A1 solution phase) where the MC carbides/nitrides/carbonitrides (i.e. the C-/N-rich sides of the FCC_A1 miscibility-gap, often (while not always) being referred to as `FCC_A1#2`, `FCC_A1#3`, etc.) are not stable, and during the MAP command the MC carbides/nitrides/carbonitrides may first become metastable with a composition different from the metallic FCC_A1 phase and later also stable. The advanced mapping procedure (enforced by the Global Minimization Technique) inside the Thermo-Calc software (both the Console Mode and Graphical Mode) can efficiently and effectively handle complex miscibility gaps in multicomponent heterogeneous systems.

To get a complete phase diagram, sometimes it may be necessary to have multiple starting equilibrium-points, and/or to have added multiple initial-equilibrium points (through ADD_INITIAL_EQUILIBRIUM) inside various phase-region boundaries under certain direction(s).

POST

The POST module (post-processor) is a submodule to the POLY module and has its own set of commands. The TAB, BIN, TERN, POT, SCHEIL and POURBAIX modules use the POST module features as part of the automatic generation of the plots.

Using the POST Module

Syntax	POST
	Switches to the POST module, which has its own command set.

READ_WORKSPACES

This command is used in both the POLY and GES (GIBBS) modules.

Workspace Files

The POLY3 and GIBBS workspaces and the calculated results from the MAP and STEP commands can be READ from a file where they are saved with SAVE_WORKSPACES. Such a *.POLY3 file is not printable.

Syntax	READ_WORKSPACES
Options	`File name` is the name of a saved POLY3-file where the POLY3 and GIBBS workspaces shall be read from must be specified. You do not need to type the extension if it is the default *.POLY3, otherwise type the whole POLY-file name. A reminder that Linux and Mac are case sensitive; when applicable ensure you enter file extensions with capital letters. A window opens so that the path (in the **Look in** field) and **File name** can be specified. The **Files of type** (i.e. POLY3) cannot be changed. Click **Open** to open the POLY3 and GIBBS workspaces from the saved *.POLY3 file.
	When reading back an original POLY3 workspace that has already been saved as an *.POLY3 file in the current Thermo-Calc (Console Mode) run or had been read from an existing POLY3 file under the current work area, while some additional changes in the settings may be made but do not need to be kept in further steps in the current Thermo-Calc (Console Mode) run or any diagram is plotted in the POST module, you can type `READ,,` or `READ_WORKSPACE ,,`

REINITIATE_MODULE

This command is for the POLY module.

This command makes sure that the whole POLY module (and thus the entire POLY workspace) is reinitiated to the state as it was when first entered.

Syntax	REINITIATE_MODULE
	All the defined components, defined conditions, changed status, entered symbols, defined independent axis-variables, calculated starting equilibrium-points, added initial equilibrium points, stepped/mapped equilibrium data, and so forth, are removed completely. The saved file name is restored to the default.

SAVE_WORKSPACES

This command is available for both the POLY and GES (GIBBS) modules.

Workspace Files

You can save the current status and workspaces, including thermodynamic data, conditions, options and results from a single, stepping or mapping calculation on a *.POLY3 file. The workspaces are saved to a file with this command. This is useful so you have access to the workspace for later use or when you need to terminate the current Console Mode session.

- In the Gibbs (GES) module workspace, all thermochemical data are stored.
- In the POLY module workspace, all the last set of conditions and equilibrium state, changed status, entered symbols, advanced options, defined stepping/mapping variables, added initial equilibria, stepped/mapped results, etc., are stored, so it also contain the GES workspace.
- When you are in a response-driven module such as POTENTIAL or SCHEIL for example, a workspace file is automatically opened. In the workspace file, system definitions, conditions for the calculation, calculation results, and plot settings are saved. The file is saved in the current working directory, and is named after the name of the module that created it. For example, the POTENTIAL module saves a workspace file called `POT.POLY3` ; the POURBAIX module saves a file called `POURBAIX.POLY3` and so forth.

After a SAVE_WORKSPACES command, you can always come back to exactly the state you had when you issued the command by giving a READ_WORKSPACE command. For example, after saving the POLY and GIBBS workspaces to a file, you can leave the program and at a later time READ the file and continue from the saved state.

Important Information About Map and Step Commands

A STEP or MAP command automatically saves the workspace with the most recently specified name. Do not use the SAVE_WORKSPACES command after a MAP or STEP command.

The results from the STEP or MAP commands are destroyed by the SAVE_WORKSPACE command. You can append several results obtained by sequential STEP or MAP calculations without destroying the previous results, whilst SAVE_WORKSPACE erases them all. Keeping this in mind is important and useful particularly for calculating various isothermal (or isoplethal) sections and plotting them on the same diagram in a single Thermo-Calc run.

To suspend some of the STEP or MAP results, use the AMEND_STORED_EQUILIBRIA command.

Syntax	SAVE_WORKSPACES
Options	A `file name` must be specified. The default extension of the POLY workspace file is *.POLY3 but you can have any other file extension. Linux and Mac are case sensitive so ensure you enter `.POLY3`. A **Save** window displays if a file name is not given after the command, so that the path (in the **Save in** field) and **File name** can be specified. The **Files of type** cannot be changed. If there is already a file with the same file name under the directory a warning message displays. Click **OK** to overwrite the current POLY or GIBBS workspace onto the existing file. Click **Cancel** to return to the module. You can use the SAVE command with an unspecified name (i.e. through `SAVE ,,,` command-sequence) to save the POLY or GIBBS workspace. When saving a POLY3 workspace under a name that already exists under the current work area, which is saved by default (after running a special module, e.g. BIN, TERN, POT, SCHEIL and POURBAIX) or in an earlier stage of the current Console Mode session or in a previous run (which is READ into the current POLY3 workspace), you can type `SAVE,,Y` or `SAVE_WORKSPACE ,,y`. However, this must also be avoided if some results from previous MAP or STEP calculations shall not be destroyed.

SELECT_EQUILIBRIUM

This command is available with the POLY and ED-EXP modules.

If you create more than one initial equilibrium (during data-assessments using the PARROT/ED_EXP modules), you can switch between them using the SELECT_EQUILIBRIUM command.

Syntax	SELECT_EQUILIBRIUM
Prompt	`Number /Next/: <Choice on equilibrium>` Options: `FIRST`, `LAST`, `NEXT`, `PREVIOUS` or `PRESENT`. Most commands affect only the `PRESENT` equilibrium. However, the REINITIATE_MODULE and DEFINE_COMPONENTS commands remove all the stored equilibria.

SET_ALL_START_VALUES

This command is available for the POLY and ED-EXP modules.

Use the SET_ALL_START_VALUES command to set start values, e.g. if the calculation fails or if you have a miscibility gap or ordering. If temperature and pressure are not conditions, you are asked for values of them. Then for each phase prompt on if it should be stable and on its constitution.

Syntax	SET_ALL_START_VALUES
	`T /XXXX/: <Temperature in K>` If the temperature is not a condition, supply a guess of its final value (in K).
	`P /100000/: <Pressure in Pa>` If the pressure is not a condition supply a guess of its final value (in Pa).
Prompts	`Automatic start values for phase constitutions? /N/: <Y, N or F>` • For N, enter an initial amount of each entered phase and the major constituents or site fraction of each constituent. • For Y, the program automatically sets the start values for phase constitutions in all possible phases. • `F` is for force. In some cases the calculation fails because impossible conditions are set, e.g. `W(C)=1.5` `[W(C)` is mass fraction and must thus be less than unity. The program tries to fulfill this condition by putting maximum amount of carbon in all phases, but can fail anyway. When you detect the error and set `W(C) to 0.015`, the calculation may still fail because it could start from the previous values. To get back to 'fresh' start values, choose `F`.
	`Should <phase> be stable /N/: <Y/1 or N/2>` A guess if this phase should be stable or not is requested. All entered phases are prompted for this question and next two. You cannot have more phases stable than you have components, but at least one (which dissolves all constituents) must be set as stable. For backward compatibility, this question can be answered by 1 (for Yes) or 0 (for No). The `phase` name may have a hash sign # followed by a digit, e.g. `BCC_A2#2`. For phases with miscibility gaps, there should be two phases with the same name but with different numbers after the hash sign.
	`Major constituent(s): <Name of major constituent(s) in the phase>` The constituent with the largest fraction in the phase should be specified. If there are more than one constituent with a large fraction, give them all on the same line. If the default major constituents should be used answer with an asterisk (*). By giving $ the constituent is not changed. If there should be no major constituent give NONE and or if the major constituent(s) are improperly specified, you are asked for individual fractions in the phase.

Syntax	SET_ALL_START_VALUES
	`Y(<phase>,<constituent>) /.XXXXXXXXXX/: <.YYYYY>` The current value (`.XXXXXXXXXX`) is default. You can accept the default by pressing <Enter> or give a new value (`.YYYYY`). The phase name or constituent name may have a hash sign # followed by a digit, e.g. `Y(BCC_A2#2,FE), Y(BCC_A2#2,C#2)`. For phases with miscibility gaps, there should be two phases with the same name but with different numbers after the hash sign. For phases with sublattices, the constituents in sublattice 2 or higher is also be suffixed with a hash sign # followed by a digit.

SET_AXIS_VARIABLE

In order to calculate a diagram, set at least one axis variable in a stepping calculation, or at least two axis variables in a mapping calculation. For property diagrams, one axis is enough; for phase diagrams two or more are necessary. Any condition that can be set to calculate an equilibrium can be used as an axis variable (with its lower and upper limits and step length) by using SET_AXIS_VARIABLE, and the POLY program does, after a STEP or MAP command, vary the value of the condition between the limits set on its related axis variable. As an extraordinarily unique and powerful feature of the Thermo-Calc software, up to five independent axis variables can possibly be used in a mapping calculation of a multicomponent heterogeneous system; however, the axis numbers 3, 4 and 5 must have chemical potentials of components (or temperature or pressure) as conditions.

Syntax	SET_AXIS_VARIABLE
Prompts	`Axis number /#/: <An axis number>` Specify a number between 1 and 5. The axis numbers 3, 4 and 5 must have chemical potentials of components (or temperature or pressure) as conditions.
	`Condition /None/: <One condition>` Here the condition that should be varied along the axis must be given. The condition is specified as in SET_CONDITION, for example `W(C)` for mass fraction of carbon. By accepting `NONE`, the axis is removed.
	`Min value /0/: <Min value>` Specify the minimum value of the axis condition.
	`Max value /1/: <Max value>` Specify the maximum value of the axis condition.
	`Increment /.025/: <Step length>` Specify the maximum step length. By default, this is 1/40 of the total axis length.

You can give SET_AXIS_VARIABLE without having set a condition on the axis variable. Under such circumstances, the relevant condition is automatically created and the value set between the minimum and maximum axis limits; however, as a side effect, the POLY module creates two conditions, `P=1e5` and `N=1` (these have not been defined as a condition yet), in case you set an axis variable which is not already a condition.

You can use a logarithmic axis during calculations. This is useful for low fractions like in a gas phase where `1e-7` to `1e-2` might be an interesting range. The pressure is also suitable for logarithmic step. You specify the logarithmic axis by giving an asterisk * after the increment value.

The increment in this case is treated as a factor.

For example,

```
S-A-V 1 P 1E5 1E25 5*
```

This makes axis 1 a logarithmic axis where the difference between two calculated values makes a factor 5.

The factor must be larger than 1.0.

In some cases, such as when the DEFINE_DIAGRAM command is used or a special advanced module (e.g. BIN, TERN, POT, SCHEIL or POURBAIX) is called, some axis variables are automatically set by the program, not necessarily by this command.

SET_CONDITION

This command is available with the POLY and ED-EXP modules.

Use the SET_CONDITION command to specify the equilibrium conditions for the calculation. All kinds of state variables, as well as most of the `M/W/V/F`-suffixed state variables (for normalization) and `R`-suffixed state variables (with respect to chosen reference states), can be used as conditions. In addition to temperature and pressure conditions, a multicomponent system can have mixed types of conditions. You should repeat this command for a multicomponent system until the degree of freedom in the defined system becomes zero. When a FIXED phase status is used on a specific phase (use CHANGE_STATUS), it is equivalent to one condition (implying that particular phase is stable in the defined system).

Syntax	SET_CONDITION

	Each condition must be given explicitly, but can be given on the same line (separated by a comma (,) or an empty space) or on separate lines with each one started with the command.
	
	Example
	`SET_COND T=1273, P=1E5, W(C)=.0015, X(LIQ,CR)=.22, ACR(N)=.2`
	or
	`SET_COND T=1273, P=1E5`
	`SET_COND W(C)=.0015, X(LIQ,CR)=.22 ACR(N)=.2`
	In this example, the temperature is set to 1273 K, the pressure to 1 bar (1E5 Pascal), the mass (weight) fraction of C to 0.0015 and the mole fraction of Cr to 0.22 and the activity of N to 0.2.

Prompt	`State variable expression: <State variable name or linear expression> or a linear expression of state variables.` Some of the state variables that can be used in conditions are: • `T`: temperature in the system (in K) • `P`: pressure in the system (in Pascal) • `N`: system size (mole number in moles) • `B`: system size (mass in grams) • `N(<component>)`: mole number of a component in the system • `X(<component>)`: mole fraction of a component in the system • `W(<component>)`: weight fraction of a component in the system • For the SET_CONDITION command this is `ACR(<component>)`: activity of a component in the system. For the SET-ALTERNATIVE_CONDITION command, this is `ACR`(<`phase`>,<`component`>) (activity of a component in a phase) • For the SET_CONDITION command this is `MUR(<component>)`: chemical potential of a component in the system. For the SET-ALTERNATIVE_CONDITION command, this is `MUR` (<`phase`>,<`component`>) (chemical potential of a component in a phase)

Syntax	SET_CONDITION

- `X(<phase>,<component>)`: mole fraction of a component in a phase
- `W(<phase>,<component>)`: weight fraction of a component in a phase
- `ACR(<species>,<phase>)`: activity of a species referred to a phase
- `MUR(<species>,<phase>)`: chemical potential of a species referred to a phase
- `H`: enthalpy in the system (in J)
- `HM(<phase>)`: enthalpy of a phase (in J/mol)

There are many state variables that can be used in conditions. For more information, enter an `INFO STATE_VARIABLES` command. A condition is normally a value of a single state variable with its value.

Example

```
T=1273.15 P=1E5
X(C)=.002
W(CR)=0.5
ACR(CR)=0.85
X(FCC,C)=.001
H=-250000
 HM(BCC)=-225000
```

A condition can also be a value of a linear expression involving more than one state variable. For example,

```
X(LIQ,S)-X(PYRR,S)=0
```

This means that it is a condition that the mole fraction of `S` component should be the same in the LIQUID and PYRRHOTITE phases. In practice, that should be the congruent melting point.

After the equal sign only a numeric value is allowed in the expression.

`Factor: <A factor for the state variable, or a continuation>`

This question means you did not answer the previous question. The program is then expecting a single state variable or a complete state variable expression, or the numeric factor in an expression with only one state variable. In a state variable expression a state variable may be preceded by a constant factor. An example of this is:

```
2*MUR(FE)+3*MUR(O)=-35000
```

This means that it should be a condition that two times the chemical potential of `FE` plus three times the chemical potential of `O` should be -35000 J/mol.

`State variable: <A specified state variable, or a continuation>`

This question is prompted if a single state variable name has not given in either the prompt `State variable expression` or `Factor`, or a state variable expression is given but the expression is incomplete, for example, `T-` or `2*MUR(FE)+`, for which the program is then expecting a continuation of the unfinished expression. You need to specify a state variable or a complete state variable expression, or complete the unfinished state variable expression. If a numeric factor is given before this prompt,

Syntax	SET_CONDITION
	only one state variable can be specified; otherwise, the program only takes the first state variable to complete the expression (i.e. the factor times the state variable).
	`Value /X/: <A numeric value, a constant or a variable>` The value of the condition. This can be a numeric value, a constant or a variable. A suggestion is given as the default value. The special value `NONE` means that the condition is removed; for example `T=NONE` takes away the temperature condition.

SET_INPUT_AMOUNTS

Specify how a system is made up from mixing of various substances. It is useful with a substance database. In the C-H-O-N system, you can, for example, give:

```
S-I-A N(H2)=10, N(H2O)=25, N(C1O2)=5, N(N2)=100
```

The POLY module automatically converts this into conditions for the current set of components. In the case when the elements are defined as the components, the command above is equivalent to

```
SET-CONDITION N(H)=70, N(O)=35, N(C)=5, N(N)=200
```

Syntax	SET_INPUT_AMOUNTS
Prompts	`Quantity: <N(<specie>) or B(<specie>)>` You can give the amount also preceded with an equal sign `=` [e.g. `N(H2)=10` or `B(H2O)=1000`], or press <Enter> for the next prompt on the amount of the quantity.
	`Amount: <Value of the quantity>` Specify the numerical value of the quantity. You can give negative amounts in the SET-INPUT-AMOUNTS command.

SET_INTERACTIVE

In the POST module this is called SET_INTERACTIVE_MODE.

Use the SET_INTERACTIVE command to use it in demonstration or macro files to stop the execution of the command file and pass over input focus to the keyboard.

SET_NUMERICAL_LIMITS

This command is available for the POLY, Scheil, and ED-EXP modules.

Use the SET_NUMERICAL_LIMITS command to change the criteria for convergence. This is to speed up a calculation in a complex system.

If there is any convergence problem in finding a stable solution at any stage during a calculation procedure enforced by COMPUTE_EQUILIBRIUM, STEP_WITH_OPTIONS, MAP or ADVANCED_OPTIONS), this message displays:

```
Convergence problems, increasing smallest site-fraction from 1.00E-30
to hardware precision 2.00E-14. You can restore using SET-NUMERICAL-
LIMITS
```

This implies that smallest site fraction in the current POLY workspace is automatically increased from the default value 1.00E-30 to the hardware-dependent precision (under Linux, as 2.00E-14). For other subsequent POLY module calculations, you can use this command to restore or reset the smallest site fraction to the previous or another preferred value, as well as to reset other numerical limits.

Syntax	SET_NUMERICAL_LIMITS
Prompt	`Maximum number of iterations /500/:` By default, the program tries 500 iterations before it gives up. As some models give computation times of more than 1 CPU second/iteration, this number is also used to check the CPU time and the calculation stops if 500 CPU seconds/iterations are used.
	`Required accuracy /1E-6/:` This is a relative accuracy, and the program requires that the relative difference in each variable must be lower than this value before it has converged. A larger value normally means fewer iterations but less accurate solutions. The value should be at least one order of magnitude larger than the machine precision.
	`Smallest fraction /1E-12/:` This is the value assigned to constituents that are unstable. It is normally only in the gas phase you can find such low fractions. The default value for the smallest site-fractions is 1E-12 for all phases, except for IDEAL phase with one sublattice site (such as the GAS mixture phase in many databases) for which the default value is always as 1E-30 (unless you have used the SET_NUMERICAL_LIMITS command to reset an even-lower value (e.g. 1E-45, that is naturally enforced to all the phases in the system).
	`Approximate driving force for metastable phases /Y/:` `Y` is the default. Enter `N` to change the default as required and based on the options described below. This setting involves the convergence of metastable phases and affects their driving forces. It can also have an effect on when an equilibrium is considered successful. The default is to allow an equilibrium with metastable phases that have not converged, as long as the stable phases have converged. This is efficient but often causes approximate values of the driving

Syntax	SET_NUMERICAL_LIMITS
	forces for the metastable phases. If you change the default, it enforces metastable phases to converge. This gives accurate driving forces for metastable phases as well as stable phases. It can however take a slightly longer time, and if metastable phases do not converge it causes the equilibrium calculation to fail.

SET_REFERENCE_STATE

This command is available for the POLY, ED-EXP and POST modules.

The reference state for a component is important when calculating activities, chemical potentials, and enthalpies and is determined by the database being used. For each component the data must be referred to a selected phase, temperature, and pressure, i.e. the reference state.

All data in all phases where this component dissolves must use the same reference state. However, different databases can use different reference states for the same element/component. It is important to be careful when combining data obtained from different databases.

By default, activities, chemical potentials, and so forth are computed relative to the reference state used by the database. If the reference state in the database is not suitable for your purposes, use the SET_REFERENCE_STATE command to set the reference state for a component using `SER`, i.e. the Stable Element Reference (which is usually set as default for a major component in alloys dominated by the component). In such cases, the temperature and pressure for the reference state is not needed.

In order to specify conditions in the specific reference state, you can append an `R` to the state variables. Thus, `AC` is the activity (of a system component or of a species in a phase) with respect to the default reference state, and `ACR` is the activity with respect to the selected reference state; MU is the chemical potential of a system component with respect to the default reference state, and `MUR` stands for the chemical potential with respect to the selected reference state. The `AC` and `ACR` variables, for both components in a system and species in a phase, can be specified in natural logarithm, e.g. LNAC(Fe), LNACR(C), LNAC(O2,GAS), LNACR (O2,GAS).

For the POST module, and after calculating with the STEP_WITH_OPTIONS or MAP commands, the reference state for a component can also be changed to plot various properties of the component in the entire system or in a specific phase. Then you can set the diagram axes as the chemical potential or activity quantities with the `R` suffix, i.e. MUR(comp), MUR(comp,ph), ACR(comp), ACR(comp,ph) or the common logarithms [e.g. LNACR(comp,ph)].

Syntax	SET_REFERENCE_STATE
Prompts	`Component: <Name of the component>` The name of the component must be given.
	`Reference phase: <Name of a phase used as the new reference state>`

Syntax	SET_REFERENCE_STATE
	Enter the `Name of a phase` for the system. For a phase to be usable as a reference for a component, the component needs to have the same composition as an end member of the phase. The reference state is an end member of a phase. The selection of the end member associated with the reference state is only performed once this command is executed. If a component has the same composition as several end members of the chosen reference phase, then the end member that is selected at the specified temperature and pressure will have the lowest Gibbs energy. The following are example using temperature. Pressure is used in the same way: • In the Fe-C system, BCC can be a reference state for Fe but not for C since BCC can exist as pure Fe but cannot exist as pure C. • If GAS is chosen as the reference phase of component O at such a high temperature that O1 has the lowest energy, then O1 remains the reference state even at calculations performed at lower temperatures where O2 has a lower energy than O1. • Setting the reference state for component O as gas (one sublattice) with constituents O1, O2 and O3 results in O2 being the reference state if, at the present temperature, pure O2 has the lowest energy of O1, O2 and O3. If the reference state is set above a critical higher temperature, then O1 has the lowest energy and consequently becomes the reference state.
	`Temperature /*/: <Temperature for the reference state>` Select the Temperature (in K) for the reference state. The wildcard value * means the current temperature is used at the time of evaluation of the reference energy for the calculation. The temperature set with this command does not affect the temperature used when evaluating the energy of the reference state during the end member selection process.
	`Pressure /1E5/: <Pressure for the reference state>` Select the Pressure (in Pa) for the reference state. The wildcard value * means the current pressure is used for evaluating the reference energy at the time of calculation.

	Examples
	
	`S-R-S Fe SER`
	`S-R-S Cr FCC * 100000`
	`S-R-S H2O AQUEOUS * 100000`
	`S-R-S ZE REF_ELECTRODE * 100000`

SET_START_CONSTITUTION

This command is available with the POLY and ED-EXP modules.

The SET_START_CONSTITUTION command is similar to SET_ALL_START_VALUES, but is used for an individual phase that may have a wrong constitution.

Syntax	SET_START_CONSTITUTION
Prompts	`Phase name: <Name of a phase, and possible major constituent(s)>` Specify the name of a phase for which the constitution shall be set. If there is a major constituent of the phase, you must specify this on the same line as the phase name. By giving an*, select the default major constituents. A $ means keeping the same constitution, and `NONE` means to give individual site-fractions.
	`Y(<Phase>#<Composition_set>,<Constituent>#<Sublattice>) /xxx/: <SF>` The site fraction (`SF`) of the constituent shall be given. The default value `xxx` is the last calculated one.

SET_START_VALUE

This command is available with the POLY and ED-EXP modules.

The SET_START_VALUE command is not often required as the automatic start values can be handled for most problems.

Use the SET_START_VALUE command to set a start value of an individual variable.

Syntax	SET_START_VALUE
Prompts	`State variable: <Name of a state variable>` The state variable must be given.
	`Value` Specify the value to be assigned the state variable as start value.

SHOW_VALUE

This command is available for the POLY and ED-EXP modules.

Use the SHOW_VALUE command to show the current value of any state variable, function, or variable.

Syntax	SHOW_VALUE
Prompt	`State variable or symbol: <Name(s) of state variable(s) or symbol(s)>` A single or several state variables or symbols (entered functions or variables) can be specified.

The wildcard * can be used to denote all phases or all components.

You can use the dollar-sign `$` to denote all stable phases. Thus, the command SHOW W(*,*)lists the mass fraction of all phases, whereas `SHOW W($,*)` lists the mass fraction of all stable phases.

If you `SHOW` a function, all functions are evaluated using the current values of the state variables. But if you `SHOW` a variable, it retains its value from the time it was `ENTERED` or last `EVALUATED`.

Therefore to save a value from one calculation to another, `ENTER` it to a variable. This is frequently done in the PARROT module to transfer values between equilibria.

STEP_WITH_OPTIONS

This command is for the POLY module.

The STEP_WITH_OPTIONS (short name, STEP) command initiates the stepping procedure to make a calculation of property diagrams in a multicomponent heterogeneous system. A property diagram is usually stepped under one defined independent stepping axis-variable, and is often constructed by the defined independent mapping axis-variable against a chosen property (for the system, or for a specific phase, or for a certain species).

In the POLY module, it is possible to compute a series of equilibria with one condition as the stepping axis variable. This is achieved by first calculating a single equilibrium, and then selecting one of the conditions as the axis variable. The minimum and maximum value and the incremental step along the axis must also be given. By default, the global minimization technique is used .

A property diagram consists of property lines that change (normally) along with the stepping axis-variable. From a single STEP calculation, many different types of property diagrams in the defined multicomponent heterogeneous systems can be plotted. Various types of property diagrams are generated by the stepping calculations.

About Property Diagrams

Normally, before the command can be invoked, you need to have already calculated an initial equilibrium point and set one independent variable (i.e. the controlling condition in the system) . This is done using SET_AXIS_VARIABLE. You then list the current values of the axis variable for each calculated equilibrium, as well as the corresponding information when the set of stable phases changes.

By default, the global minimization technique is enabled, You can turn this off by using the command-sequence ADVANCED_OPTIONS → GLOBAL_MINIMIZATION.

You can choose how often to do a global minimization test using the command-sequence ADVANCED_OPTIONS → STEP_AND_MAP → GLOBAL TEST INTERVAL.

Syntax	STEP_WITH_OPTIONS
Prompt	`Option? /Normal/: <A chosen option, N, I, S, O, E, M, T, or P>`

Syntax	STEP_WITH_OPTIONS
	N = Normal, I = Initial equilibria, S = Separate phases, O = One phase at a time, E = Evaluate, M = Mixed Scheil, T= T0, and P Paraequilibrium

Normal (N)

When you accept the default, Normal (N), it allows a stepping calculation with the chosen independently-varying equilibrium condition (axis-variable). Only the step axis value is changed between each step.

When you repeat the STEP → NORMAL command-sequence, you can make several stepping calculations while still keep all the stepping-calculation results in the current POLY3 workspaces.

The calculation results are saved in the default `RESULT.POLY3` file or you can specify to save it in the `<MyName>.POLY3` file. This is as long as there is no SAVE_WORKSPACES command before the second set of command sequences (STEP → NORMAL). Repeated stepped results can be restored into the same current POLY3 workspaces/file.

Linux and Mac are case sensitive so ensure you enter `.POLY3`.

The addition of several steps enables you to generate special types of property diagrams and to calculate and plot special phase boundary lines on phase diagrams, such as:

- The missing part(s) of a specific property [that are calculated under another controlling condition inside the range of the stepping-variable] on the same property diagram.
- Two or more sets of a specific property [that are calculated under different controlling conditions and stepped over the same stepping-variable range] on the same property diagram for the same system.
- Calculate some special phase-boundary lines [especially for some defined secondary phase transformations or alike, e.g. the BCC_A1 <--> BCC_B2 phase-boundary, or equal-Gm for two specific phases, or equal-fraction or equal-activity for a certain species in two specific phases, that shall be calculated under different controlling-conditions and also be stepped over different stepping variable(s)], and then plot (or

impose) them onto a corresponding phase diagram (which can be resulted from several such STEP → NORMAL calculations or even from a separate MAP calculation) for the same system.

Initial_Equilibria (I)

An initial equilibria is added at each calculated point. This can be useful, for instance, to generate a set of isothermal calculations.

When you choose `I`, an initial equilibrium is stored at each calculated equilibria. It is intended to generate a matrix of calculated initial equilibria, first stepped under a STEP INITIAL_ EQUILIBRIA command-sequence and then repeated by another STEP NORMAL command-sequence (or even continued by a MAP command).

For example, you can first use the temperature condition as the stepping axis-variable with this option, which calculates a number of initial equilibrium points and automatically adds each one as an initial equilibria for another STEP → NORMAL command-sequence (or even for a MAP command). Before the second STEP command (i.e. the STEP → NORMAL command-sequence), you can chose a compositional condition as the new stepping axis-variable; then the STEP → NORMAL command-sequence uses those created starting equilibrium points (at different temperatures) and steps in such a new compositional variable. As a result, these two STEP commands together give a matrix of values.

Separate_Phases (S)

In this way, you can calculate how the Gibbs energy for a number of phases varies for different compositions. This is particularly useful to calculate Gibbs energies for complex phases with miscibility gaps and for an ordered phase that is never disordered (e.g. SIMGMA-phase, G-phase, MU-phase, etc.).

One_Phase_at_Time (O)

This option is recommended for STEPPING heterogeneous systems with both ordered phases and the disordered pairs.

When you choose `O`, the stepping calculation is conducted individually for one phase at a time. That is, it is stepped over the whole stepping variable range, but the stepping is repeated for all the entered phases in the defined system. This is particularly useful to properly step in composition for an equilibrium heterogeneous system with both ordered phases and the

disordered pairs. Thus, instead of calculating for the same composition for each of the phases at each composition step, it starts the stepping in each of the phases in the default most-stable compositions (the major constitutions).

Evaluate (E)

For Scheil-Gulliver simulations it is recommended you use the SCHEIL module.

Evaluate `E` is an advanced option and is useful when additional conditions (instead of the stepping variable) require changing during a stepping calculation. It allows a stepping calculation in a single axis with simultaneous evaluation of one or more variables after each step. As variables can be used as conditions, it means that you can change the conditions during the stepping. After a successful EVALUATE calculation, you can go to the POST module to manually define and plot property diagrams.

The variables given are evaluated after each step, which may change other conditions. This can be useful to perform the Ordinary ScheilGulliver Approach (non-equilibrium transformations) for simulating alloy solidification without back diffusion of fast-diffusing interstitial components in solid phases. However, it is recommended you use the SCHEIL module.

Specify the prompt:

```
Variable name(s): <Variable name>
```

The names of the variables that shall be evaluated after each step must be typed here.

The miscibility gap test is automatically used during stepping (see ADVANCED_OPTIONS) if a phase has two or more composition sets.

The miscibility gap test means that you can start calculating from high temperatures in a steel where the MC carbide is not stable. During the calculation, the MC carbide first becomes metastable with a composition different from the metallic FCC phase and later also becomes stable.

See Console Mode example tcex30A.

Mixed_Scheil (M)

For Scheil-Gulliver simulations it is recommended you use the SCHEIL module.

This is an advanced stepping calculation designed for the Extended Scheil-Gulliver Approach (partial-equilibrium transformations) to simulate alloy solidifications with back diffusion of one or more fast-diffusing interstitial components (such as C, N, O, S, etc.) in solid phases is performed. It also will consider BCC-->FCC phase transformation (practically for steels) along the alloy solidification process.

To ensure a successful stepping calculation of mixed Scheil-Gulliver simulation of solidification process of a defined alloy system with a certain initial overall composition, it is important to note the following:

- For solution phases with possibility of miscibility gap existence, you have appropriately added the necessary composition set(s);
- You have already set the temperature condition as the stepping SET_AXIS_VARIABLE command, with minimum and maximum temperature points as well as an appropriate s temperature step for the cooling process).
- There must be a composition condition for each of the back diffusion components (i.e. fast-diffusing interstitial components, such as C, N and/or other elements) that are already defined in terms of mole-fraction or mass-fraction, e.g. `X(C)` and `W(N)`. Otherwise, a stepping calculation with this option can fail.
- An initial equilibrium in which the LIQUID mixture phase is the only stable must be calculated. This is why it is good to start with a relatively high temperature condition for the initial equilibrium calculation. It is always necessary to reject or suspend the GAS mixture phase (if it exists) before the C-E and STEP commands, to avoid its formation along with LIQUID.
- In cases where fast-diffusing interstitial components are specified as back diffusion components, you can choose to `allow BCC>FCC` phase transformation (practically for steels) during the alloy solidification process.

These are the prompts for this option:

```
Fast diffusing components: <Fast diffusion interstitial(s)>
```

Specify one or more interstitial component(s) as the back diffusion component(s).

- If there is only one fast-diffusing interstitial component (e.g. C or N), type its name;
- If there are two or more fast-diffusing interstitial components (e.g. C, N and S), always type the names on the same line at once (separated by an empty space in between, e.g. C N S);
- If there is no fast-diffusing interstitial component to be considered, type NONE to ignore back diffusion entirely, meaning a normal Scheil-Gulliver simulation is performed.

Such specified back diffusion interstitial component(s) must be appropriately defined according to the phase constitution definitions of some major alloy solution phases (e.g. FCC, BCC, HCP, etc.). These are located on the interstitial/vacancy sublattices in such alloy solution phases; otherwise, such a Scheil-Gulliver simulation may not make sense at all.

```
Allow BCC -> FCC ? /Y/:
```

By default the BCC-->FCC phase transformation is allowed. This is usually a typical phenomenon along the cooling processes of steels/Fe-alloys.

During the calculation the simulated solidification path, including the locally-equilibrated phase assemblage (region), captured temperature condition (T in K), remaining liquid phase (NL, mole fraction), overall formed solid phases (NS, mole fraction) and latent heat formation (NH, J/mol) along the cooling process are shown after the information on starting temperature point of the alloy solidification process, e.g.

```
 Solidification starts at 1743.15 K
  Phase Region from  1.744150E+03 for:     LIQUID
  Phase Region from  1.742525E+03 for:
    LIQUID
    FCC_A1#1
      1742.5250         0.9960         0.0040        -1.1824
      1742.4000         0.9795         0.0205      -202.1585   . . . . . .
  Phase Region from  1.733150E+03 for:
    LIQUID
    BCC_A2
    FCC_A1#1
      1733.1500         0.3294         0.6707     -8032.6240
      1733.0250         0.3237         0.6763     -8095.1490   . . . . . .
```

After a successful calculation, you can go to the POST module to manually define and plot property diagrams for the alloy solidification process according to the chosen Scheil-Gulliver model, or to impose existing relevant experimental information or other types of calculated solidification results [e.g. Scheil-Gulliver simulation with or without considering fast-diffusing interstitial component(s), full-equilibrium approach, or Diffusion Module (DICTRA)-type simulation with moving-boundary conditions] onto the same plotted property diagrams. Normally, the solidus temperature (`T` in Celsius) is set as one of the axis variables (usually as Y-axis in most cases), while the other plotted quantity on the other axis can be the amount of overall formed solid alloy phases (`NS` in mole-fraction or `BS` in mass-fraction), the amount of remaining liquid phase (`NL` in mole-fraction or `BL` in mass fraction), the heat of latent along the solidification process (`NH` in J/mol or `BH` in J/gram), among many other properties in the solidified alloy phases or in the whole alloy system.

T-zero (T)

See Console Mode example 41.

This advanced option allows a stepping calculation of the so-called T0 (T-zero) line in a diffusionless transformation (where two specific partially-equilibrated phases have the same Gibbs energy) along a composition variable which has already set as the stepping variable with SET_AXIS_VARIABLE.

The temperature condition cannot be set as the stepping variable if you want to make a STEP T-ZERO calculation.

Prior to performing the step T0 command sequence, and to ensure a successful calculation of T0 line between two specific phases after an initial equilibrium calculation in the current system, it is sometimes recommended to make a single T0 point calculation using ADVANCED_OPTIONS → T-ZERO.

Specify these prompts:

```
Name of first phase: <Phase A>
Name of second phase: <Phase B>
```

The names of the target phases, for which the Gibbs energies equal to each other at each point on the T0 line, must be entered.

During the calculation, the T0 values are shown after the corresponding scanned conditions (of the stepping composition variable), e.g.

```
Phase Region from  1.000000E-01 for:
   BCC_A2
   FCC_A1
1.000000E-01        940.24
9.250000E-02        941.20
. . . . . .
2.500000E-03        977.61
7.500000E-09        979.34
Phase Region from  1.000000E-01 for:
  BCC_A2
  FCC_A1
1.000000E-01        940.24
1.075000E-01        939.62
. . . . . .
2.950000E-01       1084.87
 3.000000E-01       1080.99
```

After a successful calculation, you can go to the POST module to plot the T0 line against the stepping composition variable or another varying axis, or to impose the calculated T0 line onto a normal phase diagram [normally plotted as a `T-X` isopleth].

Paraequilibrium (P)

See Console Mode examples 42 and 43.

This is an advanced option. Select `P` to calculate the paraequilibrium state between two specific phases (the *paraequilibrium lines*). It allows a stepping calculation of paraequilibrium lines where the chemical potential for one or more interstitial components (that are considered as back diffusion elements, such as C and N) but not for the other (s) in two partially equilibrated phases are equal.

More than one interstitial component can be treated as fast-diffusion species (such as C, N, O, S, etc., as individual or combined) in a paraequilibrium stepping calculation.

The composition condition for the interstitial components cannot be set as the stepping variable if you want to make this calculation.

To ensure a successful stepping calculation of paraequilibrium states between two specific phases in a defined alloy system, it is important to first make a starting-point equilibrium calculation with an initial overall composition in the current system. However, it is unnecessary to obtain an equilibrium in which either one or both of the target phases is stable.

The initial overall composition must have a reasonable setting for the desired paraequilibrium calculation for the two target phases. This is especially true where there is more than one interstitial component to be considered in the paraequilibrium state, because different interstitial components (for example C and N combined) may have significant different behaviours as partitioning into different structured phases; otherwise, for one chosen interstitial component the initial overall composition is OK for the paraequilibrium calculation between the specified two phases, but for other chosen interstitial component(s) it might be impossible to calculate the paraequilibrium state.

Always check if the chosen `phaseA` and `phaseB` have the exact same definition of elements and if the chosen interstitial components are all in the vacancy sublattice sites of the two phases; otherwise the program cannot find the paraequilibrium state (as it is impossible to correctly calculate u-fractions).

Always have a comprehensive understanding of the normal phase diagram for the currently investigated system, so that you make the appropriate choice of the phase pair and staring bulk composition for the system.

Always set the status of the chosen interstitial components as SPECIAL using the command:

```
CHANGE_STATUS COMPONENT <interstitial component> = SPECIAL
```

By doing this, you get a clear picture on u-fractions of various substitutional and interstitial components, which are different from the overall composition in the system. The SPECIAL status means that specified component(s) are not included in summations for mole or mass fractions. Therefore, all the composition variables plotted from the paraequilibrium calculations are u-fraction related quantities.

Always make a single-point paraequilibrium calculation by the command-sequence of ADVANCED_OPTIONS → PARAEQUILIBRIUM, prior to performing this STEP → PARAEQUILIBRIUM command-sequence, although this might not be always necessary for some systems.

With this stepping calculation specify the following:

```
Name of first phase: <Phase A>
Name of second phase: <Phase B>
```

The names of the two target phases `A` and `B`, between which the paraequilibrium states establish, must be typed at the above two prompts subsequently or on the same (first) line at once (separated by an empty space, e.g. `FCC BCC`, `FCC#2 M23C6`).

It is important to understand that this is the calculation of a paraequilibrium state between the two specified phases.

Particularly, there are these issues to consider:

1. Both chosen phases must have similar interstitial/vacancy sublattices where the fast-diffusion interstitial component(s) occupy.
2. The choice on the target phase pair must be reasonable for the defined system and specified initial overall composition.
3. Both target phases should have phase constitution definitions that cover all the defined substitutional and interstitial components of the current alloy system; or
4. It is impossible to calculate the paraequilibrium state between the target phase pairs with given interstitial component(s) in the currently defined system.

```
Fast diffusing component: /C/: <Interstitial component(s)>
Fast diffusing component: /None/: <Interstitial component(s)>
```

The name(s) of the fast-diffusing interstitial component(s) (`C` as the default single component) must be given either one by one at each of the above prompts subsequently or in a combination (separated by an empty space in between, e.g. `C N S`) at the same (first) prompt; otherwise, press <Enter> key to start the paraequilibrium line stepping-calculation.

Note the following:

Such specified fast-diffusing interstitial component(s) must be appropriately defined according to the phase constitution definitions of the two selected phases: These must be located on the interstitial/vacancy sublattices in both chosen phases.

If there is only one fast-diffusing component which is carbon, press <Enter> to accept the default value (C) at the first prompt; if the single fast-diffusing interstitial component is another element (e.g. N), appropriately type interstitial component the name at the first prompt;

If there are two or more fast-diffusing components (e.g. C and N), type their names at the above prompts subsequently or at the same (first) prompt (separated by an empty space, such as C N);

To finish the input of fast-diffusing elements, accept NONE at a repeated prompt;

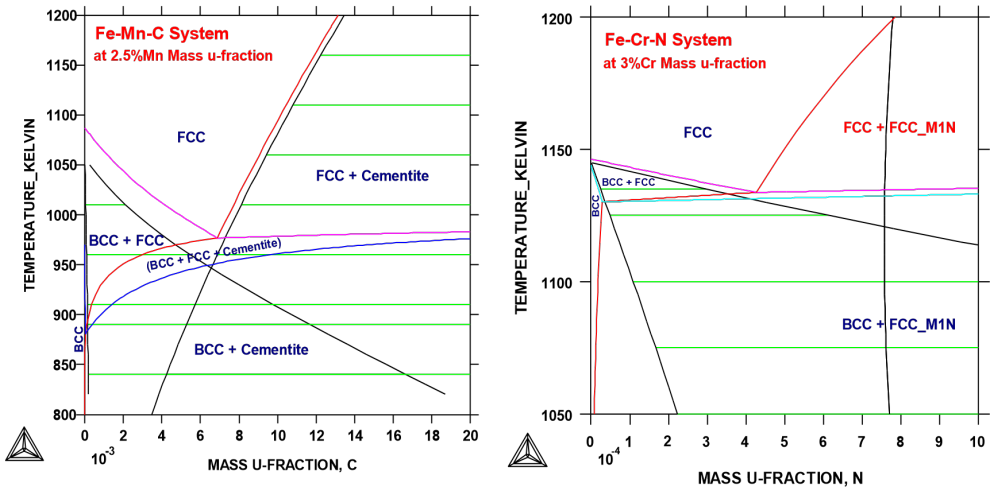
If NONE or a non-existing component name is typed at the first prompt, it means no back diffusion is to be considered, and the para-equilibrium calculation is thus cancelled entirely.

During the STEP → PARAEQUILIBRIUM calculation procedure, the calculated paraequilibrium states include the:

- corresponding stepping conditions (e.g. temperature in K, or the stepping composition variable of the matrix component or of one of substitutional components) which has already set as the stepping variable by the SET_AXIS_VAR command);
- amounts of the phase A in mole number [i.e. NP(phaseA)];
- amounts of the phase B in mole number [i.e. NP(phaseB)];
- contents of the interstitial component(s) in the phase A expressed in u-fractions [i.e. u-f(phaseA,component(s))];
- contents of the interstitial component(s) in the phase B expressed in u-fractions [i.e. u-f(phaseB,component(s))];
- LNACR(component) value(s) for the interstitial(s).

After a successful STEP → PARAEQUILIBRIUM calculation, you can go to the POST module to plot a paraequilibrium phase diagram, or to impose the calculated paraequilibrium states onto a normal phase diagram [normally plotted as a T-X isopleth with one of the considered interstitial component(s) as the x-axis variable].

However, the stepping calculation procedure for the currently specified paraequilibrium states between the two specified phases may find difficulties at some steps due to some possible numerical problems (normally regarding to the u-fractions of the interstitial components under some composition ranges), or it may completely fails. In the latter case, it implies that the chosen target phase pair may be unreasonable for the defined alloy system or for the defined initial overall composition, or one or both phases may have inappropriate phase constitution definitions regarding the specified interstitial component(s) and substitutional components. Then, you must either modify the settings of initial overall composition or specify the reasonable target phase pair with an appropriate choice of the fast diffusion interstitials in the defined alloy system.



The figure shows the plot of a paraequilibrium calculation of isopleths: Formation of para-pearlite in two Fe-based alloys, with equilibrium results appended.

The calculated paraequilibrium phase boundaries (black lines) are shown with tie-lines (in green-colour). In the Fe-2.5Mn-C alloy system, C is considered as fast diffusing interstitial component in the BCC+FCC and FCC+Cementite paraequilibrium stepping calculations; while in the Fe-3Cr-N alloy system, N is treated as fast diffusing interstitial components in the BCC+FCC and FCC+FCC_ M1N (i.e. FCC#1+FCC#2) paraequilibrium stepping calculations.

During a STEP calculation, the value of the stepping axis variable for each calculated equilibrium is listed and also the set of stable phases.

You can terminate the mapping of a line by pressing a single <Ctrl-A> (Windows) or <Ctrl-C> (Linux). This can be useful in order to stop a longish calculation without losing what is already calculated.

If there is any convergence problem in finding a stable solution at any stage during a calculation procedure enforced by a STEP_WITH_OPTIONS command-sequence, this message displays:

```
Convergence problems, increasing smallest site-fraction from 1.00E-30  to hardware
precision 2.00E-14. You can restore using SET-NUMERICAL-LIMITS
```

This implies that smallest site fraction in the current POLY3 workspace is automatically increased from the default value `1.00E-30` to the hardware-dependent precision (under Linux, as `2.00E-14`). For other subsequent POLY-module calculation in the current TC run, you can use the POLY command SET_NUMERICAL_LIMITS to restore or reset the smallest site fraction to the previous or another preferred value, as well as to reset other numerical limits.

Complex miscibility gaps of various solution phases are automatically detected during a stepping calculation, and two or more composition sets for each of such solution phases are automatically generated as well, through an automatic Global Minimization Test procedure (by specifying a `Global Test Interval` value and confirming the `Automatically add initial equilibria` in the ADVANCED_OPTION STEP_AND_MAP command-sequence). As a particular case, such an automatic Global Minimization Test ensures that you can now start calculating from high temperatures in an austenitic steel (metallic FCC_A1 solution phase) where the MC carbides/nitrides/carbonitrides (i.e. the C-/N-rich sides of the FCC_A1 miscibility-gap, often (while not always) being referred to as `FCC_A1#2`, `FCC_A1#3`, etc.) are not stable, and during the MAP command the MC carbides/nitrides/carbonitrides may first become metastable with a composition different from the metallic FCC_A1 phase and later also stable.

Occasionally, it may be necessary to have a specified increment other than the default value for the defined stepping axis-variable, in order to calculate/plot a smoother property diagram.

To get a complete property diagram, sometimes (especially in some earlier Thermo-Calc versions) it may also be required to have more than one starting equilibrium-points (under another starting equilibrium condition), and repeat the stepping calculation over the same stepping axis-variable range (while without over-writing the same POLY3 workspaces via a SAVE_WORKSPACE command). However, using the current STEP procedure such a requirement become less necessary.

TABULATE

This command is available for a table entered in either the POLY or POST module.

For any entered table, this command gives a table of values from equilibria calculated with a STEP command.

Unlike the TAB module's command (also called TABULATE) it is not possible to plot columns from the tabulated tables. For this use normal POST commands.

Syntax	TABULATE
Prompts	`Name: <Name of a table entered in either POLY or POST>` Specify a table name that is entered in either the POLY or POST module.
	`Output on screen or file /Screen/:` Specify a file name if you want to save on a file the table values along the defined STEP calculation, or press <Enter> if want to see the table values displayed.

ADD_COMMENT

This command is for the Gibbs Energy System (GES) module.

Use the ADD_COMMENT command to add a comment or make notes about parameters.

AMEND_ELEMENT_DATA

This command is for the Gibbs Energy System (GES) module.

The data for an element (in the SER, the Stable Element Reference, state) can be changed by this command. It should only be used for the elements that do not have any data in the database because the element data available in the database is set by the database-developer for the purpose of internal consistency. Except for the mass, the other values have no influence on the calculations.

Syntax	AMEND_ELEMENT_DATA
Prompts	`Element name: <Element name>` Specify the name of the element for which you want to change the data.
	`New stable element reference /ABCD/: <Name of ser>` Press <Enter> to accept the default `SER` or specify a new SER for the element. Important: The default name should not be changed if this data is retrieved from a database. This name is used when parameters for a phase are listed and the database assumes that the stable element reference is the same as in the database. Only if the element's data have not been fetched from a database, e.g. entered manually, can you enter a new SER.
	`New atomic mass /xx.xxxx/: <yyyyyy>` Press <Enter> to accept the default atomic mass or specify a new value for the element. The atomic mass of the element is given in g/mol.
	`New h(298.15)-h(0) /xxx.xxx/: <yyyyy>` Press <Enter> to accept the default H(298.15)-H(0) or specify a new value for the element. H(298.15)-H(0) is the enthalpy difference between 298.15 K and 0 K for the element in its SER state.
	`New s(298.15) /xx.xxxx/: <yyyyy>` Press <Enter> to accept the default S(298.15) or specify a new value for the element. S(298.15) is the absolute value of the entropy at 298.15 K for the element in its SER state.
	`Default element reference state symbol index /#/: <index>` The index only changes the symbol, not any value. Normally the index is set correctly by the database. Only when manually entering data, you must set the index to get the correct symbol. Specify an index for the default listing parameters (symbol), or press <Enter> to accept the pre-set index. 0 is for `G`, 1 is for `H298` and 2 is for `H0`. The index is to define the symbol printed in parameter listings. The symbol can be: • `G` the data are referred to Gibbs energy at a variable temperature (also called *lattice stability*). • `H298` the data are referred to the enthalpy of the element at 298.15 K and 1 bar.

Syntax	AMEND_ELEMENT_DATA
	• `H0` is the same as `H298` but at the temperature 0 K.

AMEND_PARAMETER

This command is for the Gibbs Energy System (GES) module.

There is also a PARROT module command with the same name.

Use this command to interactively change/amend the temperature-pressure function of a parameter. This is useful to correct typing errors because the old function is made available on the terminal for interactive editing.

About the ENTER_PARAMETER Command

Syntax	AMEND_PARAMETER

Prompts	`Parameter: <Parameter name>`
	Specify a correct parameter name. If a parameter name is not acceptable or you only press <Enter>, the error message displays:
	`Error, please re-enter each part separately`
	The program prompts for separate input for each part for a parameter name.

	`Identifier (/X/): <G or L, or TC, or BM, or V0 or VA or VC or VK>` Specify one of these legal identifiers as described for ENTER_PARAMETER.
	`Phase name (/ABCD/): <Phase name>` Specify the phase name.
	`Constituent (in sublattice # /ABC/): <Species name>` Specify the constituent name.
	`Interacting constituent (in sublattice # /xyz/): <Species name>` Specify the interacting constituent name: If there is no interacting constituent, press <Enter>.
	`Interacting constituent (in sublattice # /xyz/): <Species name>` If there are more than one interacting constituents, specify them; otherwise press <Enter>.
	`Degree /#/: <Degree>` Specify a numerical number as the degree of the phase parameter.

	After the parameter name is specified correctly, the program lists its current definition (either present in the database or defined by the ENTER_PARAMETER command), such as:
	`L(PHASE2,AL,MG;1)=`
	`298.15<T<2000.00: +5000`
	`2000.00<T<4500.00: +4500`
	`4500.00<T<6000.00: +4000`
	Then you are prompted to change the parameter definition, as shown below:

Syntax	AMEND_PARAMETER

	`Do you want to change the number of ranges /No/:`
	
	Enter Y if you want to change the number of ranges for the chosen function, or change some of the temperature limits in the definition. Then retype both the low/high temperature limits and functions.
	
	If you do not want to change the number of ranges but want to change the function(s) in one or more ranges, press <Enter> to accept the default N, then the whole definition of the chosen parameter in all ranges (if any) is listed on screen, such as:
	
	`DIFFERENT FUNCTIONS IN THESE RANGES`
	`298.15<T<2000.00`
	`2000.00<T<4500.00`
	`4500.00<T<6000.00`
	
	The prompt is given:
	
	`Do you want to change range limits /No/:`
	
	If there is more than one range, this question is prompted press <Enter>.

	`Range number (0 to exit) /0/: <Range number>` If the function of a parameter is different in two or more temperature ranges, you must specify the range of the function of which you want to amend. Or press <Enter> or type `0` to exit this command without making any changes.

	`Function:`
	
	The previous function is available for editing. The editing is performed within the general subroutine FOOLED, as described in AMEND_SYMBOL. This routine prompts as follows:
	
	`1:+:>`
	
	The prompt consists of the current position in the string and the character at that position between colons, (::).
	
	Commands
	
	These commands can be given:
	
	• Help: `?`
	• Move CP to last or first character: `<+/-> A`
	• Delete characters from CP: `<+-#characters> D`
	• Exit: `E`
	• Find: `<#occurrences> F<string>@`
	• Insert: `I<string>@`
	• Move: `<+-#positions> M`
	• Restore string: `R`
	• Substitute: `S<OLD>@<NEW>@`
	• Type string: `T`
	
	Where CP denotes the current position in a string, # means number of, @ is a terminator of an input or search string.

Syntax	AMEND_PARAMETER
	When the string is typed the character at the current position is replaced by an underscore _. To finish the editing of the current function, type `E` at the prompt.

Solution Models in the GIBBS (GES) Module

AMEND_PHASE_DESCRIPTION

The AMEND_PHASE_DESCRIPTION command is used to specify/amend phase descriptions if a phase has a miscibility gap, uses a special excess energy model, or has a specific additional contribution to its Gibbs energy, for example.

This topic outlines the application of each option and includes important information about each command.

There are many solution models implemented in the GIBBS module (type `INFO MODELS` to see details about various thermodynamic models). However, these are switched on and handled differently via various GIBBS routines/commands:

- The first models the non-ideality as excess parts, i.e. by amending the phase's EXCESS_ MODEL and/or TERNARY_EXTRAPOLAT models.
- The second models the non-ideality as ADDITIONAL parts, i.e. by amending the phase's other subjects in this command, e.g. MAGNETIC_ORDERING for the Magnetic Ordering Model, DISORDERED_PART for the CVM Approach in modeling chemical ordering/disordering phenomenon, QUASICHEM_IONIC for using a quasi-chemical entropy term for an ionic two-sublattice liquid solution phase, QUASICHEM_FACT00 or QUASICHEM_IRSID for describing a substitutional liquid solution phase, DEBYE_HUCKEL for the DHLL/SIT Model in describing a dilute aqueous solution phase, etc.
- The third implements the model entirely or partially into the GIBBS module and related database(s), such as for the electrostatic contribution in an AQUEOUS solution phase by the Complete Revised_HKF Model, the Murngham Model, Birch-Murngham Model or Generalized PVT Model for high-pressure/temperature volume contribution in a solid or liquid phase, the SUPERFLUID Model for the non-ideal EOS and non-ideal mixing in a gaseous mixture.

NEW_CONSTITUENT

Use this if you want to add a new constituent to a phase. It is illegal to add new constituents to an ionic two-sublattice liquid phase.

RENAME_PHASE

Use this to change the names of some specific phases. For example, a phase called *FE3O4_S* may be better named *Magnetite* to help identify it during the calculations and postprocessing. This is also a way to delete a phase by hiding it under a new name.

SITE_RATIOS

Use this to change the number of sites (i.e. the stoichiometric coefficients of various sublattices) in a sublattice phase.

COMPOSITION_SETS

Use this for solution phases that may have miscibility gap(s). However, this is less important today and often unnecessary to define additional composition set(s), since the implemented Global Minimization Technique can usually detect and add such composition set(s) in an automatic manner where it is really necessary during equilibrium calculations (of single-points, stepping or mapping).

MAJOR_CONSTITUENT

Use this to set major constituent(s) on each sublattice in each composition set for a solution phase. This is useful to make calculations converge faster because it may simplify giving start values when calculating the equilibrium as those phases with miscibility gaps should have different major constituents for each composition set. The databases often set major constituents for several phases automatically when data are retrieved.

FRACTION_LIMITS

Use this to limit the application range (in terms of mole-fractions of all the involved elements) of a particular solution phase. This is useful to avoid automatic creations (enforced by the Global Minimization Technique) of additional composition sets for some solution phases (such as AQUEOUS solutions or dilute Fe-based liquid mixtures) of which the used models [e.g. the `SIT Model` or the `Complete Revised_HKF Model` for AQUEOUS solution, or the modified dilute solution parameters (plus a quadratic term, according to Hillert (1986) based on the SigworthElliot Model [1974Sig] for Fe-rich liquid mixture] cannot be appropriately applied on a full scale.

Globally set the composition limits (in terms of mole fractions of various elements) in a specific solution phase, so that whenever the program finds a potential phase composition or a new composition set of possible miscibility gap(s) but that is out of this globally-set composition range, the program automatically ignores such a phase composition in an equilibrium calculation. This can be done either permanently inside a database (by enforcing this option for amending the phase-description of the solution phase) or temporarily within the GIBBS module (by using this phase-description amendment option).

This is important for solution phases for which the thermodynamic models and assessed data for the phases are for specific composition ranges, for example, the AQUEOUS phase in the TCAQ/PAQ and AQS/PAQS databases is only applicable for H_2O-dominant aqueous solution phase.

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

Specify the low and high mole-fraction limits for each of the elements possibly available within the considered phase (in the currently defined system, or in a certain database). Do this for all the possible elements (defined in the phase) in a single AMEND_PHASE_DESCRIPTION FRACTION_LIMITS command-sequence, for example:

```
TYPE_DEFINITION R GES AM_PH_DES FE_LIQUID FRACTION_LIMITS Fe 0 0.6
    Ag 0 0.01 Al 0 0.05 Ca 0 0.05 Co 0 0.01 Cr 0 0.01
    Cu 0 0.02 Mg 0 0.05 Mn 0 0.05 Mo 0 0.05 Nb 0 0.05
    Ni 0 0.05 Pb 0 0.05 Si 0 0.10 Sn 0 0.02 Ti 0 0.05
U 0 0.01 V 0 0.02 W 0 0.02 Zr 0 0.03
    B 0 0.01 C 0 0.01 H 0 0.01 N 0 0.01 O 0 0.01
P 0 0.01 S 0 0.01 !
```

NEVER_DISORDER

The contribution from the disordered phase are added to the ordered phase. Use this to avoid entering several parameters to the ordered phase in the database. Instead it can be expressed as one parameter in the disordered phase.

The reference [2018Sun] section 2.3.4 has extensive details about this model. Original references from [1994Dup] and [2000Ans].

DISORDERED_PART

This command is needed for the special treatment of chemically-ordered phases where the contributions from the disordered state are described by a phase without ordering sublattices (the disordered phase name must be specified).

Several checks are made that the ordered and disordered phases are compatible (sublattices, sites and constituents). A link is then created between the phases, and the disordered phase is hidden from application programs. The Gibbs energy for the ordered phase also includes the Gibbs energy for the disordered phase.

Phases which can have an order/disorder transformation have parameters split on two phases and are referred to as the *two phase* description in the GIBBS module. One of them has sublattices for chemical ordering, the other one represents the disordered state. Normally, the ordered BCC and FCC or HCP phases may have either 2 or 4 substitutional sublattice (plus one additional interstitial site), that are handled by the Two Substitutional-Sublattice Ordering Model or Four Substitutional-Sublattice Ordering Model, respectively.

Two phase means that the *ordered* phase has parameters that describe the ordering. The *disordered* phase has all parameters for the reference state and those for describing the disordered phase. The ordered phase may occur only is some systems whereas the disordered phase may occur frequently, typical examples are the disordered FCC and BCC which may become ordered as L12 or B2 in certain systems. In order to treat multicomponent systems where some subsystems have ordering it would be necessary to transform all parameters of BCC into a B2 model.

The parameters describing the disordered phase are not changed but the Gibbs Energy system is informed that the Gibbs Energy for the two phases should be added.

The method used calculates the Gibbs Energy of a two phase model with two or four substitutional sublattices for ordering.

$$G_m = G_m^{ord}(y_i', y_i') + G_m^{dis}(x_i) - G_m^{ord}(y_i' = x_i, y_i'' = x_i)$$

The mole fractions *x*i are calculated from the site fractions *y*i. The last term means that the contribution from Gmord in a disordered state (same site fraction, equal to the mole fraction, on both sublattices) is subtracted. The effect of this is that the parameters in the ordered phase have no contribution to the disordered state.

MAGNETIC_ORDERING

Change the magnetic ordering parameter for a certain phase with magnetic ordering contribution, in terms of its anti-ferromagnetic factor. By default this is –1 for BCC phase and –3 for all other phases (FCC, HCP, etc.). The fraction value of the total enthalpy (due to short-range ordering above the magnetic transition temperature) is by default 0.40 for BCC phase and 0.28 for all other phases (FCC, HCP, etc.).

EXCESS_MODEL

See example tcex52.

Use this to change the default Excess Model (for interaction energies) from the default (REDLICH-KISTER_MUGGIANU). The model handles the excess interaction energies in a solution phase is chosen from:

- REDLICH-KISTER_MUGGIANU: for binary (R-K) & ternary (R-K-M) interactions
- REDLICH-KISTER_KOHLER: for binary (R-K) & ternary (R-K-K) interactions
- FLORY-HUGGINS POLYMER MODEL: for interactions in a polymer mixture phase (F-H)
- MIXED-EXCESS-MODELS: (R-K default) for mixed binary excess model (R-K, Legendre & Polynom) of a substitutional solution phase
- HKF: for interaction in an AQUEOUS solution phase (HKF)
- PITZER: for interaction in an AQUEOUS solution phase (PIT)
- CENTRAL_ATOM_MODEL: for interaction in a liquid slag solution phase (C-A-M)

For extrapolations of excess energies from related binary systems to ternary or higher-order systems, the Redlich-Kister binary excess interaction parameters may be extrapolated with

either a Muggianu extension (i.e. the default REDLICH-KISTER_MUGGIANU model) and a Kohler extension (i.e. the alternative REDLICH-KISTER_KOHLER model), where there is no ternary, quaternary or higher-order interaction parameter.

The REDLICHKISTER_KOHLER model is implemented only for ternary systems.

The MIXED-EXCESS-MODELS option works only for a substitutional phase with no sublattice (such as the metallic LIQUID phase) and it can be used to invoke asymmetrical simple or Legendre polynomial as binary excess energy models in addition to the default symmetrical Redlich-Kister model for the chosen pair of constituents in a substitutional phase with no sublattice. Asymmetrical here means that the power series depend only on one of the constituents, for example with expansions based on the [1-2*X(B)] term rather than [X(A)X(B)].

Binary interaction parameters for such a pair of constituents must be entered prior to turning on the non-default Legendre or Polynom models.

TERNARY_EXTRAPOLAT

See example tcex52.

Use this to change the extrapolation method from the default REDLICH-KISTER_MUGGIANU to another extrapolation model. This method extrapolates from binary to ternary (and higher-order) excess interaction parameters in a solution phase and is chosen from:

- MUGGIANU for Muggianu Extrapolation from R-K parameters
- TOOP-KOHLER for Toop-Kohler Extrapolation Model
- KOHLER-ALL for Kohler Extrapolation Model
- MUGGIANU_RESTOR for Muggianu-Restor Extrapolation Model

Only when all the relevant binary excess energies in the current solution phase are treated by the default Redlich-Kister Model (i.e. the Mixed-Excess-Model should have not been used), the MUGGIANU_RESTOR method for ternary extrapolations is equivalent to the Redlich-Kister_Muggianu Model, or the KOHLER-ALL method to the RedlichKister_Kohler Model.

The default ternary extrapolation method MUGGIANU_RESTOR applies to a solution phase as a whole, whatever the binary excess model(s) enforced to each of individual binary pairs in the phase. In case that all the binary pairs in the phase use the default binary excess model REDLICH-KISTER, then the ternary extrapolation method becomes the so-called Redlich-Kister_Muggianu Model (in short as R-K-M), for extrapolations from binary parameters to ternary (and higher-order) excess energy terms; when no ternary L parameter is entered for that, such a default R-K-M Model is always used.

The KOHLER-ALL ternary extrapolation method can be turned on also for a solution phase as a whole, whatever the binary excess model(s) enforced to each of individual binary pairs in the phase. In case that all the binary pairs in the phase use the default binary excess model.

REDLICH-KISTER, then the ternary extrapolation method becomes the so-called Redlich-Kister_Kohler Model (in short as R-K-K), for extrapolations from binary parameters to ternary (and higher-order) excess energy terms; when no ternary L parameter is entered for that, such an R-K-K Model is used.

The TOOP-KOHLER ternary extrapolation method is applied in a special way: for a specific ternary system (e.g. A-B-C) in a solution phase, specify which two constituents as the so-called Kohler constituents and the remaining constituent as the so-called Toop constituent on a given sublattice. If for the A-B-C ternary system you have specified A and B, or B and A, as the Kohler constituents (entered as the basis constituent and first interacting constituent) and C as the Toop constituent, only the A-B binary interaction parameters are used in accordance with the Kohler ternary extrapolation formula for A-B-C ternary interaction, while any other binary interaction parameters involving the Toop species C (i.e. of A-C and B-C binaries) are used in line with the Toop-Kohler ternary extrapolation formula (for the A-C-B and B-C-A ternary interactions).

DEBYE_HUCKEL

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

To use the DHLL (Debye-Hückel Limiting Law) model and SIT (Specific Ionic Interaction Theory) model for a dilute AQUEOUS solution phase, switch the DEBYE_HUCKEL part on, and it removes previously set (if any) ADDITIONAL part on the non-ideality for the chosen AQUEOUS phase.

HKF_ELECTROSTATIC

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

To use the hypothetical electrostatic contribution for the chosen phase (it must be an aqueous solution phase using the Complete Revised_HKF Model). It removes previously set (if any) ADDITIONAL part on the non-ideality for the chosen AQUEOUS solution phase.

QUASICHEM_IONIC

To use the Quasichemical-Ionic model for the chosen liquid phase, you must have already entered/retrieved a liquid phase as an ionic two-sublattice liquid solution phase (normally, that is the IONIC_LIQ phase), and then use this amending option to switch QUASICHEM_IONIC on. It creates a completely new liquid solution phase [namely the QUAS_IONIC phase which uses the Quasichemical Model for the entropy, according to Mats Hillert [2001Hil], while the original IONIC_LIQ phase remains in the system and is not changed by this option.

QUASICHEM_FACT00

See example tcex49.

To use the Quasichemical Model developed by Kongoli et al. [1998Kon], you must have entered/retrieved a liquid phase using a normal substitutional liquid model with specified associates or species (on a single lattice site), and then turn on the option QUASICHEM_FACT00. This removes the previously-set (if any) ADDITIONAL part on the non-ideality for the chosen liquid phase.

QUASICHEM_IRSID

To use the Kapoor-Frohberg-Gaye Quasichemical Cell Model (i.e. the Quasichemical Model developed by ISRID, France) for a liquid SLAG solution phase, you can use a normal liquid model with specified associates or species.

GLASS_TRANSITION

To use the special model for glass transition of a liquid phase. It removes previously set (if any) ADDITIONAL part on the non-ideality for the chosen liquid phase.

REMOVE_ADDITION

To remove all the selected ADDITIONAL part from the Gibbs energy description for the chosen phase. If preferred, set a specific phase-status bit for a phase, use the PHASE_BITS option as long you know the restrict meaning of each part of a phase- status bits.

DEFAULT_STABLE

Set phases as default-stable, which helps you to have a better guess of which phases that should be stable at the first calculation.

AMEND_PHASE_DESCRIPTION

This command is for the Gibbs Energy System (GES) module.

Also see Solution Models in the GIBBS (GES) Module for detailed information about this command and its options.

Specify/amend phase descriptions if a phase has a miscibility gap, uses a special excess energy model, or has a specific additional contribution to its Gibbs energy, for example.

Syntax	AMEND_PHASE_DESCRIPTION

Prompts	`Phase name: <Phase name>`
	Specify the name of the phase.
	`Amend what /Composition_Set/: <Subject>`
	Several subjects for the phase can be amended but most often this command is used to enter two or more composition sets for a phase. If a phase has a miscibility gap it is necessary to have two composition sets, one for each possible composition that can be stable simultaneously.
	Enter a question mark at the prompt to get a list of all possibly amended subjects for a phase.

	There are no additional prompts for DEBYE_HUCKEL, HKF_ELECTROSTATIC, GLASS_TRANSITION, QUASICHEM_FACT00, QUASICHEM_ISRID, REMOVE_ADDITION, and DEFAULT_STABLE.
`RENAME_PHASE`	`New phase name /ABCD/: <Phase name>` Give a new phase name for the chosen phase, or press <Enter> to keep the default shown.
`Site_ratios`	`Sites in first sublattice /XX/ : <YY> Sites in second sublattice /XX/ : <YY>` Specify the site numbers for each of the prompted sublattices for the current phase. Press <Enter> to accept the previous definitions.

`New_ constituent`	`Sublattice /#/: <Sublattice number>`
	Specify the sublattice where the new constituents are located.
	`Species: <Species name>`
	Give a valid species name.

`Composition_ sets`	`New highest set number /#/: <Set number n>` The default value (#) is usually one higher than the current value. All phases have initially one composition set. If a lower value (i.e. lower than the default one) is given, that specific composition sets are deleted.

Syntax	AMEND_PHASE_DESCRIPTION
	You cannot take away the first composition set. `Major constituent(s) for sublattice #: /AB/: <Major constituent(s)>` Specify the new major constituent(s) for the sublattice #, or press <Enter> to accept the default which was automatically set according to the specified composition set of the phase. This prompt is repeated for all available sublattices in the chosen phase. The major constituents in each sublattice can be given. This may simplify giving start values when calculating the equilibrium as phases with miscibility gaps should have different major constituents for each composition set.

`Major_ constituent`	`Composition set /1/: <Composition set number>`
	
	Give the composition set (digit number) for the chosen phase, or press <Enter> if you want to set major constituents for the specified composition set.
	
	`Major constituent(s) for sublattice #: /AB/: <Major constituent(s)>`
	
	Specify the new major constituent(s) for the sublattice #, or press <Enter> to accept the default which is automatically set according to the specified composition set of the phase.
	
	This prompt is repeated for all available sublattices in the chosen phase for the specified composition set.
	
	The major constituents in each sublattice can be specified. This is useful in order to make calculations converge faster and more easily (because it may simplify giving start values when calculating the equilibrium as those phases with miscibility gaps should have different major constituents for each composition set). The databases often set major constituents for several phases automatically when data are retrieved.

`Fraction_ limits`	`Element : <el1>`
	`Low fraction limit /0/ : <Appropriate low limit>`
	`High fraction limit /1/ : <Appropriate high limit >`
	`Element : <el2>`
	`Low fraction limit /0/ : <Appropriate low limit>`
	`High fraction limit /1/ : <Appropriate high limit>`
	`Element : <eln>`
	`Low fraction limit /0/ : <Appropriate low limit>`
	`High fraction limit /1/ : <Appropriate high limit >`

`Magnetic_ ordering`	`The antiferromagnetic factor /XX/: <YY>`
	
	Specify the anti-ferromagnetic factor for the chosen phase. This should be –1 for BCC phase and –3 for all other phases (FCC, HCP, etc.).
	
	`Short range order fraction of the enthalpy /XX/: <YY>`
	
	The magnetic ordering is a second-order transformation and part of the enthalpy due to this transformation is due to short-range order. This value is the fraction of the total enthalpy that is due to short-range ordering above the magnetic transition temperature.
	
	The default value (xx) is 0.40 for BCC phase, and 0.28 for all other phases (FCC, HCP, etc.).

Syntax	AMEND_PHASE_DESCRIPTION
Never_disorder	`Never disorder: <Phase name>` Give the phase name to never disorder. The contribution from the disordered phase are added to the ordered phase. Use this to avoid entering several parameters to the ordered phase in the database. Instead it can be expressed as one parameter in the disordered phase.
Disordered_part	`Disordered phase name: <Phase name>` Give the disordered phase name for which there is no ordering sublattice.

Excess_model	`Model name /ABCDEFG/: <Model name>`
	The default model is the pre-set model for the solution phase, normally the REDLICH-KISTER_MUGGIANU model, or choose another model for the phase to be amended:
	• REDLICH-KISTER_MUGGIANU
	• REDLICH-KISTER_KOHLER
	• FLORY-HUGGINS POLYMER MODEL
	• MIXED-EXCESS-MODELS (R-K default)
	• HKF
	• PITZER
	• CENTRAL_ATOM_MODEL
	The MIXED-EXCESS-MODELS option has sub-options:
	`First (the independent) constituent: <Constituent name>`
	`Second (the dependent) constituent: <Constituent name>`
	Specify the binary pair of constituents in the current substitutional solution phase (the first one as the so-called independent constituent, and the second one as the dependent constituent), for which you wish to change the binary excess model from the default REDLICH-KISTER model to another model (LEGENDRE or POLYNOM).
	You are prompted with the first sub-option (i.e. `First (the independent) constituent` after you have specified the desired binary Excess model type. To make further changes of binary excess model for other specific binary pairs in the current substitutional solution phase, press <Enter> (implying that there are no more changes of binary excess model for all other possibly-remaining binary pairs that shall still use the default REDLICH-KISTER model).
	`Excess model type: /Legendre/: <Desired binary excess model type>`
	For the currently-specified binary pair, choose one the legal binary excess models: LEGENDRE, POLYNOM or REDLICH-KISTER. If the default binary excess model REDLICH-KISTER is used for a certain binary pair, you can either specify the model name (or in short as R-K) or press <Enter>. After this sub-option, it returns to the first sub-option *First (the independent) constituent:* either for further change(s) of binary excess model of any other binary pair(s) or for termination (by pressing <Enter>) in the MIXED-EXCESS-MODELS option.

Syntax	AMEND_PHASE_DESCRIPTION

`Ternary_ extrapolat`	`Extrapolation method: /Toop-Kohler/: <Ternary model>`
	Choose a ternary extrapolation model for the current solution phase:
	• TOOP-KOHLER for Toop-Kohler Extrapolation Model
	• KOHLER-ALL for Kohler Extrapolation Model
	• MUGGIANU_RESTOR for Muggianu-Restor Extrapolation Model
	The TOOP-KOHLER option further prompts:
	`Constituent in sublattice #: <Basis constituent name>`
	`First interaction constituent: <Interacting constituent name>`
	`Toop constituent: <Toop constituent name>`
	Specify the so-called Kohler constituents (entered as the basis constituent and first interacting constituent) and Toop constituent on a given sublattice in the current solution phase.

`Quasichem_ ionic`	To use the Quasichemical Model for the chosen liquid phase, you must first enter it as an ionic liquid phase, and then use this amending option. It creates a completely new phase, the original IONIC_LIQUID phase remains in the system and is not changed. `Number of bonds/atom /2/: <Number of bonds per atom>` Specify the Z value (number of bonds per atom).
`Status_bits`	Correct the phase status bits. It is important to fully understand this command before using it: `New status word (in hexadecimal) /04204000/: <New status bits>` LIST_STATUS Normally, these should never be changed in this way, because such phase status bits are automatically set on when all the phase descriptions (predefined in databases and amended in the GIBBS module) are defined properly. The only exceptions are for the Kapoor-Frohberg-Gaye cell model for liquid SLAG solution phase, which can be set only as 04208000; and for the complete Revised HKF AQUEOUS solution model, which can be set as `02084000`.

AMEND_SYMBOL

This command is for the Gibbs Energy System (GES) module.

The same command is also available for the PARROT module.

Use the AMEND_SYMBOL command to interactively calculate the current values of a function or table (predefined by the switched database or previously entered with ENTER_SYMBOL) at the current temperature and pressure condition, and also possible to modify the definitions of variables or functions.

The current values of the temperature and pressure used to calculate the functions or tables are the ones listed with LIST_STATUS. There is no way to change the current temperature and pressure values interactively.

To modify the definitions of entered symbols (variable, functions or parameters), the performance of this command is slightly different one from another, as described below:

- For variables, the values can be changed.
- For functions the low and high temperature limits in various ranges (if any), as well the expressions, can be changed.
- For parameters the low and high temperature limits in various ranges (if any), as well the expressions, can be changed.

Syntax	AMEND_SYMBOL

Prompts	`Name: <Symbol name>`
	Specify the name of an entered symbol.
	For tables and functions (or parameters which are treated as functions after these are entered by the ENTER_SYMBOL command with the `Parameter` keyword, but not by the ENTER_PARAMETER command), after the symbol name is specified here, the program automatically calculates the values under the current temperature and pressure conditions, and lists the current values, such as:
	`FUNCTION VALUE 2.52500000E+01`
	`TABLE VALUE 1.56000000E+02`
	For variables and functions (or parameters), there are additional prompts and depend on the symbol type.

	For a variable, its current value is displayed, and you can change it to a new value: `Value /Current value/: <New value>` For a function (or a parameter entered as a symbol):

Syntax	AMEND_SYMBOL

	`Do you want to change the number of ranges /No/:`
	
	Enter Y to change the number of ranges for the function, or change some of the temperature limits in the definition, then retype both the low/high temperature limits and functions (see all the remaining details in the ENTER_SYMBOL command.
	
	If you do not want to change it, press <Enter>. The definition of the chosen function in all ranges (if any) is listed, for example:
	
	`DIFFERENT FUNCTIONS IN THESE RANGES`
	`298.15<T<2000.00`
	`2000.00<T<4500.00`
	`4500.00<T<6000.00`
	
	and this message displays:
	
	`Do you want to change range limits /No/:`
	
	If a function is different in two or more temperature ranges, you must specify the range of the function of which you want to amend. Or press <Enter> or type `0` to exit this command without making any change.

	`Range number (0 to exit) /0/: <Range number>`
	`Function:`
	
	The previous function is available for editing. The editing is performed within the general subroutine FOOLED. This routine prompts as follows:
	
	`1:+:>`
	
	The prompt consists of the current position in the string and the character at that position between colons (::).
	
	Commands
	
	These commands can be given:
	
	• Help: `?`
	• Move CP to last or first character: `<+/-> A`
	• Delete characters from CP: `<+-#characters> D`
	• Exit: `E`
	• Find: `<#occurrences> F<string>@`
	• Insert: `I<string>@`
	• Move: `<+-#positions> M`
	• Restore string: `R`
	• Substitute: `S<OLD>@<NEW>@`
	• Type string: `T`
	
	Where CP denotes the current position in a string, # means number of, @ is a terminator of an input or search string.

Syntax	AMEND_SYMBOL

When the string is typed the character at the current position is replaced by an underscore _.

To finish the editing of the current function, type `E` at the prompt.

CHANGE_STATUS

This command is for the Gibbs Energy System (GES) module.

The status of an element or species or phase can be either ENTERED or SUSPENDED. The suspended status can be either implicit or explicit. The implicitly suspended status can be set e.g. for a species if any of the elements in its chemical formula is explicitly suspended. A species that is implicitly suspended becomes entered automatically if all its elements are set entered. After this command, a message shows which elements/species/phases are suspended or restored (entered). Consequently, the status bits for the specified elements or species or phases are changed, as listed with LIST_STATUS.

Syntax	CHANGE_STATUS
Prompts	`For Element, Species or Phase /Species/: <Keyword>` Specify the keyword (element, species or phase).
	`Suspend /Y/:` By default the status is changed from ENTERED to SUSPENDED. If an element is suspended all species with this element become implicitly SUSPENDED too. A phase may become implicitly suspended if all its constituents or all constituents in a sublattice are suspended.
	`List of elements/species/phases: <Name of elements or species or phases>` Specify the names or indices of those elements or species or phases that shall become suspended or active. For names, these should be separated by a space and terminated with a semicolon (;) or an empty line. For indices it is possible to give a range by separating two numbers by a hyphen (-). The list should be terminated by a semicolon (;). Example: `5 1 7-12 FE;`

ENTER_ELEMENT

Specify a system interactively. The program searches the currently switched or preset database for data for the given elements. The data for the elements in the database are the:

- mass in g/mol
- name of the Selected Element Reference State (SER) which normally is the stable phase for the element at 298.15 K
- enthalpy difference for the element in the SER state at 298.15 K and zero K
- absolute entropy for the element in the SER state at 298.15 K.

The two predefined elements, i.e. electrons and vacancies, have the chemical symbols `/-` and `VA`, respectively. Initially, these are suspended but can be entered either by this command or CHANGE_STATUS.

If an aqueous solution phase is involved, in the GIBBS module you enter a special aqueous electron called, ZE. This is specially designed for appropriately calculating the standard electric potential in the aqueous solution system.

Syntax	ENTER_ELEMENT
Prompt	`Element name: <Element name>` Specify several elements on one line. The name of an element is its chemical symbol. The chemical symbols must be separated by spaces. Fictitious element names are legal but naturally no data are found in the database for them.
	An element name (maximum 2 characters) can either have its first letter in upper and the second (if any) in lower case (i.e. Lower Case Mode) or both letters can be in upper or lower case (i.e. Upper Case Mode). The Upper or Lower Case Mode is selected by the command REINITIATE, which removes all data, and should be executed before any other command.

ENTER_FUNCTION

This command is available with the GES and TAB modules.

Use the ENTER_FUNCTION command to define a new thermodynamic function to be included in the sixth column of tabular output. The last entered function is listed in the 6th column of all tables, and can be plotted (if choosing the Plot Column value 6) in all graphs, for all subsequently tabulated substances or reactions.

Syntax	ENTER_FUNCTION
Prompt	`Name: <Name>` `Function: <Definition>`
	A limited number of state variables, G, H, S, T, P, V and H298 can be used in the function definition. For example, -(G-H)/T can be defined as a function which is identical to S for a substance or ΔS for a reaction, G+T*S-P*V can be defined as a function which is U (internal energy) for a substance or ΔU (internal energy change) for a reaction.
Options	`Name`of the function (maximum 8 characters) and `Definition` of the function. A long function can be typed over several lines. A function should be terminated by a semicolon (;) or an empty line.

Example of ENTER_FUNCTION

For the pure substance Fe (using the SSUB database), by entering a function as `G+T*S-P*V`, the following table is obtained by typing <Enter> in the prompt `Output file /Screen/:`, and the figure by typing `6` in the prompt `Plot column /2/:`

```
TAB: ENTER-FUNCTION
Name: InEnergy
Function: G+T*S-P*V;
TAB: TABULATE_SUBSTANCE
Substance (phase): Fe
Pressure /100000/: <Enter>
Low temperature limit /298.15/: <Enter>
High temperature limit /2000/: <Enter>
Step in temperature /100/: <Enter>
Output file /try1/: try2
Graphical output? /Y/: <Enter>
Plot column? /2/: 6
```

This gives the following output:

```
O U T P U T F R O M T H E R M O - C A L C

 Column 6: InEnergy G+T*S-P*V

 Phase : FE_S                      Pressure :     100000.00

 Specie: FE

ENTER_PARAMETER

This command is for the Gibbs Energy System (GES) module.

There is also a PARROT module command with the same name.

About the ENTER_PARAMETER Command

Use this command to enter TP-function(s) for a specific parameter for a phase interactively with this command. If there is already a parameter expression defined (for this parameter), that is deleted and replaced with newly entered one.

The entered TP-Function(s) for the parameter can be changed later with the command AMEND_PARAMETER.

Syntax	ENTER_PARAMETER

Prompts	`Parameter: <Parameter name>`
	As explained in About the ENTER_PARAMETER Command, specify a correct and complete `Parameter Name`, which should contain all the necessary parts of the general form:
	`<Identifier>(<Phase>,<Constituent array>;<Digit>)`
	If a parameter name is not acceptable or <Enter>, is pressed, a message displays:
	`*** Error, please re-enter each part separately`
	and you are prompted for input for each required part for a parameter name.

Options	**Description or Information**
`Identifier`	`Identifier (/X/): <G or L, or TC, or BM, or V0 or VA or VC or VK>` If this command is used one or more times, the previous value on this prompt is set as default. Press <Enter> for the same type identifier or specify a new type.
`Phase name`	`Phase name (/ABCD/): <Phase name>` Each parameter is valid for a specific phase only. The name of that phase must be supplied (maximum 24 characters). The name can be abbreviated.
`Constituent`	`Constituent (in sublattice # /ABC/): <Species name>` A parameter is identified by the constituents on a specified sublattice site of the given phase, the stoichiometric coefficients of which are multiplied with the parameter. The name of the constituent can be abbreviated. It is the species name, not the stoichiometric formula required here. If this command is used one or more times, the previous value on this prompt is set as default. Accept it by pressing <Enter> if the constituent is the same, or specify a new species name.

Syntax	ENTER_PARAMETER
Interacting constituent	For phases with several sublattices, the program asks for one constituent in each sublattice. `Interacting constituent (in sublattice # /XYZ/): <Species name>` If this command is used one or more times, the previous value on this prompt is set as default. Press <Enter> to accept it if the constituent is the same, or specify a new species name. To cancel the default value of the interacting constituent type `NONE` or the name of another constituent. This question is repeated until all the interested interacting constituent(s) on a specific sublattice in the phase are specified, and finally an <Enter> is enforced.
Degree	`Degree /#/: <Degree>` Degree is model-dependent. Specify an integer number (a value from 0 through 9) as the degree of composition-dependent interaction contribution for the phase parameter. This is valid for excess energy (`L`), Curie temperature (`TC`) and Bohr magneton number (`BMAGN`), as well as for volume-related parameters (`V0`, `VA`, `VC` or `VK`). For binary interaction parameters, the degree is usually the power in the Redlich-Kister expression. For ternary interaction parameters, it is usually the Hillert ternary index. For a standard `G` parameter for a pure component (end-member) its degree should be always 0 and this prompt should not display.

Phase parameter	After this prompt, the program echoes on the screen the full TP-Function of the phase parameter.
	`Low temperature limit /298.15/: <Lowest temperature limit in K>`
	Specify the lowest temperature limit (in Kelvin), or the lowest-pressure limit (in Pascal but entered as a negative number), for the current TP-Function.
	`Function: <Definition for a function>`
	A TP-Function consists of terms in T and P.
	`& <Continuation of the definition for the current function>`
	Continuation of a TP-Function definition.
	`High temperature limit /6000/: <High temperature limit in K>`
	Specify the high temperature limit (in Kelvin), or the high-pressure limit (in Pascal; only if the *lowest limit* is entered as a negative number) for the current TP-Function.
	`Any more ranges? /N/:`
	Enter Y for more function(s) or N to end this command.

About the ENTER_PHASE Command

ENTER_PHASE

With the command ENTER_PHASE, the phase name, phase-type, sublattice number, and constituents or constituent array(s) for the phase are entered into the GIBBS workspaces.

About Phase Names

A thermochemical system must have at least one phase (which is a homogeneous part of the system with a uniform composition and structure). In the GIBBS module, any number of phases can be entered for a system and for each phase there must be a description of how its Gibbs energy varies with temperature, pressure and composition. A phase has a large amount of data connected to it, e.g. it starts with a phase name:

- It may be treated as a special phase-type;
- It may have structural information about sublattice(s), etc.,
- There must be a list of constituents (for a substitutional phase with no sublattice) or of constituent arrays (for a sublattice phase);
- There may be basic information on what kind of EXCESS_MODEL (polynomial expression) is used to describe the binary, ternary and/or higher-order interactions between constituents;
- There may be so-called Additional contributions to the Gibbs energy of the phase from special physical phenomena, e.g. magnetic ordering, hypothetical electrostatic interaction, and so forth;
- There must exist all the parameters required for the descriptions of thermochemical properties (i.e. `G` terms for standard Gibbs energies, and `L` terms for binary, ternary or higher-order interaction excess energies) and of some special physical properties (e.g. the Curie temperature `TC` and Bohr magneton number `BMAGN` (or `BM`) for magnetic ordering, `V0-VA-VC-VK` parameters for volume contributions, Born functions for hypothetical electrostatic interaction in an aqueous solution phase) stored in connection with the phase.

About Phase Type Code

A G phase (gaseous mixture) or an A phase (aqueous solution) is usually treated as a substitutional phase without sublattice, and that an L phase (ordinary liquid solution) is normally (but not always) modeled as a substitutional phase without sublattice, too.

The F and B phase-types are useful for ordered FCC (or HCP) and BCC solution phases handled by the so-called Four Substitutional-Sublattice Ordering Model, which always requires that the solution phase must have four sublattices for substitutional ordering and can additionally have an interstitial sublattice.

For ordered FCC or HCP phases, these four substitutional sublattices represent four corners of the regular tetrahedron on these lattices all of which are the nearest neighbours. A *Normal 4-Sublattice Model* requires that all the G parameters for each of end-members with the same elements but distributed on different sites be given separately. However, as these corners are identical lattice points, the phase-type option F means that the G parameters need be given only once. The possible permutations are handled automatically. To be more clarified: An A-B binary solution phase (with the element A locates on one sublattice site and B on three sublattice sites) treated by the Normal 4-Sublattice Model has to have 4 G parameters for 4 end-members, i.e. G(phase,A:B:B:B), G(phase,B:A:B:B), G(phase,B:B:A:B) and G(phase,B:B:B:A), because of that in the general case these G parameters can be different from each other. But for the FCC and HCP orderings, these are identical and thus all G parameters of such end-members need be given only once, and the possible permutations are then automatically handled by the GIBBS module. This significantly simplifies the usage of this model (*Four Substitutional-Sublattice Ordering Model*) in multicomponent alloys.

There are restrictions on the excess parameters allowed with the phase-type option `F`. You can only have excess parameters of these types:

```
L(phase,A,B:*:*:*;0…9)
L(phase,A,B:C,D:*:*;0…9)
```

The asterisk * means that the interaction parameter is independent on the constituents on its corresponding sublattice. No ternary interaction parameters (i.e. with three elements on one sublattice site) are allowed. The reason for this restriction is that it would be too complicated to handle all possible permutations. In the current *Four Substitutional Sublattice Ordering Model*, the binary interaction between A and B atoms is thus independent of the constituents on the other sublattices, where there are many other parameters to model the composition-dependence of the Gibbs energy (both in the ordered and disordered parts of the phase). The model for these ordered phases are always partitioned in a disordered part (with a single substitutional sublattice) and an ordered part (with four substitutional sublattices for ordering).

For ordered BCC phases, the phase-type option B means the same thing but the situation is more complicated, as the 4-sublattice ordering phase represents an irregular tetrahedron with two pairs of sites that are next nearest neighbours. Thus, for an A-B binary solution phase (with the element A locates on two sublattice site and B on other two sublattice sites) treated by the Normal 4-Sublattice Model, the end-member described by the G(phase,A:A:B:B) term has four nearest neighbour bonds between A and B atoms, whereas the end-member described by the G(phase,A:B:A:B) term has two nearest neighbour bonds between A and B atoms and two next nearest neighbour bonds

The first end-member (described by the G(phase,A:A:B:B) term) represents B2- ordering and the second (described by the G(phase,A:B:A:B) term) stands for B32-ordering. There are two permutations of the G(phase,A:A:B:B) term and four permutations of the G(phase,A:B:A:B) term, automatically conducted in the Four Substitutional-Sublattice Ordering Model. And there are also two kinds of reciprocal interaction parameters, i.e.

```
L(phase,A,B:C,D:*:*;0…9) L(phase,A,B:*:C,D:*;0…9)
```

An advanced feature with the phase-type options F and B is that a composition set that represents the solution phase has a suffix (indicating that it is really as an ordered or disordered phase) that is automatically added to its phase name in some listings of equilibrium calculations (when performing either single-point or stepping or mapping calculations, and when plotting the calculated property diagrams or phase diagrams). Such suffix indications can be:

- `_L12` or `_L10` for ordered FCC
- `_A1` for disordered FCC
- `_B2`, `_B32`, `_D03` or `_L21` for ordered BCC
- `_A2` for disordered BCC
- `_D019` and `_B19` for ordered HCP
- `_A3` for disordered HCP

Solution Phase	Suffix for Disordered Phase	Suffix for Ordered Phase
FCC PHASE	PHASE_A1	PHASE_L12
		PHASE_L10
BCC PHASE	PHASE_A2	PHASE_B2
		PHASE_B32
		PHASE_D03
		PHASE_L21

Solution Phase	Suffix for Disordered Phase	Suffix for Ordered Phase
HCP PHASE	PHASE_A3	PHASE_D019
		PHASE_B19

ENTER_PHASE

See About the ENTER_PHASE Command for details about the phase-type and other prompts.

With this command, the phase name, phase-type, sublattice number, and constituents or constituent array(s) for the phase are entered into the GIBBS workspaces. However, for the remaining parts of thermodynamic descriptions (i.e. thermochemical and physical parameters, excess model, and possibly additional contribution term) for the phase, the GIBBS commands ENTER_PARAMETER and AMEND_PHASE_DESCRIPTION, should be used sequentially.

Normally, data for a system are retrieved from the preset database after the elements and species are specified. This is automatically done through GET_DATA. In some cases, specify a phase interactively.

Syntax	**ENTER_PHASE**
Options	**Description and Information**

`Phase name`	`Name of phase: <Phase name>`
	The phase name is any string starting with a letter and containing only letters, digits or the underscore character. The phase name must be unique.
	`Type code: <Phase-type code>`
	The `Phase-type code` must be specified for the phase if it is not an ordinary solution phase. Press <Enter> if the phase is ordinary.

`Phase-type`	
`G`	Gaseous mixture phase. There may only exist one gas phase in a system.
`A`	Aqueous solution phase.
`L`	Liquid solution phase but not `A` (aqueous) or `Y` (ionic liquid)
`Y`	Ionic liquid solution phase (that is specially treated by the Ionic Two Sublattice Liquid Model).
`I`	A phase with charged species but not `G` (gaseous), `A` (aqueous) or `Y` (ionic liquid).
`F`	An ordered FCC or HCP solution phase with four substitutional sublattices (additionally, such a phase can also have an interstitial sublattice).
`B`	An ordered BCC solution phase with four substitutional sublattices (additionally, such a phase can also have an interstitial sublattice).

Syntax	ENTER_PHASE

Sublattice number	`Number of sublattices /1/: <Sublattice number>`
	
	Phases with stoichiometric constraints usually have two or more sublattices. On each sublattice one or more species can be entered as constituents. The number of sublattices must not exceed 10. Substitutional phases with no sublattices are treated as phases with one sublattice.
	
	`Number of sites on sublattice # /1/: <Site number>`
	
	For phases with sublattices, the ratio of the sites on each sublattice (donated with #) must be given. The program asks for values for all sublattices (by repeating this question for each sublattice), but these may have a common factor extracted. It is recommended to use integer numbers as sites if possible. For substitutional phases with no sublattices, this question does not show up.

Constituents	`Name of constituent: <Constituent name(s)>`
	
	For each sublattice specify at least one species as constituent. Several constituents can be given consequently (on the repeated prompt) or on the same line separated by a space. This question is repeated till pressing <Enter> or giving a semi-colon (;), meaning that the list of constituents is terminated by (;) or an empty line.
	
	`Will you add constituents later /N/:`
	
	For Y add other constituents to the phase by specifying new components in e.g. an ENTER_ PARAMETER command.
	
	If illegal constituents are used, you get a message e.g. when parameters are entered.
	
	`Do you want a list of possible parameters /N/:`
	
	Enter Y for a list of all possible parameters up to the fifth interaction order for the entered phase.

ENTER_SPECIES

Specify a species from the already entered elements. The stoichiometry of the species is the chemical formula of the species. For each species, its name and chemical formula must be given.

All elements are automatically entered simultaneously as species. The constituents of a phase must be species, but there is no thermochemical data associated with the species except as constituents of a phase.

Syntax	ENTER_SPECIES
	`Species name: <Species name>` Enter a unique species name. This is usually its chemical formula but it can be any string which starts with a letter and contains only letters or digits. Parenthesis `()` and an underscore _ are permitted. The combination /- or /+ used to denote charge.

Prompt	**Species Names Examples**
	`NACL2, FE2O3, FEO3/2, FE1O1.5, CA.5MG.5SI1O3,`
	`AL1H1O1_Al(OH) , AL1H1O1_HAlO, C2H4O3_124TRIOXOLANE, NA+, SIO4-4, H1/+1, H1O1/-1, AGC2N2-1.`
	The species name can be used to separate isomers with the same stoichiometry, e.g. `C2H2Cl2, (CHCl)2_cis, (CHCl)2_trans, CH2_CCl2.`

	`Stoichiometry /Species name/: <Chemical formula>` The elements in the chemical formula are normally separated by stoichiometric numbers. Neither parenthesis () nor an underscore _ is allowed in the chemical formula, while the special combination /- or /+ can be used. In upper case mode (see REINITIATE), the stoichiometric number unity can be excluded only if the element symbol consists of two letters. In lower case mode, the element must be typed with the first letter in UPPER case and the second in lower, and it is thus possible to distinguish CO (carbon monoxide) from Co (cobalt) without any stoichiometry number. All elements in a species must be entered prior to entering the species.

ENTER_SYMBOL

This command is for the Gibbs Energy System (GES) module.

There are also a POLY and POST module commands with the same name. However, symbols entered in the GIBBS module are not the same symbols as defined in the POLY and POST modules.

In the GIBBS module, a symbol can be used to represent a numeric quantity (e.g. a *variable*), a *function*, or a *table*. The entered symbol (with a symbol name of maximum eight characters) can be used later when parameters are entered, and this is a flexible way to manipulate thermodynamic functions. Symbols are especially useful if the same function or table is used in several thermochemical parameters. A *parameter* symbol is used to assign the values of phase parameters (which are defined with the command ENTER_PARAMETER) to specific characterized symbols. If you want to define a constant quantity, enter it as a simple function with a constant value in all (temperature) ranges.

The symbols entered in the GIBBS module can also be listed and used in the PARROT module (for data optimization) where you can use the GIBBS-entered symbols (variables, functions or parameters) to define parameters that shall be optimized.

See example 44 for an example of using variables and functions.

Syntax	ENTER_SYMBOL

Prompt	`Variable, function, table or parameter? /Function/: <Keyword>`
	The keyword can be a variable, function, table or parameter.
	• `Variables` are similar to functions because these can also be expressions of state variables. It is possible to enter a variable with a new expression anytime.
	• `Functions` are expressions of state variables or other functions.
	• `Tables` are used for listing results. A table consists of a list of any number of state variables, functions or variables.
	• `Parameter` symbols are used to assign the values of phase parameters (which are defined by the command ENTER_PARAMETER) to specific characterized symbols. If the phase parameter is not defined yet, the parameter symbol is assigned zero or a symbol which is valued as zero. In this way it is easy to refer to entered phase parameters in further defining other phase parameters.
	`Name: <Name of the symbol>`
	Each symbol has a unique name that must start with a letter and can have maximum 8 characters.
	The following prompts are based on the type of symbol.

Syntax	ENTER_SYMBOL
`Variable` symbol	`Value: <Numeric value of a variable>` Only a constant numeric value, not an expression, is accepted.

`Function` symbol	Enter the lower-temperature limit, the expression, an upper-temperature limit and if there is another expression above this upper limit:
	`Low temperature limit /298.15/: <Lowest temperature limit in K>`
	Specify the lowest-temperature limit, below which its (first) expression is not applicable. The default lowest limit of all kinds of data is 298.15 K.
	If a negative number is given as the lowest-temperature limit, it is assumed that there are breakpoints in pressure for this function; in such a case, it is interpreted as the lowest-pressure limit (in Pascal), and the other limits in the current function are also taken as pressure limit values (in Pascal).
	The temperature/pressure limits for the functions are checked during calculations. An indicator is set if the actual temperature/pressure condition is below the lowest temperature/pressure limit or above the highest temperature/pressure limit; and in such a case, an extrapolation is conducted using the TP-FUNCTIONS valid in the nearest temperature/pressure range.
	`Function: <Definition for a TP-function>`
	A TP-Function consists of terms in T and P. The expression is a FORTRAN-like expression and operators +, -, *, = and ** can be used (** only with integer powers). Unary-functions LN or LOG (both for natural logarithm) and EXP (for exponential) can also be used. An expression can be continued on more than one line. A PT-function must be terminated by a semicolon (;) or an empty line. No more than 78 characters can be written on a line. If this is not sufficient space on one line, press <Enter> and continue on the next line. The program prompts with an ampersand `&` when a continuation is expected.
	 A function can have several temperature ranges, and a different expression (i.e. a TP-Function) for each region; if required, a single function can have up to ten different temperature ranges (and thus have up to ten different TP-Functions).
	This question is repeated if the current function has more than one expression (TPFunction) in various temperature ranges [or pressure ranges; only if the *lowest limit* is entered as a negative number)].
	`& <Continuation of the definition for the current TP-Function>`
	This is for a continuation of the definition for the current TP-Function. The ampersand & means that you can continue to write the function on the new line if one line is not enough for the current TP-Function. If you are finished the current TP-Function, press <Enter> again.
	`High temperature limit /6000/: <High temperature limit in K>`
	For a TP-Function, specify the high-temperature limit, above which its current expression is not applicable. The default high-temperature limit for all kinds of data is always 6000 K.
	This question is repeated if the function has more than one expression (TPFunction) in various temperature ranges.

Syntax	ENTER_SYMBOL
	All the temperature limits for the presently-be-entered TP-Function MUST be in an increasing order; otherwise the whole function is given a single value of zero. If a negative number is given as the lowest-temperature limit, it is interpreted as the low-pressure limit (in Pascal), and the high-temperature limit is also taken as the high-pressure limit (in Pascal) for the current TP-Function. The high-temperature/pressure limit for the current applicable expression (TPFunction) is the low temperature/pressure limit for the next range if several ranges are needed to describe the temperature/pressure-dependence of this function. The temperature/pressure limits for the functions are checked during calculations. An indicator is set if the actual temperature/pressure condition is below the lowest temperature/pressure limit or above the highest temperature/pressure limit; and in such a case, an extrapolation is conducted using the TP-Function valid in the nearest temperature/pressure range. `Any more ranges /N/: <Y or N>` Answer `N` to finish the definition of the current function. If `Y` the program asks for a new function valid above the last high temperature limit and below a new high temperature limit. The maximum number of temperature ranges is 10. Important note: Make sure that the function and its first derivatives are continuous across break points.

`Table` symbol	Specify the low and high temperature limits, temperature step and tabled value at each specified temperature:
	
	`Low temperature limit /298.15/: <Low temperature limit in K>`
	
	The lowest temperature where the table has a value.
	
	`High temperature limit /6000/: <High temperature limit in K>`
	
	The highest temperature where the table has a value.
	
	`Step in temperature /100/: <Temperature step>`
	
	The step in temperature between each value in the table. This step must be constant for the whole table. If a table cannot be described with a single step it must be divided into several tables for different temperature ranges. The upper and lower limits are truncated to give reasonable values where the table values must be specified.
	
	`Table value at XX /YY/: <Table value>`
	
	The value of the table at the specified temperature (`xx`) must be given. The default value (`yy`) is the last value.

`Parameter` symbol	Input the correct name of a phase parameter (including its identifier, phase name, constituent and interacting constituent(s) in various sublattices (if exist), and degree of the parameter. Most of the settings are the same as in the ENTER_PARAMETER command or the Function symbol prompts above. `Parameter: <Parameter name>` Specify a correct and complete parameter name, which should contain all the necessary parts of the general form:

Syntax	ENTER_SYMBOL

```
<Identifier>(<Phase>,<Constituent array>;<Digit>)
```

If a parameter name is not acceptable or <Enter> is pressed, this error message displays:

```
*** Error, please re-enter each part separately
```

The program prompts for separate input for each required part for a parameter name.

```
Identifier (/X/): <G or L, or TC, or BM, or V0 or VA or VC or VK>
```

Specify one of these types of legal identifiers.

```
Phase name (/abcd/): <Phase name>
```

Specify the phase name.

```
Constituent (in sublattice # /abc/): <Species name>
```

Specify the constituent name on the specified sublattice site of the given phase.

```
Interacting constituent (in sublattice # /XYZ/): <Species name>
```

Specify the interacting constituent name on the specified sublattice site of the given phase; if there is no interacting constituent, press <Enter>.

```
Interacting constituent (in sublattice # /XYZ/): <Species name>
```

If there is more than one interacting constituent on the specified sublattice site of the given phase, specify them; otherwise press <Enter>.

```
Degree /#/: <Degree>
```

Specify an integer number (a value from 0 through 9) as the degree for the phase parameter.

```
Low temperature limit /298.15/: <Lowest temperature limit in K>
```

Specify the lowest-temperature limit (in Kelvin), or the lowest-pressure limit (in Pascal but entered as a negative number), for the current TP-Function.

```
Function: <Definition for a function>
```

Specify the desired TP-Function for the current temperature range (or current pressure range; only if the *lowest limit* is entered as a negative number).

```
& <Continuation of the definition for the current TP-function>
```

Specify the desired TP-Function continuation for the current temperature range (or current pressure range; only if the lowest limit is entered as a negative number).

```
High temperature limit /6000/: <High temperature limit in K>
```

Specify the high-temperature limit (in Kelvin), or the high-pressure limit (in Pascal; only if the lowest limit is entered as a negative number) for the current TP Function.

```
Any more ranges /N/:
```

LIST_CONSTITUTION

This command is for the Gibbs Energy System (GES) module.

Syntax	LIST_CONSTITUTION
	List all the constitutions (as site-fractions) for all the phases in the defined system.

This is mainly for software managers. There are no commands in the GIBBS monitor to set the constitution.

LIST_DATA

This command is for the Gibbs Energy System (GES) module.

Use the LIST_DATA command to retrieve and then list the data included with a database in the DATA module or directly entered in the GIBBS module. All data for the current system that is defined within the current GIBBS workspace is written in a readable manner in the output file. If no output file is specified, by default the data displays on screen. The behavior of this command differs slightly based on whether you are using GES6 (the default) or GES5.

For encrypted commercial databases you may not be able to use this command to list any retrieved data. However, it can be used to list some basic definitions (such as phase models and phase-constituents) retrieved from an encrypted database, as well as all the references related to original assessments (but not thermodynamic parameters) for the currently-defined system.

Command Prompts

After entering the command in the console, the following prompt options are available.

Syntax	LIST_DATA
Prompts	`Output to screen or file /Screen/: <File name>` Specify the name of a file in which the data shall be written in a readable manner. The default value is the screen (by pressing <Enter>).
	`Options?: <Option(s)>` Choose one or several of the following options for output. See the section about the differences between GES5 and GES6 output for these options. • `N` the output is written as a user database format. For GES6, and only for an unencrypted database, this option has a subcommand that allows filtering of phase parameters with respect to the property type e.g., to include only volume parameters and/or viscosity parameters in the output. • The subprompt is `Property type /All/`. Choose `All` or enter the property type. The valid alternatives (when available) are: V0, VA, VB, VC, VK, TC, TN, BM, MQ, MF,

Syntax	LIST_DATA
	DQ, DF, OQ, VS, G, L, THCD, ELRS, ESPD, VISC, GD, SIGM or XI • `P` the output is written as a macro file for future input. This is useful for creating `*SETUP` files for data assessments. • `S` the symbols are suppressed. • `R` the references for the parameters are listed (only for some databases in which references are available) • `L` the output is written suitable for a LaTeX preprocessor.

Output Differences: GES5 vs GES6

GES6 is a re-write and new implementation of the Gibbs Energy System module of Thermo-Calc and it is the default engine in Thermo-Calc. As of 2026b, TQ-Interface has access to it but GES5 is the default. GES5 continues to be available and works in the background of the program where necessary. The main purpose of GES6 is to support faster development and access to new features, which are then often only available in GES6.

As required you can set Thermo-Calc to use GES5 instead of the default with the SET_GES_VERSION command. The application may also automatically and temporarily switch to GES5 when a database is being used that is not compatible with GES6.

For both GES5 and GES6 and when you enter `P`, `S`, `R`, or `L`, the output data consists of a list of all elements and the data followed by a list of all phases and the data associated with each phase. The thermochemical parameters listed for each phase are always in SI units.

For GES6, and only when option `N`, `P`, or nothing is entered, the output data consists of a list of all elements and the data followed by a list of all phase definitions and the data associated with the phases, sorted by system. In these modes, and only for unencrypted databases, there is a subcommand that allows filtering of phase parameters with respect to the property type e.g., to include only volume parameters and/or viscosity parameters in the output.

Other differences between the GES5 and GES6 output are related to the output as shown below.

Output	*GES5*	*GES6*
Parameters	Includes implicitly defined zero-valued thermodynamic parameters	Only contains parameters that are actually defined in the database
Automatically suspended phases	Does not include	Includes
References	Contains references of functions and parameters with generic names, such as "REF123"	Retains the original reference names that are used in the database

LIST_PARAMETER

This command is for the Gibbs Energy System (GES) module.

There is also a PARROT module command with the same name.

Use the LIST_PARAMETER command to list the TP-function(s) of a specific parameter for a phase. You must supply the name of the phase parameter:

```
The parameter name: <Identifier>(<Phase>,<Constituent array>;<Digit>)
```

For encrypted commercial databases, you may not be able to use this command to list any retrieved parameter.

Syntax	LIST_PARAMETER

Prompts	`Parameter: <Parameter name>`
	Specify a correct and complete parameter name, which should contain all the necessary parts of the general form: <identifier>(<phase>,<constituent array>;<digit>)
	See About the ENTER_PARAMETER Command to learn how to define the parameter name.
	If a parameter name is not acceptable or <Enter> is pressed, an error message displays:
	`*** Error, please re-enter each part separately`
	The program prompts for separate input for each required part for a parameter name.

	`Identifier (/X/): <G or L, or TC, or BM, or V0 or VA or VC or VK>` Specify one of these types of legal identifiers.
	`Phase name (/ABCD/): <Phase name>` Specify the phase name.
	`Constituent (in sublattice # /ABC/): <Species name>` Specify the constituent name on the specified sublattice site of the given phase.
	`Interacting constituent (in sublattice # /XYZ/): <Species name>` Specify the interacting constituent name on the specified sublattice site of the given phase; if there is no interacting constituent, press <Enter>.
	`Interacting constituent (in sublattice # /XYZ/): <Species name>` If there is more than one interacting constituent on the specified sublattice site of the given phase, specify them; otherwise press <Enter>.
	`Degree /#/: <Degree>`

Syntax	LIST_PARAMETER
	Specify a numerical number as the degree for the phase parameter.

LIST_PHASE_DATA

This command is for the Gibbs Energy System (GES) module.

All data for a specific phase are written in a readable manner on screen. The thermochemical parameters listed for the phase are always in SI units.

For encrypted commercial databases you may not be able to use this command to list any phase data. However, this command can be used for listing some basic definitions (such as phase model and phase-constituents) for the specified phase, as well as all the references related to original assessments (but not thermodynamic parameters) for the currently-defined system.

Syntax	LIST_PHASE_DATA
Prompt	`Phase name: <Phase name>` Specify a phase name (if abbreviated, it should be unique).

Output Differences: GES5 vs GES6

GES6 is a re-write and new implementation of the Gibbs Energy System module of Thermo-Calc and it is the default engine in Thermo-Calc. As of 2026b, TQ-Interface has access to it but GES5 is the default. GES5 continues to be available and works in the background of the program where necessary. The main purpose of GES6 is to support faster development and access to new features, which are then often only available in GES6.

As required you can set Thermo-Calc to use GES5 instead of the default with the SET_GES_VERSION command. The application may also automatically and temporarily switch to GES5 when a database is being used that is not compatible with GES6.

For GES6 the output data consists of the phase definition and the data associated with the phase, sorted by system. In GES6, there is a subcommand that allows filtering of phase parameters with respect to the property type e.g., to include only volume parameters and/or viscosity parameters in the output.

LIST_STATUS

This command is for the Gibbs Energy System (GES) module.

Syntax	LLIST_STATUS
	List the entered elements, phases and species with the status word. The command is included for system managers.

Each element, species, phase and symbol has a set of status bits. The values of these bits are listed with this command.

The bits are listed as hexadecimal, i.e. four bits are written as a hexadecimal number. Two hexadecimal numbers make a byte. In hexadecimal, 0 to 9 mean normal digits. A to F means values 10 to 15. The number `E4000000` has thus bit 1, 2, 3 and 6 equal to one. The bits are numbered starting with 1 for the most significant (leftmost) bit.

Element Status Word

Set the element status word (*Bit. Meaning*) if:

1. Element cannot be deleted (only vacancy and electron)
2. Suspended (inclusive OR of bit 3 and 4)
3. Explicitly suspended
4. Implicitly suspended (cannot occur for an element)

Species Status Word

Set species status word (*Bit. Meaning*) if:

1. Species record for an element (each element has a species record)
2. Suspended (inclusive OR of bit 3 and 4)
3. Explicitly suspended
4. Implicitly suspended (e.g. if a species element is suspended)
5. Charged (inclusive OR of bit 6 and 7)
6. Negative charge

7. Positive charge
8. Vacancy
9. Component (by default the elements are the components)

Phase Status Word

Set phase status word (*Bit. Meaning*) if:

1. Ideal (no sublattices and no excess parameters)
2. Suspended (inclusive OR of bit 3 and 4)
3. Explicitly suspended
4. Implicitly suspended (e.g. if all constituents suspended)
5. Gas phase
6. Liquid phase
7. Solution phase
8. Only one constituent (in each sublattice)
9. Ions (inclusive OR of bit 10 and 12)
10. New ionic liquid model (charge balance handled internally)
11. Constituents cannot be added
12. External charge balance needed
13. Aqueous model
14. Charged species (ions)
15. Dilute entropy
16. Last calculation exceeded temperature range for any parameter
17. Kapoor-Frohberg-Gaye cell model
18. Turbo calculation used
19. Turbo calculation impossible
20. Turbo calculation illegal
21. Phase is not ideal
22. Current site fractions saved
23. This phase is the ordered part

24. This phase is the disordered part (bit 2 and 3 also set)
25. Shadow phase with diffusion data
26. Error in ionic model
27. Sometimes
28. CVM-SRO (short-range ordering) entropy expression
29. CVM initialization is made
30. Used to test quasi-chemical ordering model
31. Major constituents check even if no miscibility gap (ordering)
32. Hoch-Arpshofen model

Symbol Status Word

Set symbol status word (*Bit meaning*) if:

1. Constant
2. Variable
3. Function
4. Table
5. Value must not be amended
6. Undefined

LIST_SYMBOL

This command is for the Gibbs Energy System (GES) module.

List the symbols available in the current GIBBS workspace, which are defined (retrieved from database in the DATA module, or directly entered in the GIBBS module) and used in TP-functions for the entered model parameters for various phases in the defined system.

For encrypted commercial databases you may not be able to use this command to list any retrieved symbol.

Syntax	LIST_SYMBOL
Prompts	`Name: <Symbol name>` Specify a symbol name (either as the full name of a defined symbol, or as the first few common characters of several symbols which have names starting with such common characters). Only those symbols that match this name are listed. Or press <Enter> for a list of all the symbols defined (retrieved from database in the DATA module, or directly entered in the GIBBS module) for the current system, which are available in the current GIBBS workspace.
	`Output to screen or file /Screen/: <File name>` Specify the name of a simple-textual file in which the entered symbols shall be written in a readable manner (such a basic textual file can later on be opened and edited by any text editor). The default value is the screen (by pressing <Enter>).

READ_GES_WORKSPACE

This command is for the Gibbs Energy System (GES) module.

Workspace Files

The data saved into a `*.GES5` with SAVE_GES_WORKSPACE can be read back into the GIBBS workspace.

The saved *.GES5 files are unique for each CPU type, and therefore a file saved on one CPU type cannot be read and used on another CPU type.

Syntax	READ_GES_WORKSPACE
	Enter a **File name** and specify the working directory where to save the file in the **Look in** field. Normally the default file-type in the **Files of type** field is the correct one for the GES workspace format.

READ_WORKSPACES

This command is used in both the POLY and GES (GIBBS) modules.

Workspace Files

The POLY3 and GIBBS workspaces and the calculated results from the MAP and STEP commands can be READ from a file where they are saved with SAVE_WORKSPACES. Such a *.POLY3 file is not printable.

Syntax	READ_WORKSPACES
Options	`File name` is the name of a saved POLY3-file where the POLY3 and GIBBS workspaces shall be read from must be specified. You do not need to type the extension if it is the default *.POLY3, otherwise type the whole POLY-file name. A reminder that Linux and Mac are case sensitive; when applicable ensure you enter file extensions with capital letters. A window opens so that the path (in the **Look in** field) and **File name** can be specified. The **Files of type** (i.e. POLY3) cannot be changed. Click **Open** to open the POLY3 and GIBBS workspaces from the saved *.POLY3 file.
	When reading back an original POLY3 workspace that has already been saved as an *.POLY3 file in the current Thermo-Calc (Console Mode) run or had been read from an existing POLY3 file under the current work area, while some additional changes in the settings may be made but do not need to be kept in further steps in the current Thermo-Calc (Console Mode) run or any diagram is plotted in the POST module, you can type `READ,,` or `READ_WORKSPACE ,,`

REINITIATE

This command is for the Gibbs Energy System (GES) module.

All data in the stored GIBBS workspace are erased, and all variables are initiated to their default values.

Syntax	REINITIATE
Prompts	`Upper case only /Y/:` Press <Enter> to keep the default where the name of elements and species is in only UPPER case. Or choose N to have the elements with two letter names with the first letter in Upper case and the second in lower case. In upper case mode all input in lower case is automatically converted to upper case.
	`Lower temperature limit /298.15/: <Lowest T in K>` This value is used as the lower temperature limit when data are entered interactively.
	`Upper temperature limit /6000/: <Highest T in K>` This value is used as the upper temperature limit when data are entered interactively.
	`Default element reference state symbol index /1/: <1 or 2 or 3>` Specify a proper index for the default listing parameters (symbol), or press <Enter> to accept the preset index 1. The *index* is for defining the symbol printed in listings of parameters. The symbol can be: • `G`: the data are referred to Gibbs energy at a variable temperature (also called *Lattice Stability*). • `H298`: the data are referred to the enthalpy of the element at 298.15 K and 1 bar. • `H0` is the same as H298 but at the temperature 0 K. The index only changes the symbol, not any value. Normally the index is set correctly by the database. Only when manually entering data must you set the index to get the correct symbol. Set the index value to 0 to get the symbol `G`, to 1 to get the symbol `H298` and to 2 to get `H0`.

SAVE_GES_WORKSPACE

This command is for the Gibbs Energy System (GES) module.

Workspace Files

The data used by the GES workspace can be saved in a file with a default extension `*.GES5`. The default file name is `RESULT.GES5` or equal to the one used in a previous READ_GES_WORKSPACE command.

The output is not formatted and cannot be printed.

Syntax	SAVE_GES_WORKSPACE
	Enter a **File name** and specify the working directory where to save the file in the **Save in** field. Normally the default file-type in the **Files of type** field is the correct one for the GIBBS workspace format.

SAVE_WORKSPACES

This command is available for both the POLY and GES (GIBBS) modules.

Workspace Files

You can save the current status and workspaces, including thermodynamic data, conditions, options and results from a single, stepping or mapping calculation on a *.POLY3 file. The workspaces are saved to a file with this command. This is useful so you have access to the workspace for later use or when you need to terminate the current Console Mode session.

- In the Gibbs (GES) module workspace, all thermochemical data are stored.
- In the POLY module workspace, all the last set of conditions and equilibrium state, changed status, entered symbols, advanced options, defined stepping/mapping variables, added initial equilibria, stepped/mapped results, etc., are stored, so it also contain the GES workspace.
- When you are in a response-driven module such as POTENTIAL or SCHEIL for example, a workspace file is automatically opened. In the workspace file, system definitions, conditions for the calculation, calculation results, and plot settings are saved. The file is saved in the current working directory, and is named after the name of the module that created it. For example, the POTENTIAL module saves a workspace file called `POT.POLY3` ; the POURBAIX module saves a file called `POURBAIX.POLY3` and so forth.

After a SAVE_WORKSPACES command, you can always come back to exactly the state you had when you issued the command by giving a READ_WORKSPACE command. For example, after saving the POLY and GIBBS workspaces to a file, you can leave the program and at a later time READ the file and continue from the saved state.

Important Information About Map and Step Commands

A STEP or MAP command automatically saves the workspace with the most recently specified name. Do not use the SAVE_WORKSPACES command after a MAP or STEP command.

The results from the STEP or MAP commands are destroyed by the SAVE_WORKSPACE command. You can append several results obtained by sequential STEP or MAP calculations without destroying the previous results, whilst SAVE_WORKSPACE erases them all. Keeping this in mind is important and useful particularly for calculating various isothermal (or isoplethal) sections and plotting them on the same diagram in a single Thermo-Calc run.

To suspend some of the STEP or MAP results, use the AMEND_STORED_EQUILIBRIA command.

Syntax	SAVE_WORKSPACES
Options	A `file name` must be specified. The default extension of the POLY workspace file is *.POLY3 but you can have any other file extension. Linux and Mac are case sensitive so ensure you enter `.POLY3`. A **Save** window displays if a file name is not given after the command, so that the path (in the **Save in** field) and **File name** can be specified. The **Files of type** cannot be changed. If there is already a file with the same file name under the directory a warning message displays. Click **OK** to overwrite the current POLY or GIBBS workspace onto the existing file. Click **Cancel** to return to the module. You can use the SAVE command with an unspecified name (i.e. through `SAVE ,,,` command-sequence) to save the POLY or GIBBS workspace. When saving a POLY3 workspace under a name that already exists under the current work area, which is saved by default (after running a special module, e.g. BIN, TERN, POT, SCHEIL and POURBAIX) or in an earlier stage of the current Console Mode session or in a previous run (which is READ into the current POLY3 workspace), you can type `SAVE,,Y` or `SAVE_WORKSPACE ,,y`. However, this must also be avoided if some results from previous MAP or STEP calculations shall not be destroyed.

CALCULATE_BELOW_SOLIDUS

This command is for the SCHEIL module.

The CALCULATE_BELOW_SOLIDUS command enables or disables the calculation of solid state properties at temperatures below the solidus temperature, using the phase compositions and fractions from the Scheil calculation. By default this is disabled.

The calculation is performed at a set number of temperatures between the solidus temperature and a lower temperature, which is by default set to room temperature. The end temperature and the number of points can be changed.

Syntax	CALCULATE_BELOW_SOLIDUS

Prompts	`Calculate properties below solidus? /N/:`
	The default is `N`. Enter `Y` to calculate solid state properties below solidus .
	If `Y` is entered, then you are prompted:
	`Final temperature (C) /25/:?`
	Enter the final temperature in degrees Celsius. Must be 25 C or higher.
	`Number of points /50/:?`
	Enter the number of points where solid state properties are calculated.

CALCULATE_EVAPORATION_PROPERTIES

This command is for the SCHEIL module.

The CALCULATE_EVAPORATION_PROPERTIES command enables or disables the calculation of evaporation properties. By default this is disabled. The evaporation properties include driving force for evaporation, evaporation enthalpy, and molar mass of gas.

To be able to calculate these properties the gas phase needs to be selected (in the START_WIZARD).

Syntax	CALCULATE_EVAPORATION_PROPERTIES
Prompts	`Calculate evaporation properties? /N/:` The default is `N`. Enter `Y` to calculate evaporation properties.

CALCULATE_FROM_GAS

This command is for the SCHEIL module.

The CALCULATE_FROM_GAS command enables or disables the calculation of equilibria starting from the gas/liquid temperature, i.e. from the temperature above which the liquid phase is no longer stable. By default this is disabled (set to N). Enable this (set to Y) to perform single equilibrium calculations at 5 Kelvin (K) intervals in the two-phase region between the gas/liquid temperature and the liquid/gas temperature, which is the temperature below which the gas phase is no longer stable.

In the fully liquid region below the liquid/gas temperature single equilibrium calculations are performed at 50 K intervals until the liquidus temperature is reached. After that the Scheil solidification calculation proceeds as usual.

Syntax	CALCULATE_FROM_GAS

Prompts	`Calculate from gas/liquid temperature? /N/:`
	The default is N. Enter Y to perform equilibrium calculations from the gas/liquid temperature.
	`Gas phase name /GAS/:`
	Enter the name of the gas phase (default GAS).
	If you choose a phase that is not available in the system, Thermo-Calc checks if there is any phase present with the phase type code G.

CALCULATE_FROM_START_TEMPERATURE

This command is for the SCHEIL module.

The CALCULATE_FROM_START_TEMPERATURE command enables or disables the calculation of equilibria directly from the start temperature chosen in the START_WIZARD. By default this is disabled (set to N). Enable this (set to Y) if you want to obtain properties of the liquid phase (and gas phase if selected) before the solidification starts. Ordinarily the start temperature is only used as a start point in the search of the liquidus temperature, as the Scheil calculation starts from the liquidus temperature.

With this setting enabled single equilibrium calculations are performed at specific intervals above the liquidus temperature, and after that the Scheil solidification calculation proceeds as usual. The equilibrium calculations are performed at 50 Kelvin (K) intervals in the fully liquid region and at 5 K intervals in a possible two-phase (liquid/gas) region.

Syntax	CALCULATE_FROM_START_TEMPERATURE
Prompt	`Perform equilibrium calculations between start and liquidus temperatures? /N/:` The default is N. Enter Y to perform equilibrium calculations from the start temperature until liquidus temperature is reached (i.e. solidification starts). The calculations are performed at 5 Kelvin intervals in the two-phase gas/liquid region and at 50 Kelvin intervals in liquid.

DELTA_FERRITE_AUSTENITE_TRANSITION

This command is for the SCHEIL module.

The DELTA_FERRITE_AUSTENITE_TRANSITION command enables or disables BCC to FCC transition.

This feature should only be used for such steels for which it is reasonable to assume infinitely fast diffusion (equilibrium conditions) when delta ferrite is present. When the **Allow delta ferrite to austenite transition in steel** checkbox is selected in Graphical Mode or the DELTA_FERRITE_AUSTENITE_TRANSITION command used in Console Mode, this essentially assumes that diffusion can be considered (infinitely) fast when delta ferrite is present as a solid phase, i.e assumes an equilibrium condition. After delta ferrite is no longer stable, the usual Scheil assumptions for the selected calculation type are in effect. This setting is therefore not suitable for steels where you DO NOT have a complete BCC to FCC transition during solidification. This setting is also NOT available in combination with solute trapping.

Syntax	DELTA_FERRITE_AUSTENITE_TRANSITION
Prompt	`Allow delta-ferrite -> austenite ? /N/:` The default is `N`. Enter `Y` to enable BCC to FCC transition. This feature should only be used for such steels for which it is reasonable to assume infinitely fast diffusion (equilibrium conditions) when delta ferrite is present. See the above for details.

EVALUATE_SEGREGATION_PROFILE

This command is for the SCHEIL module.

This feature is not supported with fast diffusers.

Enable this feature before executing the START_WIZARD command.

Use the EVALUATE_SEGREGATION_PROFILE command in order to evaluate a segregation profile while performing the Scheil calculation. The Scheil calculation itself does not contain a spatial dimension. However, if it is assumed that the molar volume is constant and equal for all elements, and if a length is provided over which solidification occurs (for example the secondary dendrite arm spacing) then the generated profile corresponds to the segregation that would be obtained under the assumptions of a Scheil calculation. The grid is then equidistant and can be used as input for a DICTRA simulation.

The generated text file contains, on each line, the mole fractions of all elements in alphabetical order at a certain grid point. If the composition is the same on several consecutive lines it means that the composition of the then remaining liquid has reached a state in which there are no degrees of freedom.

Syntax	EVALUATE_SEGREGATION_PROFILE
Prompt	`Evaluate segregation profile? /N/` If the answer is Y, a segregation profile will be evaluated and saved to disc. This feature is not supported with fast diffusers. You cannot select fast diffusers if evaluation of the segregation profile is enabled.
	`Number of grid points /100/` Enter the number of grid points for the segregation profile. An xf.txt file dialogue window opens and allows you to specify the name of the file in which the segregation profile is written.

About the xf.txt File

The file is started with this command, and available after the Scheil simulation is finished. The XF.txt file contains one line per grid point entered here.

In a macro file it is possible to enter all arguments on a single line, e.g. `EVALUATE_SEGREGATION_PROFILE Y 100 XF.TXT`, meaning that the segregation profile is evaluated over 100 grid points and saved to a file (XF.TXT) in the current working directory. The grid coordinate (actually fraction solid, but used later as distance) is not recorded in the XF.txt file.

The file contains one column per element, listing the mole-fraction of each in alphabetical order, including the dependent element. As I understand it, it is the total concentration of each element in each point at the end point of the Scheil simulation.

The XF.txt is then used with INPUT_SCHEIL_PROFILE command in the DICTRA module. Remember to use the same number of grid points in the DICTRA region as in this file.

GLOBAL_MINIMIZATION

This command is for the SCHEIL module.

Global minimization is enabled by default (i.e. set to `Y`) and global minimization is used throughout the simulation.

It is recommended to keep global minimization on as it makes the calculation more accurate. However, turn it off if you find that the calculation is taking too long for any particular system, and accuracy is not the highest priority.

For the GLOBAL_MINIMIZATION command, a global equilibrium test is performed when an equilibrium is reached, at selected intervals. By default it is at every 10th Scheil step but this can be changed using the command TEST_INTERVAL_FOR_GLOBAL. The global equilibrium test is also done every time the set of stable phases tries to change. This costs more computer time but the calculations are more robust.

Syntax	GLOBAL_MINIMIZATION
Prompt	`Use global minimization? /Y/` By default this is set to `Y`. This costs more computer time but the calculations are more robust.

LIQUID_PHASE_NAME

This command is for the SCHEIL module.

Use the LIQUID_PHASE_NAME command to use the liquid phase name from the database definitions or enter another phase name.

Syntax	LIQUID_PHASE_NAME
Prompt	`Liquid phase name /Default/` Default selects the liquid phase from the database definitions, otherwise enter a phase name.

SAVE_FILE_NAME

This command is for the SCHEIL module.

Use the SAVE_FILE_NAME command to save the file. The files get the console number added to this name, e.g. `005.->Scheil_006.POLY3 and Scheil_segregation_profile.txt`).

Syntax	SAVE_FILE_NAME
Prompt	Name of files to be saved, POLY and segregation profiles. Linux and Mac are case sensitive so ensure you enter `.POLY3`.

SET_MAX_GRID_POINTS_FOR_GLOBAL

This command is for the SCHEIL module.

Use the SET_MAX_GRID_POINTS_FOR_GLOBAL command to set the maximum number of gridpoints per phase for global minimization. The default is 2000.

Syntax	SET_MAX_GRID_POINTS_FOR_GLOBAL
Prompt	`Maximum number of gridpoints per phase /2000/:` Enter the maximum number of gridpoints per phase for global minimization

SET_NUMERICAL_LIMITS

This command is available for the POLY, Scheil, and ED-EXP modules.

Use the SET_NUMERICAL_LIMITS command to change the criteria for convergence. This is to speed up a calculation in a complex system.

If there is any convergence problem in finding a stable solution at any stage during a calculation procedure enforced by COMPUTE_EQUILIBRIUM, STEP_WITH_OPTIONS, MAP or ADVANCED_OPTIONS), this message displays:

```
Convergence problems, increasing smallest site-fraction from 1.00E-30
to hardware precision 2.00E-14. You can restore using SET-NUMERICAL-
LIMITS
```

This implies that smallest site fraction in the current POLY workspace is automatically increased from the default value 1.00E-30 to the hardware-dependent precision (under Linux, as 2.00E-14). For other subsequent POLY module calculations, you can use this command to restore or reset the smallest site fraction to the previous or another preferred value, as well as to reset other numerical limits.

Syntax	SET_NUMERICAL_LIMITS
Prompt	`Maximum number of iterations /500/:` By default, the program tries 500 iterations before it gives up. As some models give computation times of more than 1 CPU second/iteration, this number is also used to check the CPU time and the calculation stops if 500 CPU seconds/iterations are used.
	`Required accuracy /1E-6/:` This is a relative accuracy, and the program requires that the relative difference in each variable must be lower than this value before it has converged. A larger value normally means fewer iterations but less accurate solutions. The value should be at least one order of magnitude larger than the machine precision.
	`Smallest fraction /1E-12/:` This is the value assigned to constituents that are unstable. It is normally only in the gas phase you can find such low fractions. The default value for the smallest site-fractions is 1E-12 for all phases, except for IDEAL phase with one sublattice site (such as the GAS mixture phase in many databases) for which the default value is always as 1E-30 (unless you have used the SET_NUMERICAL_LIMITS command to reset an even-lower value (e.g. 1E-45, that is naturally enforced to all the phases in the system).
	`Approximate driving force for metastable phases /Y/:` `Y` is the default. Enter `N` to change the default as required and based on the options described below. This setting involves the convergence of metastable phases and affects their driving forces. It can also have an effect on when an equilibrium is considered successful. The default is to allow an equilibrium with metastable phases that have not converged, as long as the stable phases have converged. This is efficient but often causes approximate values of the driving

Syntax	SET_NUMERICAL_LIMITS
	forces for the metastable phases. If you change the default, it enforces metastable phases to converge. This gives accurate driving forces for metastable phases as well as stable phases. It can however take a slightly longer time, and if metastable phases do not converge it causes the equilibrium calculation to fail.

SKIP_STEP_CALCULATION

This command is for the SCHEIL module.

Use the SKIP_STEP_CALCULATION command to skip the step (also called *one axis*) calculation that is by default performed before the Scheil calculation in Thermo-Calc. The step calculation is used to plot the equilibrium solidification curve, which is shown for comparison if the default axis variables are used. This is sometimes referred to as the *equilibrium line*.

If a comparison to equilibrium is not necessary, change the default setting and then only a Scheil calculation is performed. This results in a much faster calculation, which for a complex system may be preferable.

Syntax	SKIP_STEP_CALCULATION
Prompt	`Skip the step calculation before Scheil (equilibrium curve)? /N/:` By default this is set to `N`. If a comparison to equilibrium is not necessary, enter `Y` and only a Scheil calculation is performed.

SOLUTE_TRAPPING

This command is for the SCHEIL module.

The SOLUTE_TRAPPING command enables solute trapping. Once enabled, there are additional prompts and settings that are included and described with the START_WIZARD command (see Back Diffusion and Solute Trapping Settings).

Syntax	SOLUTE_TRAPPING
Prompt	`Consider solute trapping in primary phase? /N/` The default (N) does not use solute trapping. If you choose Y, then solute trapping is used.

When the USE_BACK_DIFFUSION command is enabled, the SOLUTE TRAPPING command is automatically disabled (set to N).

Details about the solute trapping model theory are in About Scheil with Solute Trapping.

START_WIZARD

This command is for the SCHEIL module.

About the Scheil-Gulliver Solidification Simulations

Use the START_WIZARD command have step-by-step prompts to create a Scheil simulation.

You are prompted for settings including the major element or alloy, composition input in mass (weight) percent, the alloying elements, the temperature, fast diffusing components, and whether any phase should have a miscibility gap check. There are additional prompts included in the Start Wizard if USE BACK DIFFUSION or SOLUTE TRAPPING commands are set to `Yes` to enable back diffusion and solute trapping, respectively.

The Scheil with back diffusion feature is only available for systems with diffusion data, i.e. this model requires the use of a mobility database.

Use the other commands to make changes to settings that are not included in this wizard.

- EVALUATE_SEGREGATION_PROFILE
- GLOBAL_MINIMIZATION
- LIQUID_PHASE_NAME
- SAVE_FILE_NAME
- STORED_COMPOSITION_TYPE
- TEMPERATURE_STEP
- TERMINATION_CRITERIA

If you also have a license for the Diffusion Module (DICTRA), you can import a previously calculated Scheil segregation profile into the software using the command INPUT_SCHEIL_PROFILE.

Syntax	START_WIZARD

Prompt	The following is a list of the prompts. Press <Enter> to accept the defaults that are shown between the forward slashes (*/default/*).
	`Database /<Default>/:`
	The available thermodynamic database and its version are available to enter (based on license). Enter `?` for a list.
	`Major element or alloy:`

Syntax	START_WIZARD

The major element in the system, e.g. Fe for a steel.

```
Composition input in mass (weight) percent? /Y/:
```

Set whether to specify the `Composition input in mass (weight) percent` (the default) or in `Mole percent`. Enter `Y` for mass percent and `N` for mole percent.

```
1st alloying element:
```

You can specify all the alloying elements and their corresponding compositions on the same line when you are prompted to specify your first alloying element. For example, you can enter `Cr 5 Ni 1 Mo 0.5 C 0.01 N 0.02`.

You can directly specify mass or mole percent after the name (for example, enter `Cr 5`). If this is not specified, then you are prompted to enter it separately.

```
Mass (weight) percent /1/
2nd alloying element:
```

Specify the other alloying elements in the same way as you specify the first (for example, `C 1`).

```
Mass (weight) percent /1/
Next alloying element:
```

After you have specified your last alloying element, press <Enter> when requested to specify the next element. This ends the process of defining the bulk composition of the alloy system.

```
Temperature (C) /2000/:
```

Enter a value for the temperature in degrees C (Celsius) . This value should be sufficiently high so that the solidification simulation starts with the alloy system in the liquid single-phase region.

Decide which phases (if any) to reject at the `Reject phase(s)` prompt. Enter the name of the phases to reject or press <Enter> for `NONE`.

Decide whether to `Restore phase(s)`. You may want to restore a phase that you rejected when you ran the simulation earlier, or you may want to restore a phase that is rejected by default in your database. Enter the name of the phases to restore or press <Enter> for `NONE`.

Then you are asked to confirm whether these phases should be retained in this system:

```
OK? /Y/:
```

Press <Enter> to accept the default `Y` or type `N` and press <Enter>. Thermodynamic data about the alloy system you defined is retrieved from the database.

```
Should any phase have a miscibility gap check? /N/:
```

If you answer `Y`, you are prompted to specify the `Phase with miscibility gap`. Answer with a solution phase name(s) (e.g. `FCC`) as well as the `Major constituents for sublattice` (for each sublattice site) (for this example, `Cr` is entered for sublattice 1 and `C` for sublattice 2).

Press Enter to specify another phase.

```
Fast diffusing components: /None/:
```

Enter the elements that diffuse fast in solid phases and can assume to be in equilibrium in the whole phase. E.g. C in a steel.

Back Diffusion and Solute Trapping Settings

The following prompts are included with the Start Wizard at various points in the set up if the:

- USE_BACK_DIFFUSION command is set to `Y` to enable back diffusion
- SOLUTE_TRAPPING command is set to `Y` to enable solute trapping

Syntax	START_WIZARD

Back Diffusion settings	`Mobility Database /<Default>/:`
	The available mobility database and its version are available to enter (based on license). Enter `?` for a list.
	You then are shown a list of what phases are available for the database and the defined system and have the opportunity to reject or restore phases at the next prompts.
	`Reject phase(s) /NONE/:`
	`Restore phase(s): /NONE/:`
	Then you are asked to confirm whether these phases should be retained in this system:
	`OK? /Y/:`
	Press <Enter> to accept the default `Y` or type `N` and press <Enter>.
	`Temperature time dependence /LINEAR/:`
	Specify the type of temperature time dependence. Press <Enter> to accept this default.
	An increased value moves the result from equilibrium toward a Scheil-Gulliver calculation.
	LINEAR is the only option and it corresponds to a constant cooling rate.
	`Cooling rate (K/s) /.1/:`
	Specify the cooling rate in Kelvin per second (K/s). An increased value moves the result from equilibrium toward a Scheil-Gulliver calculation.
	`Expression for secondary dendrite arm spacing /CONSTANT/:`
	Secondary dendrite arm spacing is the distance in meters (m) between two secondary dendrite arms. Specify the type of secondary dendrite arm spacing by entering `CONSTANT` (the default) or `POWER_LAW`.
	An increased value moves the result from equilibrium toward a Scheil-Gulliver calculation. Use
	• `CONSTANT` for a constant dendrite arm spacing. If you choose this, then enter a value for the `Secondary dendrite arm spacing (m) /5E-05/:` prompt.
	• `POWER_LAW` in the form `c*(cooling rate)^-n` where `c` and `n` are entered in the next prompts. If you choose this, then enter a value for the `Exponent n /.33/:` and `Scaling factor c /5E-05/:`
	`Primary phase /AUTOMATIC/:`
	The primary phase is the phase where the back diffusion takes place.

Syntax	START_WIZARD
	If `Automatic` is selected (or kept as the default), the program tries to find the phase which gives the most back diffusion. To override this setting, choose a specific primary phase from the list. For back diffusion, only phases with diffusion data can be used as primary phases.

Solute Trapping settings	`Expression for solidification speed /SCANNING_SPEED_AND_ANGLE/:`
	SCANNING_SPEED_AND_ANGLE is currently the only available option. It is calculated as scanning speed * cos(alpha) where scanning speed and the angle alpha are given by the user.
	Decreasing the value moves the result toward a Scheil-Gulliver calculation.
	`Scanning speed (m/s) /1/:`
	Enter the Scanning speed to calculate the solidification speed, Vs = $V_{scanning}$ * cos(α) m/s, where $V_{scanning}$ is the user specified scanning speed.
	`Alpha (degrees) /45/:`
	Enter an Alpha value in degrees, which is the alpha angle, α, between the solid/liquid boundary and scanning direction.
	`Primary phase /AUTOMATIC/:`
	If `Automatic` is selected (or kept as the default), the program tries to find the phase which gives the most solute trapping. To override this setting, choose a specific primary phase from the list. For solute trapping, only phases that dissolve all elements in the system can be used as primary phases.

TEMPERATURE_STEP

This command is for the SCHEIL module.

Use the TEMPERATURE_STEP command to define a temperature step.

Syntax	TEMPERATURE_STEP
Prompt	`Set temperature step (C) /1/`

TERMINATION_CRITERIA

This command is for the SCHEIL module.

Use the TERMINATION_CRITERIA command to define the termination criteria for the fraction of liquid (unit = mole fraction) or temperature.

Syntax	TERMINATION_CRITERIA
Prompts	`Fraction of liquid or Temperature (F or T)? /F/`
	`Fraction of liquid /.01/`

TEST_INTERVAL_FOR_GLOBAL

This command is for the SCHEIL module.

By default, global minimization is enabled (i.e. set to `Y` with the command GLOBAL_MINIMIZATION).

Use the TEST_INTERVAL_FOR_GLOBAL command to change the interval at which a global equilibrium test is done, which by default is every 10th step as long as there are no changes in the set of stable phases. Every time the set of stable phases tries to change, a global equilibrium test is also done regardless of the test interval value chosen. A global equilibrium test means that the calculated equilibrium state obtained by the ordinary minimization calculation is tested against the Global Minimization Technique, and if the result is found unstable then the full global minimization calculation is performed instead.

Syntax	TEST_INTERVAL_FOR_GLOBAL
Prompt	`Global test interval /10/:` Global equilibrium test is done every Nth step, unless the set of stable phases changes. By default a test is done every 10th step. Enter a different number to change the interval.

USE_BACK_DIFFUSION

This command is for the SCHEIL module.

The Scheil with back diffusion feature is only available for systems with diffusion data, i.e. this model requires the use of a mobility database.

About the Scheil-Gulliver Solidification Simulations

The USE_BACK_DIFFUSION command enables back diffusion in the solid primary phase. Once enabled, there are additional prompts and settings that are included and described with the START_WIZARD command (see Back Diffusion and Solute Trapping Settings).

Syntax	USE_BACK_DIFFUSION
Prompt	`Use back diffusion? /N/` The default (`N`) does not use back diffusion. If you choose `Y`, then back diffusion is used. When the SOLUTE TRAPPING command is enabled, the USE_BACK_DIFFUSIONcommand is automatically disabled (set to `N`).

AMEND_PARAMETER

This command is for the PARROT module.

There is also a Gibbs (GES) module command with the same name.

Interactively modify the TP-function(s) for a specific parameter for a phase with the AMEND_PARAMETER command. This is useful in order to correct typing errors because the old function is made available for interactive editing on the terminal.

Syntax	AMEND_PARAMETER

Prompts	`Parameter: <Parameter name>`
	Specify a correct parameter name. If a parameter name is not acceptable or <Enter> is pressed, the error message displays:
	`*** Error, please re-enter each part separately`
	The program prompts for separate input for each part for a parameter name.

	`Identifier (/X/): <G or L, or TC, or BM, or V0 or VA or VC or VK>` Specify one of these types of legal identifiers ENTER_PARAMETER
	`Phase name (ABCD/): <Phase name>` Specify the phase name.
	`Constituent (in sublattice # /ABC/): <Species name>` Specify the constituent name.
	`Interacting constituent (In sublattice # /XYZ/): <Species name>` Specify the interacting constituent name; if there is no interacting constituent, press <Enter>.
	`Interacting constituent (in sublattice # /XYZ/): <Species name>` If there is more than one interacting constituent, specify these; otherwise press <Enter>.
	`Degree /#/: <Degree>` Specify a numerical number as the degree of the phase parameter.

	After the parameter name is specified correctly, the program lists its current definition (either preset in database or defined by the ENTER_PARAMETER command), such as:
	`L(PHASE2,AL,MG;1)=`
	`298.15<T<2000.00: +5000`
	`2000.00<T<4500.00: +4500`
	`4500.00<T<6000.00: +4000`
	You are prompted to change the parameter definition:

Syntax	AMEND_PARAMETER

	`Do you want to change the number of ranges /No/:`
	
	Enter Y to change the number of ranges for the chosen function, or change some of the temperature limits in the definition, then retype both the low/high temperature limits and functions
	
	If you do not want to change the number of ranges but want to change the function(s) in one or more ranges, press <Enter> and the whole definition of the chosen parameter in all ranges (if any) is listed such as:
	
	`DIFFERENT FUNCTIONS IN THESE RANGES`
	`298.15<T<2000.00`
	`2000.00<T<4500.00`
	`4500.00<T<6000.00`
	
	This message prompts:
	
	`Do you want to change range limits /No/:`
	
	If there is more than one range, this question is prompted. Press <Enter>.

	`Range number (0 to exit) /0/: <Range number>` If the function of a parameter is different in two or more temperature ranges, you must specify the range of the function of which you want to amend. Or press <Enter> or type `0` to exit this command without making any change.

	`Function`
	
	The previous function is available for editing. The editing is performed within the general subroutine `FOOLED`, as described in AMEND_SYMBOL. This routine prompts as follows:
	
	`1:+:>`
	
	The prompt consists of the current position in the string and the character at that position between colons, (::).
	
	Commands
	
	These commands can be given:
	
	• Help: `?`
	• Move CP to last or first character: `<+/-> A`
	• Delete characters from CP: `<+-#characters> D`
	• Exit: `E`
	• Find: `<#occurrences> F<string>@`
	• Insert: `I<string>@`
	• Move: `<+-#positions> M`
	• Restore string: `R`
	• Substitute: `S<OLD>@<NEW>@`
	• Type string: `T`
	
	Where CP denotes the current position in a string, # means number of, @ is a terminator of an input or search string.

Syntax	AMEND_PARAMETER
	When the string is typed the character at the current position is replaced by an underscore _. To finish the editing of the current function, type `E` at the prompt.
	`Range number (0 to exit) /0/: <Range number>` Give a range number to edit that function, or press <Enter> or type `0` to exit this command.

AMEND_SYMBOL

This command is for the PARROT module.

The same command is also available for the Gibbs (GES) module.

Use the AMEND_SYMBOL command to interactively calculate the current values of a function or table (predefined by the switched database or previously entered with ENTER_SYMBOL) at the current temperature and pressure condition, and also possible to modify the definitions of variables or functions.

The current values of the temperature and pressure used to calculate the functions or tables are the ones listed with LIST_STATUS. There is no way to change the current temperature and pressure values interactively.

To modify the definitions of entered symbols (variable, functions or parameters), the performance of this command is slightly different one from another, as described below:

- For variables, the values can be changed.
- For functions the low and high temperature limits in various ranges (if any), as well the expressions, can be changed.
- For parameters the low and high temperature limits in various ranges (if any), as well the expressions, can be changed.

Syntax	AMEND_SYMBOL

Prompts	`Name: <Symbol name>`
	Specify the name of an entered symbol.
	For tables and functions (or parameters which are treated as functions after these are entered by the ENTER_SYMBOL command with the `Parameter` keyword, but not by the ENTER_PARAMETER command), after the symbol name is specified here, the program automatically calculates the values under the current temperature and pressure conditions, and lists the current values, such as:
	`FUNCTION VALUE 2.52500000E+01`
	`TABLE VALUE 1.56000000E+02`
	For variables and functions (or parameters), there are additional prompts and depend on the symbol type.

	For a variable, its current value is displayed, and you can change it to a new value: `Value /Current value/: <New value>` For a function (or a parameter entered as a symbol):

Syntax	AMEND_SYMBOL

`Do you want to change the number of ranges /No/:`

Enter Y to change the number of ranges for the function, or change some of the temperature limits in the definition, then retype both the low/high temperature limits and functions (see all the remaining details in the ENTER_SYMBOL command.

If you do not want to change it, press <Enter>. The definition of the chosen function in all ranges (if any) is listed, for example:

```
DIFFERENT FUNCTIONS IN THESE RANGES
298.15<T<2000.00
2000.00<T<4500.00
4500.00<T<6000.00
```

and this message displays:

`Do you want to change range limits /No/:`

If a function is different in two or more temperature ranges, you must specify the range of the function of which you want to amend. Or press <Enter> or type `0` to exit this command without making any change.

`Range number (0 to exit) /0/: <Range number>`

`Function:`

The previous function is available for editing. The editing is performed within the general subroutine FOOLED. This routine prompts as follows:

`1:+:>`

The prompt consists of the current position in the string and the character at that position between colons (::).

Commands

These commands can be given:

- Help: `?`
- Move CP to last or first character: `<+/-> A`
- Delete characters from CP: `<+-#characters> D`
- Exit: `E`
- Find: `<#occurrences> F<string>@`
- Insert: `I<string>@`
- Move: `<+-#positions> M`
- Restore string: `R`
- Substitute: `S<OLD>@<NEW>@`
- Type string: `T`

Where CP denotes the current position in a string, # means number of, @ is a terminator of an input or search string.

Syntax	AMEND_SYMBOL

When the string is typed the character at the current position is replaced by an underscore _.

To finish the editing of the current function, type `E` at the prompt.

COMPILE_EXPERIMENTS

The descriptions of the experimental equilibria saved on a textual *.POP file, given as commands in the POLY and ED_EXP syntax, is compiled by this command into the PARROT structured data, i.e. stored into the current work *.PAR file which is created with CREATE_NEW_STORE_FILE, set by SET_STORE_FILE , or opened with READ_PARROT_WORKSPACES, all done before COMPILE_EXPERIMENTS.

This command also lists the compilation details on screen or onto a listing file (*.TXT).

If a syntax error in the commands is detected, the compilation is terminated. You need to correct the error in the *.POP file (using a textual editor) and recompile it with the *.PAR work (store) file.

After a successful compilation, the program translates all the experimental data points in the *.POP file into a graphical experimental data file (*.EXP) in the DATAPLOT syntax, which can be further edited and used as a graphical experimental data file (*.EXP) for the purposes of imposing onto calculated/plotted phase diagrams and/or property diagrams for comparisons during the assessment process.

Syntax	COMPILE_EXPERIMENTS
	A window displays to open the original experimental data file (*.POP). Enter a *.POP **File name** box, and specify the working directory in the **Look in** box. Normally the default file-type in the **Files of type** field is the correct one for the experimental data format (i.e. *.POP file). Click **Open** or **Cancel** button as applicable.
Prompts	`Output to screen or file /Screen/: <*.pop file name>` A list of the source code in the *.POP file and error messages during compilation is written on screen (by pressing <Enter>) or on a list *.TXT file under a specific file name which can later on be opened and edited by any basic textual editor.
	`Initiate store file /Y/:` After a successful compilation, the data in the POLY workspace is stored as a new block of equilibria on the current work (store) file. By default the store file is initiated before compilation and only the compiled block is stored on the current work file (consequently, the *.PAR file is updated). A window displays to generate/store the graphical experimental data file (*.EXP) in the DATAPLOT syntax. Enter a *.EXP file name in the **File name** field and specify the working directory when opening the *.EXP file in the **Look in** field. Normally the default file type in the **Files of type** field is the correct one for the graphical experimental data format (i.e. *.EXP file). Click **Open** or **Cancel** as applicable. To keep the current work file, enter N.

CONTINUE_OPTIMIZATION

This command is for the PARROT module.

The CONTINUE_OPTIMIZATION command continues the optimization using the same Hessian matrix.

In some cases it is not possible to attempt continuation. For example, if the optimization has already converged or if the optimizing parameters or the set of experimental equilibria used in the current optimization runs are changed. The program gives a warning message if you try to continue when you make these changes.

Syntax	CONTINUE_OPTIMIZATION

Prompts	`Are you sure? /N/: <N or Y>`
	Prior to this question, a message displays to confirm if it is OK to continue:
	`It is safe to CONTINUE only after TOO MANY ITERATIONS and no change in variables and experiments ...`
	You can accept the default (N) in order to cancel this special attempt.

	`Number of iterations /N/: <Integral number of iteration>` Specify an integral number for the optimization iteration. The specified iteration number is shown as the default number. The PARROT program tries this exact number of different sets of values of the optimizing variables without stopping the optimization even it would have converged earlier or should give up earlier.

CREATE_NEW_STORE_FILE

This file is hardware dependent and cannot be read by any text editor.

Use the CREATE_NEW_STORE_FILE to create a binary file to be used as a *work file* (also called *store file*) before any optimization can be done. The workspace used by the GIBBS, POLY and PARROT modules is stored automatically on the work file but not any experimental information. The binary work file has a default extension of `PAR` under MS-Windows or `par` under Linux/UNIX.

A work file that is created at a previous run can be used in the PARROT module with the other command SET-STORE-FILE.

Syntax	CREATE_NEW_STORE_FILE
Prompt	<*.par file name> A **Save** window displays. Enter a **File name** and specify the working directory in the **Save in** field. Normally the default file-type in the **Files of type** field is the correct one for the PARROT workspace format (i.e. PAR file). Click **Save** or **Cancel** as applicable.

EDIT_EXPERIMENTS

Use the EDIT_EXPERIMENTS command to initialize and make available the sub-module for editing experimental equilibria, i.e. the ED_EXP module. All experimental equilibria compiled from the *.POP file can be accessed in the ED_EXP module.

The ED_EXP module is similar to the normal POLY module, but some commands are special and some POLY commands are not available. In the ED_EXP module, you can calculate each equilibrium separately or together, provide start values for equilibria which failed to converge, set weights, and modify the values of experiments or conditions.

Syntax	EDIT_EXPERIMENTS
	You are now in this submodule and can start using the commands.

- The first required command after entering the ED_EXP module for the first time (from the PARROT module GOTO MODULE ED-EXP) should always be READ_BLOCK in order to load the experimental data block from the current work *PAR-file for editing.
- The READ_BLOCK command must also be used prior to any other ED_EXP command if the module is reinitiated, or if no experimental data block is not previously read from a work file compiled with a proper experimental data .POP file, or if you want to change to another data block for editing.
- If any change is made in the ED_EXP module remember to use the command SAVE_WORKSPACE before going BACK to the PARROT module.

Although the TABLE_HEAD, COMMENT and FLUSH_BUFFER commands are visible in the ED_EXP module, these cannot be used here as these only work in a *.POP file (or *.DOP file for DICTRA).

About the ENTER_PARAMETER Command

For the PARROT Module, this command is the same and is described here. See ENTER_PARAMETER for the command details.

In the descriptions of the standard thermochemical properties and special physical properties for a phase, there are a number of parameters which may depend on the temperature and pressure. The expressions for these parameters can be given in a free form as a sum of terms with powers of T and P and may also include the natural logarithm and exponential function. This type of expression is called *TP-functions*. Identical parameters (in terms of parameter-names) are stored only once in the GIBBS workspaces.

The composition-dependence of the Gibbs energy is described in the GIBBS module by the internal data structure, which is created when the phase is entered. The Gibbs energy of a phase is always referred to one formula unit of the phase, i.e. the amount derived from the number of sites (i.e. the stoichiometric coefficient) for each sublattice. If vacancy is a constituent of a sublattice, the amount of matter per formula unit of the phase may vary with composition.

Defining a Parameter

A valid parameter should have the general form of:

```
<identifier>(<phase>, <constituent array>; <digit>) <xxx> <expression> <yyy>
<keyword Y or N> <zzz> !
```

The identifier must be followed by an opening parenthesis, a phase name, a comma and a constituent array. Optionally, the constituent array can be followed by a semicolon and a digit. The parameter name is terminated by a closing parenthesis. The parameter form is defined as:

- `<identifier>` is the parameter type;
- `<phase>` is the phase name (maximum 24 characters);
- `<constituent array>` is the specific constituent array in the phase;
- `<digit>` is the degree of composition-dependent interaction contribution (an integer number from 0 through 9), that is only for excess energy (L), Curie temperature (TC) and Bohr magneton number (BMAGN), as well as for volume-related parameters (V0 or VA or VC or VK); if it is valued as zero, or if it is for the standard Gibbs energy (G) for which the degree is always zero, it can be omitted;

- `<expression>` is the mathematical relation to describe the parameter;
- `<xxx>` and `<yyy>` are the low and high temperature limits respectively for the applicable temperature range of the parameter expression;
- `<keyword Y or N>` is the indicator on if there is continuation for the parameter expression or not;
- `<zzz>` is the reference index/number for the assessment of this parameter;
- The exclamation point `!` is used to indicate that the current parameter definition is ended.

Parameter Name

The GES parameter name has a general form of:

```
<identifier>(<phase>,<constituent array>;<digit>)
```

Examples of parameter names:

- `G(GAS,C1O2)`: The Gibbs energy of formation of a CO_2 molecule in gas.
- `G(FCC,FE:VA)`: The Gibbs energy of formation of fcc Fe with interstitials.
- `L(LIQ,Fe,Cr;0`: The regular solution parameter for Fe and Cr in liquid.
- `L(LIQ,Fe,Cr;1)`: The sub-regular solution parameter.
- `TC(BCC,Fe:Va)`: The Curie temperature of bcc Fe.
- `BMAGN(BCC,Fe:Va)`: The Bohr magneton number parameter of bcc Fe.

The parameter name consists of several parts. The first is a type-identifier and these can be used:

- `G`: Standard energy parameter (Gibbs energy of formation) or for interaction parameters;
- `L`: Excess energy parameter (Gibbs energy of interaction) always used for interaction parameters;
- `TC`: Curie temperature for magnetic ordering;
- `BMAGN` or `BM`: Bohr magneton number for magnetic ordering (or Born function ωPr,Tr for aqueous solute species).
- `VO`: Molar volume at 298.15 K and 1 bar (a numeric value only);

- VA: Integrated thermal expansivity; $\int_{298.15}^{T} \alpha(T)\mathrm{dT}$
- VC: High-pressure fitting parameter;
- VK: Isothermal compressibility.

For more information about the high pressure volume, see X.-G. Lu, M. Selleby, B. Sundman, "Implementation of a new model for pressure dependence of condensed phases in Thermo-Calc", Calphad. 29, 49–55 (2005).

When necessary quantities as H (enthalpy), S (entropy), V (Volume), F (Helmholtz energy), etc., can be calculated from the Gibbs energy.

Phase Name

Specifying the PHASE NAME in uppercase is recommended; however, if you prefer to write it as a mixture of uppercase and lowercase, it automatically converts all lowercase to uppercase, as the GIBBS module only recognizes uppercase phase names. It is important that if a phase bears a legal phase-type (among G, A, Y, L, I, F and B) in its phase definition (already by the PHASE keyword; such as GAS:G, LIQUID:L,SLAG:L, IONIC-LIQ:Y, SPINEL:I, FCC_L12:F, HCP_D021:F, BCC_B2:B, AQUEOUS:A), such a valid phase-type code should not be attached to the phase name when ENTER_PARAMETER is executed.

Constituent Array

The constituent array consists of a list of constituent names. Interaction parameters have two or more constituents from the same sublattice separated by a comma. If the phase has sublattices, at least one constituent in each sublattice must be specified. The constituents in different sublattices must be given in sublattice order and are separated by a colon.

After the component array, a sub-index digit can be specified after a semicolon. This digit must be in the range 0 to 9. The interpretation of the sub-index depends on the excess energy model used for the phase. If no semicolon and digit are given, the sub-index value is assumed to be as zero.

The excess energy parameters, e.g. the regular/subregular (binary) parameter or ternary parameters, are multiplied with two or more fractions of the constituents from the same sublattice of the solution phase. These additional constituents must be given as interacting constituents (as the following prompt).

Solution phases with sublattices can have interacting constituents in each sublattice.

Interaction Parameter

An interaction parameter, which is used to describe the excess term of a quantity, must have two or more constituents that interact with each other on a specified sublattice site of the given phase. It is arbitrary which of these constituents is given as the first constituent and what is given as the interacting constituents. The software always sorts the constituents (in each sublattice) in alphabetical order when the parameter name is written as a prompt (for entering its parameter value) and when the parameter is listed (using the GIBBS commands LIST_PARAMETER or LIST_PHASE_DATA). This is important for all asymmetric interaction parameters where the sign of the interaction parameter must depend on the appearance order.

Use an asterisk* to denote that the excess interaction parameter is independent of the constituents of a specific sublattice. For example, `L(FCC_L12,AL,NI:*)` means that the interaction parameter is for the binary interaction between constituents AL and NI on the first sublattice in the `FCC_L12` solution phase, while it is independent of all constituents on the second sublattice. An interaction parameter in the list of constituents is always added to the Gibbs energy and the asterisk * is calculated with the term of [1∑y(specified constituents)], which implies that in an A-B binary system these `L` parameters are identical (but in higher-order systems, these are different):

- `L(phase,A,B)` is multiplied with X(A)*X(B)
- `L(phase,A,*)` is multiplied with X(A)*(1-X(A))
- `L(phase,B,*)` is multiplied with X(B)*(1-X(B))

If you press <Enter> when you are asked for a parameter name or if you have improperly input the entire parameter name, you are asked for each of these items in the name.

ENTER_PARAMETER

This command is for the PARROT module.

There is also a Gibbs (GES) module command with the same name.

About the ENTER_PARAMETER Command

Use this command to enter TP-function(s) for a specific parameter for a phase interactively with this command. If there is already a parameter expression defined (for this parameter), that is deleted and replaced with newly entered one.

The entered TP-Function(s) for the parameter can be changed later with the command AMEND_PARAMETER.

Syntax	ENTER_PARAMETER

Prompts	`Parameter: <Parameter name>`
	As explained in About the ENTER_PARAMETER Command, specify a correct and complete `Parameter Name`, which should contain all the necessary parts of the general form:
	`<Identifier>(<Phase>,<Constituent array>;<Digit>)`
	If a parameter name is not acceptable or <Enter>, is pressed, a message displays:
	`*** Error, please re-enter each part separately`
	and you are prompted for input for each required part for a parameter name.

Options	**Description or Information**
`Identifier`	`Identifier (/X/): <G or L, or TC, or BM, or V0 or VA or VC or VK>` If this command is used one or more times, the previous value on this prompt is set as default. Press <Enter> for the same type identifier or specify a new type.
`Phase name`	`Phase name (/ABCD/): <Phase name>` Each parameter is valid for a specific phase only. The name of that phase must be supplied (maximum 24 characters). The name can be abbreviated.
`Constituent`	`Constituent (in sublattice # /ABC/): <Species name>` A parameter is identified by the constituents on a specified sublattice site of the given phase, the stoichiometric coefficients of which are multiplied with the parameter. The name of the constituent can be abbreviated. It is the species name, not the stoichiometric formula required here. If this command is used one or more times, the previous value on this prompt is set as default. Accept it by pressing <Enter> if the constituent is the same, or specify a new species name.

Syntax	ENTER_PARAMETER
Interacting constituent	For phases with several sublattices, the program asks for one constituent in each sublattice. `Interacting constituent (in sublattice # /XYZ/): <Species name>` If this command is used one or more times, the previous value on this prompt is set as default. Press <Enter> to accept it if the constituent is the same, or specify a new species name. To cancel the default value of the interacting constituent type `NONE` or the name of another constituent. This question is repeated until all the interested interacting constituent(s) on a specific sublattice in the phase are specified, and finally an <Enter> is enforced.
Degree	`Degree /#/: <Degree>` Degree is model-dependent. Specify an integer number (a value from 0 through 9) as the degree of composition-dependent interaction contribution for the phase parameter. This is valid for excess energy (`L`), Curie temperature (`TC`) and Bohr magneton number (`BMAGN`), as well as for volume-related parameters (`V0`, `VA`, `VC` or `VK`). For binary interaction parameters, the degree is usually the power in the Redlich-Kister expression. For ternary interaction parameters, it is usually the Hillert ternary index. For a standard `G` parameter for a pure component (end-member) its degree should be always 0 and this prompt should not display.

Phase parameter	After this prompt, the program echoes on the screen the full TP-Function of the phase parameter.
	`Low temperature limit /298.15/: <Lowest temperature limit in K>`
	Specify the lowest temperature limit (in Kelvin), or the lowest-pressure limit (in Pascal but entered as a negative number), for the current TP-Function.
	`Function: <Definition for a function>`
	A TP-Function consists of terms in T and P.
	`& <Continuation of the definition for the current function>`
	Continuation of a TP-Function definition.
	`High temperature limit /6000/: <High temperature limit in K>`
	Specify the high temperature limit (in Kelvin), or the high-pressure limit (in Pascal; only if the *lowest limit* is entered as a negative number) for the current TP-Function.
	`Any more ranges? /N/:`
	Enter Y for more function(s) or N to end this command.

LIST_ALL_VARIABLES

This command is for the PARROT module.

Use the LIST_ALL_VARIABLES command to create a list of the values and status of all variables in the PARROT workspace on screen or in a text file. After an optimization some statistical information is also written. The correlation matrix is written if that option is chosen.

SET_OUTPUT_LEVELS.

Syntax	LIST_ALL_VARIABLES
Prompt	`Output to screen or file /Screen/: <File name>` A list of the current values and status, as well statistical information (if after optimization) and the correlation matrix (optionally), for all variables is written on screen (by pressing <Enter>) or on the list file under a specific file name which can later on be opened and edited by basic text editor.

Example of LIST_ALL_VARIABLES

The following is the listed variables for the example TCEX36, after the first optimization when having set all variables available for optimization.

```
== OPTIMIZING VARIABLES ==
 AVAILABLE VARIABLES ARE V1 TO V00
 VAR.  VALUE            START VALUE      SCALING FACTOR   REL.STAND.DEV
 V1     2.03729090E+04   2.03688352E+04   2.03688352E+04   3.41524152E+00
 V2    -2.94286372E+01  -2.94286372E+01  -2.94286372E+01   2.37944771E+00
 V11   -2.17373936E+04  -2.18095983E+04  -2.18095983E+04   3.97086303E-02
 V12    1.52107184E+01   1.51660547E+01   1.51660547E+01   5.84552327E-02
 V15    2.42082351E+04   2.45139169E+04   2.45139169E+04   5.00914471E+00
 V16   -8.38723972E+00  -8.83460472E+00  -8.83460472E+00   1.60961318E+01
 V17    3.08916533E+03   3.15802558E+03   3.15802558E+03   9.63738108E+00
 V19    2.20292586E+04   2.21385673E+04   2.21385673E+04   4.14274011E+01 V20   -
7.04217974E+00  -7.22424882E+00  -7.22424882E+00   1.00561540E+02
 NUMBER OF OPTIMIZING VARIABLES :  9
 ALL OTHER VARIABLES ARE FIX WITH THE VALUE ZERO
 THE SUM OF SQUARES HAS CHANGED FROM  8.00002729E+04 TO  8.00002719E+04
 DEGREES OF FREEDOM  45. REDUCED SUM OF SQUARES  1.77778382E+03
```

LIST_CONDITIONS

This command is for the PARROT module.

Use the LIST_CONDITIONS command to generate a list of the current values of optimization conditions, as well the current status of listing, either on screen or in a basic text file which can be opened and edited by a text editor.

Syntax	LIST_CONDITIONS
Prompt	`Output to screen or file /Screen/: <File name>` Press <Enter> to output to screen or on the list file under a specific file name.

LIST_PARAMETER

This command is for the PARROT module.

There is also a Gibbs (GES) module command with the same name.

Use the LIST_PARAMETER command to list the TP-function(s) of a specific parameter for a phase. You must supply the name of the phase parameter:

```
The parameter name: <Identifier>(<Phase>,<Constituent array>;<Digit>)
```

For encrypted commercial databases, you may not be able to use this command to list any retrieved parameter.

Syntax	LIST_PARAMETER

Prompts	`Parameter: <Parameter name>`
	Specify a correct and complete parameter name, which should contain all the necessary parts of the general form: <identifier>(<phase>,<constituent array>;<digit>)
	See About the ENTER_PARAMETER Command to learn how to define the parameter name.
	If a parameter name is not acceptable or <Enter> is pressed, an error message displays:
	`*** Error, please re-enter each part separately`
	The program prompts for separate input for each required part for a parameter name.

	`Identifier (/X/): <G or L, or TC, or BM, or V0 or VA or VC or VK>` Specify one of these types of legal identifiers.
	`Phase name (/ABCD/): <Phase name>` Specify the phase name.
	`Constituent (in sublattice # /ABC/): <Species name>` Specify the constituent name on the specified sublattice site of the given phase.
	`Interacting constituent (in sublattice # /XYZ/): <Species name>` Specify the interacting constituent name on the specified sublattice site of the given phase; if there is no interacting constituent, press <Enter>.
	`Interacting constituent (in sublattice # /XYZ/): <Species name>` If there is more than one interacting constituent on the specified sublattice site of the given phase, specify them; otherwise press <Enter>.
	`Degree /#/: <Degree>`

Syntax	LIST_PARAMETER
	Specify a numerical number as the degree for the phase parameter.

LIST_PHASE_DATA

This command is for the PARROT module.

Use the LIST_PHASE_DATA command to list all the phase from the Gibbs (GES) module for a specific phase. These are displayed on screen. The thermochemical parameters listed for each phase are always in SI units.

Syntax	LIST_PHASE_DATA
Prompt	`Phase name: <Phase name>` Specify a phase name.

LIST_RESULT

This command is for the PARROT module.

List the result of the current optimization run on screen or in a specified file. The level of detail listed can be prescribed by the command SET_OUTPUT_LEVELS.

The LIST_RESULT command has an option G for creation of an experimental data file with two columns, one for the experimental value and the other for the calculated value. It allows plotting a diagram and visualizing the fitting results. The plot is automatically plotted and you can scale it giving commands in the POST module. The option D lists all experiments, including those with fulfilled inequalities which are suppressed with the default option C.

Syntax	LIST_RESULT
Prompt	`Full, Condensed, Detailed or Graphic format: /C/: <C or D or F or G>`
	Choose a format. • The F (full) format is obsolete but retained for backward compatibility. • C (condensed) is the default. • D (detailed) lists all experiments, including those with fulfilled inequalities (not included with the default condensed file). • The G (graphical) format creates an experimental data file containing two columns, one with the experimental value and the other with the calculated value. This allows plotting of a diagram where all symbols should be on the diagonal if the fit is perfect. The plot is automatically plotted and you can scale it giving commands in the POST module. `Output to screen or file /Screen/: <File name>` A list of the current optimization results are written on screen (by pressing <Enter>) or on the list file under a specific file name which can later on be opened and edited by basic text editor.
	The output normally consists of these parts: • A title showing the data of the action; • A message on successful optimization with the iteration number in the last optimization; • A paragraph describing the optimization condition; • A list of the latest set of optimized and fixed variables; • A paragraph describing the optimization quality (some statistical information); • A correlation matrix for all optimizing variables (optionally shown, pre-set by the SET_ OUTPUT_LEVELS command); • A list of all parameters (including their symbol names, status and current values or function expressions), and all phase descriptions (including phase name, model names, constituents, and phase's G/L/TC/BM expressions) predefined for each phase in the system (optionally shown, pre-set by the SET_OUTPUT_LEVELS command); • A paragraph describing the alternate equilibria (and possible error during optimization);

Syntax	LIST_RESULT

- A detailed list on all the equilibrium points used in the current optimization. If the alternate-mode is used in the optimization, only an error value is shown. For normal-mode calculations, a list is shown for the experimental equilibrium numbers (first column) and corresponding original experimental data (second column, in the form `quantity = value`) which are used in optimization (i.e. non-zero weighted points). Such experimental data are by each point compared by the calculated value (third column) after the last optimization. Also listed are the experimental error (column 4), the difference between the calculated value and original experimental data (column 5), and the contribution to the sum of least square (column 6).

Example of LIST_RESULT

The following is the listed result after the first optimization based on the prescribed definitions in the TCEX36a.TCM and TCEX36b.TCM, but having set all variables available for optimization.

```

LIST_STORE_FILE

This command is for the PARROT module.

Use the LIST_STORE_FILE command to display the name of the store file and its full path.

LIST_SYMBOL_IN_GES

This command is for the PARROT module.

Lists TP-function(s) for the entered model parameters for phases in the system on screen. In many cases, the optimizing variables are parts of the TP-functions which in turn are entered in model parameters for various phases in the GIBBS workspace.

The LIST_SYMBOL_IN_GES command is a way to find out how the functions depend on the optimizing variables. In the PARROT module the list is only shown on screen, not written to any file (which the LIST_SYMBOL command in the GIBBS module does).

Syntax	LIST_SYMBOL_IN_GES
Prompt	`Name: <Symbol name>` Specify a symbol name. Only those symbols that match this name are listed. Or press <Enter> for a list of all available symbols entered in the system.

OPTIMIZE_VARIABLES

This command is for the PARROT module.

Use the OPTIMIZE_VARIABLES command to perform variable optimization. All system-definition data needed for the optimization is read from the current work file (*.PAR). The result of the optimization is automatically stored in the current work file.

It initially takes a small step in each variable to find the steepest slope. You can give zero iteration to calculate the error in all selected experiments, and then use LIST_RESULT to check how good (bad) the current fit is.

Syntax	OPTIMIZE_VARIABLES
Prompt	`Number of iteration /N/: <Integral number of iteration>` Specify an integral number for the optimization iteration. The specified iteration number is shown as the default number. The PARROT module tries this number of different sets of values of the optimizing variables unless it has converged earlier, or has given up earlier.

READ_PARROT_WORKSPACES

This command is for the PARROT module.

Workspace Files

You cannot use this command if there is no work file opened or created already. Also, unlike the READ commands in other modules (e.g. GIBBS or PLOY), this command in the PARROT module does not ask for the file name where to read a previously opened/created/updated PARROT/GIBBS/POLY workspaces.

Use the READ_PARROT_WORKSPACES to read the previous PARROT/GIBBS/POLY workspaces back to replace the current PARROT/GIBBS/POLY workspaces. It is useful if late changes made through various PARROT/GIBBS/POLY commands are not satisfactory.

The previous PARROT/GIBBS/POLY workspaces are always associated with the latest action to either open a work file by SET_STORE_FILE, or to create a work file by CREATE_NEW_STORE_FILE (either interactively in the PARROT module or through a MACRO_FILE_OPEN of an *SETUP.TCM file), or to update the work file by SAVE_PARROT_WORKSPACES.

RECOVER_VARIABLES

The RECOVER_VARIABLES command is used to set back the values of all variable to the start values.

REINITIATE

This command should not be used unless you want to destroy the current PARROT workspace. However, this PARROT command does not reinitiate the GIBBS/POLY3 workspaces.

This command is for the PARROT module.

The REINITIATE command is used to reinitiate the workspace used by PARROT. All output and optimizing conditions are given their default values. All variables are set fixed with their value equal to zero.

RESCALE_VARIABLES

When using the RESCALE_VARIABLES command, the current values of all the parameters are copied to their start values and the scaling factors for further optimization. Thus it should be done now and again, in particular if you think the optimization results are improved after the previous run(s), or if any variable changes more than a factor of 10.

SAVE_PARROT_WORKSPACES

This command is for the PARROT module.

Workspace Files

If the latest changes made through various PARROT/GIBBS/POLY commands are as required, use the SAVE_PARROT_WORKSPACES command to save the current workspace (i.e. data area) used by the PARROT program (also including the current GIBBS and POLY workspaces), onto the present work *.PAR file which has already been opened by SET_STORE_FILE or been created by CREATE_NEW_STORE_FILE (either interactively in the PARROT module or through a MACRO_FILE_OPEN of an *SETUP.TCM file).

The PARROT/GIBBS/POLY workspaces are updated after each PARROT/GIBBS/POLY command. This means the current PARROT/GIBBS/POLY workspaces are always updated onto the latest work *.PAR file that is associated with the latest SET_STORE_FILE or CREATE_NEW_STORE_FILE command.

Unlike the SAVE commands in other modules (e.g. GIBBS or PLOY), this command in the PARROT module does not ask for the file name where to save the current PARROT/GIBBS/POLY workspaces. You cannot use this command if there is no work *.PAR file opened or created already.

SET_ALTERNATE_MODE

The alternate mode is described in About Alternate Mode. It should be used only to optimize start values of the model parameters in the beginning of the assessment.

Use the SET_ALTERNATE_MODE command to turn the alternate mode on or off.

With the ALTERNATE mode is possible to include functions to be evaluated together with an alternate calculation and to select ALTERNATE mode for each experimental equilibrium.

Syntax	SET_ALTERNATE_MODE
Prompt	`On /Y/:` By default alternate mode is ON.

SET_EXTERNAL_PARAMETER

This command is for the PARROT module.

Optimize model parameters of the so-called external models, which may not be as fully-implemented/integrated parts inside the GIBBS system and thus are independently defined within user-specified/written source codes. This command makes links between the PARROT optimizing variables and external model parameters.

In order to be able to build the specified external model and to use this SET_EXTERNAL_PARAMETER command, it requires you to first write codes for a preferred external model (as it is not within the standard GIBBS system of the Thermo-Calc software) and then provide it to a consultant at Thermo-Calc Software AB for the purpose of including the external model in a separate DLL that is interactively connected to the software. For more information, see theConsultancy page on our website.

Syntax	SET_EXTERNAL_PARAMETER
Prompt	`External name: <Parameter name in the external model>` Correctly specify the parameter name defined within a specified/written external model.

	`As optimizing variable number: <n>`
	Give the number of the PARROT optimizing variable, which should have a unique link to the specified parameter name of the external model.
	For example, @@ Link PARROT variables to CAM parameters:
	`SET-EXTER-PAR GT(SLAG_A,O-2,SI+4,CA+2) 1`
	`SET-EXTER-PAR ET(SLAG_A,O-2,SI+4,CA+2) 2`
	`SET-EXTER-PAR EXT(SLAG_A,O-2,SI+4,CA+2) 3`

SET_FIX_VARIABLE

Use the SET_FIX_VARIABLE command to prescribe a fixed value to a variable. The variable is considered as a constant at the optimization, usually after successful optimization runs for some specific variables (for some of the phases in the system). Such fixed variables can also be set back for further optimization run by using SET_OPTIMIZING_VARIABLE.

Syntax	SET_FIX_VARIABLE
Prompts	`Variable number: <Variable number(s)>` Specify the number of the variable. It is possible to give a range by giving two numbers with a hyphen in between (no spaces allowed), e.g. `1`. The parameters within the limits are set fixed to their current values (no question of values).
	`Start value /xxxx.xxxxx/: <A value to be fixed>` Specify a numerical value to be fixed for the selected variable (only when one variable number is specified at the previous prompt). The current value for the selected variable is shown as default. If a range of variable numbers is specified at the previous prompt, this question is not prompted, and the current values are used as fixed values.

SET_OPTIMIZING_CONDITION

This command is for the PARROT module.

Use the SET_OPTIMIZING_CONDITION command to specify the conditions for the optimization. The default values are chosen automatically by the PARROT program, and in most cases these should not be changed.

The optimization stops when the sum of errors decreases by this value, even though it might be possible to increase it further with a new OPTIMIZE command.

Syntax	SET_OPTIMIZING_CONDITION
	`Relative standard deviation for experiments? /N/:` By default the standard deviation of the experimental determinations are absolute values. Enter Y if these are used as relative weighting factors. The estimated standard deviations of the optimized variables might be different for the two cases.
Prompt	`Min save on file? /Y/:` Specify whether the program should minimize the transfer of data to and from the current work file during the optimization: • If the default (N) is kept, the workspaces are stored on the current work file after every iteration in the optimization procedure. • Enter Y to speed up the optimization. After optimization use the SAVE_PARROT_WORKSPACES command to update the progress onto the current work file.
	`Relative step for calculation of derivatives: /1e-04/: <xxx>` In the calculation of the correlation matrix for equilibria with inaccuracy in the independent state variables, some numerical derivatives might have to be calculated. Specify the relative step (`xxx`) for the calculation of these derivatives.
	`Maxfun (va05ad): /100/: <n>` The maximum number of iterations in the optimization. The same value set by the OPTIMIZE command.
	`Dmax (va05ad): /100/: <n>` An estimate of the maximum distance between the start and the final values of the variables. A smaller value makes the program vary the parameters with smaller factors.
	`H (va05ad): /1e-04/: <xxx>`

Syntax	SET_OPTIMIZING_CONDITION
	The step used in the scaled variables for calculating numerical derivatives during the optimization.
	`Acc/(initial sum of squares) (va05ad): /.001/: <xxx>`
	The break condition for the optimization. The accepted value is the difference between the true minimum and the calculated one.

SET_OPTIMIZING_VARIABLE

This command is for the PARROT module.

Use the SET_OPTIMIZING_VARIABLE command to specify which variable value should be estimated at the optimization. Such a variable can have a value of zero or another start value, or is fixed by SET_FIX_VARIABLE prior to the previous optimization run.

For a good reference prior to this command, a list of all variables (which are used to define various parameters for phases in the optimizing system, as pre-entered in the *SETUP.TCM file or interactively entered in the GIBBS module) are obtained by using LIST_ALL_VARIABLES.

Syntax	SET_OPTIMIZING_VARIABLE
Prompts	`Variable number: <Variable number(s)>` Specify the number(s) for the variable(s) to be set. Any non-zero parameter within the range is allowed to be optimized. A parameter with a current value equal to zero must be specified explicitly here in order to be optimized. Specify a range by giving two numbers connected by a hyphen (no space allowed!), e.g. `2-8`. Under this circumstance, no question of start values are asked.
	`Start value /xxxx.xxxxx/: <A guess value>` Specify a start guess of the optimum value (only when one variable number is specified at the previous prompt). The current numerical value for the selected variable is shown as default. This guess is critical as the initial guess of all parameters must make it possible to calculate the selected equilibria. If a range of variable numbers is specified at the previous prompt, this question is not prompted, and the current values (as start values) are not changed.

SET_OUTPUT_LEVELS

This command is for the PARROT module.

Use the SET_OUTPUT_LEVELS command to choose the type of information the PARROT module gives during the optimization procedure and when listing results.

Syntax	SET_OUTPUT_LEVELS
Prompts	`List increment /1/: <Increment in iteration number>` Specify the increment in iteration number for which information is listed on screen during the optimization. By giving a larger number it shortens the list.
	`List sum of squares: /Y/:` Choose whether the sum of squares is listed on screen during the optimization procedure.
	`List scaled variables: /Y/:` Choose whether the scaled variable values are listed on the terminal during the optimization procedure.
	`List weighted residuals: /N/:` Choose whether the weighted residuals are listed on the terminal during the optimization procedure.
	`List all parameters: /N/:` Choose whether all parameters in the models are listed in LIST_RESULT.
	`List correlation matrix: /N/:` Choose whether the correlation matrix of the variables are listed with the commands LIST_RESULT and LIST_ALL_VARIABLES.

SET_SCALED_VARIABLE

The SET_SCALED_VARIABLE command is similar to SET_OPTIMIZING_VARIABLE in that it specifies start values for optimizing variables. The difference being it is functional for only one optimizing variable at one time. It also prescribes a minimum and maximum value for the variable. During the optimization runs, the variable value is limited within this min-max range.

Such a variable may have a value of zero or another start value, or may be fixed by SET_FIX_VARIABLE prior to the previous optimization run. For a good reference prior to using this command, a list of all variables (which are used to define various parameters for phases in the optimizing system, as entered in the *SETUP.TCM file or interactively entered in the GIBBS module) is obtained by using LIST_ALL_VARIABLES.

Syntax	SET_SCALED_VARIABLE
Prompts	`Variable number: <Variable number(s)>` Specify the number for an optimizing variable to be set. Any non-zero parameter is allowed to be optimized, and a parameter with a current value equal to zero must be specified explicitly here in order to be optimized.
	`Start value /xxxx.xxxxx/: <A guess value>` Specify a start guess of the optimum value. The current numerical value for the selected variable is shown as default. This guess is critical as the initial guess of all parameters must make it possible to calculate the selected equilibria.
	`Min value /xxxx.xxxxx/: <A guess value>` Specify a minimum guess of the optimum value. It should be smaller than, at least equal to, the current start value for the selected variable.
	`Max value /xxxx.xxxxx/: <A guess value>` Specify a maximum guess of the optimum value. It should be larger than, at least equal to, the current start value for the selected variable.

SET_STORE_FILE

This command is for the PARROT module.

Use the SET_STORE_FILE to specify a store file (work file) to be used for compilation and optimization. The *.PAR work file must be created (CREATE_NEW_STORE_FILE) as a store file. The GIBBS, POLY and PARROT workspaces are read from the specified store file (with a default extension of PAR).

Syntax	SET_STORE_FILE
Prompt	Enter a `*.PAR file name` in the **File name** field and specify the working directory in the **Look in** field. Normally the default file-type in the **Files of type** field is the correct one for the PARROT workspace format (i.e. *.PAR file). Click **Open** or **Cancel** as applicable.

EDIT_EXPERIMENTS (ED_EXP) Submodule Commands

EDIT_EXPERIMENTS (ED-EXP) is a submodule of PARROT.

- TOGGLE_ALTERNATE_MODE
- T-ZERO_TEMPERATURE

CHANGE_STATUS

This command is available with the POLY and ED-EXP modules.

In the POLY module, use the CHANGE_STATUS command to set the status for components, species and phases in the defined system for all the sequential calculations (single-point, stepping, and mapping) in equilibrium or local/partial equilibrium state. Each component, species and phase has a status. The default status is `ENTERED`.

The most important use is to calculate metastable equilibria and metastable phase diagrams by setting some phases (that would otherwise be stable) to the SUSPENDED or DORMANT phase-status. Another important applications is to calculate paraequilibria by setting some components to the SPECIAL component-status.

For a component and for a species, the status can be one of the following:

- `ENTERED`: the component(s) or species are included in the calculation. This is the default status.
- `SUSPENDED`: the component(s) or species are not considered in the calculation.
- `SPECIAL`: the specified component(s) are not included in summations for mole or mass fractions. It only works for component(s).

Only component(s) can have the status SPECIAL, which implies that these are not included in summations for mole or mass fractions.

For example, for the *u-fractions* or other normalized fractions, when one or more of the components are excluded from the summation, you must specify which component(s) should be excluded from the calculation of mole or mass fraction. This component status is particularly useful when calculating paraequilibrium states. Such component(s) are normally interstitial component, and must have the status SPECIAL. This is assigned by the CHANGE_STATUS command.

Syntax	CHANGE_STATUS
Prompts	`For phases, species or components? /Phases/: <Keyword>` *Keyword* = phase or species or components
	`Phase name(s): <Name(s) of the phase(s)>` For `phase` as the keyword, the names of the phases that have their status changed must be given (all on one line). A comma or space must be used as separator. The status to be assigned to the phases can also be given on the same line if preceded with an equal sign (=).

Syntax	CHANGE_STATUS

An asterisk, *, can be used to denote all phases. The special notations `*S`, i.e. a wildcard * directly followed by an `S`, sign, means all suspended phases. In the same way, `*D` means all dormant phases, and `*E` means all entered phases.

`Name(s): <Name(s) of the Species or Component(s)>`

For species or components as the keyword, the names of the species or components that have their status changed must be given (all on one line). A comma or space must be used as separator. Similarly to the case of phase as the keyword, the status to be assigned to the species or components can also be given on the same line if preceded with an equal sign =.

An asterisk, *, can be used to denote all species or components. The special notations `*S`, i.e. a wildcard * directly followed by an `S`, sign, means all suspended species or components. In the same way, `*E` means all entered species or components.

`Status /Entered/: <New status>`

The `new` status to be assigned must be given.

For species, the values `ENTERED` or `SUSPENDED` can be used.

For the POLY module, using the `Entered` or `Suspended` status here has the same result as using the commands MAKE_COMPONENT_ENTERED and MAKE_COMPONENT_SUSPENDED. The exception is that any existing conditions that depend on a suspended component are removed when using the MAKE_COMPONENT_SUSPENDED command.

For components, the status `ENTERED`, `SUSPENDED` or `SPECIAL` can be given. SPECIAL means that this component is excluded from sums for mole fractions and mass fractions, which is useful when calculating the *ufractions* or other normalized fractions of system components.

For phases, the status `ENTERED`, `SUSPENDED`, `DORMANT` or `FIXED` can be given. DORMANT means the same as suspended but the driving force is calculated. FIXED means that it is a condition that the phase is stable at a certain amount.

For example, for the ufractions, when one or more of the components are excluded from the summation, you must specify which component should be excluded from the calculation of the mole fraction. This component must have the status SPECIAL. This is assigned by the CHANGE_STATUS command: `Change_Status comp C=special`.

`Start value, number of mole formula units /0/: <Initial amount>`

For ENTERED phases, an `initial amount` of the phase can be given. Normally, 0 is given if the phase is not likely to be stable, and 0.5 or 1 or any positive number if the phase could be stable, but such an initial amount is only used as the rough starting estimation in the equilibrium calculations.

`Number of mole formula units /0/: <Equilibrium amount>`

Syntax	CHANGE_STATUS
	For FIXED phases, the `equilibrium amount` of the phase [always using an initial estimation being the `NPF(phase)` value which it is the normalized mole number of components (per mole formula unit) of the specific status-fixed phase] must be given. If the equilibrium amount is zero, then the phase is at its stability limit. See Note About Specifying a FIXED Phase Status for more details.

Note About Specifying a FIXED Phase Status

Special attention should be paid when specifying a FIXED phase status in equilibrium calculations (for single points, stepping or mapping calculations), as described below.

The phase amount variables, NP(phase), BP(phase) and VP(phase), as well as all their M/W/V-suffixed quantities, should not be used as conditions. Instead, use the CHANGE_STATUS command to set a relevant condition, e.g. `CHANGE_STATUS phase <phase>=fix <amount>` where the fixed <amount> is roughly the same as the F-suffixed quantity `NPF(phase)`.

The `NPF(phase)` quantity is the normalized mole number of components (per mole formula unit) of the specific phase in the defined system, which unlike other `F`-suffixed state variables [e.g. GF(phase), HF(phase) and DGF(phase)] cannot be directly applied in any POLY command, implying that it cannot be directly evaluated or listed/shown. If intended to shown such a normalized phase amount value in an equilibrium state, you should use a properly-entered symbol (function or variable), for example: `NPFabc = NP(abc)/NA` or `NPFabc = NPM(abc)/NA*N`. N is the total system size (in mole). The NA value is a quantity that is phase-dependent (and sometimes also equilibrium-dependent for ionic solution phases), and is the total atomic number in a mole-formula-unit of the specific phase abc (excluding interstitial component and, of course, vacancy). For example, the SIGMA, FCC, BCC and LIQUID phases (among others) in a defined Fe-Cr-Ni-C-N-O system (retrieved from a specific database) may be modeled by certain models, and their NA values must be evaluated in different ways, as described below:

```
LIQUID (C,Cr,CrO3/2,Fe,FeO,FEO3/2,N,Ni,NiO)1 NA = 1
FCC_A1 (Cr,Fe,Ni)1(Va,C,N,O)1 NA = 1
BCC_A2 (Cr,Fe,Ni)1(Va,C,N,O)3 NA = 1
SIGMA (Fe,Ni)8(Cr)4(Cr,Fe,Ni)18 NA = 30
```

If in the same Fe-Cr-Ni-C-N-O system the liquid solution phase is modeled by the Two-Sublattice Ionic Liquid Model, i.e.:

```
IONIC_LIQ (Cr+3,Fe+2,Ni+2)p(VA,C,N,O-2,FEO3/2)q,7
```

then the evaluation of its NA value becomes even more complicated:

```
NA = p + q*yC2 + q*yN2 + q*yO2 2 + q*yFeO2 3/ 2
```

where the stoichiometric coefficients *p* and *q* are also dependent upon the real equilibrium state (rather than having fixed values in the system). Similar situations occur for other (solid) phases which are described by a multiple sublattice model with ionic constituents, such as SPINEL and HALITE phases in some databases.

There is no strange thing when using a zero value [i.e. `0`] in a FIXED phase-status, since it means the specified phase is stable in equilibrium state but has a zero-amount of mass in the equilibrium calculations; in other words, on a phase diagram, the specific phase is on a zero-fraction line (ZFL), i.e. it starts becoming stable on one side of a corresponding phase-boundary line or unstable on the other side of the same boundary. It is often and efficient to do so when calculating e.g. solidus equilibrium states.

However, when a non-zero value [it must always be positive; e.g. 1 or 0.5 or 0.3 or 1.5] is to be specified in a FIXED phase-status, it is unnecessarily the exactly same stable amount of the specific FIXED-status phase in a calculated equilibrium state any longer; instead, the <equilibrium amount> value is the NPF(phase) value that is only roughly used as the estimated starting-value of the FIXED-status phase in the equilibrium calculations.

Therefore, a FIXED-status for a liquid phase being unity does not necessarily imply that it is a liquidus equilibrium state (where the liquid phase is in equilibrium with some solid phases but the liquid phase takes all the mass in the defined system). A unity value for setting the liquid phase status in calculating liquidus equilibrium state can only be used when the liquid mixture phase is predefined as a single-sublattice solution phase (such as metallic liquid phase in multicomponent alloy systems) and the total system size as one mole (i.e. N=1).

When a phase is described by a solution model in which two or more sublattices are considered and these sublattice sites may also have different stoichiometric coefficients [meaning that the mixture phase could have more than one atom in formula [NA>1; see some examples above], the unity value should not be used when setting the FIXED status for the phase; instead, you should use an appropriate value that ranges from 0 to a NPF(phase) value that equals to or is smaller than 1/NA (if the total system size N=1) or 1/NA*N (if N differs from unity). For this reason, if a multicomponent system bears an IONIC_LIQUID phase that is described by the Two-Sublattice Ionic Liquid Model (or any other multiple-sublattice ionic solution phases), it is difficult to use a proper `NPF(ION_LIQ)` value in setting its FIXED phase-status, because that should be less than (or equal to) the complex value of

N/[$p + q^{*}y_{C}2 + q^{*}y_{N}2 + q^{*}y_{O}22 + q^{*}y_{FeO}2\ 3/\ 2$].

Examples

For example, to obtain the metallic fraction in a system with carbon as an interstitial component, you can set the component status for carbon as `SPECIAL`:

```
Change_Status comp C=special
```

The `SUSPENDED` status for components and species does not always work as expected.

For a phase, it may have one of these statues:

- `ENTERED`: the phase(s) are included in the equilibrium calculations and these are stable if that minimizes the total Gibbs energy in the defined system. This is the default status for all phases already retrieved from the chosen database(s). An ENTERED phase-status is always associated with an initially-estimated amount [in mole number; normally, as 0 if the phase is not likely to be stable, and as 0.5 or 1 or any positive number if the phase could be stable] but it is only used as the rough starting value in the equilibrium calculations.
- `SUSPENDED`: the phase(s) are not considered in the equilibrium calculations.
- `DORMANT`: the phase(s) are not considered in the equilibrium calculations but their driving forces for precipitation are calculated.
- `FIXED`: it is an equilibrium condition that the status-fixed phase must be stable, and be in equilibrium at a specified amount [always using an initial estimation being the `NPF (phase)` value which it is the normalized mole number of components (per mole formula unit) of the specific status-fixed phase]. See more descriptions at the end of this command.

COMMENT

This command is for the ED-EXP module.

The COMMENT command is only used in the *.POP/*.DOP files (so can be included with experimental data files) to write brief comments or descriptive information on a newly created equilibrium (experimental) data point or a set of points given in a table.

A comment can have a maximum of about 60 characters written on the same line.

COMPUTE_ALL_EQUILIBRIA

This command is for the ED-EXP module.

In ED_EXP and PARROT modules, each experiment is treated as an individual equilibrium with some measured values. These are created with CREATE_NEW_EQUILIBRIUM, and stored in an experimental data *.POP file and then compiled and saved in the POLY workspace of a PARROT work *.PAR file.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

With COMPUTE-ALL-EQUILIBRIA, all equilibria from the current to the last experimental points are calculated. If an equilibrium calculation fails, the calculation is stopped at that equilibrium. Equilibria with weight zero is skipped.

A current or present experimental point means the latest selected or calculated one. Once used the current point turns to the last point in the data block; in such a case you first use SELECT_EQUILIBRIUM so that the current point is switched to a desired one.

For this command there is always a list output on screen, which consists of six columns for all experimental points available in the current data block:

- The first column is the *equilibrium identifier* (a number) assigned by this command,
- the second the *data label* assigned with LABEL_DATA,
- the third the *number of iterations*,
- the fourth the *current weight*, and
- the fifth the *current temperature*.
- In the sixth column the *fixed stable phases* are listed together with any *comment text* given after a COMMENT in the *.POP or *.DOP file.

If the weight is zero for an equilibrium columns 3-5 are replaced by the text *<unused>*. If the alternate mode is used for some experimental points, the listing is slightly different for such points. The 3-4 columns are displayed with *alt*, instead. If an alternate calculation is failed at one experimental point, the point is automatically assigned with a zero weight, and a warning message is shown above the data line (with all six columns).

CREATE_NEW_EQUILIBRIUM

This command is available with the POLY and ED-EXP modules.

During data-assessments using the ED_EXP module (a submodule of PARROT), you can, in the POLY module, create several equilibria with different sets of conditions and phases (but normally with the same set of components). By default, there is one equilibrium. To keep the set of conditions and phase for this equilibrium, create another one using this command, and use another set of conditions for that. Two equilibria may be useful to calculate easily the enthalpy difference between two states. In the PARROT module, the experimental information is stored as a sequence of equilibria.

Syntax	CREATE_NEW_EQUILIBRIUM
Prompts	`Equilibrium number /2/: <A new equilibrium number>` Each equilibrium in the POLY workspace is identified by a unique integer number. Such an equilibrium number can be recalled with SELECT_EQUILIBRIUM.
	`Initiation code /2/:` When an equilibrium is created, you can choose to `ENTER` all components and phases (initiation code 2), `ENTER` the components only (initiation code 1) or `SUSPEND` everything (initiation code 0). No other values are legal. The entered components and phases can later be changed with CHANGE_STATUS.

DEFINE_COMPONENTS

This command is available with the POLY and ED-EXP modules.

Use the DEFINE_COMPONENTS command to change the set of components. By default, the elements are used as components. The set of components can be important because some conditions are set using components, for example, the amounts, activities or chemical potentials.

For example, in the system Fe-Si-O, you can define FEO, FE2O3, and SIO2 as components, thus replacing the default FE, SI and O.

This implies a command REINITIATE_MODULE and it should be given as the first command in the POLY module.

Syntax	DEFINE_COMPONENTS
Prompt	`Give all new components / existing components/: <New components>` The `new components` must be specified all on one line. These replace the existing component definitions. The number of components cannot be changed with this command. Use CHANGE_STATUS instead.
	To keep some existing components, it is recommended that you also enter these on the line. Otherwise, the added new components may not be defined correctly. This is especially important if some components are built out of several elements. The new components do not have to be present as species.

DELETE_SYMBOL

This command is available with the POLY and ED-EXP modules.

Use the DELETE_SYMBOL command to remove symbols i.e. constants, variables, functions or tables.

Syntax	DELETE_SYMBOL
Prompt	`Name: <Name of a symbol>` Specify the name of the symbol to be deleted. Only one symbol can be deleted each time.

ENTER_SYMBOL

This command is for the ED-EXP module.

The GES, POLY and POST modules also have a command with the same name.

Use the ENTER_SYMBOL command to enter symbols, which can be constants, variables, functions, or tables.

Syntax	ENTER_SYMBOL
Prompt	`Constant, Variable, Function or Table? /Function/: <Keyword>` The `Keyword` can be specified as `CONSTANT`, `VARIABLE`, `FUNCTION`, or `TABLE`. • CONSTANTS can only be entered once and is a means of using a name for a numeric value. For example, the value of 1 atmosphere in Pascal can be denoted by `P0` after the command ENTER_CONSTANT `P0=101325`. Defined constants can be used as values in condition assignments, for example, `SET-COND P=P0`. • FUNCTIONS are expressions of state variables or other functions. These expressions are saved, and whenever a function value is requested all functions are evaluated. The reason for this is that they may depend on each other. • VARIABLES are similar to functions because they can also be expressions of state variables. However, contrary to functions, they are only evaluated when they are entered or if they are explicitly named in an EVALUATE_FUNCTIONS command. It is possible to enter a variable with a new expression any time. This expression is evaluated directly and its value stored as the value of the variable. Defined variables can be used as values in the SET_CONDITION command. • TABLES are used for listing results from the STEP or MAP commands. A table consists of a list of any number of state variables, functions, or variables. Defined tables can also be used in the POST (post-processor) module. There is a special connection between tables and variables. If a variable is used in a table, it is evaluated for each line of the table in the TABULATE command or when the table is used in a plot.
	`Name: <Name of the symbol>` Each symbol has a unique name that must start with a letter and can have maximum 8 characters. Legal characters include letters (either UPPER or lower case), digits and underscore _. Any other special character, such as parentheses (and), plus +, minus -, slash / or \, full stop (.), are illegal for symbol names. You can enter the symbol name and the value or function on the same line; these must be separated with an equal sign =, for example, `TC=T-273.15` or `T_C=T273.15` which stands for a definition of

Syntax	ENTER_SYMBOL
	temperature in Celsius. Otherwise, these questions are asked. For different types of symbols (constant, function, variable, or table), the questions have different prompts.

	`Function: <Definition for a function or variable>`
	
	Functions and *variables* are evaluated from an expression of state variables or other functions, constants, or variables. The expression is a FORTRAN-like expression and operators +, -, *, = and ** can be used (** only with integer powers).
	
	Unary functions like `LOG`, `LOG10`, `EXP`, `SIN`, `COS`, and `ERF` can also be used. An expression can be continued on more than one line. An expression should be terminated by a semicolon (;) or an empty line (press <Enter> at the next prompt).
	
	Examples of function expressions:
	
	• `GM(LIQUID)`: The Gibbs energy of liquid per mole component
	• `H.T/4.184`: The heat capacity of the system in calories
	• `ACR(CR)/X(FCC,CR)`: The activity coefficient for Cr in FCC
	• `T-273.15`: The temperature in Celsius
	
	`&: <Continuation of the definition for the symbol>`
	
	The ampersand & means that you can continue to write the function on the new line if one line is not enough for the function. If you finish the function press <Enter> again.

	`Value: <Value for a constant>` A *constant* can only be assigned a numeric value once.
	`Value or expression: <Value of expression for a variable>` A *variable* can be assigned a numeric value or an expression. An expression is evaluated immediately and discarded. Only the numeric value is kept. This gives a possibility to save a value between calculations with different conditions because all state variables and functions are evaluated for the new conditions.

	`Variable(s): <Variable(s) in a table>`
	
	A *table* consists of a list of state variables or functions. One way to obtain results from a STEP command is through a table.
	
	Example:
	
	`ENTER TABLE K=T,X(LIQ,C),X(LIQ,CR),ACR(C)`
	
	Which means that the table called K contains four columns, i.e. the temperature, the mole fractions of C and Cr in the LIQUID phase, and the activity of C.
	
	To show the temperature in Celsius in a table, give the command ENTER_FUNCTION `TC=T-273`; and then use the symbol `TC` in the table.
	
	`& <Continuation of the definition for the table>`
	
	The ampersand `&` means that you can continue to write the table on the new line if one line is not

Syntax	ENTER_SYMBOL
	enough for the table. If you finish the table press `<Enter>` again.

EVALUATE_FUNCTIONS

This command is available with the POLY and ED-EXP modules.

Use the EVALUATE_FUNCTIONS command to evaluate and list the value of one or more, or all, entered functions or variables.

Syntax	EVALUATE_FUNCTIONS
Prompt	`Name(s): <Name(s) of defined function(s)>` The names of one or more entered functions or variables must be specified. By typing a wildcard *, all functions and variables are evaluated. Variables are evaluated only if these are explicitly named.

EXPERIMENT

This command is for the ED-EXP module.

This command is used in original experimental data files (*.POP or *.DOP), but can also be given interactively inside the ED-EXP module, to change the value or uncertainty of an experiment or to add more experimental information.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

An experiment usually consists of two parts with a colon (:) separating them:

- as a quantity relation, and
- as the uncertainty of the value for the quantity,

The quantity relation can be a normal POLY module condition or an inequality (which is similar to condition but the relation between the quantity and given value is not in equality, i.e. < or >). The uncertainty can be expressed as an absolute value or relative to the value (x%).

An experiment that uses an inequality gives zero contribution to the sum of errors in the optimization procedure of PARROT if the value is on the right side. If the value is on the wrong side, the value after the colon determines how steeply the error increases with the value.

Syntax	EXPERIMENT
	The experiment must be typed after the command. Several experiments can be given on the same line. The syntax of EXPERIMENT is similar to a CONDITION. Usually, a state variable set equal to a value with a given uncertainty is specified after the colon (:). For example, `T=1273.15:5`. An inequality, < or >, can also be used. For example: `ACR(C)<-0.01:0.001, W(BCC,AG)>0.05:10%`

Additional Information About the Experiment Command

A typical experiment added interactively specifies that a phase should not be stable in a certain experiment, because a phase may appear in a range of composition or of temperature where it has never been observed during the optimization. A phase is unstable if its driving force is negative, and you can add experimental information to enforce that. For example, you can suppress the HCP phase in an existing experimental point:

```
CHANGE-STATUS HCP=DORMANT
EXPERIMENT DGM(HCP)<-.001:.0001
```

DGM is the POLY variable for the driving force that is already divided by `RT`, and it is dimensionless. Only dormant phases can have driving forces larger than zero, as this indicates that these would be stable if allowed to form. The experiment in the above case tries to modify the model parameters to make the HCP phase unstable.

More general examples of experiment definitions:

```
EXPERIMENT X(LIQ,PB)=.10:.01 X(FCC,PB)=0.02:.01
EXPERIMENT ACR(PB)=0.8:5%
EXPERIMENT T=700:5
```

The first experiment above describes a tie-line where the experimentally measured mole fraction of Pb is 0.1 in the liquid phase and 0.02 in the FCC phase, and its uncertainty is 0.01 for both measurements. The second experiment is that the activity of Pb should be 0.8 with an uncertainty of 5 percent.

The reference state of the component Pb must be set with the command SET_REFERENCE_STATE. The final one is that the temperature should be 700 K with an uncertainty of 5 degrees.

Experiments that are functions of states variable(s) must be described as the defined functions. For example:

```
ENTER_FUNCTION HTR=HM(LIQUID)-HM(FCC);
EXPERIMENT HTR=7000:1000
```

EXPORT

This command is for the ED-EXP module.

Use the EXPORT command to transfer/export a calculated value from an equilibrium to an optimizing variable in the PARROT workspace. Thus the value can be used, for example, in the Gibbs energy description of a phase. This variable should not be optimized (i.e. it should be set as a fixed variable in PARROT).

Syntax	EXPORT
Prompt	`Function name: <Function name>#<n>` Specify the name of the function, the value of which should be transferred to a `V` variable. The number (n) of the `V` variable must be given after the function name, separated by hash character #. The function name is UPPER/lowercase sensitive, and it should normally be given in UPPER case.

Example of the EXPORT Command

```
Enter_function strngy=gm(fcc).x(cu);
Export strngy#6
```

This transfers the value of the partial derivative of the Gibbs energy of the FCC phase with respect to the mole fraction of Cu to the optimizing variable 6 (i.e. `V6`).

FLUSH_BUFFER

This command is for the ED-EXP module.

The FLUSH_BUFFER command is only used in the *.POP file (i.e. it can also be used in the experimental data files). It is needed if the number of experiments require more space than can be fitted into one buffer.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

When the PARROT program compiles experiments, it informs if any FLUSH commands are needed. FLUSH_BUFFER terminates the current block, saves it to the work file and starts a new block. With the READ command in the EDIT-EXP module, you can select the block to edit.

After a FLUSH_BUFFER command, the workspace is reinitiated and all functions or constants must be entered again in the *.POP file. You can take advantage of this; for example, you can use the FLUSH command to have blocks with different components in one *.POP file.

GRAPHICS_PLOT

This command is for the ED-EXP module.

The GRAPHICS_PLOT command can help create a experimental data file from the *.POP file. Several data sets and different symbols are allowed.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

Syntax	GRAPHICS_PLOT
	`<Dataset#> <X value> <Y value> <Symbol index>`

IMPORT

This command is for the ED-EXP module.

Use the IMPORT command to transfer/import the value of one of the optimizing variables to a constant. Normally, it is directly used inside an experimental data (*.POP) file. It is the opposite of the EXPORT command.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

The IMPORT command is useful if several experiments are done at the same activity of a component, but this activity is not known. The activity should then be optimized and all equilibria with the same activity should use the same value. In this case the variable must be set as an optimizing variable, and an initial guess of the activity should be given. During the optimization, the PARROT program tries to find the activity that gives the best fit.

If an approximate value of the activity is known, it can be supplied as an experiment.

Syntax	IMPORT
	`Constant name: <Constant name>#<n>` The value of the `V` variable must be assigned a symbolic constant. The number (`n`) of the `V` variable must be given after the constant name, separated by hash character `#`.
Prompt	The constant name is UPPER/lowercase sensitive, and it should normally be given in UPPER case.

Example of the IMPORT Command

```
Enter_constant acu=0.1
Import acu#2
```

This transfers the value of the optimizing variable 2 (i.e. `V2`) to the constant `ACU`.

LABEL_DATA

This command is for the ED-EXP module.

Use the LABEL_DATA command to add a label to the experimental equilibrium point, either as a single point or several points given individually or in a table. The label is maximum four characters and must start with the letter A. Normally, it is directly used inside an experimental data file (*.POP).

In the DICTRA module, you work with a .DOP file instead of a .POP file.

Several experimental equilibria can be given the same label, and the label can be used with SET_WEIGHT to assign the same weight to all equilibria with the same label.

Syntax	LABEL_DATA
Prompt	`Label? /A1/: a<bcd>` Specify a textual label (as maximum characters and must start with the letter A) for the current experimental equilibrium point(s).

LIST_ALL_EQUILIBRIA

This command is for the ED-EXP module.

Use the LIST_ALL_EQUILIBRIA command to list all the details (including equilibrium indicators, labels, iteration numbers, weight, and fixed phases or comments) of all equilibrium points from the current one to the last one on screen. You can always use SELECT_EQUILIBRIUM to select a specific point as the current equilibrium point for such a list.

LIST_CONDITIONS

This command is available with the POLY and ED-EXP modules.

All the conditions that are set by the SET_CONDITION command and the command-sequence CHANGE_STATUS PHASE `=FIXED <0 or 1 or alike>`, are listed when you use the LIST_CONDITIONS command. The current conditions are also listed by the LIST_EQUILIBRIUM command. The degree of freedom in the defined system is also shown.

- If this is zero, you can perform a COMPUTE_EQUILIBRIUM command.
- If it is larger than zero, some more conditions are required, and you must further set additional ones, using SET_CONDITION or CHANGE_STATUS.
- If it is negative, then too many conditions are defined and the unnecessary ones conditions need to be removed using the SET_CONDITION command (with a value of NONE for the to-be-deleted condition) or the CHANGE_STATUS command (i.e. changing a FIXED status of a phase to another type of phase status, ENTERED or DORMANT or SUSPENDED).

Example of LIST_CONDITIONS

```
P=100000, T=800, N(NI)=1E-1, N=1
FIXED PHASES
FCC_A1=1 LIQUID=0  DEGREE OF FREEDO 0
```

LIST_EQUILIBRIUM

This command is available with the POLY and ED-EXP modules.

The result (always in SI units) from the last calculated equilibrium is listed on screen or in a text file when you use the LIST_EQUILIBRIUM command.

You can also execute this command if no calculation is made or if the calculation fails. Make sure to interpret the results accordingly.

Syntax	LIST_EQUILIBRIUM
Prompt	`Output to screen or file /Screen/: <File name>` The name of the text file where the list of the calculation results shall be written.
	`Options /VWCSF/: <Option(s)>` Select the output units and formats by optionally specifying a combination of these letters. • *Fraction order:* `V` means VALUE ORDER; `A` means ALPHABETICAL ORDER. • *Fraction type*: `W` means MASS FRACTION; `X` means MOLE FRACTION. • *Composition*: `C` means only COMPOSITION; `N` means CONSTITUTION and COMPOSITION. • *Phase*: `S` means including only STABLE PHASES; `P` means including ALL NON-SUSPENDED PHASES. • *Phase name*: `F` means including COMMON PHASE Name if available; `D` mean only DATABASE PHASE NAME.
	Default options are `VWCSF`. If the output fraction type should be in mole fraction (rather than mass fraction), then give `VXCSF` or type `X` (implying that in this case the options V, C, S, and F are accepted as the listing manners for fraction order, composition and phase). If accepting all the default options, or if accepting all the altered options that had already changed when using this command previously, you can type `L_E,,,` or `LIST_EQUILIBRIUM ,,,` LIST_EQUILIBRIUM displays ORD (ordered) or DISORD (disordered) (when available). See CHANGE_LEGEND for details.

LIST_STATUS

This command is for the ED-EXP module.

There is also a POLY module command with the same name.

Use the LIST_STATUS command to list the status of components, species, or phases.

The results depend on the key word specified in the options for CHANGE_STATUS, a table with the current status of phases or species or components, or the combinations, is shown:

- For components, the statuses and reference states are listed.
- For species, only the status is listed.
- For ENTERED and FIXED phases, the status, driving forces and equilibrium amounts are listed.

The metastable phases are listed in descending order of stability. To avoid long outputs only 10 metastable phases (in ENTERED status) are listed by lines, while all other less stable phases are merged onto one line. For DORMANT phases, their phase names and driving forces are listed. For SUSPENDED phases, only the phase names are listed.

Syntax	LIST_STATUS
Prompt	Specify what to list: `Option /CPS/`:*<keyword(s)>* keyword = C or P or S, or any combination • `C`: list component status • `P`: list phase status • `S`: list species status • `CS`: list both components and species Default is `CPS`.

LIST_SYMBOLS

This command is for the ED-EXP module.

There are also POLY and POST module commands with the same name.

Use the LIST_SYMBOLS command to list the definitions for all constants, functions, variables, and tables.

In order to find the value of a function or variable, use SHOW_VALUE or EVALUATE_FUNCTIONS. A table is tabulated with the TABULATE command.

The defined variables are listed up together with the defined functions, but variable names are followed by a percentage sign %.

MAKE_POP_FILE

This command is for the ED-EXP module.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

Use the MAKE_POP_FILE command to make interactive changes and additions to the original experimental data file (the *.POP or *.DOP file). For example, to document or transfer the current or final experimental data to a *.POP file, this command will write it to a new *.POP file or overwrite previous versions.

Check the output carefully for errors. Tables in original *.POP files are written as individual experimental points. The output can be shown on screen or be saved as a new *.POP file where to write or overwrite the edited experimental information in a simple text format.

Syntax	MAKE_POP_FILE
Prompt	`Output to screen or file /Screen/: <POP/DOP-file name>` Specify a name of the new *.POP file where to write or overwrite the edited experimental information in a simple text format. If an existing *.POP file name is specified, it is overwritten.

READ_WORKSPACES

The READ_WORKSPACES command must be given each time the ED_EXP module is entered, unless it is already given once in ED_EXP and does not use LIST_RESULT or OPTIMIZE_VARIABLES in PARROT in between.

READ_WORKSPACE = READ

This command is equivalent to READ_WORKSPACES in the POLY module, but it only reads the POLY workspace from the work file set by SET_STORE_FILE in the PARROT module.

Syntax	READ_WORKSPACES
Prompt	`Block number /#/: <n>` The number of a data block that should be edited must be given. If there is no FLUSH_BUFFER command in the original POP file, then there is only one data block with the number 1.

REINITIATE_MODULE

This command is for the ED-EXP module.

The REINITIATE_MODULE command makes sure that the entire ED-EXP module is reinitiated to the original state.

All the defined components, defined conditions, changed status, entered symbols, defined independent axis-variables, calculated starting equilibrium-points, added initial equilibrium points, stepped/mapped equilibrium data, and so forth, are removed completely. The saved file name is restored to the default.

RESTORE_ALL_WEIGHTS

This command is for the ED-EXP module.

Use the RESTORE_ALL_WEIGHTS command to restore a specific weight-set (previously saved by STORE_ALL_WEIGHTS) and assign all the different experimental points in the current data block with the previously-set weights in the sequential assessments.

Syntax	RESTORE_ALL_WEIGHTS
Prompt	`Set number (0 for list) /0/: <weight-set number>` The default value 0 is for a list on screen.

SAVE_WORKSPACES

This command is for the ED-EXP module.

In the PARROT workspace the SAVE_WORKSPACES command saves the current status of the ED_EXP submodule before you switch back to the PARROT module. This is required when you want to save equilibria changes, including changes to conditions, experimental data, and/or computed equilibria results, as well as any newly added equilibria.

With this command all the changes made in the ED_EXP submodule are saved in the PARROT workspace. This means you do not need to execute SAVE_PARROT_WORKSPACES in the PARROT module.

However, when in the PARROT module, additional changes can only be saved with the SAVE_PARROT_WORKSPACES command even if they have been made prior to executing SAVE_WORKSPACES in ED_EXP.

When you exit the ED_EXP (or Thermo-Calc), the next time the file is opened it is in the same state as when you executed the SAVE_WORKSPACES command. However, if you use OPTIMIZE_VARIABLES the computed results are automatically updated.

Syntax	SAVE_WORKSPACES
	`<File name>`
Prompt	Sometimes good starting values (SET_START_VALUE) are required to successfully get or compute an equilibrium correctly. In this case, it is important to save the computed equilibrium in the PARROT workspace. It is important to remember that the computed results can be ruined by improper optimizations. For this reason, it is suggested you save the .PAR file with a different name to back up the PARROT workspace.

SELECT_EQUILIBRIUM

This command is available with the POLY and ED-EXP modules.

If you create more than one initial equilibrium (during data-assessments using the PARROT/ED_EXP modules), you can switch between them using the SELECT_EQUILIBRIUM command.

Syntax	SELECT_EQUILIBRIUM
Prompt	`Number /Next/: <Choice on equilibrium>` Options: `FIRST`, `LAST`, `NEXT`, `PREVIOUS` or `PRESENT`. Most commands affect only the `PRESENT` equilibrium. However, the REINITIATE_MODULE and DEFINE_COMPONENTS commands remove all the stored equilibria.

SET_ALL_START_VALUES

This command is available for the POLY and ED-EXP modules.

Use the SET_ALL_START_VALUES command to set start values, e.g. if the calculation fails or if you have a miscibility gap or ordering. If temperature and pressure are not conditions, you are asked for values of them. Then for each phase prompt on if it should be stable and on its constitution.

Syntax	SET_ALL_START_VALUES
	`T /XXXX/: <Temperature in K>` If the temperature is not a condition, supply a guess of its final value (in K).
	`P /100000/: <Pressure in Pa>` If the pressure is not a condition supply a guess of its final value (in Pa).
Prompts	`Automatic start values for phase constitutions? /N/: <Y, N or F>` • For N, enter an initial amount of each entered phase and the major constituents or site fraction of each constituent. • For Y, the program automatically sets the start values for phase constitutions in all possible phases. • `F` is for force. In some cases the calculation fails because impossible conditions are set, e.g. `W(C)=1.5` `[W(C)` is mass fraction and must thus be less than unity. The program tries to fulfill this condition by putting maximum amount of carbon in all phases, but can fail anyway. When you detect the error and set `W(C) to 0.015`, the calculation may still fail because it could start from the previous values. To get back to 'fresh' start values, choose `F`.
	`Should <phase> be stable /N/: <Y/1 or N/2>` A guess if this phase should be stable or not is requested. All entered phases are prompted for this question and next two. You cannot have more phases stable than you have components, but at least one (which dissolves all constituents) must be set as stable. For backward compatibility, this question can be answered by 1 (for Yes) or 0 (for No). The `phase` name may have a hash sign # followed by a digit, e.g. `BCC_A2#2`. For phases with miscibility gaps, there should be two phases with the same name but with different numbers after the hash sign.
	`Major constituent(s): <Name of major constituent(s) in the phase>` The constituent with the largest fraction in the phase should be specified. If there are more than one constituent with a large fraction, give them all on the same line. If the default major constituents should be used answer with an asterisk (*). By giving $ the constituent is not changed. If there should be no major constituent give NONE and or if the major constituent(s) are improperly specified, you are asked for individual fractions in the phase.

Syntax	SET_ALL_START_VALUES
	`Y(<phase>,<constituent>) /.XXXXXXXXXX/: <.YYYYY>` The current value (`.XXXXXXXXXX`) is default. You can accept the default by pressing <Enter> or give a new value (`.YYYYY`). The phase name or constituent name may have a hash sign # followed by a digit, e.g. `Y(BCC_A2#2,FE), Y(BCC_A2#2,C#2)`. For phases with miscibility gaps, there should be two phases with the same name but with different numbers after the hash sign. For phases with sublattices, the constituents in sublattice 2 or higher is also be suffixed with a hash sign # followed by a digit.

SET_ALTERNATE_CONDITION

This command is for the ED-EXP module.

A special command used in the experimental data *.POP file but also possible in the ED_EXP module. It is used only when you have specified that the alternate mode is set in the PARROT module.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

The SET_ALTERNATE_CONDITION command syntax is almost the same as for the POLY command SET_CONDITION while the uncertainty should also be specified.

The alternate condition (including the normally POLY module condition plus uncertainly; see below) must be given explicitly, but can be given on the same line or on separate lines with each one started with the command.

Syntax	SET_ALTERNATE_CONDITION
Prompt	`State variable expression: <State variable name or linear expression>` Give either a state variable or a linear expression of state variables.
Options	**Description and Information**
State variables	Some of the state variables that can be used in conditions are: • `T`: temperature in the system (in K) • `P`: pressure in the system (in Pascal) • `N`: system size (mole number in moles) • `B`: system size (mass in grams) • `N(<component>)`: mole number of a component in the system • `X(<component>)`: mole fraction of a component in the system • `W(<component>)`: weight fraction of a component in the system • For the SET_CONDITION command this is `ACR(<component>)`: activity of a component in the system. For the SET-ALTERNATIVE_CONDITION command, this is `ACR`(<`phase`>,<`component`>) (activity of a component in a phase) • For the SET_CONDITION command this is `MUR(<component>)`: chemical potential of a component in the system. For the SET-ALTERNATIVE_CONDITION command, this is `MUR`(<`phase`>,<`component`>) (chemical potential of a component in a phase)

Syntax	SET_ALTERNATE_CONDITION
	• `X(<phase>,<component>)`: mole fraction of a component in a phase • `W(<phase>,<component>)`: weight fraction of a component in a phase • `ACR(<species>,<phase>)`: activity of a species referred to a phase • `MUR(<species>,<phase>)`: chemical potential of a species referred to a phase • `H`: enthalpy in the system (in J) • `HM(<phase>)`: enthalpy of a phase (in J/mol)

Additional prompts	`Factor: <A factor for the state variable, or a continuation>`
	This question means that the previous question was not answered. The program is then expecting a single state variable or a complete state variable expression, or the numeric factor in an expression with only one state variable. In a state variable expression a state variable may be preceded by a constant factor. An example of this is:
	`2*MUR(FE)+3*MUR(O)=-35000`
	This means that it should be a condition that two times the chemical potential of FE plus three times the chemical potential of O should be -35000 J/mol.

	`State variable: <A specified state variable, or a continuation>` This question is prompted if a single state variable name has not given in either the prompt `State variable expression` or `Factor`, or a state variable expression is given but the expression is incomplete, for example, `T-` or `2*MUR(FE)+`, for which the program is then expecting a continuation of the unfinished expression. You need to specify a state variable or a complete state variable expression, or complete the unfinished state variable expression. If a numeric factor is given before this prompt, only one state variable can be specified; otherwise, the program only takes the first state variable to complete the expression (i.e. the factor times the state variable).
	`Value /X/: <A numeric value, a constant or a variable>` The value of the condition. This can be a numeric value, a constant or a variable. A suggestion is given as the default value. The special value `NONE` means that the condition is removed.
	`Uncertainty /None/: <Uncertainty of the condition>` The uncertainty of the condition. This can be a numeric value, a constant or a variable. The default value `NONE` means that the uncertainty for the value specified above is zero. The uncertainty can either be expressed as an absolute value or relative to the value of the condition in percent (`x%`).

Notes About the SET_ALTERNATE_CONDITION Command

There are more state variables that can be used in conditions. For more information, type an INFO STATE_VARIABLES command in the POLY module. A condition is normally a value of a single state variable with its value. For example:

```
T=1273.15 P=1E5
X(C)=.002
```

```
W(CR)=1.5
ACR(CR)=0.85
X(FCC,C)=.001
H=-250000
HM(BCC)=-225000
```

A condition can also be a value of a linear expression involving more than one state variable. For example

```
X(LIQ,S)-X(PYRR,S)=0
```

This means that it is a condition that the mole fraction of `S` should be the same in the LIQUID and PYRRHOTITE phases. In practice that should be the congruent melting point.

After the equal sign only a numeric value is allowed.

SET_CONDITION

This command is available with the POLY and ED-EXP modules.

Use the SET_CONDITION command to specify the equilibrium conditions for the calculation. All kinds of state variables, as well as most of the M/W/V/F-suffixed state variables (for normalization) and R-suffixed state variables (with respect to chosen reference states), can be used as conditions. In addition to temperature and pressure conditions, a multicomponent system can have mixed types of conditions. You should repeat this command for a multicomponent system until the degree of freedom in the defined system becomes zero. When a FIXED phase status is used on a specific phase (use CHANGE_STATUS), it is equivalent to one condition (implying that particular phase is stable in the defined system).

Syntax	SET_CONDITION

	Each condition must be given explicitly, but can be given on the same line (separated by a comma (,) or an empty space) or on separate lines with each one started with the command.
	
	Example
	`SET_COND T=1273, P=1E5, W(C)=.0015, X(LIQ,CR)=.22, ACR(N)=.2`
	or
	`SET_COND T=1273, P=1E5`
	`SET_COND W(C)=.0015, X(LIQ,CR)=.22 ACR(N)=.2`
	In this example, the temperature is set to 1273 K, the pressure to 1 bar (1E5 Pascal), the mass (weight) fraction of C to 0.0015 and the mole fraction of Cr to 0.22 and the activity of N to 0.2.

Prompt	`State variable expression: <State variable name or linear expression> or a linear expression of state variables.` Some of the state variables that can be used in conditions are: • T: temperature in the system (in K) • P: pressure in the system (in Pascal) • N: system size (mole number in moles) • B: system size (mass in grams) • N(<component>): mole number of a component in the system • X(<component>): mole fraction of a component in the system • W(<component>): weight fraction of a component in the system • For the SET_CONDITION command this is ACR(<component>): activity of a component in the system. For the SET-ALTERNATIVE_CONDITION command, this is ACR(<phase>,<component>) (activity of a component in a phase) • For the SET_CONDITION command this is MUR(<component>): chemical potential of a component in the system. For the SET-ALTERNATIVE_CONDITION command, this is MUR (<phase>,<component>) (chemical potential of a component in a phase)

Syntax	SET_CONDITION

- `X(<phase>,<component>)`: mole fraction of a component in a phase
- `W(<phase>,<component>)`: weight fraction of a component in a phase
- `ACR(<species>,<phase>)`: activity of a species referred to a phase
- `MUR(<species>,<phase>)`: chemical potential of a species referred to a phase
- `H`: enthalpy in the system (in J)
- `HM(<phase>)`: enthalpy of a phase (in J/mol)

There are many state variables that can be used in conditions. For more information, enter an `INFO STATE_VARIABLES` command. A condition is normally a value of a single state variable with its value.

Example

```
T=1273.15 P=1E5
X(C)=.002
W(CR)=0.5
ACR(CR)=0.85
X(FCC,C)=.001
H=-250000
 HM(BCC)=-225000
```

A condition can also be a value of a linear expression involving more than one state variable. For example,

```
X(LIQ,S)-X(PYRR,S)=0
```

This means that it is a condition that the mole fraction of `S` component should be the same in the LIQUID and PYRRHOTITE phases. In practice, that should be the congruent melting point.

After the equal sign only a numeric value is allowed in the expression.

`Factor: <A factor for the state variable, or a continuation>`

This question means you did not answer the previous question. The program is then expecting a single state variable or a complete state variable expression, or the numeric factor in an expression with only one state variable. In a state variable expression a state variable may be preceded by a constant factor. An example of this is:

```
2*MUR(FE)+3*MUR(O)=-35000
```

This means that it should be a condition that two times the chemical potential of `FE` plus three times the chemical potential of `O` should be -35000 J/mol.

`State variable: <A specified state variable, or a continuation>`

This question is prompted if a single state variable name has not given in either the prompt `State variable expression` or `Factor`, or a state variable expression is given but the expression is incomplete, for example, `T-` or `2*MUR(FE)+`, for which the program is then expecting a continuation of the unfinished expression. You need to specify a state variable or a complete state variable expression, or complete the unfinished state variable expression. If a numeric factor is given before this prompt,

Syntax	SET_CONDITION
	only one state variable can be specified; otherwise, the program only takes the first state variable to complete the expression (i.e. the factor times the state variable).
	`Value /X/: <A numeric value, a constant or a variable>` The value of the condition. This can be a numeric value, a constant or a variable. A suggestion is given as the default value. The special value `NONE` means that the condition is removed; for example `T=NONE` takes away the temperature condition.

SET_NUMERICAL_LIMITS

This command is available for the POLY, Scheil, and ED-EXP modules.

Use the SET_NUMERICAL_LIMITS command to change the criteria for convergence. This is to speed up a calculation in a complex system.

If there is any convergence problem in finding a stable solution at any stage during a calculation procedure enforced by COMPUTE_EQUILIBRIUM, STEP_WITH_OPTIONS, MAP or ADVANCED_OPTIONS), this message displays:

```
Convergence problems, increasing smallest site-fraction from 1.00E-30
to hardware precision 2.00E-14. You can restore using SET-NUMERICAL-
LIMITS
```

This implies that smallest site fraction in the current POLY workspace is automatically increased from the default value 1.00E-30 to the hardware-dependent precision (under Linux, as 2.00E-14). For other subsequent POLY module calculations, you can use this command to restore or reset the smallest site fraction to the previous or another preferred value, as well as to reset other numerical limits.

Syntax	SET_NUMERICAL_LIMITS
Prompt	`Maximum number of iterations /500/:` By default, the program tries 500 iterations before it gives up. As some models give computation times of more than 1 CPU second/iteration, this number is also used to check the CPU time and the calculation stops if 500 CPU seconds/iterations are used.
	`Required accuracy /1E-6/:` This is a relative accuracy, and the program requires that the relative difference in each variable must be lower than this value before it has converged. A larger value normally means fewer iterations but less accurate solutions. The value should be at least one order of magnitude larger than the machine precision.
	`Smallest fraction /1E-12/:` This is the value assigned to constituents that are unstable. It is normally only in the gas phase you can find such low fractions. The default value for the smallest site-fractions is 1E-12 for all phases, except for IDEAL phase with one sublattice site (such as the GAS mixture phase in many databases) for which the default value is always as 1E-30 (unless you have used the SET_NUMERICAL_LIMITS command to reset an even-lower value (e.g. 1E-45, that is naturally enforced to all the phases in the system).
	`Approximate driving force for metastable phases /Y/:` `Y` is the default. Enter `N` to change the default as required and based on the options described below. This setting involves the convergence of metastable phases and affects their driving forces. It can also have an effect on when an equilibrium is considered successful. The default is to allow an equilibrium with metastable phases that have not converged, as long as the stable phases have converged. This is efficient but often causes approximate values of the driving

Syntax	SET_NUMERICAL_LIMITS
	forces for the metastable phases. If you change the default, it enforces metastable phases to converge. This gives accurate driving forces for metastable phases as well as stable phases. It can however take a slightly longer time, and if metastable phases do not converge it causes the equilibrium calculation to fail.

SET_REFERENCE_STATE

This command is available for the POLY, ED-EXP and POST modules.

The reference state for a component is important when calculating activities, chemical potentials, and enthalpies and is determined by the database being used. For each component the data must be referred to a selected phase, temperature, and pressure, i.e. the reference state.

All data in all phases where this component dissolves must use the same reference state. However, different databases can use different reference states for the same element/component. It is important to be careful when combining data obtained from different databases.

By default, activities, chemical potentials, and so forth are computed relative to the reference state used by the database. If the reference state in the database is not suitable for your purposes, use the SET_REFERENCE_STATE command to set the reference state for a component using `SER`, i.e. the Stable Element Reference (which is usually set as default for a major component in alloys dominated by the component). In such cases, the temperature and pressure for the reference state is not needed.

In order to specify conditions in the specific reference state, you can append an `R` to the state variables. Thus, `AC` is the activity (of a system component or of a species in a phase) with respect to the default reference state, and `ACR` is the activity with respect to the selected reference state; MU is the chemical potential of a system component with respect to the default reference state, and `MUR` stands for the chemical potential with respect to the selected reference state. The `AC` and `ACR` variables, for both components in a system and species in a phase, can be specified in natural logarithm, e.g. LNAC(Fe), LNACR(C), LNAC(O2,GAS), LNACR (O2,GAS).

For the POST module, and after calculating with the STEP_WITH_OPTIONS or MAP commands, the reference state for a component can also be changed to plot various properties of the component in the entire system or in a specific phase. Then you can set the diagram axes as the chemical potential or activity quantities with the `R` suffix, i.e. MUR(comp), MUR(comp,ph), ACR(comp), ACR(comp,ph) or the common logarithms [e.g. LNACR(comp,ph)].

Syntax	SET_REFERENCE_STATE
Prompts	`Component: <Name of the component>` The name of the component must be given.
	`Reference phase: <Name of a phase used as the new reference state>`

Syntax	SET_REFERENCE_STATE
	Enter the `Name of a phase` for the system. For a phase to be usable as a reference for a component, the component needs to have the same composition as an end member of the phase. The reference state is an end member of a phase. The selection of the end member associated with the reference state is only performed once this command is executed. If a component has the same composition as several end members of the chosen reference phase, then the end member that is selected at the specified temperature and pressure will have the lowest Gibbs energy. The following are example using temperature. Pressure is used in the same way: • In the Fe-C system, BCC can be a reference state for Fe but not for C since BCC can exist as pure Fe but cannot exist as pure C. • If GAS is chosen as the reference phase of component O at such a high temperature that O1 has the lowest energy, then O1 remains the reference state even at calculations performed at lower temperatures where O2 has a lower energy than O1. • Setting the reference state for component O as gas (one sublattice) with constituents O1, O2 and O3 results in O2 being the reference state if, at the present temperature, pure O2 has the lowest energy of O1, O2 and O3. If the reference state is set above a critical higher temperature, then O1 has the lowest energy and consequently becomes the reference state.
	`Temperature /*/: <Temperature for the reference state>` Select the Temperature (in K) for the reference state. The wildcard value * means the current temperature is used at the time of evaluation of the reference energy for the calculation. The temperature set with this command does not affect the temperature used when evaluating the energy of the reference state during the end member selection process.
	`Pressure /1E5/: <Pressure for the reference state>` Select the Pressure (in Pa) for the reference state. The wildcard value * means the current pressure is used for evaluating the reference energy at the time of calculation.

	Examples
	
	`S-R-S Fe SER`
	`S-R-S Cr FCC * 100000`
	`S-R-S H2O AQUEOUS * 100000`
	`S-R-S ZE REF_ELECTRODE * 100000`

SET_START_CONSTITUTION

This command is available with the POLY and ED-EXP modules.

The SET_START_CONSTITUTION command is similar to SET_ALL_START_VALUES, but is used for an individual phase that may have a wrong constitution.

Syntax	SET_START_CONSTITUTION
Prompts	`Phase name: <Name of a phase, and possible major constituent(s)>` Specify the name of a phase for which the constitution shall be set. If there is a major constituent of the phase, you must specify this on the same line as the phase name. By giving an*, select the default major constituents. A $ means keeping the same constitution, and `NONE` means to give individual site-fractions.
	`Y(<Phase>#<Composition_set>,<Constituent>#<Sublattice>) /xxx/: <SF>` The site fraction (`SF`) of the constituent shall be given. The default value `xxx` is the last calculated one.

SET_START_VALUE

This command is available with the POLY and ED-EXP modules.

The SET_START_VALUE command is not often required as the automatic start values can be handled for most problems.

Use the SET_START_VALUE command to set a start value of an individual variable.

Syntax	SET_START_VALUE
Prompts	`State variable: <Name of a state variable>` The state variable must be given.
	`Value` Specify the value to be assigned the state variable as start value.

SET_WEIGHT

This command is for the ED-EXP module.

Each experimental value has an uncertainty associated with it, specified by the value after the colon (:) with the command EXPERIMENT. During an optimization the absolute difference between the experimental and calculated values gives a contribution to the sum of error.

With the SET_WEIGHT command, you can change the scale of such a contribution (the uncertainty) for a single experimental point, or the contributions (all uncertainties) for a set of equilibria. The default weight is always unity. A value smaller than one means that the experiments should have less weight. A value larger than one that these should have higher weight. The special value zero means that the set of equilibria should be ignored in editing in ED_EXP (as is given) and in OPTIMIZE_VARIABLES in PARROT.

The weight may be needed to obtain a balance between different kinds of experiments. For example, if there are only five experimental values of the composition of a phase diagram but 500 experimental values of activities or enthalpies, then the five composition points may have to be given higher weight than unity, otherwise these are not well described by the optimizing procedure.

Syntax	SET_WEIGHT
Prompts	`Value /1/: <Weight value>` Specify a weight of the experiments in the specified equilibria (asked in the next prompt). The contribution to the sum of errors of these experiments are multiplied by this weight. The weight is squared, thus use 0.7 to make the error half (0.49) as big, and 1.4 to make it twice (1.96) as large.
	`Equilibria (range) or label(s) /Present/:<Selection>` Define the equilibria. These are available in the read data block from the current work file and are given the above-defined weight. The selection may be given as a range but the equilibrium numbers must then be separated only by a minus sign. The start and end equilibrium numbers must be available in the read data block read from the current work file.

Syntax	SET_WEIGHT
	For example, `5-101`, means that all equilibria starting from the identifier 5 until the identifier `101`. Some of numbers between these two identifiers may not exist in the data block. The selection may also be given as one or more labels (which should be separated only by a space). All equilibria with the specified label(s) in the read data block are given the above-defined weight. By pressing <Enter> to accept the default value `present`, the above defined weight is only assigned to the current or present experimental point (which is selected by the POLY SELECT_EQUILIBRIUM command). If is used but no specific equilibrium point is selected afterwards, the last point in the read data block remains the `present` point.

SHOW_VALUE

This command is available for the POLY and ED-EXP modules.

Use the SHOW_VALUE command to show the current value of any state variable, function, or variable.

Syntax	SHOW_VALUE
Prompt	`State variable or symbol: <Name(s) of state variable(s) or symbol(s)>` A single or several state variables or symbols (entered functions or variables) can be specified.

The wildcard * can be used to denote all phases or all components.

You can use the dollar-sign `$` to denote all stable phases. Thus, the command SHOW W(*,*)lists the mass fraction of all phases, whereas `SHOW W($,*)` lists the mass fraction of all stable phases.

If you `SHOW` a function, all functions are evaluated using the current values of the state variables. But if you `SHOW` a variable, it retains its value from the time it was `ENTERED` or last `EVALUATED`.

Therefore to save a value from one calculation to another, `ENTER` it to a variable. This is frequently done in the PARROT module to transfer values between equilibria.

STORE_ALL_WEIGHTS

Use the STORE_ALL_WEIGHTS command to store a new weight-set that is the current situation of specified weights for all the different experimental points read from the currently-selected experimental data block in an assessment. This is useful when you want to try various weight-settings for some experimental points or for all the points, and then compare the assessment results from different weight-sets. Such a saved weight-set can be recalled and restored for all experimental data point with RESTORE_ALL_WEIGHTS sequentially.

Syntax	STORE_ALL_WEIGHTS
Prompt	`Command line: <Weight-set name>` Give a weight-set name (comment line texts) for the current weight set for all experimental points.

TABLE_HEAD, TABLE_VALUES, and TABLE_END

The TABLE_HEAD, TABLE_VALUES, and TABLE_END commands are used only in the *.POP file. It represents a convenient way to enter many experimental measurements of the same type in a table format.

In the DICTRA module, you work with a .DOP file instead of a .POP file.

These commands should always be used together and in a sequence, meaning that a table should always start with the TABLE-HEAD command, then TABLE-VALUES, and finish with TABLE-END. Between TABLE_HEAD and TABLE-VALUES also add definition lines (e.g. on phase status, reference states, conditions, experiments, labels, etc.) for the experimental measurements of the current information type.

Syntax	TABLE_HEAD, TABLE_VALUES, and TABLE_END
Prompt	
	After the TABLE-HEAD command, there must be an equilibrium description similar to a single experimental equilibrium but with some special notation. Then, there is always a TABLE-VALUES command, after which the actual data is given in columns. At the end of each table, there must be a TABLE-END command. The TABLE-HEAD command must be followed by a numeric value. This is used to generate unique numeric identifiers for all the equilibria in the table. The numeric identifier is incremented by one for each experimental (equilibrium) point in the table.

Example

An example of the use of a table for enthalpy measurements in the liquid is given here. Much more elaborate tables can be used

```
$ Enthalpies of mixing, Topor and Kleppa, Met Trans 1984 TABLE-HEAD 1
CREATE_NEW @@ 1
CHANGE-STATUS PHASE LIQ=FIX 1
SET-REFERENCE-STATE AU LIQ * 1E5
SET-REFERENCE-STATE CU LIQ * 1E5
SET-CONDITION P=1E5 T=1379 X(LIQ,AU)=@1
LABEL ALH
EXPER HMR=@2:5%
TABLE_VALUES
0.0115 -322
0.0563 -1520
0.8499 -2976
```

Syntax	TABLE_HEAD, TABLE_VALUES, and TABLE_END

```
0.9002 -2114
TABLE_END
```

The equilibrium description between TABLE-HEAD and TABLE-VALUES is similar as for a single experiment, except for these details:

- `@@` Used to automatically generate a series of identifying numbers instead of creating only one with the command CREATE_NEW_EQUILIBRIUM. The program automatically generates the identifying numbers starting after the number given after the TABLE-HEAD command (in this case it is 1).
- `@1` values in the table are specified by an @ sign followed by a column number. In the above case, the mole fraction of Au in the liquid is in column 1 (see the line for SET_CONDITION). The columns may have other information than values, and you can use phase names or any text. If the text contains spaces or special characters, it must be surrounded by double quotes in the table, e.g. "`ABC DEF&ghi`".
- For the *syntax checker* all commands describing the equilibrium must be in UPPER case after the TABLE_HEAD command.
- After the TABLE-VALUES command, there should be one line for each experimental measurement of the same type giving the values or texts that should be copied into the places of the condition or experiment defined by `@1`, `t`, etc. You can have columns that are not used but there must be exactly the same number of columns of each line, otherwise the syntax checker gives an error message in the PARROT module.

TRANSFER_START_VALUES

This command is for the ED-EXP module.

In the ED_EXP module it is time consuming to calculate all equilibria when the optimization is sensitive to start values of the composition of the phases. Usually in one data block there are several experimental points with the same kind of equilibrium and each must have its start value set. When you manage to calculate equilibriums of such experimental points, the TRANSFER_START_VALUES command is useful to transfer the site fractions from a successfully-calculated equilibria to the present experimental point.

Syntax	TRANSFER_START_VALUES
Prompt	`From equilibrium /Previous/: <Equilibrium number>` The equilibrium number is the numeric identifier for the equilibrium from which the start values should be copied to the present experimental point. `Previous` is the default if you press <Enter>.

Example 2 of TABULATE_SUBSTANCE *1209*

ENTER_FUNCTION

This command is available with the GES and TAB modules.

Use the ENTER_FUNCTION command to define a new thermodynamic function to be included in the sixth column of tabular output. The last entered function is listed in the 6th column of all tables, and can be plotted (if choosing the Plot Column value 6) in all graphs, for all subsequently tabulated substances or reactions.

Syntax	ENTER_FUNCTION
Prompt	`Name: <Name>` `Function: <Definition>`
	A limited number of state variables, G, H, S, T, P, V and H298 can be used in the function definition. For example, -(G-H)/T can be defined as a function which is identical to S for a substance or ΔS for a reaction, G+T*S-P*V can be defined as a function which is U (internal energy) for a substance or ΔU (internal energy change) for a reaction.
Options	`Name`of the function (maximum 8 characters) and `Definition` of the function. A long function can be typed over several lines. A function should be terminated by a semicolon (;) or an empty line.

Example of ENTER_FUNCTION

For the pure substance Fe (using the SSUB database), by entering a function as `G+T*S-P*V`, the following table is obtained by typing <Enter> in the prompt `Output file /Screen/:`, and the figure by typing `6` in the prompt `Plot column /2/:`

```
TAB: ENTER-FUNCTION
Name: InEnergy
Function: G+T*S-P*V;
TAB: TABULATE_SUBSTANCE
Substance (phase): Fe
Pressure /100000/: <Enter>
Low temperature limit /298.15/: <Enter>
High temperature limit /2000/: <Enter>
Step in temperature /100/: <Enter>
Output file /try1/: try2
Graphical output? /Y/: <Enter>
Plot column? /2/: 6
```

This gives the following output:

```
O U T P U T F R O M T H E R M O - C A L C

 Column 6: InEnergy G+T*S-P*V

 Phase : FE_S                      Pressure :     100000.00

 Specie: FE

ENTER_REACTION

This command is for the TABULATE_REACTION (TAB) module.

The ENTER_REACTION command is the same as TABULATE_REACTION in that both the chemical reaction can be specified and the thermodynamic property changes for the reaction can be generated as a table, and plotted as a graph or saved as an experimental file (with an extension of .EXP). The thermodynamic data are automatically retrieved from the SSUB database (by default), or the current database set by SWITCH_DATABASE (thus there is no need to use the TDB module before this command). You can select any other database by using the SWITCH_DATABASE command in the TAB module. The rules to specify a reaction are the same as TABULATE_REACTION.

Syntax	ENTER_REACTION
Prompts	`Same reaction? /Y/:` This displays if there is at least one reaction already defined either by ENTER_REACTION or TABULATE_REACTION. For `Y` the next prompt for defining reaction is not asked.

	`Reaction: <Chemical reaction equation> & <RA+RB=PC+PD>`
	A long reaction can be typed over several lines. A reaction should be terminated by a semicolon (`;`) or an empty line. A list showing the used database, defined elements, getting-data sequence, references, etc.:
	`Pressure /100000/: <Pressure of interest, in pa>`
	`Low temperature limit /298.15/: <T-low, in K>`
	`High temperature limit /2000/: <T-high, in K> Step in temperature /100/: <T-step>`

	`Output file /Screen: <Return for screen, or type a file name>` If you type `Return for screen` a list of thermodynamic property changes for the defined/chosen reaction is shown up as a table (which is demonstrated in the example outputs given below), and the command is terminated. If typing a file name, the table is displayed and saved as an *.EXP or an *.TAB file. Then prompts:
	`Graphical output /Y/:` For `N` a table is output to the screen and this table is saved as a basic text file with the default extension .TAB under the current working directory. In this case, the graph cannot be plotted. By default a table is created with all thermodynamic functions as normal (which is displayed on screen) and generates a graph with temperature on the X-axis and a chosen property on a certain column in the table on the Y-axis (which is plotted on screen and saved as an *.EXP file). You are also prompted for the plot column.
	`Plot column? /2/: <1 or 2 or 3 or 4 or 5 or 6>` Specify which property (as column number) to be plotted as the Y-axis (versus temperature as X-axis) as a graph on the screen. Simultaneously, all tabulated properties and the Y-axis setting (i.e. the plotted column) for the graph is written into an *.EXP file using the DATAPLOT format. The default column 2 is heat capacity, 3 enthalpy, 4 entropy and 5 Gibbs energy, and the additional column 6 is a user-entered function. The table displays on the screen. The plot then displays on the screen, followed

Syntax	ENTER_REACTION
	by a POST prompt. The POST module (postprocessor) automatically opens, and all types of the POST-module commands to refine the plotted diagram may be used. Possibilities include scaling the X/Y-axis, changing the X/Y-axis texts, etc. The command BACK or EXIT at the POST prompt always takes you back to the TAB module.

LIST_SUBSTANCES

This command is for the TABULATE_REACTION (TAB) module.

Use the LIST_SUBSTANCES command to list all species in the current database with a certain set of elements. This is useful to specify species as pure substances in the command TABULATE_SUBSTANCE.

Syntax	LIST_SUBSTANCES
Prompts	`With elements /*/ <* or a set of elements>` The elements building up various species must be specified. The wildcard * means all elements in the current database. If some elements are specified, it also prompts for how to list species with such elements.
	`Exclusively with those elements /Y/:` All species (not phases) in the current database are searched. Keep the default (Y) if you do not want other elements included in the search except for those specified. Enter N to list all species containing at least one of the specified elements.

Example of LIST_SUBSTANCES

For the SSOL database, there are different lists, as shown below:

```
TAB: l-sub
With elements /*/: <Enter>
VA                       AG                       AL
AM                       AS                       AU
B                        BA                       BE BI BR C
CA                       CD                       CE

SET_ENERGY_UNIT

Use the SET_ENERGY_UNIT command to set the energy unit as calories or Joule, in all the subsequent outputs (tables, graphs, and files) in the current calculation operation.

Syntax	SET_ENERGY_UNIT
Prompt	`Energy unit (C=Cal, J=Joule) /J/: <Unit>`

SET_PLOT_FORMAT

This command is for the TABULATE_REACTION (TAB) module.

Use the SET_PLOT_FORMAT command to set the plotting format while the result is plotted on screen or the file is saved as EXP file [using DATAPLOT graphical format] and TAB file (as a basic text file and as displayed on screen).

This command is different from SET_PLOT_FORMAT in the POST module, but is identical to SET_PLOT_ENVIRONMENT in the SYS (system utility) monitor.

Syntax	SET_PLOT_FORMAT
Options	The default set `Unit`is `1` (Windows) or `9` (Linux) for graphical presentation on screen, or all other units for outputs as *.EXP and *.TAB files. Also set the format of the graphical output to different graphical devices. The default unit 22 (1 for legacy Windows, and 9 for legacy Linux) may be altered with SET_PLOT_ENVIRONMENT in the SYS monitor or by the TC.INI file.

SWITCH_DATABASE

This command is for the TABULATE_REACTION (TAB) module.

By default, the TAB module always automatically retrieves thermodynamic data for substances or reactant/product substances in a defined reaction, or for pure phases or ideal solution phases, from the SSUB Substances database. However, you can select thermodynamic data for complex non-ideal solution phases from another database, which is possible with the SWITCH_DATABASE command.

Syntax	SWITCH_DATABASE
Prompt	`Database /XYZ/: <new database name>` Specify a `New database name`. `XYZ` stands for the default SSUB database or the current database which is switched on. If an appropriate database name is not given and the `USER` option is not used, a list displays of available databases. Use one of these databases: • PURE = SGTE Pure Elements Database • SSUB = SGTE Substances Database • USER = user defined database

The SWITCH_DATABASE command switches (or changes) from the current database to a new one, and reinitializes the entire TAB module for defining a substance or reaction and the GIBBS workspace for storing retrieved data. All the directly connected databases as predefined by the original database initiation file `tc_initd.tdb` are listed by pressing the <Enter> key without giving any argument. You can also supply your own database by giving the argument USER and then the database name and, if it is not located in the current working directory, its correct path.

This command (when required to use another database for subsequent tabulations) must be used before executing the TAB commands TABULATE_SUBSTANCE for substances, and ENTER_REACTION or TABULATE_REACTION for reactions.

When a predefined database or an appropriate USER database is switched on, the DATA command GET_DATA is automatically executed.

DATABASE NAME: The new database is specified by typing the abbreviation given in the front of one of the available predefined databases. For convenience when switching/appending databases you can add them to the predefined database list in the database initiation file `tc_initd.tdb` of your installed software.

When this command is used in a macro (*.TCM) file, if the `USER` option is selected, the database setup file name (*setup.TDB) containing the setup definitions of the user database, and its correct path, must be provided.

If a USER database name or its path is not given on the same line of the SWITCH_DATABASE command, or if it is incomplete or incorrect, an Open window displays to specify the filename of the database setup file name (*setup.TDB) of the to-be-switched USER database.

Unlike in the TDB module, if a user database is chosen, the Gibbs energy system is also reinitialized and only data from the user databases are retrieved for tabulations.

After this command, those commands to define systems (in terms of either elements or species), to reject/restore phases or species, retrieve data, as well as to append data from additional database(s), can be done.

TABULATE

This command is for the TABULATE_REACTION (TAB) module.

The TABULATE command gives the values of an already-defined table (with various properties varied with the stepping axis variable) from equilibria calculated with a STEP command. You can tabulate a table even if the table is entered after the step calculation.

Syntax	TABULATE
Prompts	`Name: <Name of a defined table>` The name of the table must be given. The table must be entered.
	`Output to Screen or file /Screen/: <File name>` The table can be listed on the screen (by pressing <Enter>), on a file (the file name must be specified here).

TABULATE_DERIVATIVES

This command is for the TABULATE_REACTION (TAB) module.

The TABULATE_DERIVATIVES command is mainly for system debugging purposes and for experienced users. It automatically calculates all partial derivatives for a pure phase or solution phase at a given composition.

This is not the same as the chemical potential.

Before using the TABULATE_DERIVATIVES command, the system must be defined and thermodynamic data retrieved from an appropriate solution database in the TDB module. The phase name can be given in either upper, lower or mixed cases, and can be abbreviated until it is unique, e.g. fcc, BCC, cem, Liq, etc. as the SSOL database is used for the tabulations, or GAS, FE-S, wustite, Fe2O3-hem, etc. as the SSUB database is used. The module then optionally goes through a specific sublattice or all the possible sublattices for the specified phase, as well as through the whole framework of a currently defined system (including all the defined elements/species, as well as the default defined vacancy and electron if necessary for the current database), when it prompts for inputs of site fractions for various species possibly occupying such sublattices. Therefore, thermodynamic properties can be tabulated for a pure phase, or for a solution phase as a pure end-member (with a composition definition for the corresponding non-interacting species on all necessary sublattices in the end-member), or for a solution phase as a real solution (with a composition definition for related interacting species on all necessary sublattices in the solution).

Syntax	TABULATE_DERIVATIVES
Prompts	`Phase name /XXXX/: <Name of the phase>` Specify the phase name of a pure phase or a solution phase. `XXXX` is the last phase the TAB module accounted for. It automatically prompts for other options and necessary inputs for the definition of the composition of the specified phase. For a pure phase (such as `Fe-S`, `Wustite`, and `Fe2O3-Hematite`), no further composition definition is needed. For a solution phase with one sublattice (such as `AQUEOUS` solution, `GAS` mixture and `SLAG` solution), it requests *n*-1 site-fraction inputs for the phase constituents (if there are *n* species in the defined phase within the whole framework of currently defined system, including all the defined elements/species, as well as the default defined vacancy and electron if necessary for the current database); the *n*th species is automatically assigned as the rest.

Syntax	TABULATE_DERIVATIVES
	The sum of input site fractions must not exceed unity.
	`Temperature /2000/: <Temperature of interest, in K>` Specify the temperature of interest in K.
	`Pressure /100000/: <Pressure of interest, in pa>` Specify the pressure of interest in Pa.

Example Prompts for TABULATE_DERIVATIVES

For example, these prompts and inputs can be seen for a `LIQUID` solution phase (from the SSOL database) within the Fe-Cr-Ni-C-N-O framework (Note that by default, the unprompted `Ni` species are assigned as the rest):

```
FRACTION OF CONSTITUENT (RETURN FOR PROMPT): <RETURN> C /1/: .05
CR /1/: .1
FE /1/: < RETURN>
SUM OF FRACTIONS EXCEED UNITY, PLEASE REENTER
FE /1/: .8
N /1/: .005
```

For a solution phase with two or more sublattices (such as FCC alloy solution, and ION_LIQ ionic liquid solution), it first asks for which sublattice the site-fractions of constituents shall be specified: the default value 0 for all possible sublattices, and a given positive number for a specific sublattice (of course, this number must be reasonable for the currently specified phase, i.e. it must be smaller than the total sublattice number of the phase). Then, for the given sublattice or for all sublattices, it prompts for all the necessary inputs of site-fractions for the possible constituents on each sublattice n-1 times if there are n species on such a sublattice in the defined phase; the nth species on each of the sublattices is automatically assigned as the rest. For example, the following prompts and inputs can be seen for an FCC solution phase (from the SSOL database) within the Fe-Cr-Ni-C-N-O framework (Note that by default, the unprompted O species on its sublattice 1 and VA on its sublattice 2 are assigned as the rest):

```
SPECIFY SUBLATTICE (0 FOR ALL) /0/: <RETURN>
FRACTIONS IN SUBLATTICE 1
CR /1/: .1
FE /1/: .8
```

```
NI /1/: .0995
FRACTIONS IN SUBLATTICE 2
C /1/: .05
N /1/: .05
```

Example Output for TABULATE_DERIVATIVES

For the FCC phase in the Fe-Cr-Ni-C-N-O system (using the SSOL database), the following table is obtained at a specified composition:

```
TAB: TAB_DER
Phase name /BCC/: FCC
SPECIFY SUBLATTICE (0 FOR ALL) /0/: <Enter>
FRACTIONS IN SUBLATTICE 1
CR /1/: .1
FE /1/: .8
NI /1/: .3
SUM OF FRACTIONS EXCEED UNITY, PLEASE REENTER
NI /0/: .0995
FRACTIONS IN SUBLATTICE 2
C /1/: .05
N /1/: .05

TABULATE_REACTION

This command is for the TABULATE_REACTION (TAB) module.

Use the TABULATE_REACTION command to tabulate thermodynamic property changes for a chemical reaction as a table, or variation of one chosen property can be plotted against temperature as a graph, or saved as an experimental file (with an extension of .EXP). The thermodynamic data are automatically retrieved from the SSUB5 database (by default), or the current database set by the SWITCH_DATABASE command (thus there is no need to use the DATA module before this command). You can select any other database by using SWITCH_DATABASE.

It is important to remember the rules to specify a reaction:

- The reaction is specified, by giving the reactants and products, such as `Ga+S=GaS`, `5Al+2Fe=Al5Fe2`.
- Under Linux environments, the notation for a chemical formula treats upper and lower cases as the same (such as `ga+s=GaS`, `5Al+2Fe=al5fe2`); but under Windows, the TAB module only accepts upper cases, e.g. `GA+S=GAS`, `5AL+2FE=AL5FE2`.
- Elements with a single letter symbol must be followed by a stoichiometry factor, even if it is 1; thus, the symbol `CO` is taken as cobalt, carbon monoxide must be given as `C1O1` (or `O1C1`).
- All the reactants and products must be defined as species-stoichiometries in the currently-used database; in other words, the reaction definition only accepts already-defined species-stoichiometries as reactants and products. For example, if a database does not have a species defined with a stoichiometry of Al5Fe2 {e.g. the Al and Fe (but not Al5Fe2) may be defined as species, and the Al5Fe2 phase may be defined as a two-sublattice stoichiometric phase [Al]5[Fe]2, rather than a single sublattice stoichiometric phase [Al5Fe2]}, then the reaction 5Al+2Fe=Al5Fe2 cannot be tabulated.
- Make sure that the Gibbs free energy expression for a stoichiometric phase is really corresponding to the species-stoichiometry. For example, if a database has a definition of Function GAL5FE2 for 1/7 of the AL5FE2 formula, then the relation G(Al5Fe2)=7*GAL5FE2 must be defined; otherwise, the tabulated thermodynamic properties for the reaction 5Al+2Fe=Al5Fe2 is wrong.

Syntax	TABULATE_REACTION
Prompts	`Same reaction? /Y/:` This prompt displays if there is at least one reaction already defined either with the commands ENTER_REACTION or TABULATE_REACTION. The following prompts only display if `N` is entered.
	`Reaction: <Chemical reaction equation> & <RA+RB=PC+PD>` A long reaction can be typed over several lines. A reaction should be terminated by a semicolon (`;`) or

Syntax	TABULATE_REACTION

	an empty line. A list showing the used database, defined elements, getting-data sequence, references, etc.
	`Pressure /100000/: <pressure of interest, in pa>`
	`Low temperature limit /298.15/: <T-low, in K> Specify the starting temperature K.`
	`High temperature limit /298.15/: <T-high, in K> Specify the ending temperature K. Step in temperature /100/: <T-step> Specify the temperature step for the tabulation.`

	`Output file /Screen/: <Return for screen, or type a file name>` If you type `Return for screen`, a list of thermodynamic property changes for the defined/chosen reaction is shown as a table (which is demonstrated in the example outputs given below), and the command is terminated. If typing a file name, the table is both displayed on screen and saved as an *.EXP or a *.TAB file, and the program prompts:
	`Graphical output /Y/:` • For N a table is output to the screen, and the same table is saved as a basic text file with the default extension .TAB under the current working directory. In this case, the graph cannot be plotted. • For Y a table is created with all thermodynamic functions as normal (which is displayed on screen) and generates a graph with temperature on the X-axis and a chosen property on a certain column in the table on the Y-axis (which is plotted on screen and saved as an *.EXP file), and it also asks which column is to be plotted on the resulting graph:
	`Plot column? /2/: <1 or 2 or 3 or 4 or 5 or 6>` Specify which property (as column number) to be plotted as the Y-axis (versus temperature as X-axis) as a graph on the screen. Simultaneously, all tabulated properties and the Y-axis setting (i.e. the plotted column) for the graph is written into an *.EXP file using the DATAPLOT format. The default column 2 is heat capacity, 3 enthalpy, 4 entropy and 5 Gibbs energy, and the additional column 6 is a user-entered function. The table displays on the screen. The plot then displays on the screen, followed by a POST: prompt. The POST module automatically opens, and all types of the POST module commands to refine the plotted diagram may be used. Possibilities include scaling the X/Y-axis, changing the X/Y-axis texts, etc. The command BACK or EXIT at the `POST:` prompt always takes you back to the TAB module.

Example of TABULATE_REACTION

For the reaction Ga+S=GaS (using the SSUB database), the following table is obtained by typing <Enter> in the prompt Output file /SCREEN/, and the figure by typing `2` in the prompt `Plot column /2/:`

```
O U T P U T F R O M T H E R M O - C A L C
 Reaction: S+GA=GA1S1
stable as S_S
GA stable as GA_S
```

```
GA1S1 stable as GA1S1_S

TABULATE_SUBSTANCE

This command is for the TABULATE_REACTION (TAB) module.

Use the TABULATE_SUBSTANCE command to tabulate thermodynamic properties of a substance (with a given chemical formula but it is not certain in which phase/state it may form) or a pure stoichiometric phase (getting data from a specific substance database such as SSUB, or from a specific solution database such as SSOL and TCFE), or of a solution phase with a fixed composition (getting data from a specific solution database such as SSOL and TCFE), under a constant pressure and various temperatures.

In case of a pure stoichiometric phase or a solution phase with a fixed composition, you must already define the system and get thermodynamic data from an appropriate solution database in the TDB module before using this TAB command. The phase name can be given either upper or lower or mixed cases, and can be abbreviated until it is unique, e.g. `fcc`, `BCC`, `Liq`, `cem`, `Al5Fe2`, etc. as the SSOL database is used for the tabulations, or `GAS`, `FE-S`, `wustite`, `Fe2O3-hem`, etc. as the SSUB database is used. The module then optionally goes through a specific sublattice or all the possible sublattices for the specified phase, as well as through the whole framework of a currently defined system (including all the defined elements/species, as well as the default defined vacancy and electron if necessary for the current database), when it prompts for inputs of site fractions for various species possibly occupying such sublattices. Therefore, you can tabulate thermodynamic properties for a pure phase, or for a solution phase as a pure end-member (with a composition definition for the corresponding non-interacting species on all necessary sublattices in the end-member), or for a solution phase as a real solution (with a composition definition for related interacting species on all necessary sublattices in the solution).

Moreover, the variation for one of the tabulated properties for a substance, a pure stoichiometric phase, or a solution phase with a fixed composition can be plotted against temperature as a graph or saved as an experimental file (with an extension of .EXP).

Syntax	TABULATE_SUBSTANCE
Prompt	`Substance (phase): <Name of the species or phase>` In case of a substance, give its chemical formula, e.g. Fe, H2, C1H6, FeC1, CaC1O3, MgSiO3, etc. When the TABULATE_SUBSTANCE <SUBSTANCE> command sequence is used for the first time in the TAB module, it always uses the SSUB Substances database as the default. If SSUB is not available and a specific database has not been switched on yet, it may prompt to specify an appropriate substance or solution database (e.g. typing `SSUB<version number>`; `SSOL<version number>`; `TCFE<version number>` etc.). Prior to this command, you can also use SWITCH_DATABASE to set the current database. If a solution database is set as the current database, only the neutral species that are valid substance standing by themselves as phases can be tabulated.

Syntax	TABULATE_SUBSTANCE

Before other prompts, a list of the used database, defined elements, getting-data sequence, references, etc. is displayed on screen. From such information, you know what the TAB module is performing.

In case of a pure stoichiometric phase or a solution phase, give its phase name, e.g. FCC, CEMENTITE, LIQUID, SLAG, AQUEOUS, GAS, Al5Fe2, Fe-S, Wustite, Fe2O3-Hematite, etc.

REMEMBER: It is important that you have already defined the system and gotten thermodynamic data from an appropriate solution database in the TDB module before using this TAB_SUB command. It automatically prompts for other options and necessary inputs for the definition of the composition of the specified phase.

For a pure stoichiometric phase defined with one single sublattice (such as Fe-S, Wustite, and Fe2O3-Hematite), no further composition definition is needed.

For a solution phase defined with one sublattice (such as AQUEOUS solution, GAS mixture and SLAG solution), it requests n-1 site-fraction inputs for the phase constituents (if there are *n* species in the defined phase within the whole framework of currently defined system, including all the defined elements/species, as well as the default defined vacancy and electron if necessary for the current database); the *n*th species is automatically assigned as the rest.

The sum of input site fractions must not exceed unity. For example, the following prompts and inputs can be seen for a LIQUID solution phase (from the SSOL database) within the Fe-Cr-Ni-C-N-O framework (Note that by default, the unprompted Ni species is assigned as the rest):

```
Fraction of constituent (return for prompt): <Return>
   C /1/: .05
   CR /1/: .1
   FE /1/: <RETURN>
```

```
Sum of fractions exceed unity, please reenter
   FE /1/: .8
   N /1/: .005
```

For a pure stoichiometric phase defined with two or more sublattices (such as Al5Fe2 inter-metallic stoichiometric phase) and for a solution phase defined with two or more sublattices (such as FCC alloy solution, and ION_LIQ ionic liquid solution, Al5Fe4 inter-metallic solution phase), it first asks for which sublattice the site-fractions of constituents shall be specified: the default value 0 for all possible sublattices, and a given positive number for a specific sublattice (this number must be reasonable for the currently specified phase, i.e. it must be smaller than the total sublattice number of the phase). Then, for the given sublattice or for all sublattices, it prompts for all the necessary inputs of site-fractions for the possible constituents on each sublattice *n*-1 times if there are n species on such a sublattice in the defined phase; the *n*th species on each of the sublattices are automatically assigned as

Syntax	TABULATE_SUBSTANCE
	the rest. For example, these prompts and inputs can be seen for an FCC solution phase (from the SSOL database) within the Fe-Cr-Ni-C-N-O framework (Note that by default, the unprompted `O` species on its sublattice `1` and `VA` on its sublattice `2` is assigned as the rest):

	`Specify sublattice (0 for all) /0:`
	`FRACTIONS IN SUBLATTICE 1`
	`CR /1/: .1`
	`FE /1/: .8`
	`NI /1/: .0995`
	`FRACTIONS IN SUBLATTICE 2`
	`C /1/: .05`
	`N /1/: .05`

	`Pressure /100000/: <Pressure of interest, in pa>` Specify the constant pressure condition in Pa.
	`Low temperature limit /298.15/: <T-low, in K>` Specify the starting temperature K.
	`High temperature limit /298.15/: <T-high, in K>` Specify the ending temperature K.
	`Step in temperature /100/: <T-step> Specify the temperature step for the tabulation.`
	`Output file /Screen/: <Return for screen, or type a file name>` If you type `Return for screen` a list of basic thermodynamic functions for the chosen substance or for the specified pure or solution phase with the fixed composition is shown up as a table (which is demonstrated in the example outputs given below), and the command is terminated. If typing a file name, the table is both displayed on screen and saved as an *.EXP or a *.TAB file, and the program further prompts:
	`Graphical output /Y/:` • For N a table is output to the screen, and the same table is saved as a basic text file with the default extension .TAB under the current working directory. In this case, the graph cannot be plotted. • For Y a table is created with all the thermodynamic functions as normal (which is displayed on screen) as well as generates a graph with temperature on the X-axis and a chosen property on a certain column in the table on the Y-axis (which is plotted on screen and saved as an *.EXP file), and it also ask which column is to be plotted on the resulting graph:
	`Plot column ? /2/: <1 or 2 or 3 or 4 or 5 or 6>` Specify which property (as column number) to be plotted as the Y-axis (versus temperature as X-axis) as a graph on the screen. Simultaneously, all tabulated properties and the Y-axis setting (i.e. the plotted column) for the graph is written into an *.EXP file using the DATAPLOT format. The default column 2 is heat capacity, 3 enthalpy, 4 entropy and 5 Gibbs energy, and the additional column 6 is a user-entered function. The table displays on the screen. The plot then displays on the screen, followed by a POST: prompt. The POST module (postprocessor) automatically opens, and all types of the POST-module commands to refine the plotted diagram may be used. Possibilities include scaling the X/Y-axis,

Syntax	TABULATE_SUBSTANCE
	changing the X/Y-axis texts, etc. The command BACK or EXIT at the POST: prompt always takes you back to the TAB module.

Example 1 of TABULATE_SUBSTANCE

For the FCC alloy phase as a non-ideal solution with a fixed composition

```
[Fe0.80,Cr0.10,Ni0.0995,O0.005][C0.05,N0.05,VA0.90]
```

The following table is obtained by typing `Return for screen` at the prompt `Output file /SCREEN/`:

```
O U T P U T F R O M T H E R M O - C A L C
Phase : FCC                        Pressure :     100000.00
 Specie: CR1/--2

CREATE_DIVIDERS

This command is for the REACTOR_SIMULATOR (REACTOR) module.

Use the CREATE_DIVIDERS command to define the segment boundaries and the ways on how to distribute phases between various segments and to split the feeds of heat and mass.

Syntax	CREATE_DIVIDERS
Prompts	`Number of dividers /4/: <The number of dividers>` Specify the number of dividers (boundaries between various segments) in the reactor. It is normally the segment number plus one: for example, if the stage box number is defined as 4, the divider number should be defined as 5.
	`Number of outputs for divider # /3/: <The number of outputs>` Specify the number of outputs for a specific divider #.
	`Percent of input to output 1 /100/: <Percent of input>` Define the percentage of input to the output 1 in the current divider #.
	`Percent of input to output ## /100/: <Percent(s) of input(s)>` Define the percentages of inputs to the outputs ## in the current divider #. It is repeated till the last output is specified.

CREATE_PIPES

This command is for the REACTOR_SIMULATOR (REACTOR) module.

Use the CREATE_PIPES command to define the pipes between various segments and the ways on how the mass and heat transport between the surroundings (with the record number as 0) and the reactor, among various segments in the reactor, and along various dividers (segment boundaries in the reactor).

Syntax	CREATE_PIPES
Prompts	`From record: <A record number>` Specify a record number. If there are four segments in the reactor, these records are available: • `0` surroundings • `1-4` stage boxes (segments) • `5-9` dividers (segment boundaries)
	`Pipe to record: <Another record number>` Specify another record number to which the mass or heat flows from the current record (specified above). Before this prompt, a message shown on the screen indicates what kind of mass or heat flow (according to the definitions of stage boxes and dividers, which have already been created prior to this command) should be specified in the pipe. This is repeated for all inputs and/or outputs for mass and/or heat in current record.

CREATE_STAGE_BOXES

This command is for the REACTOR_SIMULATOR (REACTOR) module.

Use the CREATE_STAGE_BOXES command to create several reaction stages as boxes (segments), where the you define the feed in either mass input and initial temperature or heat input from surroundings, as well as the mass out and initial temperature in each of the segments.

Syntax	CREATE_STAGE_BOXES
Prompts	`Number of stage boxes /4/: <The number of stage boxes>` Specify the number of stage boxes in the reactor. Then define the feed of mass and/or energy (from surroundings to) the rector.
	`Give feed to system: <Feed>` One feed (of mass or heat) to the reactor must be specified here. Two types of feeds can be used: • As input amount of heat (enthalpy): `H=Value`. • As input amount of specific species or element and its initial temperature: `N (SPECIES)=Value, Input temperature` (in one line, or the input temperature in the next prompt).
	`Input temperature /298.15/: <Input temperature>`

	`Give feed to system: <Feed>`
	Specify other feeds (mass or energy) to the reactor. Press <Enter> to finish the feed inputs, and then:
	`Give for stage box #`
	Now start to define the type of stage box (segment is specifically numbered as #), and to specify a guess of initial temperature and an output for each phase in the segment.

	`Type of box/Equilibrium/: <Type of box>` Only the `EQUILIBRIUM` type is allowed. Press <Enter> to accept it.
	`Is the stage heat controlled? /Y/: <Yes or No>` Y means the current segment is heat controlled.
	`Initial guess of temperature? /1000/: <Initial temperature>` Give a guess of initial temperature (in K) for the current segment; press <Enter> to accept the default.
	`Give initial amount: <Initial amount of mass or heat>` The initial amount of mass and/or heat in the current segment can be specified here. Two types of initial amount can be used: • As initial amount of heat (enthalpy): `H=Value`. • As initial amount of specific species or element and its initial temperature: `N (SPECIES)=Value, Input temperature` (in one line, or the input temperature in the next prompt).

Syntax	CREATE_STAGE_BOXES
	`Input temperature /298.15/: <Input temperature>`

	`Give initial amount: <Initial amount of mass or heat>`
	Specify initial amount (mass or energy) in the current segment. Press <Enter> to finish the initial amount inputs, and then this message displays:
	`Each phase may have a separate output, give these`
	Now start to define the output for each phase.

	`Phase name /Rest/: <Name of phase>` Specify a phase that has a separate output, e.g. `GAS`; by pressing <Enter> to accept that all `REST` phases do not have separate outputs. Then the program asks for further definitions of all the other segments (one by one), repeating some of the above questions, till the last segment in the reactor is defined.

EXECUTE_POLY3_COMMAND

This command is for the REACTOR_SIMULATOR (REACTOR) module.

Use the EXECUTE_POLY3_COMMAND to directly use all kinds of POLY commands inside the REACTOR module. Any legal POLY commands can be entered.

LIST_RECORDS

This command is for the REACTOR_SIMULATOR (REACTOR) module.

Use the LIST_RECORDS command to ist all the already-created records for the reactor (including stage boxes, dividers, pipes, etc.)

READ_WORKSPACE

This command is for the REACTOR_SIMULATOR (REACTOR) module.

The REACTOR workspace (along with the related POLY and GIBBS workspaces) and the simulated results from the SIMULATE command can be read by the READ_WORKSPACE command from a binary file where they must be saved with SAVE_WORKSPACE. The *.RCT file is not printable.

Syntax	READ_WORKSPACE
Options	`File name`: The name of a saved *.RCT file where the REACTOR and POLY/GIBBS workspaces shall be read from must be specified. You do not need to type the extension if it is the default .RCT, otherwise type the whole *.RCT file name. An **Open** window displays if a file name is not given after the command or its path is incorrect, so that the path (in the **Look in** field) and **File name** can be specified. The **Files of type** (i.e. RCT) cannot be changed.

SAVE_WORKSPACES

This command is for the REACTOR_SIMULATOR (REACTOR) module.

The POLY module and Gibbs (GES) module also have a command with the same name.

The workspaces are saved to a file with this command. In the REACTOR workspace, all definitions of multi-stage steady-state rector and its distribution coefficients are saved, together with the GIBBS and POLY workspaces.

After using the SAVE_WORKSPACES command, you can always return to the state when you issued the command by giving a READ command.

After saving the workspaces to a file, you can exit the software and at a later time READ the file and continue from the saved state.

START_SIMULATION automatically saves on the work file with the most lately specified name. To avoid destroying the simulated results, do not SAVE after a START_SIMULATE command is enforced, similar to that you should not use SAVE after a STEP or MAP command. You may append several results by START_SIMULATE without destroying the previous results but SAVE erases them all.

Syntax	SAVE_WORKSPACES
	`File name` A file name must be specified. The default extension of the RCT file is .RCT, while or any other extension as required A **Save** window displays if a file name is not given after the command, so that the path (in the **Save in** field) and **File name** can be specified. The **Files of type** (i.e. RCT) cannot be changed. If there is already a file with the same file name under the directory a warming message displays. Click **OK** to overwrite the current REACTOR (and POLY3/GIBBS) workspaces onto the existing *.RCT file. Click **Cancel** to return to the REACTOR module. You can use the SAVE command with an unspecified name (i.e. through `SAVE , , ,` command-sequence) to save the REACTOR (and POLY3/GIBBS) workspaces..

START_SIMULATION

This command is for the REACTOR_SIMULATOR (REACTOR) module.

Use the START_SIMULATION command to start the reactor simulation, and list the results for all iterations. The output for each iteration consists of the conditions set in each segment, and you can also select some state variables to list. After each loop, the temperatures in all segments are listed.

Syntax	START_SIMULATION
Prompts	`Max number of loops /10/: <The max number of loops>` Give the max number of loops. The reactor simulation repeats until this loop number is reached.
	`Output to screen or file /Screen/: <File name or return>` Decide on either listing simulation results on the screen (by pressing <Enter>) or saving them on an experimental file (with the default extension .EXP). The conditions in each segment are not saved in the file, only on the screen.
	`Output variables /T BP($)/: <Variable name(s)>` Specify the variable name(s) that is also listed on the screen together with the conditions in each segment, or in the output experimental file.

Example of START_SIMULATION

For a four-stage reactor, the output at a certain iteration may look like this:

```
H=-991745.1, P=100000, N(C)=2.8468936, N(N)=6.78399966E-4, N(O)=3.8171615,

ADD_LABEL_TEXT

Use the ADD_LABEL_TEXT command to add a text to an area in a phase diagram or a property diagram. The label is written starting from the specified coordinates. Optionally, you can also let the program automatically add the text by first calculating an equilibrium state at the specified coordinates and then making a label out of the stable phase names.

The label texts and coordinates, either added by the ADD_LABEL_TEXT command or modified with MODIFY_LABEL_TEXT (or manually edited in the **Console Results** window), are stored in the workspace, and these may later be saved onto an *.EXP file (with MAKE_EXPERIMENTAL_DATAFILE).

In some cases such an optional calculation for automatic phase region labeling may not work. It is not possible to automatically add labels for certain sets of axes, like entropy, enthalpy, pH, Eh, etc.

Plot Labels

Syntax	ADD_LABEL_TEXT
Prompts	`Give X coordinate in axis units: <Value of the X coordinate>` Specify the value of the X coordinate where the label is to start.
	`Give Y coordinate in axis units: <Value of the X coordinate>` The labels disappear if any axis is changed after wards. Specify the value of the Y coordinate where the label is to start.
	`Automatic phase labels? /Y/:` By default the program automatically calculates the equilibrium at the given coordinates and generates a label with the names of the stable phases. However, the automatic calculation works only for phase diagrams that are mapped with two axes in the POLY module, and sometimes it may not work correctly especially for complex heterogeneous interaction systems; in such cases, a message displays.

	`Text: <Text for the label>`
	If you answer N enter text at the prompt. You can enter simple text, use LaTeX, rotate the text, as well as adjust the font size.
	LaTeX: You can use LaTeX commands to enter text and symbols. First enter the command followed by the expression or string, for example to display `Al2O3` with subscripts:
	`\latex Mole-fraction Al_2O_3`

Syntax	ADD_LABEL_TEXT

By default when using the LaTeX command, you are in math mode and Thermo-Calc automatically interprets the entered text as math. The above link uses the dollar sign ($) in all the examples but this is NOT required. For example, if you enter `$E=mc^2$` this is displayed including the $ instead of the equation.

To add a mixture of plain text and equation text, you can exit math mode using the string \textsf followed by the text to display enclosed in curly brackets.

For example `\latex \textsf{Mole-fraction }Al_2O_3` displays this sans serif label

Mole-fraction Al_2O_3

White space has to be entered in the text context and not outside in math mode.

Rotate the text: If you want to rotate the label, start a text string with the rotation command (which is case sensitive and must be in lower case letters) then enter the number of degrees to rotate the label. For example, to rotate the label 45 degrees enter:

```
\rotation 45
```

To rotate the text and use LaTeX, the rotation command must be used first. For example:

```
\rotation 45 \latex Mole-fraction Al_2O_3
```

Rotates the text 45° and includes subscripts in the title Mole-fraction Al_2O_3.

```
Text size: /.35/: <Size for the label>
```

A smaller size of the text may be necessary to fit the label text into the diagram. A default size is given using the latest size in adding label texts, or .35 if the command is called for the first time. A recommended size is e.g. 0.25.

These changes to plot labels can also be manually edited in the **Console Results** window.

Examples of ADD_LABEL_TEXT

To produce a label with the unit Celsius:

```
\textsf{Temperature []^\circ C\textsf{]}
```

Text with white space, suitable for an axis label:

```
\textsf{Text with space} Al_2O_3
```

APPEND_EXPERIMENTAL_DATA

Use the APPEND_EXPERIMENTAL_DATA command to add experimental data and text onto a calculated diagram. This is done by placing the experimental data and text on a formatted textual file (always having an extension of EXP) that is prepared outside of Thermo-Calc software (Console Mode and Graphical Mode), according to the syntax of the DATAPLOT Graphical Language.

The picture generated from the data is superimposed on the ordinary graphical output from the postprocessor. Such an experimental data file (*.EXP) may be created by an ordinary textual editor.

Another important usage of this command is to superimpose plots from several independent calculations. For this purpose, there is a command MAKE_EXPERIMENTAL_DATAFILE, which dumps a calculated diagram on an EXP file according to the DATAPLOT syntax. With the aid of a normal text editor, many such files may be merged together. Remember that you can only have one prologue section on each such EXP file.

Syntax	APPEND_EXPERIMENTAL_DATA
Prompts	`Use experimental data (Y or N) /N/:` By default, no experimental data are plotted. Enter Y to use the data from an experimental data file in the next plot. An **Open** window displays to specify the name of the file with the experimental data.
	`Prologue number: /0/: <Prologue number>` Select which prologue to use. In a prologue, you can, for example, give the scaling of an axis, the axis texts, and so on. By answering -1, a list of all prologues on the file is given; and by 0, no experimental data are appended.
	`Dataset number(s) /-1/: <Dataset number(s)>` Select from which dataset(s) data should be read. Several datasets may be given separated with commas or spaces. By answering -1, a list of all datasets on the file is given; and by 0, no experimental data are appended.

CHANGE_LEGEND

Use the CHANGE_LEGEND command when there is a legend in the diagram you can add certain labels to the phase name such as append constitution and/or ordering descriptions, and include common phase names.

LIST_EQUILIBRIUM also displays `ORD` (ordered) or `DISORD` (disordered) (when available).

In some cases the legend only shows the phase name for a line when SET_LABEL_CURVE_OPTION is set to `F`.

For examples and more details about what these options show, see About Legend Styles and Legend and Label Styles where it is described for Graphical Mode.

Syntax	CHANGE_LEGEND
Prompt	`Set suffix for phase names in legend? (All, None, Constitution, Ordering, Common/None/):` • `None`: The legend only includes the database names of the phases. • `Common`: When available, a common phase name is included in the legend. This is the default. • `Constitution`: The constitution is added to the standard description. • `Ordering`: When applicable, the ordering is added to the standard description. • `All`: All options for phase labels are included.

DUMP_DIAGRAM

The DUMP_DIAGRAM command is an alternative command used to create output. First use the PLOT_DIAGRAM command to send output to the Console Results window. Then you can save it to a file either using this command or right-click the diagram in the Console Results window and select Save as.

Similar to PRINT_DIAGRAM, it does not matter what graphic device/printer is set up. The command can convert the diagram shown in the Console Results window to the selected format.

Syntax	DUMP_DIAGRAM
Prompt	`Output format/: (jpg,ps,pdf,svg,emf,gif,png) /png/`
	Enter a format or press <Enter> to accept the default (png). If you choose to enter the parameters and file name in one line (i.e. when you are entering the command), the **Save** window does not open as described below. For example, if you enter `dump_diagram png test` at the prompt, an image file called **test.png** is output to the same folder where the macro file is stored. If a file with the specified name already exists, you are prompted to overwrite the old file. You can alternatively add `Y` or `N` to the command string to specify whether to overwrite the file or not e.g. `dump_diagram png test y`. A **Save** window opens if you have not specified a file name. Select a directory path and enter a **File name**. If a file with the specified name already exists, then you are prompted whether to overwrite the old file or not. The third argument of the command (Y) allows you to specify whether to overwrite the old file or not (N).

After the output is done, the temporarily set graphic device for conversion and printing is switched back to the one set by the command SET_PLOT_FORMAT, so that you can save the graph in file(s) using PLOT_DIAGRAM.

ENTER_SYMBOL

This command is for the POST module.

There are also a GES and POLY module commands with the same name.

Symbols are a useful feature of the POLY and POST modules to define quantities that are convenient. Symbols can be constants, variables, functions or tables.

Functions or tables (with defined functions as values) can be entered in the POST module after a stepping or mapping calculation, for purposes of plotting such entered functions or tables as axis variables.

Within the POLY module, symbols are normally defined prior to an equilibrium calculation (enforced by a C_E command), stepping calculation (enforced by the command STEP_WITH_OPTIONS) or mapping calculation (enforced by MAP). These can be entered after an equilibrium calculation; however, for defined functions, variable or tables, it requires using EVALUATE_FUNCTIONS before showing the corresponding values in the calculated equilibrium state.

The symbols entered in the POST module are not saved in the currently-loaded POLY3 workspaces. Therefore, if you want to apply such symbols in other similar calculations for the same defined system, you must use the ENTER_SYMBOL command prior to the STEPPING or MAPPING calculation in the POLY module.

See example 44 for an example of using variables and functions.

Use the ENTER_SYMBOL command to enter symbols, which can be constants, variables, functions, or tables.

Syntax	ENTER_SYMBOL
Prompt	`Constant, Variable, Function or Table? /Function/: <Keyword>` The `Keyword` can be specified as `CONSTANT`, `VARIABLE`, `FUNCTION`, or `TABLE`. • CONSTANTS can only be entered once and is a means of using a name for a numeric value. For example, the value of 1 atmosphere in Pascal can be denoted by `P0` after the command ENTER_CONSTANT `P0=101325`. Defined constants can be used as values in condition assignments, for example, `SET-COND P=P0`. • FUNCTIONS are expressions of state variables or other functions. These expressions are saved, and whenever a function value is requested all functions are evaluated. The reason for this is that they may depend on each other. • VARIABLES are similar to functions because they can also be expressions of state variables. However, contrary to functions, they are only evaluated when they are entered or if they are explicitly named in an EVALUATE_FUNCTIONS command. It is possible to enter a variable with a new expression any time. This expression is evaluated directly and its value stored as the

Syntax	ENTER_SYMBOL

value of the variable. Defined variables can be used as values in the SET_CONDITION command.

- TABLES are used for listing results from the STEP or MAP commands. A table consists of a list of any number of state variables, functions, or variables. Defined tables can also be used in the POST (post-processor) module.

There is a special connection between tables and variables. If a variable is used in a table, it is evaluated for each line of the table in the TABULATE command or when the table is used in a plot.

`Name: <Name of the symbol>`

Each symbol has a unique name that must start with a letter and can have maximum 8 characters. Legal characters include letters (either UPPER or lower case), digits and underscore _. Any other special character, such as parentheses (and), plus +, minus -, slash / or \, full stop (.), are illegal for symbol names.

You can enter the symbol name and the value or function on the same line; these must be separated with an equal sign =, for example, `TC=T-273.15` or `T_C=T273.15` which stands for a definition of temperature in Celsius. Otherwise, these questions are asked.

For different types of symbols (constant, function, variable, or table), the questions have different prompts.

`Function: <Definition for a function or variable>`

Functions and *variables* are evaluated from an expression of state variables or other functions, constants, or variables. The expression is a FORTRAN-like expression and operators +, -, *, = and ** can be used (** only with integer powers).

Unary functions like `LOG`, `LOG10`, `EXP`, `SIN`, `COS`, and `ERF` can also be used. An expression can be continued on more than one line. An expression should be terminated by a semicolon (;) or an empty line (press <Enter> at the next prompt).

Examples of function expressions:

- `GM(LIQUID)`: The Gibbs energy of liquid per mole component
- `H.T/4.184`: The heat capacity of the system in calories
- `ACR(CR)/X(FCC,CR)`: The activity coefficient for Cr in FCC
- `T-273.15`: The temperature in Celsius

`&: <Continuation of the definition for the symbol>`

The ampersand & means that you can continue to write the function on the new line if one line is not

Syntax	ENTER_SYMBOL
	enough for the function. If you finish the function press <Enter> again.
	`Value: <Value for a constant>` A *constant* can only be assigned a numeric value once.
	`Value or expression: <Value of expression for a variable>` A *variable* can be assigned a numeric value or an expression. An expression is evaluated immediately and discarded. Only the numeric value is kept. This gives a possibility to save a value between calculations with different conditions because all state variables and functions are evaluated for the new conditions.

	`Variable(s): <Variable(s) in a table>`
	A *table* consists of a list of state variables or functions. One way to obtain results from a STEP command is through a table.
	Example:
	`ENTER TABLE K=T,X(LIQ,C),X(LIQ,CR),ACR(C)`
	Which means that the table called K contains four columns, i.e. the temperature, the mole fractions of C and Cr in the LIQUID phase, and the activity of C.
	To show the temperature in Celsius in a table, give the command ENTER_FUNCTION `TC=T-273`; and then use the symbol `TC` in the table.
	`& <Continuation of the definition for the table>`
	The ampersand `&` means that you can continue to write the table on the new line if one line is not enough for the table. If you finish the table press `<Enter>` again.

FIND_LINE

The FIND_LINE command identifies various property curves on a plotted property diagram (after a stepping calculation); it also works well in find stable phase regions on a phase diagram (after a mapping calculation).

Syntax	FIND_LINE
Prompts	`X coordinate /.484623611/: <Value of the X coordinate>` Specify the `value of the X coordinate` where you want to find the details of property curve (or phase region).
	`Y coordinate /.5153737962/: <Value of the Y coordinate>` Specify the `value of the Y coordinate` where you want to find the details of property curve (or phase region). The POST module displays the identified property (for a property curve on a property diagram), or the identified stable phase-assemblage (for a phase region on a phase diagram).

LIST_DATA_TABLE

This is a POST module command.

The LIST_DATA_TABLE command is used for listing various properties (i.e. the Y-axis variable on a property diagram) that change with an independent variable (i.e. the X-axis variable on a property diagram), which have already been defined in the POST module (and often are plotted on the **Console Results** window), but only after a STEP calculation.

The listing output can be either on screen or in a spreadsheet file in the MS Excel format (under specified file name with the default file extension of XLS), which can be further edited or used for graphical handling by opening the file (using the MS-Excel program) outside of the Thermo-Calc software system.

This command only works for a property diagram after a stepping calculation but not for any phase diagram after a mapping calculation.

Syntax	LIST_DATA_TABLE
Prompt	`Output to screen or file /Screen/: <File name or return >` Specify a file name if you want to save on a spreadsheet file (in the MS Excel format, with the default extension of `XLS`) on which the already-defined properties on a property diagram (after a STEP calculation) is saved, or press <Enter> if want to see a simple textual table on screen (for the already-defined properties that change alone with an independent variable).

LIST_PLOT_SETTINGS

This is a POST module command.

Use the LIST_PLOT_SETTINGS command to list the present values of most parameters specifying the type of diagram to be plotted.

LIST_SYMBOLS

This command is for the POST module.

There is also a POLY module command with the same name.

Use the LIST_SYMBOLS command to list the definitions for all constants, functions, variables, and tables.

In order to find the value of a function or variable, use SHOW_VALUE or EVALUATE_FUNCTIONS. A table is tabulated with the TABULATE command.

The defined variables are listed up together with the defined functions, but variable names are followed by a percentage sign %.

LIST_TIME_STEPS

This for the POST PROCESSOR module.

Use the LIST_TIME_STEPS command to list all integration time steps.

MAKE_EXPERIMENTAL_DATAFILE

Use the MAKE_EXPERIMENTAL_DATAFILE command to write the graphical information onto screen or a formatted text file (always having an extension of .EXP) using the DATAPLOT graphical format. In order to merge two or more diagrams from separate calculations, you can write them out on files with this command, and then add/edit them together with a normal text editor.

There is another type of experimental data file that is generated in Thermo-Calc when working with the PARROT module. For more information seeExperimental Data Files (*.POP, *.DOP).

Syntax	MAKE_EXPERIMENTAL_DATAFILE
Prompt	`Output to screen or file /Screen/: <Name of a file or return>` Specify the name of the desired file. Press <Enter> for a list. Otherwise enter a file name where the graphical information is written. The default file extension is `EXP` (for Windows) or `exp` (for Linux).

MODIFY_LABEL_TEXT

Use the MODIFY_LABEL_TEXT command to move a label created with the command ADD_LABEL_TEXT to another position, or replace its text with another one.

The label texts and the coordinates, either added by ADD_LABEL_TEXT command or modified by this command or manually edited on the Console Results window, are stored in the workspace, and can be saved onto an *.EXP file (through MAKE_EXPERIMENTAL_DATAFILE).

Syntax	MODIFY_LABEL_TEXT
Prompts	`Which label to modify? /#/: <Number of the label>` Before this prompt, all the labels created by the ADD_LABEL_TEXT command is listed with an identifying number. Specify the `Number of the label` you want to modify. The default one (#) is the last added label.
	`New X coordinate: /xxx/: <New X position>` Specify the `New X position`. The previous X coordinate is displayed. Press <Enter> to accept.
	`New Y coordinate: /yyy/: <New Y position>` Specify the `New Y position`. The previous Y coordinate is displayed. Press <Enter> to accept.
	`New text /ABCDEFGH.../: <New labeling text>` Specify the `New labeling text`. The previous text is displayed. Press <Enter> to accept. The new label text must not be longer than the previous text.

PLOT_DIAGRAM

After you use the SET_PLOT_FORMAT command to define the default graphic device (the printer) you can use a PLOT_DIAGRAM command to either save the calculation output to a file or display the output in the Console Results window.

The diagram axes must be set first.

The functionality of this command is shared in two ways:

- in PLOT_DIAGRAM for normal screen display and file saving and
- *Windows OS*: If the device is not defined, you can alternatively use PRINT_DIAGRAM for a hard copy.

A file with a proper extension for the selected graphic format (set by SET_PLOT_FORMAT) is saved under the current working directory. If no extension is given in the file name, the default extension e.g. ps for Postscript portrait/landscape modes, P7 or p7 for HPGL landscape, P8 or p8 for HPGL portrait, etc.) is automatically given to the file name.

If the default device is set (SET_PLOT_FORMAT), press <Enter> to plot the diagram on the screen in the Console Results window or give a file name to save it.

Syntax	PLOT_DIAGRAM

Prompt	`Output to screen or file /Screen/: <Name of a file or return for screen>`
	`Specify the name of the file`
	
	For Linux users, the prompt is `PLOTFILE /SCREEN/`).

PRINT_DIAGRAM

Saving and Printing the Output in Console Mode

First use PLOT_DIAGRAM to create a diagram that displays in the **Console Results** window. Then after entering the PRINT_DIAGRAM command, the **Print** window opens where you can choose additional settings for a hard copy of the diagram.

PRINT_DIAGRAM functions in the same way as in the **Console Results** window where you can right-click a diagram and choose **Print**.

QUICK_EXPERIMENTAL_PLOT

The QUICK_EXPERIMENTAL_PLOT command is is similar to APPEND_EXPERIMENTAL_DATA but can be used when there is no graphical information to be plotted in the POLY3 workspace. It defines a pair of axes, sets the axis labels to X and Y, and scales both X- and Y-axes between 0.0 and 1.0 unless a prologue is read from the DATAPLOT (*.EXP) data file.

Plotting Experimental Data Files

Syntax	QUICK_EXPERIMENTAL_PLOT
Prompts	`Prologue number: /0/: <Prologue number>` An **Open** window displays. Select the prologue to use. In a prologue, you can, for example, give the scaling of an axis, the axis texts, and so on. By answering -1, a list of all prologues on the file is given; and with 0, no experimental data are appended.
	`Dataset number(s) /-1/: <Dataset number(s)>` Select from which dataset(s) data should be read. Several datasets may be given separated with commas or spaces. By answering `-1`, a list of all datasets on the file is given; and with `0`, no experimental data are appended.

REDUCE_TIMESTEPS_TO_PLOT

The REDUCE_TIMESTEPS_TO_PLOT command reduces the number of timesteps used in a plot. The command requires a fraction of the total number of stored timesteps, where `1` is to use all timesteps and `0` is to use no timesteps.

If post-processing a large store file with too many timesteps, this factor may be automatically reduced.

Syntax	REDUCE_TIMESTEPS_TO_PLOT
Prompt	`Fraction of Timesteps to Use /1/:` The fraction of the total number of stored timesteps to be used in the post-processing, where `1` is to use all timesteps and `0` is to use no timesteps.

REINITIATE_PLOT_SETTINGS

The REINITIATE_PLOT_SETTINGS command gives default values to all parameters describing the diagram. All plot settings made in the POST module are deleted, and it returns to the initial settings when the POST module is entered.

RESTORE_PHASE_IN_PLOT

The RESTORE_PHASE_IN_PLOT command restores a phase previously suspended from the plot with SUSPEND_PHASE_IN_PLOT. It works only after at least one phase is suspended.

Syntax	RESTORE_PHASE_IN_PLOT
Prompt	`Phase name: <Name of a phase>` Give the name of the phase to be restored.

SELECT_CELL

Use the SELECT_CELL command to select the cell data to be processed. You can only plot data from one cell at a time. Type ? to get a list of valid cell numbers. This command is for the POST PROCESSOR.

Also see the DICTRA module prompt of the same nameSELECT_CELL.

The current cell number is displayed as a part of the POST PROCESSOR prompt.

Syntax	SELECT_CELL
Prompt	`Number` Number of the cell to be selected. Specify cell number by giving an integer or one of the key words NEXT or PREVIOUS.
	`Tabulate` Tabulate a named table. The independent variable is always printed in the first column.
	`Name` Give the symbolic name of the table.
	`Output file /Screen/` Select output device/file. Press Enter to get output on the screen.

SELECT_PLOT

Select a plot (diagram) within the current **Results** tab in the **Console Results** window.

Syntax	SELECT_PLOT
Prompt	`Plot <N/New>` Where `N` is a positive integer. Enter the number of the plot that is selected in the **Console Results** window (in the currently selected **Results** tab). If a plot with that number does not exist, it is created. The default parameter value is `NEW`. If this is entered, then a new plot is created. Create a new plot can also be done by pressing <Ctrl+Shift+T>.

SET_AXIS_LENGTH

Use the SET_AXIS_LENGTH command to change the real length of an axis in inches. The default number of tic-marks on an axis is 10 when the relative length is 1. The number and units per tic-mark must be a multiple of 1, 2 or 5 to obtain a reasonable scaling of an axis.

Syntax	SET_AXIS_LENGTH
Prompts	`Axis (X, Y or Z): <Name of an axis>` Specify which axis to set the length.
	`Axis length /11.5/: <New relative axis length>` Specify the new real axis length in inches. The relative length 1 corresponds to 10 tic-marks on the axis.

SET_AXIS_PLOT_STATUS

Use the SET_AXIS_PLOT_STATUS command to specify whether the axis title texts and axis label texts are to be plotted or not on a diagram. It does not work for the axis lines and tic-marks. If you want to plot a diagram without tic-marks, use SET_TIC_TYPE first.

This can be used to merge different diagrams on a pen-plotter or to obtain the diagram faster. The default status is that all the set axes are to be plotted.

Syntax	SET_AXIS_PLOT_STATUS
Prompt	`Axis plot (Y or N) /Y/: (Y or N)`

SET_AXIS_TEXT_STATUS

Use the SET_AXIS_TEXT_STATUS command to change the axis text from the automatic text given by the axis specification to a text.

ADD_LABEL_TEXT

Syntax	SET_AXIS_TEXT_STATUS
Prompts	`Axis (X, Y or Z): <Name of an axis>` Specify which axis text status to change.
	`Automatic axis text (Y or N) /N/:` Specify if automatic axis text is to be used.
	`Axis text: <Enter axis text>` You can enter simple text, use LaTeX, rotate the text, as well as adjust the font size.

SET_AXIS_TYPE

Use the SET_AXIS_TYPE command to change the axis type among linear, logarithmic, and inverse axis.

Syntax	SET_AXIS_TYPE
Prompts	`Axis (X, Y or Z): <Name of an axis>` Specify which axis to change the axis type.
	`Axis type /Linear/: <New axis type>` Specify which new axis type to set. Select `LIN`ear (default), `LOG`arithmic or `INV`erse. Only the three first characters are relevant.

SET_COLOR

Some devices support colors or line thickness. With the SET_COLOR command, select different colors or line types on some types of information on a diagram.

The SET_COLOR command can fail if a chosen device does not support colors or line thickness.

This command gives four sequential prompts (i.e. text and axis, invariant equilibria, tie-lines, and all other lines), with the keyword and default option (both listed below). Depending on if the switched-on graphic device (by SET_PLOT_FORMAT) supports colors or line types, the POST automatically switches on the appropriate Keyword.

Syntax	SET_COLOR

Prompt	`Text and axis keyword /Default option/`
	`<Return or new option>`
	`Invariant equilibria keyword /Default option/: <Return or new option>`
	`Tie-lines color keyword /Default option/: <Return or new option>`
	`Keyword of all other lines /Default option/: <Return or new option>`
	This is usually for the solubility lines.

The `Keyword` is either `Color` or `LineType`, depending on if color or line type is supported by the switched-on graphic device (by SET_PLOT_FORMAT); the POST module *automatically* switches on the appropriate `Keyword` .

Color Options

The options for `Color` are:

BACKGROUND	BLUE	PURPLE	GRAY
FOREGROUND (default)	YELLOW	GOLD4	ORANGERED3
RED (default for invariant equilibria)	MAGENTA	TURQUOISE4	MAROON
GREEN (default for tie lines)	CYAN	PINK	PLUM
	SIENNA	OLIVEDRAB	SEAGREEN

	ORANGE1	CORAL1	USERDEF

LineType Options

The options for `LineType` are:

INVISIBLE	VERY_THICK (default for invariant equilibria)
NORMAL (default)	THIN (default for tie lines)
THICK	VERY_THIN
DASHED	DOTTED

SET_CORNER_TEXT

Use the SET_CORNER_TEXT command to add text to the corners on a plotted diagram. Normally, you can write such texts as a subtitle.

The primary database (not the appended ones) used in calculations and the calculated conditions are automatically plotted at the upper-left corner as a part of the header on all plotted diagram. Unless the plotting option WRITE CONDITIONS is switched off by the command SET_PLOT_OPTIONS, the calculated conditions are always written on plotted diagrams; and only when the plotting option PLOT HEADER is switched off by the command SET_PLOT_OPTIONS, the used database also always appear. Under such circumstance, avoid writing texts at the UPPER_LEFT corners.

Syntax	SET_CORNER_TEXT
Prompt	`Corner/Lower_Left/: <Return or new option>` Choose an option: • LOWER_LEFT • UPPER_LEFT • UPPER_RIGHT • LOWER_RIGHT • TOP_OF_TRIANGLE
	`Text: <Texts as a subtitle or a note>` Write the texts that are to be written on the specified diagram corner.

SET_DIAGRAM_AXIS

Use the SET_DIAGRAM_AXIS command to specify an axis variable for a plot or a listing. To be able to plot a diagram, at least two axis variables (X and Y) must be specified. In Console Mode, three axes (X, Y, and Z) can be specified for a diagram.

The axis variables in the plot can be different from the number of axis used for the mapping.

If you want to plot a phase diagram with tie-lines in the plane after a MAP calculation, then the composition axis must be `mole-fraction` or `weight-fraction`, or `mole-percent` or `weight-percent` of one specific component. You must not use the stable variable `x(comp)` or `w(comp)` even if that is what you used when calculating the diagram, because that only gives one side of the two-phase region. It may be sufficient to indicate that mole-fraction is the same as the stable variable `x(*,comp)`, and weight-fraction is the same as the stable variable `w(*,comp)`.

If you plot a phase diagram where the tie-lines are not in the plane after a MAP calculation, then `mole-fraction` and `x(comp)` are identical.

When you plot a property diagram after a STEP calculation and want a composition axis variable, you should normally use x(comp) and not mole-fraction.

The axis must have exactly the same number of columns, or one axis must have one column. In the first case the columns are plotted matching them one by one; in the latter all columns on one axis is plotted against the single column. For example, you can have the temperature on one axis and the amount of each phase on the other. The amount of each phase is the state variable `NP(*)` in mole fraction or `BPW(*)` for mass fractions of phases.

Automatic diagram axis: The POST module can set automatic diagram axis identical to those used in the MAP command.

If the state variable `x(comp)` is used in a MAP calculation, then mole-fraction of the component is used as diagram axis; if a potential or some other state variables are used, then that is used as a diagram axis.

After a STEP calculation, automatic diagram axis is not set as there is only one axis used in the calculation.

Syntax	SET_DIAGRAM_AXIS
	`Axis (X, Y or Z): <Axis name>` Specify which axis (X or Y or Z) to set with a variable.

Syntax	SET_DIAGRAM_AXIS
Prompts	`Variable type: <Variable name>` Specify a variable for the chosen axis here. The valid variables are: • TEMPERATURE-CELSIUS as temperature in °C • TEMPERATURE as temperature in K • PRESSURE as pressure in Pa • ACTIVITY for a component • LNACTIVITY for a component [ln(ACR(component)] • MOLE-FRACTION for a component • MOLE-PERCENT for a component • WEIGHT-FRACTION for a component • WEIGHT-PERCENT for a component • ENTHALPY as enthalpy in J/mol • ENTROPY as entropy in J/mol/K • NONE to clear the axis • Any valid state variable including those with wildcards, e.g. NP(*) or x(*,component). Due to the use of wildcard * in such a state variable, the program asks for a column number. • Any entered function or variable. • Any entered table.
	If you specify an entered table as the variable, then you are given these prompts: `For component: <Component name>` When an activity, mole or weight fraction or percent of a component shall be plotted, the component name must be supplied here.
	`Column number: <Column number(s)>` Specify the column number(s) in the chosen table that are to be plotted onto the earlier specified axis. For example: • `1` for column 1 • `2,3` for columns 2 and 3 • `2,3 >5` for column 2,3 and all columns above column 5 • `*` for all columns

SET_DIAGRAM_TYPE

Use the SET_DIAGRAM_TYPE command to choose the diagram type as perpendicular plot or triangular plot (Gibbs triangle, especially for ternary systems). The default is with a perpendicular axes.

For phase diagrams of ternary or pseudo-ternary systems, it is usually need to plot isothermal sections as triangular grams. If desired, all lines outside the region limited by a line joining the end points of the X- and Y-axis is removed.

Syntax	SET_DIAGRAM_TYPE

Prompts	`Triangular diagram (Y or N) /N/:`
	The default is to set a perpendicular axis. Perpendicular diagrams have (almost) the same scaling on both axes.
	`Create tetrahedron WRML file (Y or N) /N/:`
	 The 3D plotting in Console Mode does not work. Enter Y to specify a triangular plot instead.

	`Plot 3rd axis (Y or N) /N/:` If a triangular plot is selected, enter Y to specify a 3rd axis and to connect (and plot) the end points of the X- and Y-axes.
	`Clip along 3rd axis (Y or N) /N/:` If a triangular plot is selected, enter Y so that all lines outside the region limited by a line joining the end points of the X- and Y-axis are removed.

SET_FONT

Use the SET_FONT command to select the font to use for labels and numbers when plotting the diagram under the currently selected graphic device (SET_PLOT_FORMAT). For some devices there may be other fonts available and these are selected by SET_PLOT_FORMAT.

Syntax	SET_FONT
Prompts	`Select font number /1/: <#>` Specify an available font number # as the default font for the current graphic device, or accept the font number 1 by pressing <Enter>. By typing a question mark `?` here, the program lists the available fonts under the currently selected graphic device.
	`Font size /.34/: <##>` The size of the chosen font is specified. A value around 0.34 is recommended.

SET_INTERACTIVE_MODE

In the POLY module this is called SET_INTERACTIVE.

Use the SET_INTERACTIVE_MODE command to use it in demonstration or macro files to stop the execution of the command file and pass over input focus to the keyboard.

SET_LABEL_CURVE_OPTION

Use the SET_LABEL_CURVE_OPTION command to identify the curves drawn in the post-processor by marking each curve with a digit and then list the meaning of these digits beside the plot.

The number of digits can be quite large in some cases. If so, use SET_FONT and reduce the font size; usually, 0.2 is sufficient.

Syntax	SET_LABEL_CURVE_OPTION
Prompt	`Curve label option (A, B, C, D, E, F OR N) /A/: <Option>`

The options:

- `A`: List stable phases along line
- `B`: As A but curves with same fixed phase have same number
- `C`: List axis quantities
- `D`: As `C` but curves with same quantities have same number
- `E`: As `B` with changing colors
- `F`: As `D` with changing colors
- `N`: No labels

This question is rather cryptic but usually the option B or E is good for phase diagrams (after a MAP command) and option D or F for property diagrams (after a STEP command). Those interested can try out the option A and C by themselves.

Option B or E lists the fixed phases along each curve, whereas option D or F gives the axis variables used along each curve. E provides varied colors for different stable-phase curves on phase diagrams (after a MAP command); F provides varied colors for different property curves on property diagrams (after a STEP command). The option `N` (NONE) disables all curve labels and lists.

If, for example, you use `T` (temperature in K) as the variable axis in a STEP command and then plot the amount of stable phases (with SET_DIAGRAM_AXIS `Y NP(*)`) on the Y-axis versus `T-C` on the X-axis, then the list may have lines like:

```
1: T-273.15, NP(LIQUID)
2: T-273.15, NP(FCC_A1)
```

This means that for curve `1` the X-axis is `T-273.15` (the same for all curves, of course) and `NP(LIQUID)` on the Y-axis. Curve `2` has the same X-axis but `NP(FCC_A1)` on the Y-axis.

SET_PLOT_FORMAT

Use the SET_PLOT_FORMAT command to adjust the format of the graphical output to another graphical device. This default can be changed with the SET_PLOT_ENVIRONMENT command in the SYSTEM MONITOR.

Syntax	SET_PLOT_FORMAT
Prompt	`Graphic device number /#/: <Number of the device>` Specify a graphic device number. Depending on the hardware, different plot formats (graphic devices) may be available. These are listed online by giving a question mark `?`. For some formats there can be additional sub-prompts (Y or N) about the available fonts being used for the chosen format. Also enter Y for further specifications, e.g. font type and size.

SET_PLOT_OPTIONS

When you use the SET_PLOT_OPTIONS command, you are prompted for and can toggle on (`Y`) or off (`N`) the plotting of some options on all subsequently generated diagrams.

For the `Always initiate POST on re-entering` prompt, the default is Y which implies that the POST module automatically reinitiates whenever the POLY3 workspace is changed upon re-entering. If answered N the same diagram axis variables are kept even if the workspaces in the POLY module are read from or written to a *.POLY3 file. The N answer is useful when there are several sets of *.POLY3 files with the same calculation but for different sets of model parameters.

For the `Always solid line` prompt, the default answer is `N` which means that the POST module plots solid lines for stable phases but dashed lines for metastable phases. This is normally for plotting property diagram after a STEPPING calculation; however, when there is a metastable extrapolation in a phase region on a phase diagram after a MAPPING calculation, this is also enforced. When the alternative answer Y is chosen, all the lines are always plotted in solid lines.

Syntax	SET_PLOT_OPTIONS
Prompts	`Plot header /Y/:` Toggle the plotting of the header text above a diagram.
	`Plot logo /Y/:` Toggle the plotting of the Thermo-Calc logo at the lower-left corner of a diagram.
	`Plot footer /Y/:` Toggle the plotting of the footer identifier text at the right margin of a diagram.
	`White-Contoured-PS-CHARS /Y/:` By default, the PostScript characters are written as a white contoured status.
	`Plot remote exponent(s) /Y/:` By default the remote exponent on the axis is plotted.
	`Plot symbols at node points /0/: <#>` This makes it possible to plot symbols at the node points on plotted lines on a diagram.
	`Symbol size /.1/: <.#>` Set the size of symbols which are plotted at the node points.
	`Write condition? /Y/:` By default, the initial equilibrium conditions for the current calculations are automatically plotted at the upper-left corner as a part of the header. If you enter N, the calculated conditions are not included on a plotted diagram.
	`Write database name? /Y/:`

Syntax	SET_PLOT_OPTIONS
	By default, the primary database (not appended ones) used in the current calculations are plotted at the upper-left corner as a part of the header. If you enter N, the database name is not included on a plotted diagram.
	`Always initiate POST on re-entering: /Y/:` By default the POST module automatically reinitiates whenever the POLY3 workspaces are changed upon re-entering. If you enter N, the same diagram axis variables are kept even if the workspaces in the POLY module is read from or written to a *.POLY3 file. This can be useful when there are several sets of *.POLY3 files with the same calculation but for different set of model parameters.
	`Always solid line: /N/:` By default the POST module plots solid lines for stable phases and dashed lines for metastable phases. This is normally for plotting property diagrams after a STEPPING calculation. However, when there is a metastable extrapolation in a phase region on a phase diagram after a MAPPING calculation, this is also enforced. Enter Y to always plot solid lines in this case, for example.

SET_PLOT_SIZE

Use the SET_PLOT_SIZE command to change the size of the diagram by specifying a global plot size (as a relative scaling factor). The default value of the relative scaling factor is 1, while the real size of the plotted diagram depends on what output device is chosen with SET_PLOT_FORMAT. The default plot size (corresponding to the default global plot size 1) is adjusted to the chosen device.

Syntax	SET_PLOT_SIZE
Prompt	`Global plot size /1/: <Relative scaling factor>` Enter the relative scaling factor as a numerical number (e.g. `0.5`, `0.8`, `1.0`, `1.5`, etc.). By pressing <Enter>, the default relative scaling factor (`1`) is accepted.

SET_PREFIX_SCALING

Use the SET_PREFIX_SCALING command to specify on which axis is to have a prefix scaling then set the scaling of remote exponents with certain powers.

Syntax	SET_PREFIX_SCALING
Prompt	`Axis (X, Y or Z): <Name of an axis>` Specify which axis is to have a prefix scaling.
	`Use prefix scaling /Y/: (Y or N or #)` • `NO` switches off its action. • `YES` arranges the prefix scaling so that the axis scaling is done with the remote exponents being powers of three, i.e. `...,-6,-3,0,3,6,...`. The default is 3. • # is an integer number that sets the remote exponents as being powers of # (as the powers for the remote exponents).

SET_RASTER_STATUS

Use the SET_RASTER_STATUS command to plot a raster (i.e. with gridlines on both axis directions) in the diagram.

Syntax	SET_RASTER_STATUS
Prompt	`Raster plot (Y or N) /N/:` By default no raster is plotted. Enter Y to plot using a raster plot.

SET_REFERENCE_STATE

This command is available for the POLY, ED-EXP and POST modules.

The reference state for a component is important when calculating activities, chemical potentials, and enthalpies and is determined by the database being used. For each component the data must be referred to a selected phase, temperature, and pressure, i.e. the reference state.

All data in all phases where this component dissolves must use the same reference state. However, different databases can use different reference states for the same element/component. It is important to be careful when combining data obtained from different databases.

By default, activities, chemical potentials, and so forth are computed relative to the reference state used by the database. If the reference state in the database is not suitable for your purposes, use the SET_REFERENCE_STATE command to set the reference state for a component using `SER`, i.e. the Stable Element Reference (which is usually set as default for a major component in alloys dominated by the component). In such cases, the temperature and pressure for the reference state is not needed.

In order to specify conditions in the specific reference state, you can append an `R` to the state variables. Thus, `AC` is the activity (of a system component or of a species in a phase) with respect to the default reference state, and `ACR` is the activity with respect to the selected reference state; MU is the chemical potential of a system component with respect to the default reference state, and `MUR` stands for the chemical potential with respect to the selected reference state. The `AC` and `ACR` variables, for both components in a system and species in a phase, can be specified in natural logarithm, e.g. LNAC(Fe), LNACR(C), LNAC(O2,GAS), LNACR (O2,GAS).

For the POST module, and after calculating with the STEP_WITH_OPTIONS or MAP commands, the reference state for a component can also be changed to plot various properties of the component in the entire system or in a specific phase. Then you can set the diagram axes as the chemical potential or activity quantities with the `R` suffix, i.e. MUR(comp), MUR(comp,ph), ACR(comp), ACR(comp,ph) or the common logarithms [e.g. LNACR(comp,ph)].

Syntax	SET_REFERENCE_STATE
Prompts	`Component: <Name of the component>` The name of the component must be given.
	`Reference phase: <Name of a phase used as the new reference state>`

Syntax	SET_REFERENCE_STATE
	Enter the `Name of a phase` for the system. For a phase to be usable as a reference for a component, the component needs to have the same composition as an end member of the phase. The reference state is an end member of a phase. The selection of the end member associated with the reference state is only performed once this command is executed. If a component has the same composition as several end members of the chosen reference phase, then the end member that is selected at the specified temperature and pressure will have the lowest Gibbs energy. The following are example using temperature. Pressure is used in the same way: • In the Fe-C system, BCC can be a reference state for Fe but not for C since BCC can exist as pure Fe but cannot exist as pure C. • If GAS is chosen as the reference phase of component O at such a high temperature that O1 has the lowest energy, then O1 remains the reference state even at calculations performed at lower temperatures where O2 has a lower energy than O1. • Setting the reference state for component O as gas (one sublattice) with constituents O1, O2 and O3 results in O2 being the reference state if, at the present temperature, pure O2 has the lowest energy of O1, O2 and O3. If the reference state is set above a critical higher temperature, then O1 has the lowest energy and consequently becomes the reference state.
	`Temperature /*/: <Temperature for the reference state>` Select the Temperature (in K) for the reference state. The wildcard value * means the current temperature is used at the time of evaluation of the reference energy for the calculation. The temperature set with this command does not affect the temperature used when evaluating the energy of the reference state during the end member selection process.
	`Pressure /1E5/: <Pressure for the reference state>` Select the Pressure (in Pa) for the reference state. The wildcard value * means the current pressure is used for evaluating the reference energy at the time of calculation.

	Examples
	
	`S-R-S Fe SER`
	`S-R-S Cr FCC * 100000`
	`S-R-S H2O AQUEOUS * 100000`
	`S-R-S ZE REF_ELECTRODE * 100000`

SET_SCALING_STATUS

When an axis variable is selected by SET_DIAGRAM_AXIS, the scaling status for the axis is always set to automatic scaling. Using the SET_SCALING_STATUS command, choose between manual or automatic scaling on a specified axis. If manual scaling is chosen, specify a minimum and a maximum value. Manual scaling can be used to magnify interesting parts of a diagram.

Syntax	SET_SCALING_STATUS
Prompts	`Axis (X, Y or Z): <Name of an axis>` Specify which axis that you want to set the scaling status.
	`Automatic scaling (Y or N) /N/:` The default is manual scaling. Enter Y for automatic scaling (N). For manual scaling specify the Min and Max values.
	`Min value: <Minimum value>` The minimum value at the start point of the specified axis.
	`Max value: <Maximum value>` The maximum value at the end point of the specified axis.

SET_TIC_TYPE

Use the SET_TIC_TYPE command to change the drawing of the axis tics. You may alter the placement of tic marks on the axis, e.g. inside or outside or no tic marks. The size of tic marks cannot be altered by this command, but these are adjusted based on the selected graphic device and the defined relative scaling factor (global plot size).

Syntax	SET_TIC_TYPE
Prompt	`TIC Type /1/: <1 or -1 or 0>` The tic type 1 is default, i.e. the tics are drawn outside the diagram. -1 means that the tics are inside the diagram and 0 means no tics.

SET_TIELINE_STATUS

If the tie-lines are in the plane of the calculation, you can select to plot the tie-lines in two-phase fields with the SET_TIELINE_STATUS command.

Syntax	SET_TIELINE_STATUS
Prompt	`Plotting every tie-line no. /0/: <Number of tie-lines>` The tie-lines plotted are not equally spaced by the graphics software. Instead, you can select to plot a subset of the calculated tie-lines, i.e. every one (1), every second (2), every three (3), etc. By accepting the default value 0, no tie-line is plotted.

SET_TITLE

Use the SET_TITLE command to specify a title that displays on all listed tables and plotted diagrams from the POST module.

There is a maximum length of about 60 characters for the title. You can enter simple text, use LaTeX, rotate the text, as well as adjust the font size.

ADD_LABEL_TEXT

Syntax	SET_TITLE
Prompt	`Title` Enter the title you want to appear on all tabulation or graphic outputs.

SET_TRUE_MANUAL_SCALING

The tic-marks on the axes are normally placed in even intervals using the whole axis length. The scaling routine adjusts the given minimum and maximum values slightly to accomplish this. If such an automatic adjustment behavior is unwanted, it can be avoided by using the SET_TRUE_MANUAL_SCALING command (followed by a message showing the TRUE MANUAL SCALING set for a specific axis).

The SET_TRUE_MANUAL_SCALING command works like a toggle. To reset the automatic scaling behaviour, repeat the command a second time for that specific axis (followed by a message saying the SEMI_MANUAL SCALING set for the specific axis.

Syntax	SET_TRUE_MANUAL_SCALING
Prompt	`Axis (X, Y or Z): <Name of an axis>` Specify which axis (X or Y or Z) you want to toggle between automatic adjustments or avoid the adjustment of the given maximum and minimum values.

SUSPEND_PHASE_IN_PLOT

Use the SUSPEND_PHASE_IN_PLOT command to specify that lines originating from the presence of a certain phase shall not be plotted on a diagram. If you want to bring the suspended phase back to the diagram, use RESTORE_PHASE_IN_PLOT.

Syntax	SUSPEND_PHASE_IN_PLOT
Prompt	`Phase name: <Name of a phase>` Specify the name of the phase to be suspended from the diagram.

TABULATE

This command is available for a table entered in either the POLY or POST module.

For any entered table, the TABULATE command gives a table of values from equilibria calculated with a STEP command.

Unlike the TAB module's command (also called TABULATE) it is not possible to plot columns from the tabulated tables. For this use normal POST commands.

Syntax	TABULATE
Prompts	`Name: <Name of a table entered in either POLY or POST>` Specify a table name that is entered in either the POLY or POST module.
	`Output on screen or file /Screen/:` Specify a file name if you want to save on a file the table values along the defined STEP calculation, or press <Enter> if want to see the table values displayed.

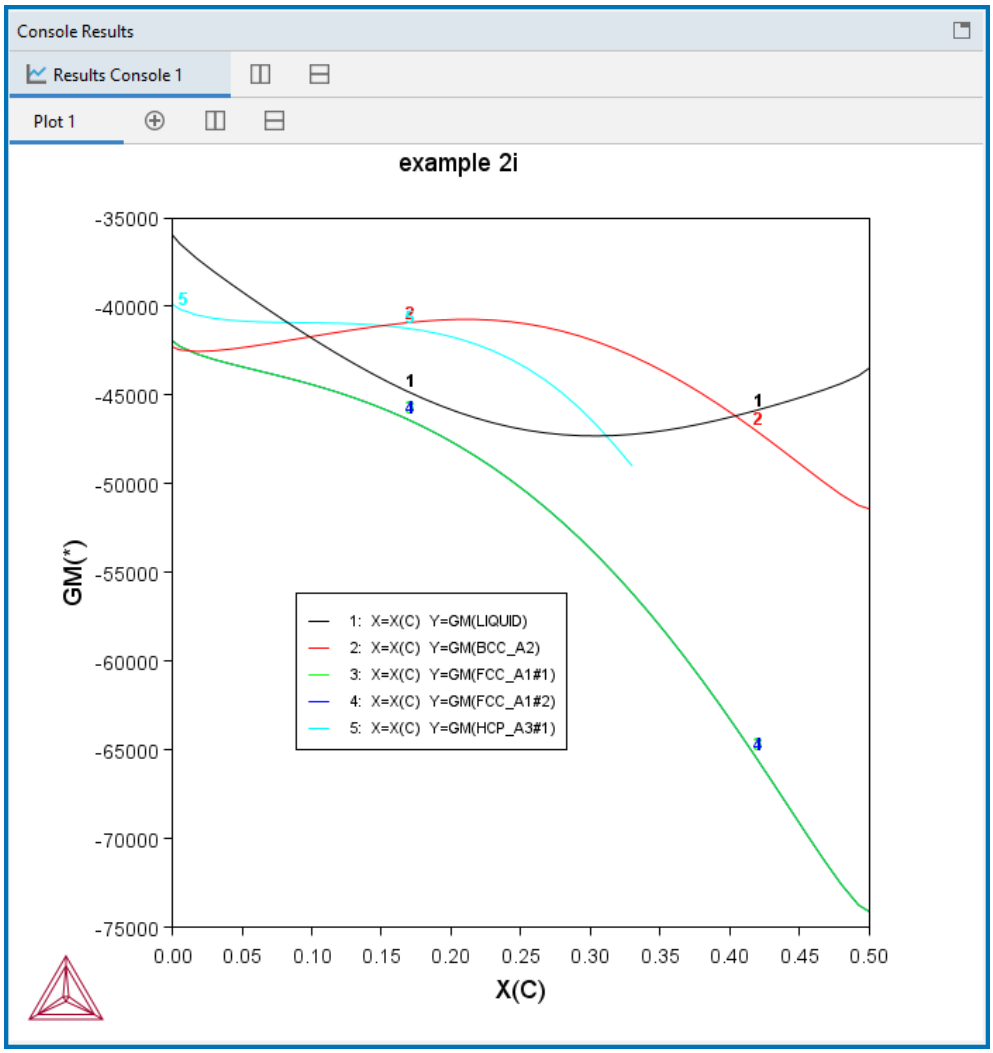
Console Mode Results

The results of a calculation in Thermo-Calc can be plotted by the post-processor module, also called the POST module. The diagram is displayed in the **Console Results** window.

In the POST module, you can define and plot various kinds of diagrams based on a calculation. You can modify diagram type, which variables to plot on each axis and between which minimum and maximum values, append experimental data from an EXP-file, change labels and symbols in the diagram, zoom in on (and out from) a certain region in a diagram, etc.

If you calculate a property or phase diagram in POLY, then you have to open the POST module yourself. If your calculation was performed by a response-driven module such as SCHEIL or POURBAIX, then the plotting of a diagram based your calculation is part of the dialogue of questions and answers you have in that module (but under the hood, the response-driven module is actually utilizing the POST module to get the plotting done).



Example of output to the Console Results window.

Using the POST Module

Use the POST module after a STEP_WITH_OPTIONS or MAP calculation to generate *graphical* or *tabulated* presentations on screen or into files.

The graphical files are available in different formats (e.g. PS, EMF, PNG, BMP, PDF, JPG, TIF) or data forms (e.g. EXP, TAB and WRL). The graphical output can be phase diagrams, property diagrams, diffusion profiles and other types of plots. The tabulated presentation is into a basic text file (TXT) or a spreadsheet (e.g. an MS Excel file with an extension of .XLS).

The POST module (post-processor) is a submodule to the POLY module and has its own set of commands. The TAB, BIN, TERN, POT, SCHEIL and POURBAIX modules use the POST module features as part of the automatic generation of the plots.

Within the POST module, you can choose any state variable, any derived variable, or any entered symbol (functions or variable) as the X/Y-axis.

Thermophysical Properties Models, Data, and Variables

When a diagram is plotted, appearance parameters for defining a high-standard graph can be further specified, e.g. curve labelling options, diagram titles and subtitles, plot size, axis length, axis types, axis-tic type, tie-line status, automatic or manual scaling and zooming, semi-automatic or manual labeling on phase boundaries and phase regions, graphic formats, text fonts, colors, raster plot, etc.

You can append experimental data onto a plotted diagram. You can also save the coordinates onto a textual file, which can be edited and used as an experimental data file to be merged onto another diagram or as a part of a setup file for PARROT-module assessment.

Phases can be suspended or restored in a plotted diagram. The reference states for components can also be modified for the resulted diagrams. Moreover, you can translate a plotted property diagram (after a stepping calculation) into a tabulated form, such as a simple list on screen or a textual file, and a spreadsheet .

Plotting Diagrams

Plotting a diagram is to graphically represent how several variables (typically two variables) co-vary. Each axis in a property diagram or a phase diagram represents the value of one variable. The default variables represented by the X- and Y-axes are the following:

- If you plot a diagram based on the results of a mapping operation (a phase diagram), then by default the X- and Y-axes represent the mapping axis variables 1 and 2 (set using SET_AXIS_VARIABLE in POLY).
- If you plot a diagram based on the results of a stepping operation (a property diagram), then by default, the X-axis represents the stepping variable (set using SET_AXIS_VARIABLE) and the Y-axis represents the sum of the mole fractions of all phases (that is, NP(*)).

How to Plot a Diagram

To plot a diagram, you must have already made a stepping or mapping operation in POLY (or in some cases, made a calculation as part of some opening a response-driven module), and you must have entered the POST module.

The POST command is available inside POLY. Use POST to enter the POST module

1. If you want to directly plot your diagram with the default variables represented by the X- and Y-axes, type `Plot` and press <Enter>. This plots a property or phase diagram with the default variables represented at each axis. If you do not want to plot your diagram with these default variables, go to the next step.
2. Use SET_DIAGRAM_AXIS to set which variables to plot on the X-axis and the Y-axis. For example, if you want to plot a phase diagram with pressure on the Y-axis and temperature on the X-axis, type:

   ```
   SET_DIAGRAM_AXIS X T
   SET_DIAGRAM_AXIS Y P
   ```

3. Use PLOT_DIAGRAM to plot your diagram.

Saving and Printing the Output in Console Mode

Global Settings: Graphical and Console Mode Plotting

Output can refer to results in the form of tabulated data in a table or a diagram.

The terms *diagram* and *plot* are interchangeable. The commands in Console Mode generally use the term diagram and in Graphical Mode it is also called a plot (e.g. the Plot Renderer).

Commands to Save and Print Diagrams

Use the following commands to create diagrams, which then display in the **Console Results** window. From this window, you can right-click the diagram and choose **Save as** or **Print**. You can also use the following commands for these actions.

PLOT_DIAGRAM

After you use the SET_PLOT_FORMAT command to define the default graphic device (the printer) you can use a PLOT_DIAGRAM command to either save the calculation output to a file or display the output in the **Console Results** window.

DUMP_DIAGRAM

DUMP_DIAGRAM is an alternative command used to create output. After a diagram is displayed to the **Console Results** window with the PLOT_DIAGRAM command, you can save (dump) it to a file using this command.

MAKE_EXPERIMENTAL_DATAFILE

Use MAKE_EXPERIMENTAL_DATAFILE to save all the data about the plotted diagram in an EXP-file. An EXP-file is a plain text file that describes the diagram in the DATAPLOT graphical language. Note that information about the underlying calculations that the diagram is based on is not saved in an EXP-file.

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

PRINT_DIAGRAM

First use PLOT_DIAGRAM to create output that displays in the **Console Results** window. Then after entering the PRINT_DIAGRAM command, the **Print** window opens where you can choose additional settings for a hard copy of the diagram.

Commands to Save Tables

Tables or tabulated data can be listed in the **Console** window. You then use commands to save the text to different file formats (txt, html, or xls) where you can then print the information.

- LIST_DATA_TABLE: Use this command to output to the screen or to file.
- TABULATE

Saving Diagrams

You can save the output in a variety of file formats. For JPG and PNG images you can also adjust the image quality.

In Console Mode, the diagram is output to the **Console Results** window after using the PLOT_DIAGRAM command.

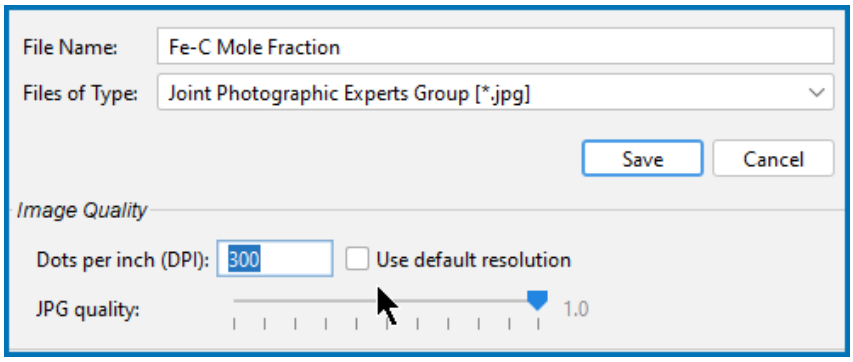
In Graphical Mode, the diagram is output to the **Visualizations** window after performing a tree that includes a Plot Renderer.

In the **Visualizations** window, right-click the diagram and select **Save as**.

In the Graphical Mode **Configuration** window you can also click the **Save Diagram** (or **Save table**) buttons to open the **Save** window.

Then in the **Save** window:

1. Navigate to where you want to save the diagram.
2. Enter a **File name**.
3. From the **Files of type** list choose **png** (the default), **jpg**, **ps**, **pdf**, **gif**, **svg**, or **emf**.
4. For PNG and JPG files only, under the **Image Quality** section, choose to improve the resolution of the image. For JPG files you can also adjust the file size.
    - To change the resolution of a PNG or JPG image, click to clear the **Use screen resolution** checkbox. Then enter a numerical value in the **Dots per inch (DPI)** field.
    - For JPEG files, you can also use the slider to choose a number between 0 and 1 for the **JPG quality**. The default is 0.9. The lower the number, the smaller the file.



5. When you are ready, click **Save**.

Printing Diagrams

In the **Console Results** window, right-click the diagram and choose **Print**. Select additional settings as required on the **Print** window.

Use the LIST_DATA_TABLE command to save to file and then print the file.

Modifying Diagrams

Modifying a diagram amounts to changing the settings that determine how the POST module presents the calculated results and plots a new diagram. Suppose that you have already plotted a binary phase diagram with the mapping axis variables temperature and mole fraction of one of your components (the Fe component, say) on the X- and Y-axes. If you then want to modify your diagram so that the Y-axis instead represents, say, the mass fraction of Fe rather than the mole fraction, then you use SET_DIAGRAM_AXIS to set diagram axis `Y` to `w(Fe)`, and then use PLOT_DIAGRAM.

There are many ways in which you can modify your diagram and how it is presented. Any modification made in the plot settings is taken into account the next time you use PLOT.

Example Commands

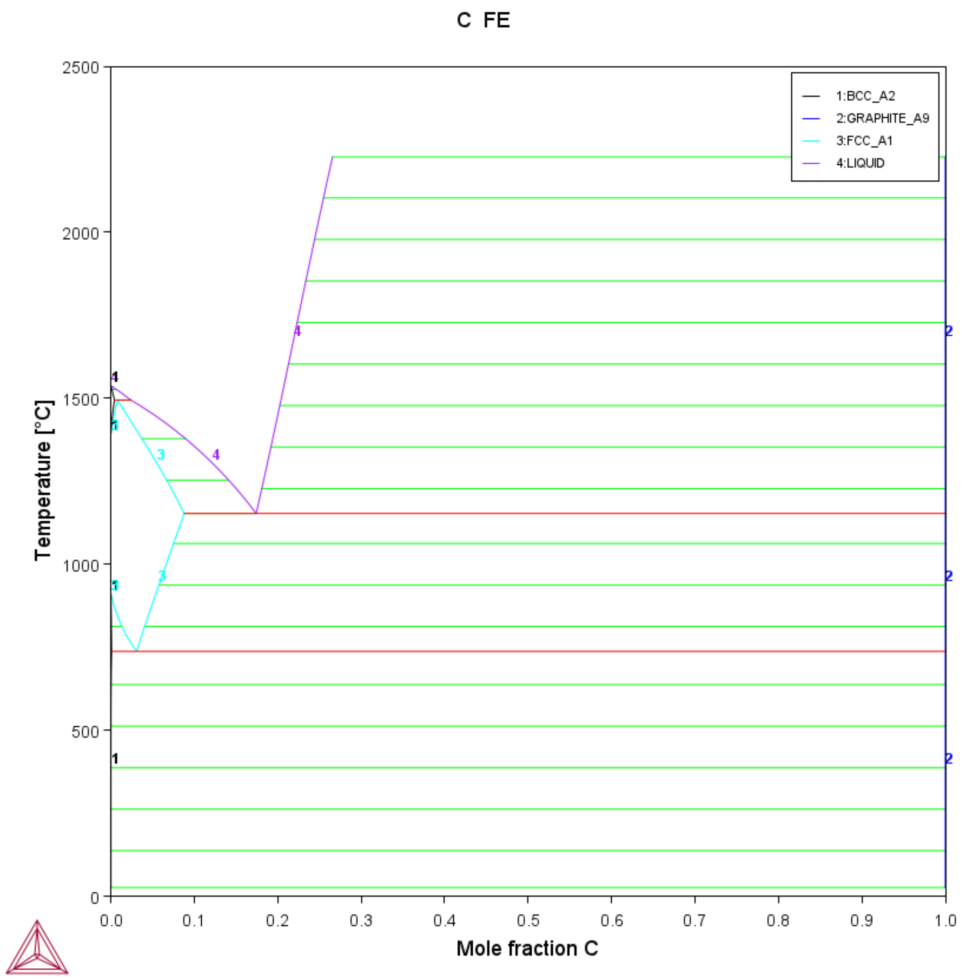
The following are some of the modifications you can make. Use:

- SET_TITLE to set add a title or to change an already existing title. The title is displayed above the plotted diagram in the Console Results window.
- ADD_LABEL_TEXT to add a label text that starts at a certain X- and Y-coordinate. If you have plotted a phase diagram, then you can let Thermo-Calc set the label text that specifies the names of the stable phases at that coordinate.
- SET_AXIS_TYPE to set whether the scale of an axis is linear, logarithmic or inverse.
- SET_DIAGRAM_TYPE to plot a triangular diagram with the X-axis on the triangle's base and the Y-axis on the triangle's left side. Such a diagram is often useful if you want to plot the fractions of two components in a ternary diagram.
- SET_SCALING_STATUS to modify the range of values that are displayed on an axis. In effect, you can use it to zoom in or out of the diagram. For example, to set the scale of the X-axis to range from 0 to 0 .3, type:

  ```
  SET_SCALING_STATUS X N 0 0.3
  ```

  The `X` specifies which axis to change the scaling on, the `N` turns off Thermo-Calc's automatic scaling, and `0` and `0.3` specifies the minimum and maximum values on the scale. You can turn on automatic scaling again by setting the second parameter to `Y`.

- SET_LABEL_CURVE_OPTION to label each set of curves that have the same stable phases with a certain digit. A legend is also added, where you specify which phases each digit designates.



C FE
1:BCC_A2
2:GRAPHITE_A9

Loading Saved Diagrams

If you have previously saved a diagram in an EXP-file, then you can load and superimpose the diagram on another diagram. Both the following command requires you to specify which prologue and dataset(s) that are loaded from an experimental data file.

Use APPEND_EXPERIMENTAL_DATA to plot selected data from an experimental data file (EXP-file). If you have set the axes of the diagram already, the labels on the diagram are not changed when you plot the additional data from the EXP-file, irrespectively of the data in that file.

Use QUICK_EXPERIMENTAL_PLOT to plot selected data from an experimental data file (EXP-file). If you have set the axes of the diagram already, these settings are overwritten with the axes settings from the EXP-file.

Working with the Console Mode Output

Learn how to control various output to the Console window, including how to pause, resume, or stop a command already underway.

Pausing, Resuming, or Stopping Output to the Console Window

In response to a command or a lengthy calculation, Thermo-Calc may display a lot of text in the Console window. Use these keyboard shortcuts to pause, resume, or stop a process.

- To pause the text on printing press <Ctrl+S>.
- To resume the printing on screen, press <Ctrl+Q>.
- When Thermo-Calc is performing a stepping or mapping operation, the results are continuously printed in the Console window. To stop the calculation of the current region of the mapping and stop the output, press <Ctrl-A> (Windows) or <Ctrl-C> (Linux).

Controlling Console Output

In response to a command or a lengthy calculation, Thermo-Calc may display a lot of text in the Console window. Use these keyboard shortcuts to pause, resume or stop a process.

- To pause the text on printing press <Ctrl+S>.
- To resume the printing on screen, press <Ctrl+Q>.
- When Thermo-Calc is performing a stepping or mapping operation, the results are continuously printed in the Console window. To terminate the calculation of the current region of the mapping and stop the output, press <Ctrl-A> (Windows) or <Ctrl-C> (Linux).

In Console Mode, sometimes the output overflows the window text buffer. This is how to increase the buffer size.

1. In the Console window right-click the tab to edit. For example, if this is the first tab, it is labeled **Console 1**.
2. Select **Properties** and either enter a number in the field or use the arrows to increase or decrease the **Buffer size**.

Thermo-Calc Console Mode Examples

All the Thermo-Calc Console Mode macro files and the outputs are also combined into one file that you can search and read. This is available as a PDF on our website. For the current version of the PDF, navigate to *Current Documentation > Examples > Thermo-Calc Console Mode*. A direct link to the PDF is here. The PDF is also found in the Archive and saved by release version.

Binary Phase Diagram Examples

tcex01 - Calculating the Binary Fe-C Phase Diagram

This example calculates the binary Fe-C phase diagram using the Binary module. The TCBIN database is used and included with your installation.

Some of the main commands used:

- LIST_EQUILIBRIUM
- LIST_STATUS
- LIST_CONDITIONS
- CHANGE_STATUS
- COMPUTE_EQUILIBRIUM
- SET_DIAGRAM_AXIS
- SET_TIELINE_STATUS
- PLOT_DIAGRAM
- SET_SCALING_STATUS
- SET_LABEL_CURVE_OPTION
- ADD_LABEL_TEXT
- MODIFY_LABEL_TEXT

tcex04 - Calculating the Fe-Cr Miscibility Gap

This example calculates the miscibility gap in the Fe-Cr system. The FEDEMO database is used and included with your installation.

These commands are used:

- SWITCH_DATABASE
- GET_DATA
- LIST_EQUILIBRIUM
- SET_AXIS_VARIABLE
- DEFINE_SYSTEM

- AMEND_PHASE_DESCRIPTION
- SET_CONDITION
- SAVE_WORKSPACES
- REJECT
- LIST_STATUS
- COMPUTE_EQUILIBRIUM
- SET_TIELINE_STATUS

tcex13 - Calculating the Binary Al-Ti Phase Diagram and its G Curve

This example calculates an Al-Ti binary phase diagram and G curve using the BINARY module. The TCBIN database is used and included with your installation.

tcex16 - Second Order Transition of the Al-Fe System

This example calculates the second order transition line in the BCC field of the Al-Fe system.

This uses the SSOL database. A license is required to run the example.

These commands are of note and used in this example:

- REJECT
- RESTORE
- ADVANCED_OPTIONS
- SET_SCALING_STATUS
- DEFINE_SYSTEM
- MAKE_EXPERIMENTAL_DATAFILE
- LIST_EQUILIBRIUM
- APPEND_EXPERIMENTAL_DATA
- STEP_WITH_OPTIONS

tcex17 - The Pseudo-binary System - CaO-SiO2

This example calculates the pseudo-binary system CaO-SiO_2 using the OXDEMO database, which is included with your installation.

The oxide demo (OXDEMO) database can be used both for pseudo-binary systems like the one in this case, CaO-SiO_2, or for full ternary systems like Ca-Fe-O.

For a more advanced example in Graphical Mode using the TCS Metal Oxide Solutions Database (TCOX), see T_17: Al2O3-MgO Phase Diagram.

These commands are of note and used in this example:

- LIST_SYSTEM
- REJECT and RESTORE
- AMEND_PHASE_DESCRIPTION
- LIST_STATUS
- DEFINE_COMPONENTS
- SET_CONDITION
- COMPUTE_EQUILIBRIUM and LIST_EQUILIBRIUM

tcex26 - The As-Ga Phase Diagram: Plotting the Partial Pressures of a Gas Species

This is an example of plotting the partial pressures of a gas species along the solubility lines in the As-Ga phase diagram. The calculation makes it possible to monitor the input gases to a process of depositing solid As-Ga. The data is taken from the PG35 Binary Semi-Conductors database.

These commands are of note and used in this example:

- REJECT
- RESTORE
- SET_DIAGRAM_AXIS
- SET_SCALING_STATUS
- SET_AXIS_TEXT_STATUS
- SET_LABEL_CURVE_OPTION

tcex31 - Using GES to Calculate CVM

Using the Gibbs Energy System (GES) module, this example calculates the CVM and compares it with the sublattices of a fictitious A B system. You also learn how to overlay diagrams from two calculations.

This example uses some GES commands that are not yet supported by GES6. Therefore, we enforce the use of GES5.

These GES commands are of note and used in this example:

- ENTER_ELEMENT
- ENTER_SPECIES
- ENTER_SYMBOL
- ENTER_PHASE
- ENTER_PARAMETER
- LIST_PHASE_DATA

tcex34 - The Al-Zn Phase Diagram and its G Curve

This example uses the BINARY module to calculate the phase diagram and G curves in the Al-Zn system. It uses the TCBIN database included with your installation.

Property Diagram Examples

tcex02 - Plotting Thermodynamic Functions

This example shows how to plot thermodynamic functions in unary, binary, and ternary systems. It also involves working with partial derivatives and partial quantities.

This uses the SSOL database. A license is required to run the example.

These commands are used and may be of interest:

GOTO_MODULE	GET_DATA	SET_CONDITION
SWITCH_DATABASE	AMEND_PHASE_DESCRIPTION	LIST_EQUILIBRIUM
DEFINE_SYSTEM	COMPUTE_EQUILIBRIUM	SET_AXIS_VARIABLE
SAVE_WORKSPACES	STEP_WITH_OPTIONS	SET_DIAGRAM_AXIS
ENTER_SYMBOL	PLOT_DIAGRAM	SET_LABEL_CURVE_OPTION
REJECT	RESTORE	LIST_SYSTEM
LIST_STATUS	CHANGE_STATUS	SHOW_VALUE
SET_INTERACTIVE		

tcex08 - Property Diagrams for a High Speed Steel

This example shows how to calculate property diagrams for a high speed steel i.e. phase fraction plots, activity vs temperature, and so forth.

This uses the TCFE database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_DIAGRAM
- DEFINE_ELEMENTS
- AMEND_PHASE_DESCRIPTION
- REINITIATE_PLOT_SETTINGS

tcex09 - Calculating a Dew Point with POLY3

This is an example calculating the dew point in the POLY3 module. The SUBDEMO database is used and included with your installation.

The STEP_WITH_OPTIONS and MAP commands are of note and used in this example.

tcex11 - Oxidation of Cu2S with an H2O/O2 Gas Mixture

This example demonstrates the oxidation of Cu_2S with an H_2O/O_2 gas mixture. Thermo-Calc is used to find the optimum O/H ratio (i.e. oxygen potential) as certain oxygen potential values can desulphurize Cu_2S without forming copper oxides.

In Thermo-Calc, the problem reduces to perform equilibria calculations in a Cu-S-H-O system. The amounts of the components should be kept to correct ratio corresponding to Cu_2S and H_2O using a command SET_INPUT_AMOUNTS in POLY3. Initially, O/H = 0.5 is given. Optimum O/H ratio is calculated with the desired calculation conditions. For example, to simulate one phase disappearing, you can FIX the phase with zero amount.

The *tcex11.TDB* file is used to access data and this is included with your installation.

These commands are of also of note and used in this example:

- SET_NUMERICAL_LIMITS
- SET_REFERENCE_STATE
- SHOW_VALUE

tcex12 - Tabulation of Thermodynamic Data for Reactions

This example shows a number of independent cases using the TABULATE_REACTION (TAB) module to tabulate thermodynamic data for reactions.

This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- TABULATE_REACTION
- DEFINE_SPECIES
- ENTER_FUNCTION
- QUICK_EXPERIMENTAL_PLOT
- SET_SCALING_STATUS
- LIST_SUBSTANCES
- TABULATE_SUBSTANCE

tcex22 - Calculating an Adiabatic Flame Temperature

This example examines a heat balance when C_3H_8 is burned in oxygen by calculating the adiabatic flame temperature.

This uses the SSUB database. A license is required to run the example.

tcex23 - Calculating a Paraequilibrium and the T0 Temperature in a Low Alloyed Steel

This example calculates a paraequilibrium and the T0 temperature in a low alloyed steel.

This uses the TCFE database. A license is required to run the example.

tcex28 - Pitting Resistance Equivalence (PRE) for a Duplex Stainless Steel

This example calculates the Pitting Resistance Equivalence (PRE) for a duplex stainless steel.

This uses the TCFE database. A license is required to run the example.

These commands are of note and used in this example:

- REJECT
- RESTORE
- DEFINE_ELEMENTS
- AMEND_PHASE_DESCRIPTION
- EVALUATE_FUNCTIONS
- SET_START_CONSTITUTION

tcex29 - Calculating the Speciation of a Gas

This example shows how to calculate the speciation of a gas.

This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- SET_INPUT_AMOUNTS
- LIST_CONDITIONS
- SET_CONDITION

tcex32 - Calculating Oxide Layers on Steel

This example calculates oxide layers on a steel.

This uses the TCOX database. A license is required to run the example.

These commands are of note and used in this example:

- SET_START_CONSTITUTION
- SET_REFERENCE_STATE
- APPEND_DATABASE

tcex41 - Calculating a Solubility Product

Calculation of a solubility product.

This uses the TCFE database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_ELEMENTS
- REINITIATE_PLOT_SETTINGS
- SET_DIAGRAM_AXIS

tcex49 - Quasichemical Model Using GES

This example shows how to enter parameters for a FACT quasichemical liquid model and how to calculate the sulfur activity using the GIBBS_ENERGY_SYSTEM (GES) module commands.

This example uses some GES commands that are not yet supported by GES6. Therefore, the example uses GES5.

These commands are of note and used in this example:

- ENTER_ELEMENT
- ENTER_SYMBOL
- AMEND_ELEMENT_DATA
- ENTER_PARAMETER
- ENTER_SPECIES
- SET_REFERENCE_STATE
- SHOW_VALUE

Ternary Phase Diagram Examples

tcex03 - Calculating an Isothermal Section

This example calculates an isothermal section using the Ternary module. The FEDEMO database is used and included with your installation.

These commands are used:

- AMEND_PHASE_DESCRIPTION
- ADD_LABEL_TEXT
- PLOT_DIAGRAM
- SET_DIAGRAM_AXIS; SET_DIAGRAM_TYPE; and SET_AXIS_TYPE
- SET_REFERENCE_STATE
- CHANGE_STATUS
- SET_SCALING_STATUS

tcex05 - Calculating a Vertical Section in the Al-Cu-Si System

This example calculates a vertical section in the Al-Cu-Si system and of a vertical section from Al to 10% Cu_2Si. The ALDEMO database is used and included with your installation.

tcex14 - Variations in Solidification of an Al-Mg-Si Alloy

This example calculates the heat and heat capacity variations during solidification of an Al-Mg-Si alloy. The ALDEMO database is used and included with your installation.

These commands are of note and used in this example:

- LIST_SYSTEM
- LIST_CONDITIONS
- SET_AXIS_TEXT_STATUS

tcex17 - The Pseudo-binary System - CaO-SiO2

This example calculates the pseudo-binary system CaO-SiO_2 using the OXDEMO database, which is included with your installation.

The oxide demo (OXDEMO) database can be used both for pseudo-binary systems like the one in this case, CaO-SiO_2, or for full ternary systems like Ca-Fe-O.

For a more advanced example in Graphical Mode using the TCS Metal Oxide Solutions Database (TCOX), see T_17: Al2O3-MgO Phase Diagram.

These commands are of note and used in this example:

- LIST_SYSTEM
- REJECT and RESTORE
- AMEND_PHASE_DESCRIPTION
- LIST_STATUS
- DEFINE_COMPONENTS
- SET_CONDITION
- COMPUTE_EQUILIBRIUM and LIST_EQUILIBRIUM

tcex19a and tcex19b - Mapping of Univariant Equilibria with the Liquid in Al-Cu-Si

- Part A. Step-by-step calculation using the POLY3 module.
- Part B. Using the TERNARY module, you can get the information on invariant reactions, such as temperature and compositions.

The database used with this example is included with the file named tcex19_cost2.TDB. It is in the same folder as this example.

These commands are of note and used in these examples:

- DEFINE_SYSTEM
- GET_DATA
- AMEND_PHASE_DESCRIPTION
- SET_CONDITION and LIST_CONDITIONS

- ADVANCED_OPTIONS
- SAVE_WORKSPACES and READ_WORKSPACES
- APPEND_EXPERIMENTAL_DATA
- MAKE_EXPERIMENTAL_DATAFILE

tcex21 - Calculating a Ternary Isotherm in Fe-Cr-Ni

This example calculates a ternary isotherm in Fe-Cr-Ni with a user-defined database included with the example in the file named *tcex21.TDB*.

These commands are of note and used in this example:

- DEFINE_SYSTEM
- GET_DATA
- SET_CONDITION
- SET_DIAGRAM_TYPE

tcex33 - An Fe-Cr-C Isopleth

This example is a benchmark calculation of an isopleth in the Fe-Cr-C system. The FEDEMO database is used and included with your installation.

tcex37 - Calculating an Isothermal Section

This example shows how to use command lines to enter and calculate an isothermal section using the POLY3 module. The FEDEMO database is used and included with your installation.

tcex42 - Paraequilibrium Calculation - Formation of Para-pearlite - Isopleth

This uses the TCFE database. A license is required to run the example.

This example uses an Fe-Mn-C system at 2.5%Mn Mass u-fraction to show a paraequilibrium calculation where there is formation of para-pearlite. It is an isopleth calculation and shows the STEP_WITH_OPTIONS command using the Paraequilibrium option.

tcex43 - Paraequilibrium Calculation - Formation of Para-pearlite - Isothermal

This uses the TCFE database. A license is required to run the example.

This example uses an Fe-Mn-C system at 700 °C to show a paraequilibrium calculation where there is formation of para-pearlite. It is an isothermal calculation and shows the STEP_WITH_OPTIONS command using the Paraequilibrium option.

Multicomponent Phase Diagram Examples

tcex06 - An Isopleth in Low Alloyed Fe-Mn-Si-Cr-Ni-C Steel

This example calculates a multicomponent phase diagram using the DEFINE_MATERIAL command in POLY and the TCFE steel database. The material contains 1.5 %Cr + 0.4 %Mn + 3.5 %Ni + 0.3 %Si and 1 %C (by weight). These conditions and the temperature are set by the DEFINE_MATERIAL command.

After the first equilibrium results, a phase diagram is calculated with one axis variable as temperature and the other as the carbon content.

This uses the TCFE database. A license is required to run the example.

tcex10 - Preventing Cr2O3 Clogging in a Continuous Casting Process

The example calculates an equilibrium with suspended or dormant phases and shows how to avoid Cr-oxide clogging in a continuous casting process.

This uses the TCOX database. A license is required to run the example.

The background of this example is that a manufacturer wanted to increase the Cr content of a material from 18 to 25 weight percent. They then had trouble in the continuous casting of this material because solid Cr_2O_3 was formed.

Using Thermo-Calc to calculate the equilibria in the steel/slag system, a simple correction was found: modify the Mn or Si content to decrease the oxygen potential.

In Thermo-Calc, you can FIX a phase with zero amount to simulate how to avoid forming this phase. You then release one of the conditions, usually one of the compositions, and this composition is determined by the equilibrium calculation.

These commands are of note and used in this example:

- DEFINE_SYSTEM
- CHANGE_STATUS
- COMPUTE_EQUILIBRIUM
- DEFINE_SYSTEM
- DEFINE_SYSTEM

- LIST_CONDITIONS
- LIST_EQUILIBRIUM
- LIST_STATUS
- SET_CONDITION
- SET_NUMERICAL_LIMITS
- SET_REFERENCE_STATE
- SHOW_VALUE

tcex23 - Calculating a Paraequilibrium and the T0 Temperature in a Low Alloyed Steel

This example calculates a paraequilibrium and the T0 temperature in a low alloyed steel.

This uses the TCFE database. A license is required to run the example.

tcex27 - Calculating Chemical Vapor Depositions (CVD)

This example calculates the chemical vapor deposition (CVD).

This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_COMPONENTS
- SET_CONDITION
- ADD_INITIAL_EQUILIBRIUM
- LIST_AXIS_VARIABLE
- LIST_INITIAL_EQUILIBRIA

Thermodynamic and Related Quantities Examples

tcex02 - Plotting Thermodynamic Functions

This example shows how to plot thermodynamic functions in unary, binary, and ternary systems. It also involves working with partial derivatives and partial quantities.

This uses the SSOL database. A license is required to run the example.

These commands are used and may be of interest:

GOTO_MODULE	GET_DATA	SET_CONDITION
SWITCH_DATABASE	AMEND_PHASE_DESCRIPTION	LIST_EQUILIBRIUM
DEFINE_SYSTEM	COMPUTE_EQUILIBRIUM	SET_AXIS_VARIABLE
SAVE_WORKSPACES	STEP_WITH_OPTIONS	SET_DIAGRAM_AXIS
ENTER_SYMBOL	PLOT_DIAGRAM	SET_LABEL_CURVE_OPTION
REJECT	RESTORE	LIST_SYSTEM
LIST_STATUS	CHANGE_STATUS	SHOW_VALUE
SET_INTERACTIVE		

tcex13 - Calculating the Binary Al-Ti Phase Diagram and its G Curve

This example calculates an Al-Ti binary phase diagram and G curve using the BINARY module. The TCBIN database is used and included with your installation.

tcex14 - Variations in Solidification of an Al-Mg-Si Alloy

This example calculates the heat and heat capacity variations during solidification of an Al-Mg-Si alloy. The ALDEMO database is used and included with your installation.

These commands are of note and used in this example:

- LIST_SYSTEM
- LIST_CONDITIONS
- SET_AXIS_TEXT_STATUS

tcex18 - A3 Temperature of a Steel

This example calculates the A3 temperature of a steel and examines the influence of each alloying element on this temperature.

A3 temperature is the temperature where ferrite starts to form from austenite. You can easily read A3 from an Fe-C phase diagram. However, for complex multicomponent steels no simple diagram can be used. Using POLY, it is easy to find out the influence of each alloying element on the A3 temperature. This information is useful if you want to modify the compositions of a steel but keep A3 unchanged.

This uses the TCFE database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_ELEMENTS
- AMEND_PHASE_DESCRIPTION
- COMPUTE_TRANSITION
- DEFINE_MATERIAL
- ENTER_SYMBOL
- SHOW_VALUE

tcex22 - Calculating an Adiabatic Flame Temperature

This example examines a heat balance when C_3H_8 is burned in oxygen by calculating the adiabatic flame temperature.

This uses the SSUB database. A license is required to run the example.

tcex26 - The As-Ga Phase Diagram: Plotting the Partial Pressures of a Gas Species

This is an example of plotting the partial pressures of a gas species along the solubility lines in the As-Ga phase diagram. The calculation makes it possible to monitor the input gases to a process of depositing solid As-Ga. The data is taken from the PG35 Binary Semi-Conductors database.

These commands are of note and used in this example:

- REJECT
- RESTORE
- SET_DIAGRAM_AXIS
- SET_SCALING_STATUS
- SET_AXIS_TEXT_STATUS
- SET_LABEL_CURVE_OPTION

tcex34 - The Al-Zn Phase Diagram and its G Curve

This example uses the BINARY module to calculate the phase diagram and G curves in the Al-Zn system. It uses the TCBIN database included with your installation.

tcex39 - Calculating Reversible Carnot Cycles of a Heat Engine

This example shows how to calculate the reversible Carnot cycle of a heat engine using one mole of an ideal gas with two fictitious species A and A2. The GES, POLY3, and POST modules are used, as well as the SUBDEMO database, which is included with your installation.

One application of the Second Law is to the efficiencies of heat engines, pumps and refrigerators. Whenever there is a difference of temperature, work can be produced - the principle of heat engines. The Gibbs energy also enables the prediction of the maximum work that a process may achieve. The goal of this example is to help relate the results to different thermodynamic quantities.

These commands are of note and used in this example:

- REINITIATE
- ENTER_PARAMETER
- ENTER_SPECIES
- SET_PLOT_FORMAT
- ENTER_PHASE

tcex51 - Calculation of Molar Volume, Thermal Expansivity, and Density

This example uses the POLY3 module to calculate the molar volume, thermal expansivity and density of the FCC_A1, BCC_A2 LIQUID, and liquid phases of C-Fe. The FEDMO database is used and this example is available to all users.

Single Equilibrium Calculation Examples

tcex07 - Single Equilibria in Low Alloyed Fe-Mn-Si-Cr-Ni-C Steel

This example shows how to calculate a single equilibria in a low alloyed Fe-Mn-Si-Cr-Ni-C steel. There are two common ways to perform a single equilibrium calculation:

- Get data from a database, then in POLY use SET_CONDITION and COMPUTE_EQUILIBRIUM.
- Go directly to POLY and use DEFINE_MATERIAL.

The COMPUTE_TRANSITION command is also used to determine the temperature or composition where one phase forms or disappears. It is the same as the CHANGE_STATUS → SET_CONDITION→ COMPUTE_EQUILIBRIUM sequence of commands.

A STEP_WITH_OPTIONS command using the option *normal* is also used in addition to the other commands that should be becoming more familiar as you work through the examples.

This uses the TCFE database. A license is required to run the example.

tcex18 - A3 Temperature of a Steel

This example calculates the A3 temperature of a steel and examines the influence of each alloying element on this temperature.

A3 temperature is the temperature where ferrite starts to form from austenite. You can easily read A3 from an Fe-C phase diagram. However, for complex multicomponent steels no simple diagram can be used. Using POLY, it is easy to find out the influence of each alloying element on the A3 temperature. This information is useful if you want to modify the compositions of a steel but keep A3 unchanged.

This uses the TCFE database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_ELEMENTS
- AMEND_PHASE_DESCRIPTION
- COMPUTE_TRANSITION
- DEFINE_MATERIAL
- ENTER_SYMBOL
- SHOW_VALUE

tcex20 - Adiabatic Decompression in a Geological System

This example calculates the adiabatic decompression in a geological system using the geochemical database. The database is included with the file named PGEO.TDB, which is in the same folder as this example.

These commands are of note and used in this example:

- DEFINE_SYSTEM
- DEFINE_COMPONENTS
- SET_INPUT_AMOUNTS
- LIST_CONDITIONS
- SET_CONDITION
- SHOW_VALUE

Potential Diagram Example

tcex35 - Calculating a Potential Diagram

This example uses the POTENTIAL module to calculate a potential diagram. Note that there are no commands for this module, you just follow the prompts. The SUBDEMO database is used and included with your installation.

Scheil-Gulliver Examples

About the Scheil-Gulliver Solidification Simulations

tcex15 - Simulating the Solidification of a Cr-Ni Alloy

This is an example of a solidification simulation of a Cr-Ni alloy. There is no back diffusion in the solid, i.e. this is a classic Scheil-Gulliver simulation. The FEDMO database is used and included with your installation.

These commands are of note and used in this example:

- START_WIZARD
- COMPUTE_TRANSITION
- ADD_INITIAL_EQUILIBRIUM
- ENTER_SYMBOL
- ADVANCED_OPTIONS
- STEP_WITH_OPTIONS
- MAKE_EXPERIMENTAL_DATAFILE
- CHANGE_STATUS

tcex30a and 30b - Scheil Calculation for an Al-4Mg-2Si-2Cu Alloy

The Equilibrium Calculation Module (POLY3) and About the Scheil-Gulliver Solidification Simulations

These examples show two ways to do a Scheil calculation for an Al-4Mg-2Si-2Cu alloy. In part A, you use the POLY3 module and the STEP_WITH_OPTIONS command with an EVALUATE option. Then in part B you use the SCHEIL module commands to do the same thing. Data from the COST2 database is used and included with the example in the file named *tcex30_cost2.TDB*.

tcex48 - Scheil Solidification with C Back Diffusion

The FEDEMO database is used and the example is available to all users.

This is an example of Scheil solidification with simulated back diffusion of carbon in solid phases. The results are compared between a simple Scheil and equilibrium calculation. First perform a Partial Equilibrium Scheil by assigning carbon as a fast diffusing element. Plot solidification curve and a microsegregation diagram and save to file (so called .exp files). The "back diffusion" of C in solid phases is not from any calculation involving kinetics, but comes from the equilibration of chemical potential of C at each step in temperature, thus allowing each already solidified part of the system to change its C concentration.

See tcex54 for an example that calculates "real" back diffusion. This model requires a kinetic (mobility) database in addition to the thermodynamic one. Also see About the Scheil-Gulliver Solidification Simulations for details about the different Scheil options.

tcex54 - Scheil Solidification of an Al-2.1Cu-1Si Alloy including Back Diffusion

This is an example of a solidification simulation of a Al-2.1Cu-1Si alloy. The back diffusion option in the Scheil module is used, i.e. there is back diffusion in the primary phase. The example uses both the thermodynamic ALDEMO and mobility MALDEMO demo databases included with your installation.

tcex57 - Scheil Solidification with Solute Trapping

This is an example of a solidification simulation of a Al-7.5Si-0.2Cu system. The solute trapping option in the Scheil module is used. The example uses the thermodynamic ALDEMO demo database included with your installation.

See the Graphical Mode example T_13: Scheil Solidification with Solute Trapping for an additional comparison to Classic Scheil.

Chemical Ordering Example

tcex16 - Second Order Transition of the Al-Fe System

This example calculates the second order transition line in the BCC field of the Al-Fe system.

This uses the SSOL database. A license is required to run the example.

These commands are of note and used in this example:

- REJECT
- RESTORE
- ADVANCED_OPTIONS
- SET_SCALING_STATUS
- DEFINE_SYSTEM
- MAKE_EXPERIMENTAL_DATAFILE
- LIST_EQUILIBRIUM
- APPEND_EXPERIMENTAL_DATA
- STEP_WITH_OPTIONS

Gibbs Energy System (GES) Examples

tcex31 - Using GES to Calculate CVM

Using the Gibbs Energy System (GES) module, this example calculates the CVM and compares it with the sublattices of a fictitious A B system. You also learn how to overlay diagrams from two calculations.

This example uses some GES commands that are not yet supported by GES6. Therefore, we enforce the use of GES5.

These GES commands are of note and used in this example:

- ENTER_ELEMENT
- ENTER_SPECIES
- ENTER_SYMBOL
- ENTER_PHASE
- ENTER_PARAMETER
- LIST_PHASE_DATA

tcex38 - Calculating the Morral “Rose”

This example uses the Gibbs energy system (GES) module to calculate the Morral rose, which are miscibility gaps.

These commands are of note and used in this example:

- REINITIATE
- ENTER_ELEMENT
- AMEND_ELEMENT_DATA
- ENTER_PARAMETER
- ENTER_PHASE

tcex39 - Calculating Reversible Carnot Cycles of a Heat Engine

This example shows how to calculate the reversible Carnot cycle of a heat engine using one mole of an ideal gas with two fictitious species A and A2. The GES, POLY3, and POST modules are used, as well as the SUBDEMO database, which is included with your installation.

One application of the Second Law is to the efficiencies of heat engines, pumps and refrigerators. Whenever there is a difference of temperature, work can be produced - the principle of heat engines. The Gibbs energy also enables the prediction of the maximum work that a process may achieve. The goal of this example is to help relate the results to different thermodynamic quantities.

These commands are of note and used in this example:

- REINITIATE
- ENTER_PARAMETER
- ENTER_SPECIES
- SET_PLOT_FORMAT
- ENTER_PHASE

tcex49 - Quasichemical Model Using GES

This example shows how to enter parameters for a FACT quasichemical liquid model and how to calculate the sulfur activity using the GIBBS_ENERGY_SYSTEM (GES) module commands.

This example uses some GES commands that are not yet supported by GES6. Therefore, the example uses GES5.

These commands are of note and used in this example:

- ENTER_ELEMENT
- ENTER_SYMBOL
- AMEND_ELEMENT_DATA
- ENTER_PARAMETER
- ENTER_SPECIES
- SET_REFERENCE_STATE
- SHOW_VALUE

tcex52 - Changing the Excess Models for Interaction Parameters in a Solution Phase

Solution Models in the GIBBS (GES) Module

This example uses some GES commands that are not yet supported by GES6. Therefore, the example uses GES5.

This example shows how to change the excess models for binary and ternary interactions in a solution phase, either

- through direct interactive amendments of phase descriptions within the GIBBS_ ENERGY_SYSTEM (GES) module, or
- enforced by specific type-definitions given in a database file retrieved by the DATABASE_RETRIEVAL module (also called the TDB module).

For binary excess models, the example changes it from the default *R-K model* to a *Mixed-Excess-Model*. The phase has to be a substitutional phase in this case.

For ternary extrapolation models, the example changes it from the default *R-K-M model* to a *Toop_Kohler model*.

Notes Related to tcex52 Example

The following is included in the macro file as part of the instructions but may be of use to users:

Amending the Binary Excess Model

The default binary excess model is the Redlich-Kister Model for all the three associated binary interaction pairs (A-B, A-C and B-C) in the substitutional LIQUID solution phase (without sublattice) that consists of three elements (A, B and C).

Before changing this default binary excess model for the ternary LIQUID solution phase, one must have already entered the G parameters (for standard Gibbs energies of all pure end-members) and L parameters (for binary R-K excess interaction energies), as shown in the example.

In this particular example, we want to change from the default R-K binary excess model to the Mixed-Excess-Model (with three different binary excess models, namely Legendre, Polynom and Redlich-Kister models, applied to the A-B, A-C and B-C binaries, respectively), as demonstrated below:

For the A-B interaction, the Legendre binary excess model should be used (rather than the default Redlich-Kister Model), with the first species (i.e. A) as the independent constituent and the second species (i.e. B) as the dependent constituent, while the L parameters for the A-B interaction shall remain the same as those handled by the R-K model.

For the A-C interaction, the Polynom binary excess model should be used (rather than the default Redlich-Kister Model), with the second species (i.e. C) as the independent constituent and the first species (i.e. A) as the dependent constituent, while the L parameters for the A-C interaction shall remain the same as those handled by the R-K model.

Amending the Ternary Extrapolation Model

The default ternary excess model is the Redlich-Kister_Muggianu Model (i.e., the MUGGIANU_RESTOR method for ternary extrapolation based on binary parameters) for the associated ternary interaction terms; when no ternary L parameter is entered for that, such a default Redlich-Kister_Muggianu Model is thus to be used for extrapolation from binary excess energies to ternary interactions in the substitutional LIQUID solution phase (without sublattice) that consists of three elements (A, B and C).

However, in this particular example as illustrated in the following, we shall change from this default R-K-M ternary excess model to the TOOP-KOHLER method for the ternary extrapolation method, with the species C as the Toop constituent, while the species A and B as the Kohler constituents (entering A and B, or B and A, as the basis constituent and first interacting constituent). This will implicitly enforce that, during the ternary extrapolation, only the A-B binary interaction parameters are utilized in accordance with the Kohler ternary extrapolation formula for A-B-C ternary interaction, while any other binary interaction parameters used in line with the Toop-Kohler ternary extrapolation formula (for the A-C-B and B-C-A ternary interactions). This makes the extrapolated ternary excess interaction terms different from those handled either by the default MUGGIANU_RESTOR method or by the alternative KOHLER-ALL method.

Note that only when all the relevant binary excess energies in a ternary system are treated by the default Redlich-Kister Model (i.e., the Mixed-Excess-Model should have not been used), the MUGGIANU_RESTOR method for ternary extrapolations is equivalent to the Redlich-Kister_Muggianu Model, or the KOHLER-ALL method to the Redlich-Kister_Kohler Model.

T0 Temperature Example

tcex23 - Calculating a Paraequilibrium and the T0 Temperature in a Low Alloyed Steel

This example calculates a paraequilibrium and the T0 temperature in a low alloyed steel.

This uses the TCFE database. A license is required to run the example.

Paraequilibrium Examples

tcex23 - Calculating a Paraequilibrium and the T0 Temperature in a Low Alloyed Steel

This example calculates a paraequilibrium and the T0 temperature in a low alloyed steel.

This uses the TCFE database. A license is required to run the example.

tcex42 - Paraequilibrium Calculation - Formation of Para-pearlite - Isopleth

This uses the TCFE database. A license is required to run the example.

This example uses an Fe-Mn-C system at 2.5%Mn Mass u-fraction to show a paraequilibrium calculation where there is formation of para-pearlite. It is an isopleth calculation and shows the STEP_WITH_OPTIONS command using the Paraequilibrium option.

tcex43 - Paraequilibrium Calculation - Formation of Para-pearlite - Isothermal

This uses the TCFE database. A license is required to run the example.

This example uses an Fe-Mn-C system at 700 °C to show a paraequilibrium calculation where there is formation of para-pearlite. It is an isothermal calculation and shows the STEP_WITH_OPTIONS command using the Paraequilibrium option.

Functions and Variables Examples

tcex44 - Exploring Variables and Functions

This example uses variables and functions to predict properties e.g. proof strength for an austenitic stainless steel at elevated temperatures (20-550 °C). The example was created using an expression from [2000Eli].

This uses the TCFE database. A license is required to run the example.

In Graphical Mode there is a Yield Strength Property Model that does not require user input of empirical functions. See About the Yield Strength Property Model.

Reference

[2000Eli] J. Eliasson, R. Sandström, Proof strength values for austenitic stainless steels at elevated temperatures. Steel Res. 71, 249–254 (2000).

PARROT and EDIT_EXPERIMENT Examples

tcex36a - Using PARROT and EDIT EXPERIMENTS

The example is divided into parts corresponding to the files in the **tcex36a** folder. It is recommended you open *tcex.36.readme* before continuing with this advanced exercise.

Also see the *Data Optimization User Guide*.

Each problem has "selected" experimental data. The example uses a fictitious binary A-B system where element A is BCC until it melts. Element B is BCC up to 1100 K and FCC above. There is a compound A2B stable in a limited temperature range.

- The creation of the "setup" file is described (*tcex36a.TCM*) where you enter the elements and phases into the Gibbs Energy System (GES) module
- The creation of the experimental data file is described (*tcex 36b.TCM*). When you run the TCEX36a macro, the contents of this macro file is automatically launched and the experimental data file created.
- The actual run in the PARROT module in order to obtain the result (*tcex 36cpd.TCM*)

There are many commands used in this advanced example (listed in alphabetical order):

ADVANCED_OPTIONS	AMEND_ELEMENT_DATA	AMEND_PHASE_DESCRIPTION
APPEND_EXPERIMENTAL_DATA	COMPILE_EXPERIMENTS	
CONTINUE_OPTIMIZATION	CREATE_NEW_EQUILIBRIUM	CREATE_NEW_STORE_FILE
DEFINE_COMPONENTS	EDIT_EXPERIMENTS	ENTER_PARAMETER
ENTER_PHASE	LABEL_DATA	LIST_ALL_VARIABLES
LIST_PHASE_DATA	LIST_RESULT	MACRO_FILE_OPEN
OPTIMIZE_VARIABLES	QUICK_EXPERIMENTAL_PLOT	READ_WORKSPACES

RESCALE_VARIABLES	SAVE_PARROT_WORKSPACES	SAVE_WORKSPACES
SELECT_EQUILIBRIUM	SET_ALL_START_VALUES	SET_ALTERNATE_CONDITION
SET_ALTERNATE_MODE	SET_FIX_VARIABLE	SET_OPTIMIZING_VARIABLE
SET_STORE_FILE	SET_WEIGHT	

Pourbaix Diagram Examples

As of Thermo-Calc 2026a, the Aqueous Calculator is available in Graphical Mode. Both the Calculator and the Aqueous Calculation template allows for efficient setup of advanced aqueous calculations compared to the Console Mode POURBAIX module. Two Graphical Mode examples, T_21: Pourbaix Diagrams of Fe with the Aqueous Calculator and T_22: Aqueous pH of Solutions, are included with your installation and it is recommended to use Graphical Mode for aqueous calculations.

tcex40

This is the first in a series of examples to demonstrate the classic POURBAIX module calculations and plotting.

Additional Console Mode examples (TCEX40A, TCEX40B, TCEX40C, and TCEX40E) are provided to demonstrate options and features in the classic version of the Pourbaix module and to show more other applications of the TCAQ3.1 and older and AQS aqueous solution databases i.e., with appended data from the SSOL and SSUB databases. There is a historical text file *TCEX40-README.txt*, which is located in the **Extended** subfolder, which details these complex additional examples. However, it is recommended that you use the Aqueous Calculations template in Graphical Mode instead.

This example automatically calculates and plots a Pourbaix diagram for 0.001 m Fe in a 0.1 m NaCl aqueous solution at 25 °C and 1 bar. Other diagrams, along various phase boundaries for the same interactions resulted from the same Pourbaix module calculation, are also plotted. The txex40 example uses the PAQ2 (TCS Public Aqueous Solution Database using the SIT aqueous solution model) included with your installation.

There are new Graphical Mode examples that also use this database and the Aqueous Calculator. See Aqueous and Pourbaix Diagram Examples Summary.

tcex53 - Pourbaix Diagram Calculations for a Heterogeneous Interaction System

This example uses the PAQ2 database to calculate some Pourbaix diagrams. The DATABASE_RETRIEVAL (TDB), GIBBS_ENERGY_SYSTEM (GES), POLY3, and POST modules are used for the Fe-X-H2O-NaCl heterogeneous interaction system, where X = Cr-Ni-Co.

There are new Graphical Mode examples that also use this database and the Aqueous Calculator. See Aqueous and Pourbaix Diagram Examples Summary.

Tabulate Reaction (TAB) Example

tcex12 - Tabulation of Thermodynamic Data for Reactions

This example shows a number of independent cases using the TABULATE_REACTION (TAB) module to tabulate thermodynamic data for reactions.

This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- TABULATE_REACTION
- DEFINE_SPECIES
- ENTER_FUNCTION
- QUICK_EXPERIMENTAL_PLOT
- SET_SCALING_STATUS
- LIST_SUBSTANCES
- TABULATE_SUBSTANCE

REACTOR Module Example

tcex24 - Simulation of the Silicon Arc Furnace

This is a simple reactor model with output of gases at the top and output of condensed phases at the bottom. The gas phase from one segment flows to higher segments, 80% reacts in the first above, 15% in the second above and 5% in the third above.

The condensed phases flow downwards and all of it goes to the next lowest segment. Heat can be added at any module. The only way to specify the initial state of the reactants added to the reactor is to specify the heat content.

This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_SPECIES
- CREATE_STAGE_BOXES
- CREATE_DIVIDERS
- CREATE_PIPES
- START_SIMULATION

Thermophysical Properties Examples

tcex55 - Plotting Viscosity of Cr-Ni at 1873 K

This is an example of including viscosity in the calculations.

Using the FEDEMO database, which is the free demonstration version of the TCS Steel and Fe-alloys Database (TCFE), the viscosity of metallic liquids is plotted at 1873 K for Cu-Ni and compared to experimental data from [2005Sat].

Reference

[2005Sat] Y. Sato, K. Sugisawa, D. Aoki, T. Yamamura, Viscosities of Fe–Ni, Fe–Co and Ni–Co binary melts, Meas. Sci. Technol. 16, 363–371 (2005).

The example includes an experimental data (`*.exp`) file called `Cr-Ni_1873K.exp`.

The same example is also provided in Graphical Mode as **T_12_Viscosity_in_Cr-Ni.tcu**.

tcex56 - Plotting Surface Tension of Cu-Zr at 1373 K

This is an example of including surface tension in the calculations.

Using the CUDEMO database, which is the free demonstration version of the TCS Cu-based Alloys Database (TCCU), the surface tension of liquid metallic is plotted at 1373 K for Cu-Zr and compared to experimental data from [2005Kra].

Reference

[2005Kra] V. P. Krasovskyy, Y. V. Naidich, N. A. Krasovskaya, Surface tension and density of copper–Zirconium alloys in contact with fluoride refractories, J. Mater. Sci. 40, 2367–2369 (2005).

The example includes an experimental data (`*.exp`) file called `Cr-Zr_ALDEMO.exp`.

The same example is also provided in Graphical Mode as **T_11_Surface_tension_in_Cu-Zr.tcu**.

tcex58 and tcex59 - Molar Volume

There are two examples that include molar volume in the calculations and use the ALDEMO database, which is the free demonstration version of the TCS Al-based Alloys Database (TCAL).

The examples calculate volumetric thermal expansion coefficients of the L12-type Al3Sc (tcex58) and the L12-type Al3Zr (tcex59), respectively. Both Al3Zr and Al3Sc are modeled as the same phase (named as AL3SC, since Al3Sc is stable while Al3Zr is metastable).

The examples include an experimental data (`.exp`) file called Al3X.exp, which is the same for both examples to read the data from [2015Sah].

The same example, combining both tcex58 and tcex59 is also provided in Graphical Mode as **T_15_Molar_Volume_for_Al3Sc-Al3Zr.tcu**.

Reference

[2015Sah] S. Saha, T. Z. Todorova, J. W. Zwanziger, Temperature dependent lattice misfit and coherency of Al3X (X=Sc, Zr, Ti and Nb) particles in an Al matrix. Acta Mater. 89, 109–115 (2015).

tcex60 - Electrical Resistivity and Thermal Conductivity

This example calculates the electrical resistivity (ELRS) and thermal conductivity (THCD) or pure Cu. It makes a step calculation over a wide temperature range, covering both the FCC_A1 state and the liquid state. It plots thermal conductivity of the system (both FCC_A1 and liquid) and that of a single phase (taking FCC_A1 as an example), respectively. Also plots electrical resistivity of the system and that of FCC_A1.

The example is available to all users as it uses the ALDEMO database, which is the free demonstration version of the TCS Al-based Alloys Database (TCAL).

The example includes two experimental data (`*.exp`) files called 1972Ho_cu_thcd.exp and 1981Ho_cu_elrs.exp.

The same example is also provided in Graphical Mode as **T_16_Electrical_ Resistivity_Thermal_Conductivity_Cu.tcu**

Learn More about the Thermophysical Properties

The thermophysical properties are included with most of the Thermo-Calc databases starting with Thermo-Calc software version 2020a.

You can learn more about the models by searching the help (press F1 when in Thermo-Calc).

You can find information on our website about the properties that can be calculated with Thermo-Calc and the Add-on Modules.

Application Examples

tcex09 - Calculating a Dew Point with POLY3

This is an example calculating the dew point in the POLY3 module. The SUBDEMO database is used and included with your installation.

The STEP_WITH_OPTIONS and MAP commands are of note and used in this example.

tcex10 - Preventing Cr2O3 Clogging in a Continuous Casting Process

The example calculates an equilibrium with suspended or dormant phases and shows how to avoid Cr-oxide clogging in a continuous casting process.

This uses the TCOX database. A license is required to run the example.

The background of this example is that a manufacturer wanted to increase the Cr content of a material from 18 to 25 weight percent. They then had trouble in the continuous casting of this material because solid Cr_2O_3 was formed.

Using Thermo-Calc to calculate the equilibria in the steel/slag system, a simple correction was found: modify the Mn or Si content to decrease the oxygen potential.

In Thermo-Calc, you can FIX a phase with zero amount to simulate how to avoid forming this phase. You then release one of the conditions, usually one of the compositions, and this composition is determined by the equilibrium calculation.

These commands are of note and used in this example:

- DEFINE_SYSTEM
- CHANGE_STATUS
- COMPUTE_EQUILIBRIUM
- DEFINE_SYSTEM
- DEFINE_SYSTEM
- LIST_CONDITIONS
- LIST_EQUILIBRIUM
- LIST_STATUS
- SET_CONDITION

- SET_NUMERICAL_LIMITS
- SET_REFERENCE_STATE
- SHOW_VALUE

tcex11 - Oxidation of Cu2S with an H2O/O2 Gas Mixture

This example demonstrates the oxidation of Cu_2S with an H_2O/O_2 gas mixture. Thermo-Calc is used to find the optimum O/H ratio (i.e. oxygen potential) as certain oxygen potential values can desulphurize Cu_2S without forming copper oxides.

In Thermo-Calc, the problem reduces to perform equilibria calculations in a Cu-S-H-O system. The amounts of the components should be kept to correct ratio corresponding to Cu_2S and H_2O using a command SET_INPUT_AMOUNTS in POLY3. Initially, O/H = 0.5 is given. Optimum O/H ratio is calculated with the desired calculation conditions. For example, to simulate one phase disappearing, you can FIX the phase with zero amount.

The *tcex11.TDB* file is used to access data and this is included with your installation.

These commands are of also of note and used in this example:

- SET_NUMERICAL_LIMITS
- SET_REFERENCE_STATE
- SHOW_VALUE

tcex20 - Adiabatic Decompression in a Geological System

This example calculates the adiabatic decompression in a geological system using the geochemical database. The database is included with the file named PGEO.TDB, which is in the same folder as this example.

These commands are of note and used in this example:

- DEFINE_SYSTEM
- DEFINE_COMPONENTS
- SET_INPUT_AMOUNTS
- LIST_CONDITIONS
- SET_CONDITION
- SHOW_VALUE

tcex24 - Simulation of the Silicon Arc Furnace

This is a simple reactor model with output of gases at the top and output of condensed phases at the bottom. The gas phase from one segment flows to higher segments, 80% reacts in the first above, 15% in the second above and 5% in the third above.

The condensed phases flow downwards and all of it goes to the next lowest segment. Heat can be added at any module. The only way to specify the initial state of the reactants added to the reactor is to specify the heat content.

This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_SPECIES
- CREATE_STAGE_BOXES
- CREATE_DIVIDERS
- CREATE_PIPES
- START_SIMULATION

tcex27 - Calculating Chemical Vapor Depositions (CVD)

This example calculates the chemical vapor deposition (CVD).

This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- DEFINE_COMPONENTS
- SET_CONDITION
- ADD_INITIAL_EQUILIBRIUM
- LIST_AXIS_VARIABLE
- LIST_INITIAL_EQUILIBRIA

tcex28 - Pitting Resistance Equivalence (PRE) for a Duplex Stainless Steel

This example calculates the Pitting Resistance Equivalence (PRE) for a duplex stainless steel.

> This uses the TCFE database. A license is required to run the example.

These commands are of note and used in this example:

- REJECT
- RESTORE
- DEFINE_ELEMENTS
- AMEND_PHASE_DESCRIPTION
- EVALUATE_FUNCTIONS
- SET_START_CONSTITUTION

tcex29 - Calculating the Speciation of a Gas

This example shows how to calculate the speciation of a gas.

> This uses the SSUB database. A license is required to run the example.

These commands are of note and used in this example:

- SET_INPUT_AMOUNTS
- LIST_CONDITIONS
- SET_CONDITION

Data Optimization (PARROT)

In Thermo-Calc, optimization is completed using the built-in PARROT Module, which is available in all Thermo-Calc and Diffusion Module (DICTRA) Console Mode installations.

Introduction to Data Optimization

These sections describe the basic idea behind data optimization, contains brief descriptions of the modules and file types that you work with while doing your optimization, as well as rough outline of overarching workflow that you typically follow when working with optimization.

To use these advanced features it is important that you are familiar with using Thermo-Calc Console Mode. You need to understand the principles of thermodynamics and be familiar with the theoretical foundations of computational thermodynamics.

Learn More

More about data optimization and PARROT, including a video about how to use PARROT, is available on the Thermo-Calc Software website. The video is also available on our YouTube playlist.

Discover more or refresh your skills with an Advanced Lecture Series on Fundamentals of Thermodynamics, created by Professor John Ågren, one of the original developers of Thermo-Calc.

Press F1 to search the help for information about all the commands available in the Thermo-Calc Console Mode, including PARROT and ED_EXP. Note that the commands listed under PARROT and ED_EXP are only commands that are specific to PARROT and/or ED_EXP. These modules also contain some commands that are also available in POLY.

Thermo-Calc Console Mode example tcex36 is a detailed example of assessment and optimization in Thermo-Calc.

Data Optimization

In a thermodynamic database, each phase in a system is characterized using a mathematical model of its Gibbs energy. The Gibbs energy of a phase depends on various state variables. It can be defined individually even in a heterogeneous system with many stable phases since the properties of one phase are completely independent of the properties of the other phases in the system. In most alloy systems, the thermodynamic properties of a phase can be modeled by expressing how the Gibbs energy depends on temperature and composition. State variables such as pressure, volume or entropy can also serve as parameters in the Gibbs energy expression. The Gibbs energy of the whole system is the sum of the products of the Gibbs energy of each phase multiplied by the amount of that phase.

How the Gibbs energy of the phase varies with various state variables is determined by a mathematical model and how various adjustable parameters of the model is set. By optimizing these parameters, you can calculate the thermodynamic properties of a system under various conditions (by calculating phase diagrams for example). The thermodynamic properties themselves are functions of temperature, pressure or composition. They include, among other properties, standard enthalpy of formation, entropy, heat capacity, molar volume, thermal expansivity, compressibility and Curie temperature for magnetic transformations.

Data optimization is about adjusting the model parameters so that calculated equilibria fit well with experimental data. An important part of a data optimization is therefore collecting and assessing available experimental and theoretical information about phase equilibria and thermochemical properties of a system.

When you optimize the parameters of the model of a phase, you put what is called optimizing variables into the Gibbs energy expressions of those parameters. During the optimization, the values of these variables are varied in order to find a fit between the calculated equilibria and the experimental data that you base the optimization on. Once you have settled on a Gibbs energy expression for a certain parameter of a phase of the element, then you must stick to this expression in all future optimizations involving the element. If you do not do this, then you must re-optimize all previous systems that involve this element when the expression is changed.

The Thermo-Calc software allows you to optimize parameters that characterize not only binary systems, but also ternary system and systems of even higher orders. You can even optimize parameters that characterize systems of different orders at the same time.

Learn More

More about data optimization and PARROT, including a video about how to use PARROT, is available on the Thermo-Calc Software website. The video is also available on our YouTube playlist.

Discover more or refresh your skills with an Advanced Lecture Series on Fundamentals of Thermodynamics, created by Professor John Ågren, one of the original developers of Thermo-Calc.

The Least-Squares Method

Data optimization in Thermo-Calc is based on the least-squares method for fitting values calculated on the basis of a model with observed quantities. The software is accordingly trying to find the optimizing variable values that lead the minimized sum of the squares of the differences between the calculated values and the observed quantities (that is, of the errors or residuals).

The least-squares method works best under the following conditions:

- The observed quantities have a Gaussian probability distribution.
- The observed quantities are only subject to random errors.
- The different observations (experiments) are uncorrelated
- The standard deviation of each observation can be estimated.
- The number of observations is large.
- The models used give precise predictions.

Of course, these conditions are usually not all met in a normal thermodynamic assessment. But even in non-ideal conditions, there is no known method that works better than the least-squares method.

The CALPHAD Approach

The data optimization functionality in Thermo-Calc works according to the CALPHAD approach to computational thermodynamics. This approach builds on the development of models that accurately represent thermodynamic properties for various phases. These models enable you to predict the thermodynamic properties of multicomponent systems-based data concerning binary and ternary subsystems. The predictions can take many factors into accounts, such as, for example, crystallography, type of bonding, order-disorder transitions and magnetic properties.

Optimization Workspaces **1357**

Method for Optimization and Simulation **1358**

Data Optimization in Thermo-Calc

The actual performance of the optimization of a system is primarily done in the PARROT module, and in its sub-module ED_EXP. The POLY and POST modules are used to calculate and plot property or phase diagrams based on the optimized variables. This allows you to visually assess how good a fit you have achieved between your calculated results and your experimental data.

The end result of a successful optimization is typically an updated Thermo-Calc database file (with filename extension *.TDB) or a new database file.

Data Optimization Workflow

When you carry out an optimization using Thermo-Calc, you typically follow a workflow as outlined below.

1. Collect experimental data about your system from various sources such as journal articles and reports.
2. Create a POP file in which you enter the experimental data you have collected.
3. Create a setup macro file in which you define your system and the variables you want to optimize. A useful general procedure is to first find a minimum set of variables that allows you to calculate most of the experiments.
4. Run the setup macro file.
5. Compile your POP file. This file often contains errors, which need to be corrected, and the file recompiled several times before the compilation is completed without errors.
6. In the ED_EXP module, check that the experiments in your POP file reach equilibrium with reasonable results. If any experiments do not reach equilibrium with reasonable results, then try changing the starting values on equilibrium conditions (such as composition) to see whether the equilibrium can be computed after all. If this does not work, then you can temporarily exclude the experiment from the optimization. At a later stage in the optimization, when the optimizing variables have different values, you can check whether the experiments can be computed with reasonable results.
7. Back in the PARROT module, run the first optimization cycle and evaluate the feedback in the console. You can also plot diagrams in the POLY module that allow you to visually inspect the fit between calculated optimization results and the experimental data. If you are not satisfied with the fit, then enter the ED_EXP module again and adjust the weights of the experiments in a way that is likely to improve the fit and run another optimization cycle. Reiterate until you are satisfied with the fit.
8. Once you get the optimization stable and smooth with the minimum set of variables chosen in step 3 above, try using different sets of variables to see whether improvements are possible.
9. When you are satisfied with the fit between calculated results and experimental data with your final set of optimizing variables, update your setup file and POP file. In the setup file, enter the calculated optimizing variable values as the variables' start values. In the POP file, enter the final weights of the experiments. With these files updated, you can easily regenerate the parameter values of your optimized system. Having the files updated also makes it easier to optimize the system again in light of new data or new theoretical models.
10. Finally, update the database with your calculated results or create a new database with information about the system that you have optimized.

The PARROT Module

The PARROT module consists of a comprehensive subroutine package for data evaluation of thermodynamic model parameters from experimental data. The module has 99 variables that you can use for optimization and the module can handle a thousand experimental measurements in an optimization. However, there are limits on the simultaneous numbers of variables and experiments. These limits are listed at each optimization.

The PARROT module is part of the Thermo-Calc software. The module is not included in the software development kits (SDKs).

The experimental data is entered and edited in a sub-module of PARROT: The EDIT_EXPERIMENTS Module.

The EDIT_EXPERIMENTS Module

The EDIT_EXPERIMENTS module, or ED_EXP for short, is used for entering, evaluating, and editing experimental data. To enter the module, go to The PARROT Module and then issue the command EDIT_EXPERIMENTS.

Since ED_EXP uses the POLY module for doing equilibrium calculations of experimental data points, many POLY commands are also available in the ED_EXP module. However, the commands may work somewhat differently in the two modules. There are also unique ED_EXP commands which are not found in POLY.

When you execute ED_EXP commands, the PARROT workspace is modified. However, note that you must always first use READ_WORKSPACES in ED_EXP before doing anything in the module. The command loads the experimental data that you are going to work with during the optimization. Furthermore, before leaving ED_EXP you must use SAVE_WORKSPACES or the results of your work in the ED_EXP module is lost.

Data Optimization in Other Modules

All kinds of thermodynamic data, calculated equilibrium states or dynamic parameters are transferred back and forth between the PARROT and the GIBBS module as well between these and the POLY module. Whenever an optimization run is performed, PARROT calls the GIBBS module for stored system definition data and model parameters.

In Thermo-Calc, the GIBBS module (the Gibbs Energy System) handles the models of the various phases that can form in a multicomponent system. It stores thermodynamic data and performs various Gibbs energy equilibrium calculations. It contains subroutines to analytically calculate the first and second partial derivatives of integral Gibbs energy with respect to any set of variables. Many thermodynamic models for various types of substances are implemented in the module. Some commands that are available in the PARROT module are also available in the GIBBS module.

In the GIBBS module, parameters of the Gibbs energy models are referred to as *TP-functions*.

PARROT calls the POLY module for equilibrium calculations. The POLY module is used for calculating and storing complex heterogeneous equilibria.

Optimization File Types

These are the important files you work with when optimizing.

File type	*Description*
POP file	The POP file (Parrot OPtimization file) is the file that contains all the experimental data that you use for optimizing Gibbs energy values for your system. The POP file is a plain text file that contains ED_EXP commands. By default, the file has the filename extension *.POP in Thermo-Calc.
Setup file	The setup file is a Thermo-Calc macro file (*.TCM). This file typically contains commands that define your system, opens the PARROT workspace (and associated GIBBS and POLY workspaces) and sets optimizing variables.
Other macro files	It is often useful to have other macro files than the setup file at hand while you are doing your optimization. For example, it is convenient to have a macro file that automatically plots phase diagrams or other diagrams based on the latest values of your optimizing variables. An optimization process typically involves many optimization cycles, so this operation needs to be done many times during a typical optimization.
Workspace files	The PARROT module has its own workspace with dynamic memories, similar to the workspaces of POLY and GIBBS. It is stored and updated in a PARROT workspace file with the filename extension *.PAR. The workspace file is a binary file whose format is hardware dependent. This means that the format is unique for each type of CPU. Hence, a workspace file saved on a computer with one type of CPU cannot be used on a computer with another type of CPU.
EXP-file	The EXP-file is a plain text file with information in the form of DATAPLOT Graphical Language commands. These commands can specify some or all of the data points in your POP file. This allows you to plot these data points on top of your plotted optimization results (with the POST commands APPEND_EXPERIMENTAL_DATA or QUICK_EXPERIMENTAL_PLOT). You can then visually assess the fit between these results and the experimental data. The PARROT workspace is not influenced in any way by the creation or use of EXP-files.

Optimization Workspaces

When writing the setup file, you enter a CREATE_NEW_STORE_FILE command which creates a PARROT workspace file. Alternatively, select an existing PARROT workspace file with SET_STORE_FILE. The workspace file is automatically updated and saved with the latest optimization results (after each use of the OPTIMIZE_VARIABLES command). You can also explicitly instruct Thermo-Calc to save the workspace using SAVE_PARROT_WORKSPACES. If you want to get rid of your latest changes and return to the state of your workspace when it was last saved, use READ_PARROT_WORKSPACES.

When the PARROT workspace is saved, parts of the POLY and GIBBS workspaces are also saved to the PARROT workspace file, along with the PARROT workspace itself. Using the POLY command SAVE_WORKSPACES creates a new POLY3 file, nothing is saved to the PARROT workspace file.

If you do any POLY calculations based on data in the current workspace file, then a *.POLY3 file is created, which contains a copy of the current set of parameters. If you continue on your optimization and read the old *.POLY3 file, then the new set of parameters is overwritten with the old set. It is therefore recommended that you never read a *.POLY3 or *.GES5 file while you are doing an optimization.

Method for Optimization and Simulation

The PARROT module typically uses ordinary POLY minimization for equilibrium calculations. The global minimization technique that is used in POLY cannot be used because it automatically creates new composition sets which corrupt the PARROT workspace. Furthermore, the equilibrium definitions that you use as input for your optimization must each be attributed to a specific phase. Some of these definitions may specify some local or partial equilibrium state rather than a global minimum. However, it is possible to use the global minimization technique for some equilibrium calculations by using the ED_EXP command ADVANCED_OPTIONS with the `Toggle_Alternate` option.

Optimization in PARROT is performed on the basis of a 'maximum likelihood' principle. According to this principle, the best fit between various calculated results and all the input of experimental data is found where the sum of the square of the weighted residuals is at its minimum.

Typically, the results of an optimization is considered to be better the fewer optimizing variables that are needed to get the same level of fit between computed results and experimental data. If you can get almost the same fit using eight instead of twelve parameters, then this should be considered to be a significant improvement. When more parameters are used, the values of the individual parameters tend to become unrealistic. This is particularly true when it comes to temperature-dependent parameters. However, relatively small differences in the number of parameters are often insignificant. For example, it does not typically matter whether you used 24 or 25 parameters to reach a certain degree of fit.

It is often difficult to compare the quality of different optimizations based on the number of optimizing variables that have been optimized. Since you may rely more or less heavily on different pieces of available experimental data (and do so with good reason), it is possible that two different users could end up with very different numbers of parameters for the same system. For example, suppose you optimize the Fe-Al system to incorporate it into an Al database, while someone else optimizes the same system to incorporate it into an Fe database. In this situation, the two of you would probably make different judgements about which experimental information your calculated results must have a good fit with.

Creating the POP File

Before starting an optimization in Thermo-Calc, you must collect relevant experimental data about your system that is available in the research literature. This data is then entered in the POP file. The experimental data points and measurements are entered in this plain text file in the form of ED_EXP commands.

The syntax of the POP file is in principle independent of the models used for describing the phases in the system.

Experimental Information

An optimization of thermodynamic model parameters should be based on a range of reliable experimental results that is as wide as possible, as well as on empirical or semi-empirical correlations and theoretical considerations. During an optimization in Thermo-Calc, many kinds of thermochemical and thermophysical data can be mixed and used together.

The information needed for an optimization represent measurements of thermodynamic parameters in the system at equilibrium. These can be measurements of any of the thermodynamic quantities that can be set as conditions in Thermo-Calc. The information may represent measurements of activities or enthalpies in single-phase regions for example, or solubilities or transformation temperatures in a multi-phase region.

For each equilibrium that is used in the optimization, at least one quantity must have been measured and you also need to know the conditions that must be set to compute the system's equilibrium state. For example, consider a binary system in a single-phase region. Suppose that you have measured the temperature, pressure, composition and the chemical potential. Three of these quantities are necessary to specify the equilibrium state and the forth can be used as experimental information to model the phase.

If you have a two-phase region and know the temperature and pressure conditions, as well as which the stable phases are, then you could use the compositions of one or both phases as experimental data. The former information about the conditions is sufficient to determine the equilibrium. The experimental information can then be used to optimize the parameters that are used to characterise and model the system.

For examples how to enter various kinds of experimental data in the POP file, see Experiments and Experimental Data.

Conflicting or Missing Information

You are likely to sometimes have inconsistent or conflicting experimental information. In principle, all available experimental data should still be entered into the POP file, unless you have good reasons to exclude some information. For example, if you have reason to believe that the samples used in some experiments were not pure, then these experiments could be excluded from the POP file.

For some systems, you have very little experimental data to go on. When this is the case, do not try to fit the available data uncritically with high accuracy without considering possible errors. You can look for data in systems with similar elements to get an idea about what the

reasonable estimates of data that is lacking could be. Or you can use calculations from first principles or semi-empirical methods to get reasonable estimates that can be used as experimental data.

Invariant Equilibria Information

The most valuable experimental information for an optimization is information about stable invariant equilibria. An invariant equilibrium is such that neither pressure, temperature nor composition can be changed without there being a change in the set of phases present in the system. It is recommended that all information about invariant equilibria for a system is included in the POP file. These equilibria need not all be based on explicit experimental measurements of thermodynamic properties.

Reasonable estimates from available experimental data are often useful to include in the POP file. Such estimates, which should be based on the available experimental data, helps Thermo-Calc find a good set of start values on the optimization variables. However, at the end of the assessment, these estimated equilibria should be excluded and you should complete the optimization based only on the experimental information that is based on measurements.

With some experience from phase diagram evaluation, it is possible to make reasonable estimates of metastable invariant equilibria. Such estimates helps reduce the number of phases that are assessed simultaneously during the optimization. For example, you may assume that a certain intermediate phase does not form in a system. Then extrapolate the liquidus curves below the stable three-phase equilibria and finally, estimate temperatures and compositions of metastable three-phase equilibria between two other phases and the liquid.

Another useful technique is to extrapolate a liquidus line from a peritectic equilibrium to estimate the congruent melting temperature of a compound. This estimate may be more useful than the information about the peritectic equilibrium itself as the equilibrium involves only two phases.

Equilibria in Higher-Order Systems Information

When you optimize a binary system, the available experimental information can often be described equally well by very different sets of parameters. Information about ternary and higher order systems that include the components of the binary system are then often useful for optimizing the binary system (the same is true of information about quaternary system with respect to optimizing ternary systems). Often, it is only when you extrapolate the optimized parameters to a higher-order system that you can judge which of the sets of model parameters that is best. Sometimes information from several ternary systems is required to make a reliable judgement about which set of parameters best describes a particular binary

system.

Heat Capacity Information

If you want to optimize your system based on data about heat capacities, then the corresponding parameters should first be optimized separately before you perform the general optimization of your system. The parameters should be kept fixed during the general optimization. This is because it is normally not possible to optimize heat capacity data together with other data in a meaningful way. If you do this, then it is very likely that the parameters related to the heat capacity are badly determined.

POP File Syntax

It is recommended that you specify an experimental equilibrium as close as possible to actual experimental conditions. Ideally, there is information about the set of stable phases, temperature, pressure and some or all compositions for the equilibrium.

In addition, it is recommended that you keep the POP file well-organised and extensively commented. This is especially important if someone else reassesses the system when new experimental information is available.

If you have too many equilibria defined in your file, or if you define equilibria with different sets of components in the same file, then you must divide the POP file in *blocks* (using the FLUSH_BUFFER command). You know whether you have defined too many equilibria for one block when you compile the file. A too large number of equilibria leads to an error message when the file is compiled.

If you use the DEFINE_COMPONENTS command, then it must be the first command in the POP file (or if you have several blocks, DEFINE_COMPONENTS can also be put as the first command after FLUSH_BUFFER). This is because the command automatically reinitiates the current workspace, so the effect of any commands placed before it are not saved.

The last command in the POP file should always be SAVE_WORKSPACES .

Legal Commands in a POP File

The following commands can be used in a POP file.

- ADVANCED_OPTIONS
- CHANGE_STATUS
- COMMENT
- CREATE_NEW_EQUILIBRIUM
- DEFINE_COMPONENTS
- ENTER_SYMBOL
- EVALUATE_FUNCTIONS
- EXPERIMENT
- EXPORT

- FLUSH_BUFFER
- IMPORT
- LABEL_DATA
- SAVE_WORKSPACES
- SET_ALL_START_VALUES
- SET_ALTERNATE_CONDITION
- SET_CONDITION
- SET_NUMERICAL_LIMITS
- SET_REFERENCE_STATE
- SET_START_VALUE
- SET_WEIGHT
- TABLE_HEAD, TABLE_VALUES, and TABLE_END

Entering Experimental Information

A POP file in Thermo-Calc (*.POP) mainly consists of descriptions of equilibria, each equilibrium describing a data point that is based on an experiment from the existing literature on your system. An equilibrium is specified using ED_EXP commands.

The following is an example of a specification of an equilibrium with a single stable phase in the Au-Cu system. Equilibria with a single stable phase are often from experiments where enthalpies of mixing or chemical potentials have been measured.

```
CREATE_NEW_EQUILIBRIUM 1 1
CHANGE_STATUS PHASE LIQUID=FIX 1
SET_CONDITION T=1379 P=1E5 X(LIQUID,AU)=0.0563
SET_REFERENCE_STATE AU LIQ * 1E5
SET_REFERENCE_STATE CU LIQ * 1E5
EXPERIMENT HMR=-1520:200
COMMENT Measurement by Topor and Kleppa, Met trans 1984
```

Creating a New Equilibrium

The first command in an equilibrium specification is always CREATE_NEW_EQUILIBRIUM. This command takes two integers as arguments. The first integer should specify a unique identifier that can be used later to refer to the equilibrium in question. The second integer is an initialisation code 0, 1 or 2:

- Code 1: This means that all components are entered but all phases are suspended. This code is appropriate in most cases.
- Code 0: This means that all components and phases in the equilibrium are suspended initially. This code is needed if you are using experimental data about systems of different orders simultaneously, such as data about both binary and ternary systems for example.
- Code 2: This means that all components and phases are initially entered.

For example, the first command in the example above creates an equilibrium data point with the unique identifier 1. All components of the system are entered but all phases are suspended:

```
CREATE_NEW_EQUILIBRIUM 1 1
```

Setting Equilibrium Conditions and Uncertainty

All the equilibrium-related commands that are placed in between two CREATE_NEW_EQUILIBRIUM commands are interpreted as specifying the conditions of the equilibrium created by the first command. The values of these conditions should be based on the conditions specified in the experiment that you base the equilibrium definition on.

In the example, the CHANGE_STATUS command specifies that the equilibrium is a single-phase equilibrium with the liquid phase.

```
CHANGE_STATUS PHASE LIQUID=FIX 1
```

Furthermore, the temperature is 1379 K, the pressure is 1 bar (1E5 Pa) and the mole fraction of Au is 0.0563.

```
SET_CONDITION T=1379 P=1E5 X(LIQUID,AU)=0.0563
```

Sometimes you have reason to think that some information about an equilibrium condition may not be accurate. If this is the case, then you specify the degree of uncertainty for a condition with a colon after the condition quantity, directly followed by either an absolute value or a percentage. For example, if you have reason to doubt the reliability of the Au mole fraction measurement, then you could write:

```
SET_CONDITION T=1379 P=1E5 X(LIQUID,AU)=0.0563:10%
```

This indicates that you think the Au mole fraction is between 0.0507 and 0.0619. PARROT calculates the equilibrium twice, once for 0.0507 and once for 0.0619, and then computes the change of each experimental value between these two equilibria. This change is used to modify the uncertainty specified for the experimental value.

Entering the Experimental Value and its Uncertainty

The possibility of specifying uncertainties on conditions may be useful when you have experimental data about a ternary system. In a binary system, a tie-line is determined by the two phases, the temperature and the pressure. Measurements of the compositions of both phases can then be used as experimental data. To specify the tie-line in a ternary two-phase equilibrium one of the four compositions must also be set as a condition. If the measurement of this composition has the same uncertainty as the other compositions, then you can assign this same degree of uncertainty both to the composition selected as a condition and the compositions selected as experimental data. Alternatively, the sample (overall) composition could be used as a condition and all four phase compositions could be used as experiment values. These phases must have the status *entered* (not fixed) since the relative amount of each is unknown.

Setting Reference States

If you want to specify a non-default reference state for one or several of your system components, then you do this with the SET_REFERENCE_STATE command. In the following example, the reference states for Au and Cu are set to the liquid phase at current temperature (*) and a pressure of 1E5 Pa.

```
SET_REFERENCE_STATE AU LIQ * 1E5
SET_REFERENCE_STATE CU LIQ * 1E5
```

In order for these reference states to be taken into account, the R suffix must be used when the measurement of the enthalpy per mole of the system is entered for an experiment.

Reference State Suffix R

Suffixes

You can use the reference state suffix R for some thermodynamic variables to calculate their value with respect to a reference state that you have previously set for a system component with the SET_REFERENCE_STATE command in POLY (or in response-driven modules such as the POURBAIX module). The value of energy-related variables that are used with the R suffix depends on the reference states of all the components in the defined system.

It is possible to use an R suffix on all compositional extensive state variables as well, but the value of the state variable is always the same, with or without the suffix.

If the reference state for a system component is the default reference state (the stable reference state (SER) which is defined in a Thermo-Calc database), then MUR(comp)= MU (comp), ACR(comp)= AC(comp) and LNACR(comp)= LNAC(comp).

In the case of some thermodynamic variables, you can also use the R suffix to express chemical potentials and activities of species relative to some single-substitutional-lattice solution

phases (such as aqueous solution, gaseous mixture, metallic liquid solution, slag mixture or MO solid solution). These state variables are MU(sp,ph), MUR(sp,ph), AC(sp,ph), ACR(sp,ph), LNAC(sp,ph) and LNACR(sp,ph).

The reference states and standard states of various solution species are pre-defined for some solution phases in some databases. For all solution species in any solution model in any database, it is always the case that MUR(sp,ph)= MU(sp,ph), ACR(sp,ph)= AC(sp,ph) and LNACR (sp,ph)= LNAC(sp,ph).

Entering the Experimental Value and its Uncertainty

The EXPERIMENT command is used to specify the quantity that the calculated results should be fitted to. When specifying this quantity, you both specify the measured quantity itself and your estimation of the uncertainty of this value.

In the example, the EXPERIMENT command specifies the enthalpy per mole of the system, where this value is specified with respect to non-default reference states that you have set in the equilibrium specification:

```
EXPERIMENT HMR=-1520:200
```

The value before the colon is the quantity of the variable. The value after the colon is an assessment of the uncertainty of this quantity. A higher value means a greater uncertainty. In the example, the uncertainty has been specified with an absolute value but it could also be specified in percent of the quantity:

```
EXPERIMENT HMR=-1520:13%
```

Several experiments can be specified after the experiment command. Besides assigning values to conditions, it is also possible to specify that a certain quantity is greater than or less than a certain value. For instance, the following command would specify that the activity of the C-component is less than 0.01 and the mass fraction of the BCC phase of Ag is greater than 0.05:

```
EXPERIMENT ACR(C)<0.01:0.001 W(BCC,AG)>0.05:10%
```

Note that an experimental quantity can typically also be treated as an equilibrium condition, and vice versa. Which measured quantities that you treat as conditions and which quantities you treat as experimental data should be based on the accuracy of the different measurements. In most cases, the quantity that is based on the experimental technique with the lowest accuracy should be used as the experimental value.

Entering Many Equilibria as a Table

When one thermodynamic variable (e.g. heat capacity) has been measured as a function of another (e.g. temperature), then experimental data is often presented as a table. By using the TABLE_HEAD, TABLE_VALUES, and TABLE_END commands, you can enter such experimental information into the POP file in the form of a table. These three commands should always be used together and must be entered in the right order. See TABLE_HEAD, TABLE_VALUES, and TABLE_END.

The TABLE_HEAD command is followed by a number. This number identifies the table as a whole, but also uniquely identifies the first equilibrium that is included in the table. This numeric identifier is incremented by one for each additional equilibrium in the table. Each row in the table represents one equilibrium. Thus, the equilibrium defined by the first row in the table above (on the line immediately below TABLE_VALUE) is uniquely identified with the number 1, the equilibrium defined by the second row by number 2, and so on until the last equilibrium on the sixth row, which is identified by the number 6.

Since the unique identifiers of the equilibria in the table are automatically generated from the unique numerical identifier that you give to the table, the unique numerical identifier that is normally given to the CREATE_NEW_EQUILIBRIUM command is replaced by two at signs (@@).

At least one of the equilibria conditions specified with the SET_CONDITION command must be a condition whose value is set by the numbers in one of the table columns. To assign the numbers in a column to a condition, use the syntax SET_CONDITION `<condition>=@<column number>`. For instance, in the example above, the mole fraction of X(ALO3/2) is for each equilibrium given by the number in the first column of the table.

At least one of the measured variables that are entered with the experiment command must be a variable whose value is set by the numbers in a table column. To assign the numbers in a column to a measured variable, use the syntax EXPERIMENT `<variable>=@<column number>`. In the example above, the measured temperature for each equilibrium is given by the number in the second table column.

The actual table should be entered between TABLE_VALUES and TABLE_END. Separate the columns with tabs or any number of spaces. The columns do not have to contain numbers, but can also contain other types of values, such as phase names for example. If a column contains text with spaces or special characters, then the text must be surrounded by double quotes (`"ABC DEF&ghi"`, for example). The table may have columns that are not used, but each row must have exactly the same number of columns.

The following block of commands exemplifies how a table can be entered into a POP file:

```
TABLE_HEAD 1
CREATE_NEW_EQUILIBRIUM @@ 1
```

```
CHANGE_STATUS PHASE TETR=FIX 0
CHANGE_STATUS PHASE ION=ENT 1
SET_CONDITION P=101325 N=1 ACR(O2,GAS)=.21 X(ALO3/2)=@1
EXPERIMENT T=@2:5
TABLE_VALUE
0.4608 2476
0.5714 2380
0.6682 2276
0.7496 2176
0.5038 2426
0.6313 2249
TABLE_END
```

Setting Site Fraction Start Values

In some systems, you have to set non-default composition start values on some experiments in order to get them to converge properly during optimization. This may be important if your system has a miscibility gap for example, in which case several equilibria with different compositions exist at certain temperatures. In such cases, you have to make sure it is specified in the POP file which side of the miscibility gap the equilibrium is on. The calculated equilibrium could otherwise end up on the wrong side, resulting in a large error.

In the POP file, you can set the site fraction of a constituent on an equilibrium with SET_START_VALUE.

For example, the following command sets the composition start value of VA constituent of the FCC_A1 phase to 0.99:

```
SET_START_VALUE Y(FCC_A1,VA#2)=0.99
```

Setting the mole fraction for a component in a phase is not as reliable as setting the site fraction.

Additional equilibria entered after the last SET_START_VALUE command are automatically given a similar start value if the following command appears previously in the POP file:

```
SET_ALL_START_VALUES Y
```

If start values are not set automatically for phase constituents, then you may have to set the composition start value for each equilibrium (or table of equilibria) separately.

Commenting About an Equilibrium

The COMMENT command inserts a comment about the equilibrium that is saved to the PARROT workspace file when the POP file is compiled. The comment must be entered on one line.

Comments can also be entered immediately after a dollar sign ($), but these are not saved to the PARROT workspace. Instead, these comments are ignored by Thermo-Calc when the POP file is compiled.

Simultaneous Use of Binary and Ternary Experiments

You can use experimental information about binary and ternary systems (as well as systems of even higher order) in the same POP file and optimization. To do this, you must inform the PARROT module that not all components of the ternary system (or system of even higher order) should be considered. This allows you, for example, to use experimental information about a binary equilibrium that exists within a ternary system.

Use CHANGE_STATUS with the keyword component and which components that should be entered. You should also give the initialization code 0 (rather than 1) to the CREATE_NEW_EQUILIBRIUM command. This code indicates that all components must be entered.

For example, the following set of ED_EXP commands characterises a binary (A-B) three-phase equilibrium (FCC-BCC-LIQ) in a ternary system (A-B-C). It can be used in a POP file that otherwise only contain experimental information about the ternary system (A-B-C):

```
CREATE_NEW_EQUILIBRIUM 1 0
CHANGE_STATUS COMPONENT A B = ENTERED
CHANGE_STATUS PHASE FCC BCC LIQ=FIX 1
SET_CONDITION P=1E5
EXPERIMENT T=1177:10
COMMENT from A-B
```

Using Stability Conditions

Early in the optimization when parameter values are not so good it is often useful to set the driving force for precipitation of a phase (per mole of components) to make sure that it appears where it should. The DGM condition is very useful for making sure that phases appear where they should. It can be removed when the optimization becomes stable.

The DGM condition is also useful for suppressing phases that appear where they should not appear. Do this by setting the value and the uncertainty to something reasonable. For example, the driving force for precipitation of the BCC phase could be set as follows:

```
DGM(BCC)<-0.1:0.1
```

This produces an error even before BCC becomes stable and the weight of the experiment in question can be adjusted as needed. If you specify that the driving force for the BCC phase should be below 0 (DGM(BCC)<0:1E-4 for example), then the optimization converges extremely slowly (if at all). With such a sharp error condition, calculating the equilibrium is like finding the minimum point on a lawn that gently slopes towards a rock wall. The optimization keeps bouncing into the wall.

Another useful stability condition is the phase stability function, abbreviated QF. This can be used to specify that a phase is outside the miscibility gap for a solution phase. If QF(phase) is negative, then the phase is inside the miscibility gap; if QF(phase) is positive, then it is outside the miscibility gap.

Grouping Equilibria with Labels

If you have several equilibria describing experiments that you want to be able to treat collectively, you can give all of the equilibria one and the same label.

Use LABEL to give an equilibrium a label. The label must start with the letter A and can only be up to four characters long. For example, you can insert the following command in several equilibria specifications:

```
LABEL ALH
```

During the optimization, you could use this label to, for example, set all the equilibria that have it to the same weight in the ED_EXP module.

Dividing the POP File into Several Blocks

For two different reasons, you may have to divide your POP file into different blocks:

- PARROT uses a buffer for storing compiled experimental data. If there is not enough memory in this buffer for storing all the experiments from the POP file, then the POP file can be divided into several blocks. When PARROT encounters the end of a POP file block, it saves the experimental data that has been compiled to PARROT workspace, clears out the memory buffer and then proceeds to read the next block in the POP file. This goes on until the experimental data from all the blocks have been saved to the PARROT workspace.
- If you want to put equilibria with different sets of components in one and the same POP file, then you must divide the file up into blocks. Each block should only contain equilibria that all have the same set of components.

To divide the equilibria in the POP file into different blocks, enter the FLUSH_BUFFER command between two equilibria. This command marks the beginning of new block. When the command is encountered during the compilation of the POP file, the compilation of the current block is terminated, the equilibria saved to the PARROT workspace file and a new block is initiated. That the buffer is reinitiated means that all functions and constants that were entered in the previous block must be entered again in new block in order to be used.

When editing your experimental data in the ED_EXP module, you can select which block to load and edit using READ_WORKSPACES `<block number>`. The block before the first instance of FLUSH_BUFFER is block number 1, the block after the first instance and before the second instance is block number 2, and so on.

The Setup File

Initializing Optimizing Variables in PARROT **1387**

Creating the Workspace File **1388**

Compiling the POP File **1389**

Returning Control to the Console **1390**

Creating the Setup File

The second step is to create the setup file. This is an ordinary Thermo-Calc macro file (*.TCM). Typically, your setup file should contain the following:

- A system definition.
- A section where you enter model parameters and optimizing variables.
- A GO PARROT command.
- A section where initial values are assigned to the optimizing variables for the first optimization cycle.
- A CREATE_NEW_STORE_FILE `<filename.par>` which creates the PARROT workspace file onto which the results of your optimization are continuously saved and updated. By default this workspace file has the same filename as the setup file, but with the *.PAR filename extension.
- A COMPILE_EXPERIMENTS `<filename.pop>` command. Since you often encounter syntax errors when you first try to compile a POP file, it may be useful to execute this command from the console rather than as part of the setup macro file.
- Normally, you also have a SET_INTERACTIVE at the end of the setup file. This command returns control over Thermo-Calc to the console.

It is possible to interactively execute all these commands one at a time in the console. It may be instructive to enter the commands that would normally go into the setup file interactively while using the on-line help while you are learning to use the PARROT module.

Defining the System

If you have an existing database with information about your system, then you can write the system definition part of your setup file in two different ways.

- If you have an unencrypted user database, then you can define your system by entering DATA module commands directly in the setup file. Use the DATA commands that you normally use to define a system when doing equilibrium calculations in Thermo-Calc Console Mode.
- Define your system by entering DATA module commands directly in the console, then generate a macro file with the GIBBS command LIST_DATA `<name of setup file>.tcm p` . This command saves all the data that has been loaded in the GIBBS workspace as a macro file. This file can then be modified as required into an optimization setup file.

Creating Additional Composition Sets of a Phase

If you need several composition sets of a phase, then these should be created with the GIBBS command AMEND_PHASE_DESCRIPTION `<phase name> composition_sets <composition set number>` in the setup file.

If you add composition sets of a phase after the POP file has been compiled, the data structure in the workspace is corrupted and you have to recompile the POP file.

Entering the Optimizing Variables

When you have retrieved the data about your system for the setup file, you must manually enter the model parameters that you want to optimize. This is done using the GIBBS command ENTER_PARAMETER, but when you specify the Gibbs energy expression for the parameter, you enter variables that can be given various values into the expression. It is the values of these variables (and thus, the Gibbs energy of the parameter) that you are optimizing.

How you in detail specify the optimizing variables in your set up file depends on which phase you are trying to optimize and what thermodynamic model that is used in the optimization.

Entering Optimizing Variables in Parameter Specifications

There are ninety-nine predefined variables in the PARROT module which you can use in your optimization. These variables are referred to as `V1`, `V2`, `V3`, … `V98` and `V 99`. When the GIBBS workspace is initialized, all optimizing variables are set to a fixed numerical value of zero. When you do an optimization, there is always some variable for which you want to evaluate the best value, but you can assign fixed values to optimizing variables too. It is often useful to enter all the variables that you can conceivably want to optimize, and then you can interactively select and change which variable to focus at various stages of the optimization.

The setup file excerpts that follow show how optimizing variables are entered. However, before the optimizing variables are introduced in this example, the following command enters an ionic liquid solution phase (a phase for which you have some experimental information):

```
ENTER_PHASE IONIC_LIQ Y,
AL+3,ZR+4 ; ALO2-1,O-2 ; N N
```

This ENTER_PHASE command enters a phase called IONIC_LIQ into the GIBBS workspace. This phase is of the type ionic liquid solution, which is specified by type code `Y`. Such a phase is modeled by the *Ionic Two Sublattice Liquid Model*. The next two arguments specify the two sublattices, in this case the cations AL+3,ZR+4 and the anions ALO2-1,O-2. Components that interact in a sublattice are separated by a comma. The first `N` at the end means that no additional constituents are added to the phase. The second `N` means that a list of possible parameters for the phase should not be shown in the console.

There are model parameters that describe the phase which you do not want to optimize, in which case the Gibbs energy expression of the parameter does not contain any optimizing variables.

Example 1

For example, the following parameters of the IONIC_LIQ phase do not contain any optimizing variables:

```
ENTER_PARAMETER G(IONIC_LIQ,AL+3:ALO2-1;0) 298.15 +2*GAL2O3_L; 6000 N
ENTER_PARAMETER G(IONIC_LIQ,AL+3:O-2;0) 298.15 +GAL2O3_L+400000; 6000 N
ENTER_PARAMETER G(IONIC_LIQ,ZR+4:O-2;0) 298.15 +2*GZRO2L; 6000 N
```

These parameters define the Gibbs energy expressions for three constituents in the constituent array, namely AL+3:ALO2-1, AL+3:O-2 and ZR+4:O-2. The names that occur in these expressions—that is, GAL2O3_L and GZRO2L—are the names of complex functions of temperature that are entered in the GIBBS workspace with the ENTER_SYMBOL command.

The numbers that frame the Gibbs energy expressions specify the temperature range within which the expression should be applied. In the above, the expressions are applied in a temperature range from 298.15 K to 6000 K.

Example 2

In this example, suppose that you want to optimize the model parameter for the ZR+4:ALO2-1 combination, then you could enter the variables V1 and V2 in the Gibbs energy expression for that parameter in the following way:

```
ENTER_PARAMETER G(IONIC_LIQ,ZR+4:ALO2-1;0) 298.15 +GZRO2L +2*GAL2O3_L
+V1+V2*T; 6000 N
```

You normally have different optimizing variables in different parameters, but in some cases you may want several parameters to vary together, in which case you can use the same variable in the Gibbs energy expressions of several parameters.

Entering Interaction Parameters

For some systems, you have to consider interaction parameters in order to take excess Gibbs energy into account and correctly model the phase. By default, the software uses a Redlich-Kister expression for the excess Gibbs energy. The coefficient is entered after the constituent array when you use the ENTER_PARAMETER command. In the last section, all the parameters were entered with a coefficient of zero (0).

To take account of the excess Gibbs energy, you might enter the following:

```
ENTER_PARAMETER L(IONIC_LIQ,ZR+4:ALO2-1,O-2;0) 298.15 +V11+V12*T; 6000
N

ENTER_PARAMETER L(IONIC_LIQ,ZR+4:ALO2-1,O-2;1) 298.15 +V13+V14*T; 6000
N

ENTER_PARAMETER L(IONIC_LIQ,ZR+4:ALO2-1,O-2;2) 298.15 +V15+V16*T; 6000
N
```

Parameters with interaction coefficients are referred to as *interaction parameters*. The regular parameter has a coefficient of 0. The subregular parameter has a coefficient of 1. It is possible to interaction coefficients up to a value of 9, but you are advised not to use more than three coefficients (that is, with coefficient values of 0, 1 and 2).

Initializing Optimizing Variables in PARROT

Variables that have been entered into Gibbs energy expressions for model parameters in the setup file have to be initialized and given start values before they are optimized.

You have to estimate what start values to give to the optimizing variables based on your knowledge of the system or of relevantly similar systems. There are no general rules for what start values your optimizing variables should have. If you are not able to make any informed estimation about what start values to use, then you may not be able to find a good fit between your experimental data and your calculated results. In this case, it is often best to start the optimization in the so-called alternate mode. In alternate mode, the PARROT module helps you find some reasonable start values for your optimizing variables.

About Alternate Mode

Even if you are starting your optimization in alternate mode, you still have to initialize the optimizing variables though (you can all give them a start value of 0).

To initialize an optimizing variable and to give it a start value, use either SET_OPTIMIZING_VARIABLE or SET_SCALED_VARIABLE. Using SET-OPTIMZING_VARIABLE results in a scaling factor equal to the current value of the parameter unless the current value is zero, in which case the scaling factor is 1000. This is typically appropriate for enthalpic parameters, but not necessarily for other parameters. The scaling factor is the factor by which the optimizing variable value is varied during the optimization.

For example, if you want to optimize the variables V1, V2, V11, V13 and V17, then you could enter the following in the setup file:

```
SET_OPTIMIZING_VARIABLE 1 +43000
SET_OPTIMIZING_VARIABLE 2 -35.2
SET_OPTIMIZING_VARIABLE 11 +72000
SET_OPTIMIZING_VARIABLE 13 +27000
SET_OPTIMIZING_VARIABLE 17 -100000
```

The value given to each optimizing variable (+43000 for variable V1 for example) is also that variable's initial scaling factor. If you want to set the initial scaling factor of a variable to a value that is lower or higher than its start value, then use SET-SCALED_VARIABLE `<start value><scaling factor><min value><max value>`.

Creating the Workspace File

In the setup file, after the system definition and the entered optimizing variables, use the PARROT command CREATE_NEW_STORE_FILE to create and save a PARROT workspace file for the system defined in the setup file. For example, the following command saves all current data on system definitions (elements, species, components, phases), symbol definitions (constants, variables, functions, tables) and parameters that are stored in the workspace used by GIBBS, POLY and PARROT into a file called AL2O3-ZRO2.PAR:

```
CREATE_NEW_STORE_FILE AL2O3-ZRO2
```

The experimental information in the POP file is not saved to this PARROT workspace file.

Compiling the POP File

At the end of the setup file, use the command COMPILE_EXPERIMENTS followed by the name of your POP file to compile the data in that file and save it to the current PARROT workspace file. Note that you must first have opened or created a new PARROT workspace file before you compile your POP file. The other argument to the command can typically be given default values with comma signs (,):

```
COMPILE_EXPERIMENTS AL2O3-ZRO2.POP,,,
```

If Thermo-Calc encounters errors in the syntax of the POP file, then error messages are displayed in the console. Normally, the compilation also stops when syntax errors are encountered. If this happens, then you must correct the errors and recompile the file. It is useful to have two console windows open when you do this. That way, you can use one console for editing the experimental data and another console for compiling and reading any further error messages.

Returning Control to the Console

Put the command SET_INTERACTIVE at the end of the setup file if you want to return control to the console when the commands in the setup file have all been executed.

Optimizing the System in PARROT

When you have created a POP file, a setup macro file, and (optionally) EXP files, you should start doing optimization runs interactively in the console. This process can be divided into a number of steps (such as running optimization, evaluating optimization results, modifying weights and models and adding new information), but usually, you have to go through many optimization cycles before achieving a satisfactory fit between calculation results and experimental data.

Typically, it is not obvious when an optimization is finished. You must exercise your judgment about when the fit you have achieved is good enough.

It is possible to interactively change almost everything in the initial setup macro file and in the POP file. For example, you can add more parameters to be optimized and modify or add more experimental information.

Changes that Require POP File Recompilation

Some changes that you do interactively in the PARROT module or the ED_EXP sub-module destroys the data structure in the workspace. For example, if you add more composition sets to a phase, then the number of phases actually change and the links break between the experimental data and the thermodynamic models. Note that if the global minimization technique is used in POLY, then new composition sets that corrupts the PARROT workspace may be created automatically. If this happens, then you have to compile the POP file again.

If you recompile the POP file, then the experimental equilibria are calculated with the default start values.

Optimization Workflow

Normally, the workflow during an optimization is the following:

1. In the PARROT module, run the setup macro file using MACRO_FILE_OPEN.
2. Go to ED_EXP with EDIT_EXPERIMENTS, use READ_WORKSPACES to load your experimental data and then execute .
3. If an equilibrium cannot be computed, then this either means that the start values (site fractions, for example) were inappropriate or that the equilibrium cannot be calculated with the current set of parameters. If the latter, then the equilibrium may have to be excluded from the optimization. However, you should make an effort to exclude the possibility that the reason is just that you do not have the appropriate start values for the equilibrium.
4. When each equilibrium is either successfully computed or excluded from the calculation, go back to the PARROT module and run the OPTIMIZE_VARIABLES command. Give the number of optimization iterations you want the Thermo-Calc program to carry out as an argument to the command. This number specifies how many different sets of values for the optimizing variables that PARROT tries to fit with the experimental data. It is recommended that you run `0` iterations first to see the discrepancy between the experimental data and the initial calculated results. The current workspace file is automatically updated with the last set of optimized variables and calculated results.
5. List and evaluate the result of the optimization using LIST_RESULT. Typically, what is of interest in the results are the relative standard deviation of the optimizing variables and the error values in the list of calculated experimental data results. If the relative standard deviation for an optimizing variable is very large, this means that the variable doesn't have any effect on the computed results and that the variable should not be used (you can make PARROT ignore the variable by setting its value to `0` with SET_FIX_VARIABLE). If the relative standard deviation is close to zero for a variable, then this might indicate that you need to use more variables. When it comes to errors in the calculated equilibrium results, these can be decreased by lowering the weight that PARROT gives the experiment in the calculation (the more weight, the more the experiment affects the calculated results).
6. Use OPTIMIZE_VARIABLES or CONTINUE_OPTIMIZATION to carry out a new optimization cycle. Go back to step 5 above and continue to do optimization cycles until you judge that there is a good enough fit between your calculated results and your experimental data. It is recommended that you do not only rely on feedback from LIST_RESULT but also frequently plot various diagrams and compare them visually to some of your experimental data.

Ensuring Computation of all Equilibria

When you have run the setup macro file, you should start by trying to compute all the equilibria that were created when your POP file was compiled. To do this, you must first go to the ED_EXP submodule, and load the experimental data from the current PARROT workspace file with the READ_WORKSPACES `<block #>` command (normally, the block number is `1`).

When you have loaded all equilibria, you should try to compute them all using the ED_EXP command . A list of calculated equilibrium results are shown in the console, but the software is not able to reach an equilibrium for an experiment, then the program cancels the calculations and displays an error message.

The following list shows an example output where the first two experiments in the POP file have been successfully computed, but an equilibrium is not reached for the third experiment. No other equilibria are computed, since the calculations are aborted when the error occurs.

```
Eq Lab Iter Weight Temp  Exp Fix phases or comments
1 A1   22  1.   2575.3     IONIC_ FLUORI TETR
2 A1   18  1.   2156.9     IONIC_ CORUND TETR
 *** ERROR 1614 IN QTHISS
 *** CONDITIONS CAN NOT BE FULLFILLED
```

When this happens, try to find out why the equilibrium calculation fail. Are the condition start values that you have given the equilibrium inappropriate for example? If you have a similar equilibrium that has already been successfully computed, then you can select the equilibrium that does not work, use the ED_EXP command SET_ALL_START_VALUES and accept all the suggestions for the site fractions. Alternatively, use TRANSFER_START_VALUE `<equilibrium number>` to make the currently selected equilibrium inherit the start values of the indicated equilibrium. Run COMPUTE_EQUILIBRIUM again to see if the equilibrium can be computed with the inherited start value.

If you cannot find an explanation of why the equilibrium cannot be computed, then it may be that the experiment is faulty. If so, then this experiment should be excluded from the optimization by being given a weight of 0. You should then run COMPUTE_EQUILIBRIUM again to make sure that all equilibria can be computed. However, experiments that fail to reach equilibria could succeed in doing so if the optimizing variables have other values. It is therefore sometimes worth trying to include experiments later in the optimization process (when the optimizing variables are relatively close to their final values), even if they had to be excluded at its start. In some cases, it might also be appropriate to change the error tolerance for in an experiment (using the ED_EXP command EXPERIMENT).

You must save the PARROT workspace with SAVE_WORKSPACES before you exit the ED_EXP module.

Setting Weights

To change the weight of an experiment, first enter the ED_EXP module from PARROT using EDIT_EXPERIMENTS. Then use the SET_WEIGHT command to set the weight for a specific equilibrium (equilibrium number `3` for example), for a range of equilibria (the equilibria `10-19`) or all the equilibria that have a certain label (such as all the equilibria with the label `A1`). To save the new weight(s), use SAVE_WORKSPACES .

By default, all the experimental information in your POP file is treated equally: each experiment has a weight of `1`. However, experiments that you excluded because they did not reach equilibrium now have a weight of `0`. The higher the weight of an experiment is, the more Thermo-Calc tries to ensure that the computed result fits the condition measured in that experiment.

The contribution of an experiment's error to the sum of errors is multiplied by the square of the weight set for that experiment. In other words, if you want to cut the error of an experiment with weight 1.0 by half, then you should use a weight of 0.7. This makes the experiment's error 0.49. Setting the weight to 1.4 instead makes the error twice as large (1.96).

Note that if you use READ_WORKSPACES after you have changed weights on the experiments, your changes are lost unless you have saved those changes. In the ED_EXP module, you can get a list of all the experiments in the console if you first read the experimental data from the workspace file (with READ_WORKSPACES) and then use LIST_ALL_EQUILIBRIA.

Optimizing and Evaluating Results

When you have ensured that all the experimental data points can reach equilibrium, go back to the PARROT module and use OPTIMIZE_VARIABLES `<number of iterations>` with `0` iterations. Present the result of this initial optimization by using LIST_RESULT.

When evaluating the optimization results, the most important information is found in the list of experiments at the end of the listed results. The rightmost column shows the difference between the value of the experimental data and the value computed by Thermo-Calc in the last optimization cycle.

The following shows part of list of experiments in the output of a LIST_RESULT command:

```
106 ACR(B)=0.34                0.3127      2.89E-02 -2.7282E-02 -0.9444
107 ACR(B)=0.23                0.2085      2.89E-02 -2.1522E-02 -0.7450
108 ACR(B)=0.12                0.1042      2.89E-02 -1.5761E-02 -0.5455
110 HMR(LIQUID)=-1964          3.6380E-12  5.00E+02   1964.      3.928

117 HMR(LIQUID)=-3481         -1.8190E-12  5.00E+02   3481.      6.962    *
118 HMR(LIQUID)=-1950           0.000      5.00E+02   1950.      3.900

PARROT:
```

The experiments for which the optimization has not found a good fit are marked with an asterisk (*) or a hash sign (#) in the rightmost column. An asterisk in this column indicates that the experiment has an error that is larger than the error tolerance and a hash sign indicates that the error is much larger. The error tolerance depends on the degree of accuracy set for that particular piece of experimental information. The error values are presented in the next to rightmost column.

Note that if you are optimizing in *alternate mode*, then you usually do not need to change the weights for the experiments. Instead, you can simply run OPTIMIZE_VARIABLES again, specifying, say, thirty iterations, evaluate the results again, and continue in that way until you are satisfied with the results.

About Alternate Mode

Critical Set of Experiments

The set of weighted experiments that you end up with as a result of your optimization is referred to as the *critical set* of experiments. When you work to determine this set and the weights of the experiments, the following factors should be reflected in both the selection of experiments and the weights of those experiments:

- The reliability of the experimental technique.
- The extent of agreement/disagreement between independent measurements of the same quantity.
- The extent of agreement/disagreement between data obtained with different experimental methods.

Continuing the Optimization and Resetting Variables

To continue the optimization after you have used OPTIMIZE_VARIABLES, you can either use this command and enter `<Number of iterations>` again or CONTINUE_OPTIMIZATION `<Number of iterations>`.

If you use CONTINUE_OPTIMIZATION, then PARROT continues the optimization using the same Hessian matrix. If the optimization is going well but you run out of iterations, then continuing with the same Hessian matrix may be useful.

As before, use LIST_RESULT to inspect the fit between the calculated and the experimental values for your experiments. If necessary, adjust the weights of the experiments again in the ED_EXP module. You may even discover that you have to exclude additional experiments from the optimization.

Besides looking at the rightmost column in the list of experiments (that is produced when you use LIST_RESULT), it is also useful to look at the *sum of squares* of the errors of all the variables. This is shown in the output of OPTIMIZE_VARIABLES and CONTINUE_OPTIMIZATION. This sum should be as low as possible.

The following shows part of the output that you get when using LIST_RESULT:

```
== OPTIMIZING VARIABLES ==

AVAILABLE VARIABLES ARE V1  TO V00

VAR.   VALUE             START VALUE       SCALING FACTOR    REL.STAND.DEV
V1      6.94641846E+05    4.30000000E+04    4.30000000E+04    1.42299558E+00
V2     -3.32619842E+02   -3.52000000E+01   -3.52000000E+01    7.91369573E-01
V11     8.37422071E+04    7.20000000E+04    7.20000000E+04    2.02212692E-01
V13     2.65253341E+04    2.70000000E+04    2.70000000E+04    1.45201828E-01
V17    -3.66637428E+05   -1.00000000E+05   -1.00000000E+05    8.04279315E-01

NUMBER OF OPTIMIZING VARIABLES :   5
ALL OTHER VARIABLES ARE FIX WITH THE VALUE ZERO
THE SUM OF SQUARES HAS CHANGED FROM   3.50196879E+05 TO   3.49096720E+05
DEGREES OF FREEDOM   14.  REDUCED SUM OF SQUARES   2.49354800E+04
```

In the example you can see that the sum of squares have decreased slightly. (The final sum of squares that you get after an optimization run is also presented directly in the output from OPTIMIZE_VARIABLES and CONTINUE_OPTIMIZATION.) As long as the sum of squares figure is decreasing, the optimization is working as it should.

When your calculated results have been improving for a while, that is, when the sum of squares has been decreasing, and you are confident that you are making definitive progress, then you should use the PARROT command RESCALE_VARIABLES to reset the starting values of

the optimizing variables to their current values. When you do this, the start values and scaling factors of the optimizing variables (shown in the table's third column in the preceding screen shot), are all set to the current values (shown in the table's second column).

If your optimization is not going well, then you may want to reset the values of your optimization variables to their current start values. To do this, use RECOVER_VARIABLES.

After rescaling the variables, continue the optimization using OPTIMIZE_VARIABLES again. Cycle through calls of the commands OPTIMIZE_VARIABLES/CONTINUE_OPTIMIZATION, CONTINUE_OPTIMIZATION, RESCALE_VARIABLES and OPTIMIZE_VARIABLES again until your set of optimizing variables does not seem to improve anymore. Even when it seems to you that you have reached this point, it is recommended that you use OPTIMIZE_ VARIABLES/CONTINUE_OPTIMIZATION a few extra times to make sure that the variable values cannot be further improved, that is, that the sum of squares of the errors of all the variables cannot be reduced further. If the final solution is repeatedly calculated after the same number of iterations and reaching the same result, then it is generally reasonable to accept the current variable values.

Updating the Set of Optimizing Variables

Besides evaluating the fit between the calculated results and the experimental data, you should also ensure that you have the right number of optimizing variables. If you have too many or too few optimizing variables, then you may not be able to use your model to accurately extrapolate thermodynamic properties in a wide range of temperature, pressure and composition conditions.

With more optimization parameters, the sum of errors usually decrease, but the parameters also tend to become less precisely determined. A measure of this precision is the Relative Standard Deviation (RSD) of each optimizing variable. However, the RSD is only significant if you have used RESCALE_VARIABLES followed by an optimization which converges and the values of the variables do not change much. The RSD tells you how much the parameter can be changed in either a positive or in a negative direction without changing the reduced sum of errors with more than one unit.

A large RSD value thus means that the parameter has not been determined well.

```
== OPTIMIZING VARIABLES ==

AVAILABLE VARIABLES ARE V1  TO V00

VAR.   VALUE             START VALUE       SCALING FACTOR    REL.STAND.DEV

V20    -6.72498276E+00   -6.31334932E+00   -6.31334932E+00    1.79242248E+00

NUMBER OF OPTIMIZING VARIABLES :   7
ALL OTHER VARIABLES ARE FIX WITH THE VALUE ZERO
THE SUM OF SQUARES HAS CHANGED FROM   1.51360340E-01 TO   1.44420287E-01
DEGREES OF FREEDOM   18.  REDUCED SUM OF SQUARES   8.02334928E-03
```

If such a significant RSD has a value larger than 1, then this typically means that you are using too many optimizing variables. However, the RSD values also depend on the weighting of the experiments, so it is sometimes possible to reduce the RSD by changing weights.

The RSD should not be too low either. If one or more of them is very close to 0, then this suggests that you are trying to optimize the system with too few optimizing variables. You can add optimizing variables interactively using ENTER_PARAMETER in GIBBS. However, it is

recommended that you add a sufficient number of variables in the setup file from the start so that do not need to do this. You can fix variables to a value of 0 until you discover that they are needed.

Besides the RSD, you should also keep an eye on the variable values themselves (shown in the VALUE column, next to the leftmost column in the table shown in the preceding screenshot). If the value of a variable is in the order of 1E5 or higher and this variable has been put in the temperature-independent part of an interaction parameter's Gibbs energy expression, then you may not have the right weights on your experiments or you are using too many optimizing variables. This is also typically the case if a variable with a value in the order of 10 or more (per mole atoms) is in the temperature-dependent part of the Gibbs energy expression of an interaction parameter. Such a high parameter value may lead to inverted miscibility gaps or re-stabilisation of a phase at high temperature. It is important to keep an eye on this since the temperature-independent and the temperature-dependent interaction parameter often varies together. If the temperature-dependent interaction parameter cannot be reliably determined, you may have to fix its value.

Note that even if you have found a good enough fit between calculated and experimental values after an optimization run, a parameter value may suddenly start to change by several orders of magnitude when you use OPTIMIZE_VARIABLES is used again. If this happens, then careful reconsideration of the weighting of the experiments of the set of optimizing variables is required. However, when the optimization has converged and the parameter values remain stable after repeated use of OPTIMZE_VARIALBES, this should usually not happen.

Reducing the Number of Optimizing Variables

If you have one or more optimizing variables with RSD larger than 1, then you should remove one or more of the variables by setting them to a value of 0, or alternately, set them to a reliably estimated value (estimated based on, for example, semi-empirical methods).

To fix an optimizing variable to certain value, use the PARROT command SET_FIX_VARIABLE `<variable number> <value>`.

Plotting Intermediate Results

It is typically not sufficient to look at the plain text output of LIST_RESULT to reliably judge how the optimization is progressing. Plotting a phase or property diagram of the system you are optimizing using the POLY and POST modules is often very useful.

It is recommended that you create a macro file for plotting the diagram since you probably want to repeatedly plot the diagram as you progress with the optimization. This macro file can then be called directly from the PARROT module with the MACRO_FILE_OPEN command.

Superimposing Experimental Data from EXP Files

If you create one or several EXP files based on the experiments in your POP file, you can visually compare the fit your plot and the experimental data you are optimizing the system against. An EXP-file contains data points specified in the DATAPLOT format. You could make an EXP-file for each type of data that you are using in the optimization.

Use the POST command APPEND_EXPERIMENTAL_DATA to superimpose the data points in an EXP-file on a phase or property diagram that you have plotted. For example, to put the experimental data points from a file entitled DP.EXP onto a plotted diagram, you could enter the following:

```
APPEND_EXPERIMENTAL_DATA Y DP.EXP 0 1
```

Such a command call tells Thermo-Calc to superimpose the data points in dataset 1 of DP.EXP onto the plot in the Console Results window, but not to impose any information about axis scaling, labels and other information which is normally found in the prologue of the DP.EXP file.

The POST command QUICK_EXPERIMENTAL_PLOT can also be used to superimpose data points on a plotted phase or property diagram.

Finalizing the Optimization

Updating the Database File **1410**

Creating a Database File **1411**

Updating the Setup File and the POP file **1412**

Finishing the Optimization

When to stop optimizing is a matter of judgment. It is rarely the case that you finish optimizing a system with the feeling that it cannot be improved.

The final step is to update your files with the final results. Besides updating your database file (or alternatively, creating a new database file), it is advised that you also update your setup and POP files with the final weights and optimizing variable values.

Rounding off Optimizing Variable Values

When you save the optimizing variable values, it is important that you round off the values correctly. When you have a metallic system, it is usually best to keep whatever number of decimal digits that you need to make less than one J/mol difference at 1000 K. When you have an aqueous system or a system that you are optimizing based on data from very different temperature ranges, then this is not always the only appropriate guideline. However, rounding off the values in such a way that it gives a difference that is larger than one J/mol may lead to differences in the phase diagram.

Another approach you can take when rounding off variable values is by progressively fixing the value of more and more of the variables. This allows you to round-off all but one of the variables values so that each only has a few significant digits. Variables whose values have been rounded off in this way are easier to handle compared with those that that are rounded off so that they continue to have many significant (non-zero) digits.

To round off the variable values according to this second approach, first use SET_FIX_VARIABLE to set the variable(s) with the highest RSD to a rounded off value (such as, say, 0.4). When you then re-optimize using OPTIMIZE_VARIABLES, the sum or errors changes. However, you should get almost exactly the same sum of errors as before after you rescale the variable values using RESCALE_VARIABLES. (If the sum of errors is different, then this means that the variable with the highest RSD was not rounded off in a good way.) If you successfully round off the first variable value, then continue to round of the optimizing variable which now has the highest RSD. Continue doing this until you have fixed all but one of the optimizing variables to their rounded-off values. The final sum of errors that you get after having fixed the variable values should not deviate significantly from the initial sum of errors you had before starting to round-off the variable values.

Updating the Database File

About the Database Files

To update the database file (with filename extension TDB) open it in a text editor and enter or update each of the parameters that you have optimized.

For example, suppose you have the following command in your setup file:

```
ENTER_PARAMETER L(IONIC_LIQ,AL+3,ZR+4:O-2;0) 298.15 +V17; 6000 N
```

If you then end up with a value for optimizing variable V17 of -100000, then you should enter the following under the IONIC_LIQ phase in the database file:

```
PARAM L(IONIC_LIQ,AL+3,ZR+4:O-2;0) 298.15 -100000; 6000 N REF !
```

If you often need to round-off the optimizing variable value in some way, see Rounding off Optimizing Variable Values.

When you have updated or entered the parameters that you optimized, save the database file.

Creating a Database File

In some circumstances you may want to save all the information about your system into a new database file. To do this, go to the GIBBS module and use LIST_DATA `<Filename> N`. This creates a new user database file that contains all the information about the system that is in the workspace.

The N-argument tells the LIST_DATA command to save the output into database file rather than some other type of file, such as a macro file for example. Note that the output database file that you get from LIST_DATA have to undergo some manual editing before it can be used as proper database file.

Updating the Setup File and the POP file

It may be useful for you to be able to recreate your optimization from scratch. It is therefore recommended that you do the following when you are done with the optimization:

- Update your POP file so that it contains the weights of your critical set of experiments. Use SET_WEIGHT to set the weights directly in the POP file. You may also have to use SET_START_VALUE for some conditions in the POP file. Otherwise, you may not be able to compute the equilibria with .
- Copy the final values of your optimizing variables and set them as start values of the variables in the setup macro file (with SET_FIX_VARIABLE).

It is important to round off the values of the optimizing variables correctly. See Rounding off Optimizing Variable Values. When you have done this, you can run the setup macro file to recreate the final result of the optimization.

Alternate Mode

Topics to Explore >

About Alternate Mode **1414**

Optimizing in Alternate Mode **1415**

Preparing the POP File for Alternate Mode **1416**

Examples of SET_ALTERNATE_CONDITION **1417**

Composition of One Side of a Binary Tie-Line *1417*

Compositions of a Three-Phase Equilibrium *1417*

Composition of a Stoichiometric Phase *1417*

Entering Other Experiments in the POP with Alternate Mode *1418*

About Alternate Mode

To turn ALTERNATE_MODE ON or OFF, use the PARROT command SET_ALTERNATE_MODE.

When you have one or more multiphase equilibria (that is, with the fixed phase-status) in your POP file and the optimizing values lack appropriate starting values (such as the default value of 0 for example), then Thermo-Calc may not be able to compute the equilibria for the experiments. In these cases, a common tangent cannot be found, that is, a state where the chemical potentials for all components are the same in all phases cannot be found. A common tangent may not exist or it be found at the wrong composition or temperature given the initial set of model parameters.

If you are not able to estimate reasonable starting values for the optimizing variables, then this problem can be overcome by initially running your optimization in alternate mode. The alternate mode in PARROT module should help you find reasonable starting values for the optimizing variables. Note that you are only supposed to use alternate mode in the beginning of the optimization. Once you have achieved a reasonable fit between calculated results and experimental data, turn off alternate mode and calculate all equilibria again in the normal mode.

In alternate mode, PARROT modifies multiphase equilibria so that the chemical potentials for each stable phases is calculated separately. For example, consider the following experimental equilibrium:

```
CREATE_NEW_EQUILIBRIUM 1 1
CHANGE_STATUS PHASE LIQ FCC=FIX 1
SET_CONDITION T=1000 P=1E5
EXPERIMENT X(LIQ,B)=.2:.01 X(FCC,B)=.1
```

When PARROT optimizes in alternate mode, the computation of this equilibrium is done by way of the following two calculations:

```
CHANGE_STATUS PHASE LIQ=FIX 1
SET_CONDITION T=1000 P=1E5 X(LIQ,B)=.2
CHANGE_STATUS PHASE FCC=FIX 1
SET_CONDITION T=1000 P=1E5 X(FCC,B)=.1
```

The difference between the chemical potentials in every pair of phases is calculated and PARROT tries to adjust the parameters of the phases so that these differences are minimized. In other words, PARROT tries to make the chemical potentials equal in all phases. For PARROT to be able to do this, some additional information about the experimental multiphase equilibria is required, at least for all invariant equilibria.

Optimizing in Alternate Mode

When you are optimizing in the alternate mode, you usually do not need to enter the ED_EXP module and manually change the weights of experiments that the computed results have not been fitted well with. Instead, after using OPTIMIZE_VARIABLES initially with no iterations, and listing the result with LIST_RESULT, simply run OPTIMIZE_VARIABLES again specifying, say, thirty iterations. Continue to optimize until your optimization seems to be going in the right direction, then set the optimizing variables' starting values to their current values use RESCALE_VARIABLES before you turn alternate mode off by answering N at the SET_ALTERNATE_MODE prompt.

Preparing the POP File for Alternate Mode

Information in your POP file that concerns equilibria with ENTERED or DORMANT phases is ignored when you optimize in alternate mode.

To use the alternate mode, ensure that there is enough information about each phase in a given equilibrium. In addition to the temperature and pressure of the system, you should specify the composition of all phases in a given equilibrium. This is done with, SET_CONDITION, EXPERIMENT, or SET_ALTERNATE_CONDITION.

If both compositions of a binary tie-line have been measured, then you could specify this in the POP file in the following way:

```
CREATE_NEW_EQUILIBRIUM 1 1
CHANGE_STATUS PHASE FCC BCC=FIX 1
SET_CONDITION P=1E5 T=1000
EXPERIMENT X(BCC,B)=.2:.01 X(FCC,B)=.3:.01
```

This equilibrium could be calculated with alternate mode without any modification. The compositions specified with the experiment command is used as condition when the thermodynamic properties of each phase are calculated.

Examples of SET_ALTERNATE_CONDITION

The following topics demonstrate how SET_ALTERNATE_CONDITION is used to prepare different kinds of equilibria for optimization in alternate mode.

Composition of One Side of a Binary Tie-Line

If only one side of the tie-line has been measured, then you must provide an estimate of the composition of the other phase. You can make such an estimate with SET_ALTERNATE_CONDITION. This command has no effect unless alternate mode is turned on. The equilibrium described could thus be specified in the following way:

```
CREATE_NEW_EQUILIBRIUM 1 1
CHANGE_STATUS PHASE FCC BCC=FIX 1
SET_CONDITION P=1E5 T=1000
EXPERIMENT X(BCC,B)=.2:.01
SET_ALTERNATE_CONDITION X(FCC,B)=.3
```

When the alternate mode is turned on, the composition given by the SET_ALTERNATE_CONDITION command is used for the FCC phase. The properties of the BCC phase is calculated using the composition specified by experiment as a condition.

Compositions of a Three-Phase Equilibrium

If you have a three-phase equilibrium in your POP file, then one of its compositions can be specified as experimentally determined, while two can be provided as alternate conditions:

```
CREATE_NEW_EQUILIBRIUM 1 1
CHANGE_STATUS PHASE FCC BCC LIQ=FIX 1
SET_CONDITION P=1E5
EXPERIMENT T=912:5 X(LIQ,B)=0.2:.02
SET_ALTERNATE_CONDITION X(FCC,B)=0.1 X(BCC,B)=.4
```

Composition of a Stoichiometric Phase

When you specify the composition of stoichiometric phase with SET_ALTERNATE_CONDITION, the value must be given with at least seven decimal digits, as in the following example:

```
CREATE_NEW_EQUILIBRIUM 1 1
```

```
CHANGE_STATUS PHASE LIQ A2B=FIX 1
SET_CONDITION P=1E5 X(LIQ,B)=0.2
EXPERIMENT T=992:5
SET_ALTERNATE_CONDITION X(A2B,B)=.6666667
```

Entering Other Experiments in the POP with Alternate Mode

The following table shows some additional examples of how to enter different kinds of experiments in the POP file when you are using the alternate mode.

Example	ED_EXP commands
Two-phase equilibrium: The melting temperature of an Au-Cu alloy	`CHANGE_STATUS PHASE LIQUID FCC=FIX 1 SET_CONDITION X(FCC,CU)=0.14 P=1E5 EXPERIMENT T=970:2 SET_ALTERNATE_CONDITION X(LIQUID,CU)=0.16`
Invariant equilibrium experiment: A three-phase equilibrium in a binary system	`CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE FCC BCC LIQUID=FIX 1 SET_CONDITION P=1E5` `EXPERIMENT T=912:5 SET_ALTERNATE_CONDITION X(FCC,B)=0.1SET_ALTERNATE_CONDITION X(BCC,B)=0.4SET_ALTERNATE_CONDITION X(LIQ,B)=0.2`
Ternary system, with two compositions measured (both with uncertainty 0.02)	`CREATE_NEW_EQUILIBRUM 1 1 CHANGE_STATUS PHASE FCC BCC=FIX 1 SET_CONDITION T=1273 P=1E5 SET_CONDITION X(FCC,B)=0.1:0.02 EXPERIMENT X(FCC,C)=0.12:.02 SET_ALTERNATE_CONDITION X(BCC,B)=0.17 SET_ALTERNATE_CONDITION X (BCC,C)=0.07`

Troubleshooting

During an optimization, you are likely to run into many different problems and challenges. This topic gives some general guidelines that can help avoid common mistakes and problems.

Topics to Explore >

Useful Guidelines **1420**

Excluding and Including the Correct Equilibria **1422**

Conflicting Data **1423**

Useful Guidelines

The following rules of thumb are generally good to adhere to when you are planning and executing an optimization:

- Do not use data from thermochemical tables of unknown origin.
- Use experimentally determined properties; avoid converted quantities.
- Carefully estimate the accuracy of the experiments.
- Correct systematic errors (by adjusting a temperature scale for example).
- Use negative information such as, for example, the information that a phase should not be stable in a composition or temperature region.
- With a hundred activity measurements in a system but only ten composition points from the phase diagram, it is often appropriate to decrease the weights on the activity experiments.
- If you initially exclude any intermediate phases to only optimize the liquid and the terminal or end-member phases for the pure components, then it is often useful to compute a metastable phase diagram with just these phases. In the metastable phase diagram, the metastable solubility lines should not have any strange kinks or turns. Such a diagram is often also useful to compute at later stages in the optimization.
- When you have fitted the liquid phase and some solution phases reasonably well, then you can fix the optimizing variables that characterise these phases. You can then go on and optimize the variables for the intermediate phases.
- Phases with miscibility gaps are always difficult to optimize. Try to keep control of the miscibility gaps by using real or estimated experimental information. (Note that it is not possible to calculate the top of a miscibility gap as a single equilibrium.)
- Phases with order/disorder transformation are often difficult to optimize. It may be difficult to find the right start values on the optimizing variables. The TABULATION module can be useful sometimes. Properties for specified site fractions can be calculated in the TABULATION module. This is not possible in the POLY module since this module only calculates for equilibrium site fractions. The ordered state may also disappear during the optimization of these phases. If this happens, you may be able to add an experiment that controls the state of order.
- Only use the alternate mode to find an initial set of model parameters that can then be make it possible to calculate the experimental equilibria in the normal mode.
- When you have achieved a satisfactory fit between calculated results and experimental data with an appropriate number of optimization variables, perform a couple of final optimization runs to make sure that your results are stable.

- Make sure that the values of the optimizing variables keep within a reasonable range. If a variable starts to change several orders of magnitudes, then you must consider whether you have the right weights on the experiments and whether you are using too many optimizing variables.

Excluding and Including the Correct Equilibria

Use as few experiments as possible initially to get a reasonable overall fit. It is generally best to first focus on the invariant equilibria, as well as metastable states that can be estimated by excluding some phases. Crucially, any experiments for which the computed results are clearly faulty should be excluded from the final critical set, while all important invariant equilibria are calculated and included in this critical set.

If you cannot compute some invariant equilibria with intermediate phases, then it may be best to first exclude those phases from the optimization and only optimize the liquid and the most important solution phases. After you have obtained reasonable results for these phases, you can enter the intermediate phases back in again. With the variables for the optimized liquid and solid phases set fixed, you can finally optimize the intermediate phases.

Conflicting Data

It is important that you do not include conflicting sets of data at the same time during an optimization. After all, if they are genuinely conflicting, then at least one of the sets must be incorrect. If you have conflicting sets of data, then only use one of these sets at a time together with the rest of the data. Often, the optimization makes it clear which dataset coheres best with the other information that is available about the system.

Sometimes, conflicting data cannot be detected directly. For example, you may have activity data which is inconsistent with solubility data from the phase diagram. This would be indicated by large errors in the fit when both the activity data and the solubility data are included. To find these inconsistencies, let alone correct the errors, you may thus have to optimize with some datasets excluded.

Experiments and Experimental Data

These topics contain examples of different kinds of equilibria in different kinds of systems. They are intended to help you figure out how to use various kinds of experimental data when creating POP files. The topics that follow contain examples how to enter various kinds of experimental data into a POP file.

Phase Diagram Data

P-T-X phase diagram data for binary and ternary systems, or systems of even higher order can be used in the POP file. This includes data of the following types:

- Data about the temperature- and composition-dependence of various properties (obtained from differential thermal analysis (DTA) measurements for example), including enthalpy, lattice parameter, dilatometric length, electronic conductivity and magnetic susceptibility;
- Data about reaction types (invariant/monovariant) and phase relations obtained from qualitative or quantitative metallographic studies;
- Data about phase amounts or compositions obtained from microprobe measurements (using X-ray spectroscopy or transmission electron microscopy (TEM));
- Data about the positions or directions of two-phase tie-lines and three-phase equilibria for ternary systems.

The following table shows a POP file excerpt that demonstrates how some kinds of phase diagram data can be entered.

Example	ED_EXP Commands

Solidus (melting temperature) of an Au-Cu alloy	`CREATE_NEW_EQUILIBRIUM 1 1`
	`CHANGE_STATUS PHASE LIQUID FCC=FIX 1`
	`SET_CONDITION X(FCC,CU)=0.14 P=1E5`
	`EXPERIMENT T=970:2`

Three-phase equilibrium in a binary A-B system	`CREATE_NEW_EQUILIBRIUM 1 1`
	`CHANGE_STATUS PHASE FCC BCC LIQUID=FIX 1`
	`SET_CONDITION P=1E5`
	`EXPERIMENT T=912:5`

Congruent transformation in a binary A-B system	`CREATE_NEW_EQUILIBRIUM 1 1`
	`CHANGE_STATUS PHASE BCC LIQUID=FIX 1`
	`SET_CONDITION P=1E5 X(BCC,B)-X(LIQ,B)=0`
	`EXPERIMENT T=1213:10`

Tie-line in a ternary A-B-C system	An uncertainty factor is set not only for the experimental measurement, but also for the X(FCC,B) condition. The factor is 0.02.
	`CREATE_NEW_EQUILIBRUM 1 1`
	`CHANGE_STATUS PHASE FCC BCC=FIX 1`
	`SET_CONDITION T=1273 P=1E5 X(FCC,B)=0.1:0.02`
	`EXPERIMENT X(FCC,C)=0.12:.02`

Data for Individual Compounds

You can use data about individual components in the POP file. Such data includes activity, heat capacity, heat content, entropy, Gibbs energy of phase transformations, heat of transition, and heat of melting.

Example	ED_EXP Commands
Carbon activity data in the fcc phase	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE FCC_A1=FIX 1 CHANGE_STATUS PHASE GRAPHITE=D SET_REFERENCE_STATE C GRAPHITE,,,, SET_CONDITION P=101325 T=1273 X(MN)=0.03 SET_CONDITION X(C)=0.03 EXPERIMENT ACR(C)=0.29:5%
Ln(activity coefficient for O)	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE IONIC_LIQ=FIX 1 CHANGE_STATUS PHASE GAS=D SET_CONDITION X(O)=0.02 T=1523 P=101325 SET_REFERENCE_STATE O GAS,,,, ENTER_SYMBOL FUNCTION LNFO=LOG(ACR(O)/X(O)); EXPERIMENT LNFO=-1.5:0.01

Single Phase Mixing Enthalpies or Partial Enthalpies

You can use calorimetric data for mixing in the POP file. This data could be the result of, for example, drop calorimetry or scanning calorimetry. This includes data about, for example, enthalpy of mixing of liquids, series of mixing-enthalpy and about partial enthalpy. Information about enthalpies of mixing can also be derived from theoretical principles using special quasi-random structures (SQSs).

Example	ED_EXP Commands
Enthalpy of mixing in the liquid state of an Au-Cu alloy	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE LIQUID=FIX 1 SET_CONDITION T=1379 P=1E5 SET_CONDITION X(LIQUID,AU)=0.0563 SET_REFERENCE_STATE AU LIQ * 1E5 SET_REFERENCE_STATE CU LIQ * 1E5 EXPERIMENT HMR=-1520:200

Enthalpies of Formation and Enthalpies of Reactions

You can use calorimetric data for phase transformations in the POP file. This data could be the result of, for example, direct-reaction calorimetry, solution calorimetry or combustion calorimetry. Information about enthalpies of formation can also be derived from theoretical principles.

Example	ED_EXP commands
Enthalpy of melting of the eutectic in the Al2O3-ZrO2 binary (J/g)	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE CORUNDUM ZRO2_TETR=FIX 0 CHANGE_STATUS PHASE IONIC_LIQ=ENT 1 SET_CONDITION P=101325 N=1 LNAC(O)=-80 SET_REFERENCE_STATE ZRO2 TETR,,,,,, SET_REFERENCE_STATE AL2O3 CORUND,,,,,, EXPERIMENT HWR=1080:90
Enthalpy of formation of o-CaZrO3 from the component oxides	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE ZRO2_MONO HALITE CAZRO3_O=ENT 1 SET_CONDITION T=298.15 P=101325 N(CAO)=.5 SET_CONDITION N(ZRO2)=.5 LNAC(O)=-20 SET_REFERENCE_STATE CAO HALITE,,,, SET_REFERENCE_STATE ZRO2 ZRO2_MONO,,,, EXPERIMENT HMR(CAZRO3_O)=-15960:5%

Chemical Potentials via EMF Measurements

You can use chemical potentials and activities/activity coefficients from electromagnetic field (EMF) measurements in the POP file.

Example	ED_EXP Commands
Emf data on Cu(s)/Cu2O(s)	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE FCC CU2O=FIX 1 CHANGE_STATUS PHASE O2GAS=DORM SET_CONDITION P=101325 T=1000 SET_REFERENCE_STATE O O2GAS,, 100000 EXPERIMENT MUR(O)=-95387:1000

Driving Force for Metastable Phases

You can use chemical driving forces for metastable phases in the POP file.

Example	ED_EXP Commands
To prevent BCC_A2 to be stable	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE FCC_A1 M7C3 M23C6=FIX 1 CHANGE_STATUS PHASE BCC_A2=D SET_CONDITION P=101325 T=1473 EXPERIMENT DGM(BCC)<-0.1:0.1
To promote CEMENTITE to be stable	CHANGE_STATUS PHASE BCC M7C3 GRAPHITE=FIX 1 CHANGE_STATUS PHASE CEMENTITE=DORMANT SET_CONDITION P=P0 T=973 EXPERIMENT DGM(CEM)>0.1:0.01

Pressure-Temperature-Volume EOS Data

You can use Pressure-Temperature-Volume Equation of State (EOS) data in the POP file. Such data includes, for example, molar volume, density, thermal expansion and bulk modulus/compressibility.

Example	ED_EXP Commands
Volume of liquid Pt	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE LIQUID=ENT 1 SET_CONDITION P=101325 N=1 T=1873 EXPERIMENT VM=1.00758E-5:5%
Thermal expansion	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE FCC_A1=ENT 1 SET_CONDITION P=101325 N=1 T=400 ENTER_SYMBOL FUNCTION ALPHA=VM.T/VM/3; EXPERIMENT ALPHA=2.35E-5:5%

Crystal Structure, Lattice Parameters, and Site-Occupancy

You use information about defects, ordering or site occupancy, as well as information about crystal structures in the form of lattice parameter values. This information may come from measurements made by X-ray, neutron diffraction, Mössbauer spectroscopy or perturbed angular-correlation.

Example	ED_EXP Commands

Lattice parameter for fcc	`CREATE_NEW_EQUILIBRIUM 1 1`
	`CHANGE_STATUS PHASE FCC_A1=ENT 1`
	`SET_CONDITION P=101325 N=1 T=298.15`
	`SET_CONDITION X(CR)=0.05`
	`ENTER_SYMBOL FUNCTION LPFCC=((4*VM/6.02214179E23)** (1/3))*1E10;`
	`EXPERIMENT LPFCC=4.02:5%`

Lattice parameter for bcc	`CREATE_NEW_EQUILIBRIUM 1 1`
	`CHANGE_STATUS PHASE BCC_A2=ENT 1`
	`SET_CONDITION P=101325 N=1 T=298.15`
	`SET_CONDITION X(AL)=0.08`
	`ENTER_SYMBOL FUNCTION LPBCC=((2*VM/6.02214179E23)** (1/3))*1E10;`
	`EXPERIMENT LPBCC=2.90:5%`

Site-occupancy, degree of inversion for spinel	`CREATE_NEW_EQUILIBRIUM 1 1`
	`CHANGE_STATUS PHASE SPINEL=ENT 1`
	`SET_CONDITION P=101325 N(MG)=1 N(AL)=2 N(O)=4`
	`SET_CONDITION T=1073`
	`EXPERIMENT Y(SPINEL,AL+3#1)=0.31:5%`

Magnetism and Other Atomistic Properties

You can use data about atomistic properties such as magnetism and Curie temperatures in the POP file.

Example	ED_EXP Commands
Curie temperature of MnxFe3-xO4, x=1.26	CREATE_NEW_EQUILIBRIUM 1 1 CHANGE_STATUS PHASE SPINEL=ENT 1 SET_CONDITION T=520 P=101325 N(O)=4 SET_CONDITION N(FE)+N(MN)=3 N(MN)=1.26 EXPERIMENT TC(SPINEL)=520:5

Data About Systems of Different Orders

You might want to use data about systems of different orders in the same optimization, such as data about a binary equilibrium with components A and B in a ternary system with components A, B and C, together with data about equilibria in the binary system with components A and B. To do this, you must first suspend all components in the ternary system (A, B and C), and then set the two components you want binary information on (A and B) to status `ENTERED`.

Suspending all components is done by giving the initialization code 0 to the CREATE_NEW_EQUILIBRIUM command. The components about which you want to use binary information must then be entered again using the CHANGE_STATUS command.

Example	ED_EXP Commands

A binary (A-B) three-phase equilibrium (FCC-BCC-LIQ) in a ternary system (A-B-C)	`CREATE_NEW_EQUILIBRIUM 1 0`
	`CHANGE_STATUS COMPONENT A B = ENTERED`
	`CHANGE_STATUS PHASE FCC BCC LIQ=FIX 1`
	`SET_CONDITION P=1E5`
	`EXPERIMENT T=1177:10`

Thermodynamic Models

The most common models used in assessments are described briefly in these topics. Examples of how to write the phase definitions in the setup-file are also given for each of these models. In addition to the models described here, a large number of thermodynamic models for various phases in different states have been implemented.

Gas

The gaseous mixture phase is usually treated as a substitutional phase without sublattice. In the gaseous mixture phase, there are usually molecules formed, and the number of constituents of the gas phase is often much larger than the number of elements. These complex constituents have to be defined as species. The ideal gas model may handle a gas phase under low pressures (and low temperatures). This implies that the P-V-T relations and thermodynamic properties of pure gaseous species are calculated as for ideal gas, and that there is interaction between gaseous species in the mixture. In a defined system, there may only exist one gaseous mixture phase. Type code `G` is used for the gas phase:

```
ENTER_PHASE GAS G, 1 H,H1O1,H1O2,H2,H2O1,H2O2,O,O2,O3; N N
```

Compound Energy Formalism (CEF)

If the atoms are sufficiently different in size, electronegativity or charge, they may prefer different types of sites in the lattice of crystalline solids. In some cases, a solute atom may even occupy interstitial sites between the normal lattice sites. All such phenomena are treated in Thermo-Calc by the sublattice concept. The Compound Energy Formalism (CEF) has proved to be the most general formalism for many different types of solution phases. It is therefore by default applied to various solid solution phases in the Thermo-Calc software package. CEF can also take ionic constraints (charged cation/anion species) into account. For a comprehensive description on the CEF, please see Hillert (2001), Frisk and Selleby (2001), Sundman and Ågren (1981).

Since the CEF is used by default, no special notation is needed in the phase definition, except for ionic phases, where type code `I` is given.

Examples of phase definitions in a setup-file using the CEF:

```
ENTER_PHASE SPINEL I, 4 1 2 2 4
   FE+2,FE+3; FE+2,FE+3,VA; FE+2,VA; O-2; N N
ENTER_PHASE SIGMA, 3 10 4 16
   AL,CO,CR,FE,NB; AL,CO,CR,FE,NB; AL,CO,CR,FE,NB; N N
ENTER_PHASE FCC_A1, 2 1 1
   CR,FE,MN; C,N,VA; N N
ENTER_PHASE BCC_A2, 2 1 3
   CR,FE,MN,VA; C,N,VA; N N
```

Substitutional Liquid

The liquid phase is normally (but not always) modeled as a substitutional phase with no sublattice, which is occupied by two or more constituents. The constituents are normally the elements, but molecules or associates can also be used. Type code `L` is used for the liquid phase.

```
ENTER_PHASE LIQUID L, 1
   AL,C,CR,FE,MO,NI,SI ; N N
ENTER_PHASE LIQUID L, 1
   C,FE,FEO,FEO3/2,NI,NIO ; N N
```

Ionic Two-Sublattice Liquid Model

Within the framework of the CEF, the ionic two-sublattice liquid (I2SL) model was developed to be used when there is a tendency for ionization in the liquid, which happens in liquid oxides and sulphides for example. The same model can be used both for metallic and oxide melts. At low levels of oxygen, the model becomes equivalent to a substitutional solution model between metallic atoms. Two sublattices are assumed, one containing charged cations and one containing charged anions, neutrals and vacancies. The complication for an ionic liquid is that the numbers of sites on the cation sublattice and anion sublattice vary with the composition to preserve electroneutrality. For a comprehensive description on the I2SL model, see [1985Hil; 1991Sun]. In these references, the possible excess parameters are also discussed. Type code `Y` is used for the I2SL model.

Examples of phase definitions in a setup-file:

```
ENTER_PHASE LIQUID Y,
   AL+3,CR+2,FE+2,NI+2; VA; N N
ENTER_PHASE IONIC_LIQ Y,
   CA+2,MG+2; O-2; N N
ENTER_PHASE IONIC_LIQ Y,
   AL+3,CA+2,FE+2,MG+2,SI+4;
   ALO2-1,O-2,SIO4-4,VA,FEO3/2,SIO2; N N
```

Models for Ordered Phases

Some solution phases have chemical order-disorder transformations: for example, the disordered FCC_A1 phase can transform to the ordered $L1_2$ or $L1_0$ structure where the atoms of different kinds occupy different sublattices. In some cases, it may be advantageous and easy to describe such ordered structures as completely different phases; but in some other cases, like the B2-ordered BCC structure in Al-Fe, the disordered and ordered structures must be described as one singe phase because the transformation is of second order along a line in temperature and composition.

The ordering can easily be described by the CEF. For instance, an ordered FCC phase with only $L1_2$ or $L1_0$ ordering can be efficiently handled by the so-called Two Substitutional-Sublattice Ordering Model (2SL model), while an ordered FCC with both $L1_2$ and $L1_0$ ordering must be described with four sublattices using the so-called Four Substitutional-Sublattice Ordering Model (4SL model). Please note that in both these models, all the substitutional constituents must enter into these sublattices. In addition, you may also have one sublattice for interstitials.

Thermo-Calc supports a feature of splitting the parameters of a chemically ordered phase onto two different phase descriptions. This is very convenient. In this way, you can have one phase for all parameters describing the disordered state (the configuration independent state) and in the other phase only those parameters needed to describe the remaining part (the configuration dependent part), that is, the Gibbs energy contribution due to the ordering transformation. This has been implemented in such a way that the contribution from the configuration dependent part is zero when the solution phase is disordered. The optimization of the disordered phase is independent of the order-disorder transformation; the ordering energy is an add-on to the disordered part. This is particularly useful in higher order systems, as an ordered phase can dissolve several elements that have no particular contribution to the actual ordering. The phases Gibbs energy add together by giving this command in the setup-file: AMEND_PHASE_DESCRIPTION `<ordered phase> disordered_part <disordered phase>`

Since PARROT does not automatically create new composition sets, it is necessary to create composition sets for both the ordered and disordered phases in the setup-file: `Amend_phase_description <phase> composition_sets <new highest set number>,,,,`

Example of phase definitions for the corresponding disordered and ordered parts in a setup-file:

```
ENTER_PHASE FCC_A1, 2 1 1
   AL,CR,FE,NI; VA; N N
ENTER_PHASE FCC_L12, 3 .75 .25 1
   AL,CR,FE,NI ; AL,CR,FE,NI; VA; N N
AMEND_PHASE_DESCRIPTION FCC_L12 DIS_PART FCC_A1
```

4SL Model for FCC, HCP, and BCC

Ordered FCC, HCP and BCC solution phases handled by the 4SL model requires four sublattices for substitutional ordering and can additionally have an interstitial sublattice. A 4SL model is especially useful for modelling different kinds of ordered phases that are based on the same disordered phase, such as $L1_0$ and $L1_2$ based on FCC_A1, and B2, $D0_3$, $L2_1$ and B32 based on BCC_A2 etc.

For ordered FCC or HCP phases, these four substitutional sublattices represent four corners of the regular tetrahedron on these lattices, all of which are the nearest neighbours. These corners are equivalent lattice points, thus all G parameters for each end-member with the same elements, but distributed on different sites, must be identical. It should be emphasized that the end-member energy here represents the ordering energy rather than the formation energy of the compound.

The constraints on the parameters in the 4SL model can be derived based on the symmetry of the lattice:

$$G_{A:B:B:B}=G_{B:A:B:B}=G_{B:B:A:B}=G_{B:B:B:A}$$

$$G_{A:A:B:B}=G_{A:B:A:B}=G_{A:B:B:A}=G_{B:A:A:B}=G_{B:A:B:A}=G_{B:B:A:A}$$

$$G_{B:A:A:A}=G_{A:B:A:A}=G_{A:A:B:A}=G_{A:A:A:B}$$

$$L_{A,B:*:*:*}=L_{*:A,B:*:*}=L_{*:*:A,B:*}=L_{*:*:*:A,B}$$

The asterisk * means that the interaction parameter is independent of the occupation of that sublattice. For the disordered phase to be completely disordered, i.e. that all site fractions are equal on all four sublattices, all constraints must be correct.

For ordered BCC phases, the situation is a bit more complicated, as the four sublattice ordering phase represents an irregular tetrahedron with two pairs of sites that are next nearest neighbors. Thus, for an A-B binary solution phase, with A located on two sublattice sites and B on the other two, the end-member described by $G_{A:A:B:B}$ has four nearest neighbour bonds between A and B atoms, whereas the end-member described by $G_{A:B:A:B}$ has two nearest neighbour bonds between A and B atoms and two next nearest neighbour bonds. Many parameters thus have a relation:

$$G_{A:B:B:B}=G_{B:A:B:B}=G_{B:B:A:B}=G_{B:B:B:A}$$

$$G_{B:A:A:A}=G_{A:B:A:A}=G_{A:A:B:A}=G_{A:A:A:B}$$

$$G_{A:A:B:B}=G_{B:B:A:A}$$

$$G_{A:B:A:B}=G_{A:B:B:A}=G_{B:A:A:B}=G_{B:A:B:A}$$

$$L_{A,B:*:*:*}=L_{*:A,B:*:*}=L_{*:*:A,B:*}=L_{*:*:*:A,B}$$

The $G_{A:B:B:B}$ term represents $D0_3$, $G_{A:A:B:B}$ B2 and the $G_{A:B:A:B}$ B32 ordering. There are also two kinds of reciprocal interaction parameters:

$L_{A,B:A,B:*:*;0...9}$

$L_{A,B:*:A,B:*;0...9}$

Kusoffsky et al. (2001) have shown the influence of different parameters available in the 4SL model applied to fcc ordering. The possibility to use the 4SL model to BCC ordering has been studied by Sundman et al. (2009) in the Al-Fe system.

2SL Model for FCC, HCP, and BCC

The reason for using a 2SL model instead of a 4SL model is that the calculations are faster, but on the other hand it can only model one kind of ordered phase(s). For instance, it is not possible to model FCC with both $L1_0$ and $L2_1$, or BCC with $D0_3$ and B2, etc.

In order to get the fully disordered phase to form, constraints are needed as for the 4SL model. For the symmetric phases, e.g. B2 and $L1_0$, the relation between parameters are:

$G_{A:B}=G_{B:A}$

$L_{A,B:*}=L_{*:A,B}$

For a 2SL asymmetric model including, but not limited to, $L1_2$, more constraints are needed. This model has many complicated relations between the parameters. The relation between the parameters for the 2SL $L1_2$ model can be derived from a 4SL model. The conversion from 4SL model parameters to 2SL parameters for $L1_2$ can be found in Dupin et al. (2001) and for $L1_0$ in Yuan et al. (2012). Higher-order systems with an $L1_2$ phase modeled with two sublattices require a lot of ternary and some quaternary interaction parameters in order to make the disordered state stable. These parameters have been derived by e.g. Dupin (1995), also found in Kusoffsky et al. (2001).

Many publications exist on how to model order/disorder transformations using a two-sublattice model, see e.g. Dupin, Ansara (1999), De Keyzer et al. (2009).

Magnetic Ordering

The magnetic contribution to the Gibbs energy is given by a model proposed by Inden (1975) and adapted by Hillert and Jarl (1978), and is described by:

```
G=RTln(b+1)f(t)
```

where $t=T/T_C$.

The values of the Curie temperature, T_C, and Bohr magneton number, b, at a certain composition are then used in an optimization procedure to calculate the contribution to Gibbs energy due to magnetic ordering. Curie temperature and Bohr magneton number are given in the command ENTER_PARAMETER for phases that undergo a magnetic transition:

```
AMEND_PHASE_DESCRIPTION BCC_A2 MAGNETIC -1.0 0.4
ENTER_PARAMETER TC(BCC_A2,FE:VA;0) 298.15 +V1; 6000 N
ENTER_PARAMETER BMAGN(BCC_A2,FE:VA;0) 298.15 +V2; 6000 N
```

The arguments -1 and 0.4 specify the values of parameters in the magnetic model: -1 is the antiferromagnetic factor and 0.4 is the structure factor. Usually the antiferromagnetic factor =-1 for bcc and =-3 for fcc (and other non-bcc phases). The structure factor corresponds to the short range order fraction of the enthalpy. This factor is 0.4 for bcc and 0.28 for non-bcc phases.

Molar Volumes and High Pressure

Including volumes in a thermodynamic database enable calculations of volume changes, volume fraction, lattice mismatch in cubic structures and phase diagrams at increased pressure. Pressure independent volumes can be used up to about 1 GPa. At pressures above 1 GPa the pressure dependence of the volumes must be included by using a proper equation of state (EOS). An EOS has been developed by Lu et al. (2005), based on the EOS from Jacobs and Oonk (2000). Four parameters are used in the implementation of the model in Thermo-Calc:

- `V0`: Volume at 1 bar and at reference temperature T_0
- `VA`: Integrated thermal expansivity
- `VK`: Isothermal compressibility at 1 bar
- `VC`: Parameter to fit high pressure data

All parameters can be composition dependent in the same way as all other model parameters in Thermo-Calc. Experimental information about the temperature, pressure and composition dependence of the volume can be assessed using these model parameters. To evaluate V0, VA and VK experimental data at 1 bar only are needed.

Examples on modeling molar volume in a setup-file:

```
ENTER_PARAMETER V0(BCC_A2,FE:VA;0) 298.15 +V1; 6000 N
ENTER_PARAMETER VA(BCC_A2,FE:VA;0) 298.15 +V2*T+V3*T**2; 6000 N
ENTER_PARAMETER VC(BCC_A2,FE:VA;0) 298.15 +V4+V5*T; 6000 N
ENTER_PARAMETER VK(BCC_A2,FE:VA;0) 298.15 +V6+V7*T; 6000 N
ENTER_PARAMETER V0(FCC_A1,CR,FE:VA;0) 298.15 +V8; 6000 N
ENTER_PARAMETER VA(FCC_A1,CR,FE:VA;0) 298.15 +V9*(T-298.15); 6000 N
```

Excess Models

Unless specifically amended, the excess Gibbs energy terms are modeled by the Redlich-Kister-Muggianu Model. Other excess models for the Gibbs energy are also implemented in Thermo-Calc, such as e.g. Kohler and Toop-Kohler extrapolation models.

Thermo-Calc is not restricted to binary interaction parameters. Ternary, quaternary and higher-order interaction parameters can also be used if there is enough information to evaluate these from experimental data. The ternary interaction parameters are identified by the degrees of the so-called ternary L parameter (i.e. 0, 1 and 2) in the command ENTER_PARAMETER. If the parameter is composition-independent, you only need a single interaction parameter with a degree of zero, i.e. only the ^{0}L term. If there is a ternary composition-dependent interaction parameter, you must enter all three parameters (0,1 and 2). If such a ternary interaction parameter should be zero, then assign it a function which is zero. If the three interaction parameters have the same value, then that is identical to having a composition-independent ternary parameter.

```
ENTER_PARAMETER L(LIQUID,A,B,C;0) 298.15 +1000; 6000 N
ENTER_PARAMETER L(LIQUID,A,B,C;1) 298.15 +1000; 6000 N
ENTER_PARAMETER L(LIQUID,A,B,C;2) 298.15 +1000; 6000 N
```

is identical to

```
ENTER_PARAMETER L(LIQUID,A,B,C;0) 298.15 +1000; 6000 N
```

This also means that

```
ENTER_PARAMETER L(LIQUID,A,B,C;0) 298.15 +1000; 6000 N
ENTER_PARAMETER L(LIQUID,A,B,C;1) 298.15 +ZERO#; 6000 N
ENTER_PARAMETER L(LIQUID,A,B,C;2) 298.15 +ZERO#; 6000 N
```

is NOT identical to

```
ENTER_PARAMETER L(LIQUID,A,B,C;0) 298.15 +1000; 6000 N
```

General Einstein Model

An Einstein model implemented in a general way with multiple Einstein temperatures and accompanying weight functions.

The LNTHETA and THETAF parameters are only available with GES6.

It describes the vibrational contribution to Cp at low and intermediate temperatures.

The model is implemented as:

$$G_{Einstein} = f \times n \times R \times (\tfrac{3}{2}\Theta + 3T \times \ln(1 - e^{-\frac{\Theta}{T}}))$$

Where

- Θ is the Einstein temperature. $ln(\Theta)$ is entered as the database parameters `LNTHETA1`, `LNTHETA2`, `LNTHETA3`, `LNTHETA4`, and `LNTHETA5`.
- f is a weight function, entered as the database parameters `THETAF1`, `THETAF2`, `THETAF3`, `THETAF4`, and `THETAF5`.
- n is the number of atoms per mole formula unit
- R is the universal gas constant
- T is the temperature

Examples of parameters for this model:

```
PARAMETER LNTHETA1(GRAPHITE,C;0) 298.15 +LN(1953); 6000 N REF0 !
PARAMETER THETAF1(GRAPHITE,C;0) 298.15 +0.484786; 6000 N REF0 !
PARAMETER LNTHETA2(GRAPHITE,C;0) 298.15 +LN(947); 6000 N REF0 !
PARAMETER THETAF2(GRAPHITE,C;0) 298.15 +0.349135; 6000 N REF0 !
PARAMETER LNTHETA3(GRAPHITE,C;0) 298.15 +LN(448); 6000 N REF0 !
PARAMETER THETAF3(GRAPHITE,C;0) 298.15 +0.121463; 6000 N REF0 !
PARAMETER LNTHETA4(GRAPHITE,C;0) 298.15 +LN(193); 6000 N REF0 !
PARAMETER THETAF4(GRAPHITE,C;0) 298.15 +0.0387523; 6000 N REF0 !
PARAMETER LNTHETA5(GRAPHITE,C;0) 298.15 +LN(65); 6000 N REF0 !
PARAMETER THETAF5(GRAPHITE,C;0) 298.15 +0.0058637; 6000 N REF0 !
```

The Einstein function also can used with the GEIN(THETA) function.

For more information about this see FUNCTION and PARAMETER in the *Database Manager User Guide*.

Thermodynamic and Kinetic/Mobility Databases

This guide describes how to define and construct a thermodynamic or kinetic database. It includes details about the data structures and formats of the Thermo-Calc databases as well as the Diffusion Module (DICTRA) database-extensions.

The Thermo-Calc databases are created and maintained in the Thermo-Calc Database Format (TDB) which is an international standard for the CALPHAD-type thermodynamic calculations and kinetic simulations. This document gives a full description of the TDB format (with the Diffusion Module (DICTRA) database extension) and is a comprehensive guide about how to create and manage a Thermo-Calc (and Diffusion Module (DICTRA)) database.

Usually, a Thermo-Calc or Diffusion Module (DICTRA) database is constructed as a single text file with an extension of TDB, for example, `PAQ2setup.TDB`. For some databases (especially large databases used with older versions of Thermo-Calc or Diffusion Module (DICTRA)) a database may consist of one primary-definition file (`***setup.TDB`) and several additional-definition TDB files (such as `***param.TDB`, `***funct.TDB`, `***refer.TDB`, etc. These are built for a variety of defined parameters, functions, references and so forth, and are linked to the `***setup.TDB` file through the correct use of the TYPE_DEFINITION and/or FTP_FILE commands inside the `***setup.TDB` file.

With Thermo-Calc, the Add-on Modules and Thermo-Calc Software Development Kits (SDKs), you can code everything into a single ***setup.TDB** file for a database at any scale.

Initialization of the TDB Module

The following explains how a database initialization file is constructed to work with the so-called TDB (database) module. When you start, the TDB module looks for a file that has information about the available standard databases. The database initialization file is called `tc_initd.tdb`. By default it is located in the data subdirectory of the Thermo-Calc installation directory.

See Database Installation Folder

The location can be overridden by:

- A command line parameter `-t` followed by the path to the directory containing the `tc_initd.tdb` file.
- The environment variable `TC_DATABASE_DIRECTORY` pointing to the directory containing the `tc_initd.tdb` file. This overrides both the default value and a directory given with the `-t` command line argument.

Each database defined in `tc_initd.tdb` represents a database that can be used within Thermo-Calc. Each entry has three parts:

1. The database short-name (e.g. `FEDEMO`, maximum seven characters, no white space, no commas).
2. The path to the database setup file (max 78 characters, no commas, can contain white space if it is a quoted absolute path).
3. A short description of the database (max 60 characters, can contain white space). The entry must end with an exclamation mark (`!`).

The paths can be relative to the `tc_initd.tdb` file or absolute. For platform independence, the recommendation is to always use forward slashes (`/`) in the paths, but on Windows backslash (`\`) also works.

You can add comment lines in the database initialization file. Comments must start with a `$` sign.

Examples

The following are examples of an initialization file defining two databases:

```
SSOL8 SSOL8\SSOL8SETUP.TDC SGTE Solutions Database version 8.0 !
MYDB1 ../../../MYDATABASES/ABC.TDB My database 1.0 !
```

In the initialization file you can also add databases with absolute file names with white space, if the path is surrounded by quotation marks (`"`):

```
TEST "G:\My Drive\My Folder\Test.TDB" My test database v0.1!
```

The use of absolute paths should be used with caution as these are not portable.

Database Definition File and Keywords

The database definition (*.TDB) file (normally named `***setup.TDB`) consists of a set of keyword codes each followed by one or several parameters (arguments).

Example of VERSION_DATA *1511*

Database Definition File Syntax

The database definition (*.TDB) file (normally named `***setup.TDB`) consists of a set of keyword codes each followed by one or several parameters (arguments).

- A complete keyword entry must end with an exclamation mark (!).
- A single keyword entry can be up to 2000 characters long. However, the maximum length of a line in an *.TDB file is 78 characters--it may be necessary to continue the keyword parameter (arguments) on several lines. The ! must be at the end of the last line.
- It is recommended to always have at least one empty space at the beginning of each continuation line for the keyword parameters (arguments); otherwise, the DATA module can misunderstand the parameters (or arguments), or issue an error message.
- The keyword and its various parameters (arguments) are separated by a space or a comma.
- A dollar sign ($) in the first position of the line indicates that the line is a comment line, which is ignored by the DATA module.

When the database is selected the DATA module only reads the database definition file (***setup.TDB) once, from beginning to end. The DATA module checks continuously when reading the definition file. This implies that (nearly) everything must be declared or defined before it is used in any other way.

For example, if the GRAPHITE phase is to be included in the database definition, the element C (carbon) and the phase GRAPHITE must be defined before declaring that carbon dissolves in graphite. This definition order is necessary to build the internal data structure acceptable by the DATA module (during its consistency checking).

This topic gives a description of the available keywords and the appropriate arguments. A basic knowledge of the Gibbs Energy System (GIBBS) module is assumed.

This syntax is used:

```
KEYWORD [arg.1]*# [arg.2]*## {optional arg.3}!
```

The keywords are written in full length but can be abbreviated as long as the abbreviation is unique. A keyword may have syntax consisting of several arguments and optional arguments. The number, # or ##, in the notation, [...]*# or [...]*##, indicates an argument with a maximum length of # ASCII characters.

Arguments within square brackets `[ . . . ]` must always be given, but are optional when enclosed in curly brackets `{ . . . }`.

ADD_CONSTITUENT

```
ADD_CONSTITUENT [phase name]*24 [constituent description]*2000 !
```

This keyword adds more constituents to a phase that already has some constituents. Its syntax is the same as for the CONSTITUENT keyword. This keyword can be used several times, if the phase is very large, e.g. a gaseous mixture or a complex aqueous solution. This is useful when there are so many constituents in a phase that the 2000 characters available for the constituent description list is not enough.

Constituents are not necessary on all sublattices. In the second example below, no addition is made to the first sublattice.

Examples of ADD_CONSTITUENT

```
ADD_CONSTITUENT GAS :S1 S2 S3 ... : !

ADD_CONSTITUENT IM-PHASE : :CR:W ... : !

ADD_CONSTITUENT AQUEOUS:A :CUCL+1 CUCL2 CUCL2-1 CUCL3-2 CUOH+1 CUO2H2
CUO3H3-1

  CUO4H4-2 CU2OH+3 CU2O2H2+2 CU3O4H4+2 NIO2H2 NIO3H3-1 NIO4H4-2 NI2OH+3

  NI4O4H4+4 ZNOH+1 ZNO2H2 ZNO3H3-1 ZNO4H4-2 ... : !
```

ADD_REFERENCE

```
ADD_REFERENCE
[REFxxx] '[Detailed reference]'
..........
.......... !
```

Use this keyword to have an unlimited number of references. The use of this is the same as that of LIST_OF_REFERENCE, and is used after it. Several ADD_REFERENCES sections can be used in a single database if there are too many references.

It is recommended to always start with a so-called *empty reference* (such as the DUMP0 reference in the following example) as the first entry in each of the ADD_REFERENCE sections to make sure that all references are listed appropriately as retrieving data by issuing the GET_DATA command.

Example of ADD_REFERENCE

```
ADD_REFERENCE
 DUMP0 'Empty reference 0'
 REF4 'J-O Andersson, B. Sundman, CALPHAD Vol 11, (1987), p 83-92
       TRITA 0270 (1986); CR-FE'
 REF5 'J-O Andersson, Met. Trans A, Vol 19A, (1988) p 627-636
       TRITA 0207 (1986); C-CR-FE'
 REFS 'Pingfang Shi (2006), TCS PTERN Public Ternary Alloys Database,
       v1.2; Modified L0(BCC,Fe,C) and L0(BCC,Cr,C) parameters
       at high temperatures.'
 ... ...
 !
ADD_REFERENCE
 DUMP1 'Empty reference 1'
 REF275 'A. Fernandez Guillermet, Z. Metallkde. Vol 79(1988) p.524-536,
       TRITA-MAC 362 (1988); C-CO-NI AND C-CO-FE-NI'
 REF393  'K. Frisk, Metall. Trans. Vol 21A (1990) p 2477-2488,
       TRITA 0409 (1989); CR-FE-N'
 REF1096 'P. Gustafson, Metall. Trans. 19A(1988) p 2547-2554,
```

```
       TRITA-MAC 348, (1987); C-CR-FE-W'
... ...
!
```

ALLOTROPIC_PHASE

```
ALLOTROPIC_PHASE [phase name]*24 [data-type code]*8 [constituent] !
```

This keyword does the same as the COMPOUND_PHASE keyword for entering an allotropic phase (maximum 24 characters), but does not enter the constituent as a species to the data structure. Use this if the species is already defined.

Example of ALLOTROPIC_PHASE

```
ALLOTROPIC_PHASE BETHA-AL2O3 % AL2O3 !
ALLOTROPIC_PHASE CRISTOBALITE % SIO2 !
ALLOTROPIC_PHASE TRIDYMITE % SIO2 !
```

ASSESSED_SYSTEMS

```
ASSESSED_SYSTEM [descriptions on special treatments for specific
assessed systems]*8000 !
```

This keyword can be included in the database definition file (the `***setup.TDB` file). A maximum of 8000 characters after the keyword (to describe some special options when the DATA, GIBBS and POLY models deal with the existing systems with assessed data) is allowed until the exclamation mark (`!`).

Several ASSESSED_SYSTEMS keywords can be used in the same TDB file in order to have more lists of assessed systems. There is no limit to the number of the entries in the same TDB file.

The assessed systems in the database, and the special treatment options, are typed after the keyword. The elements (always in UPPER CASE) in each assessed system must be in alphabetical order and be separated by a hyphen, such as `C-FE` for the Fe-C binary system, and `C-CR-FE` for the Fe-Cr-C ternary system. A space must be between each assessed system. Information on assessed binary, ternary or higher-order systems may also be given in this way.

A ternary system like C-CR-FE does not imply that the binary C-CR, C-FE and CR-FE are assessed. There is no way to indicate partially assessed systems.

- There is a field to give some descriptive information for a specific system, with various options about how to:
- Reject or restore phase(s) from the current database in the DATA module;
- Set major constituent(s) in the first composition set and to set a second composition set for a specific phase available in the current database in the GIBBS module; *and*
- Calculate this specific system in the POLY module.
- This is the facility used by the BIN (binary phase diagrams) and TERN (ternary phase diagrams) modules in the Thermo-Calc software/database package.

The descriptive information must immediately follow the specific system name, and must be enclosed within parenthesis `(` and `)`, and the left parenthesis must follow directly after the system, such as :

```
AL-NI(TDB +L12 ;G5 C—S:L12/NI:AL:VA ;P3 STP:.8/1200/1 STP:.2/600/1)
```

The syntax TDB means that the commands to the DATA module proceed, and +L12 in the example means that the phase called L12 should be restored (it has been rejected by default).

The directive `;G5` means that the following are commands to the GIBBS module. `C_S:` means creating a second composition set, after the colon follows the phase name and after the slash the major constituents.

After the directive `;P3` follows commands to the POLY module. `STP:` means setting a start point with the value of the X-axis first (composition for the second element in a binary system), the slash separates the Y-axis value (temperature), and possibly one or more directions (`-1`, `1`, `-2` or `2`).

A summary of the allowed syntax is:

TDB accepts

- `+phase` and `-phase` for restore/reject.
- `;G5` accepts
- `MAJ:phase/constituent-array` for major constituents of the first composition set.
- `C_S:phase/constituent-array` for a second composition set.
- `;P3` accepts
- `TMM:lt/ht` for the low-/high-temperature limits (`lt` and `ht`; for instance `TMM:500/4000`) suitable for calculating phase diagrams and property diagrams of a binary system.
- `*` for a default start point which is set as:
- for a binary system: at the composition `X(2nd element)=.1234`, temperature `T=1100 K` and with the default directions; or
- for a ternary system: at the compositions `X(2nd element)=.1234` and `X(3rd element)=.1234` and with the default directions.
- `STP:x/t/d1/d2/d3` for a specific start point in a binary system which is set as at the composition `X(2nd element)=x` and temperature `T=t` (in K), and with the directions `d1`, `d2` and/or `d3`.
- `STP:x1/x2/d1/d2/d3` for a specific start point in a ternary system which is set as at the compositions `X(2nd element)=x1` and `X(3rd element)=x2` and with the directions `d1`, `d2` and/or `d3`.
- The direction(s) can be defined as `-1`, `1`, `-2` or `2`. If no direction is specified, all default directions are used (meaning no `ADD` command is enforced in the POLY module).
- If only one start point is specified, the direction(s) may be omitted; if more than one start points are specified, at least one direction for each start point must be given for all start points.

Each entry for a specific binary or ternary sub-system can be written in one or several lines (each line with 78 characters).

Example of ASSESSED_SYSTEMS

```
ASSESSED_SYSTEMS
AL-NI(TDB +L12 +BCC_B2 ;G5 C_S:L12/NI:AL:VA
     ;P3 STP:.8/1000/1 STP:.45/700/1 STP:.7/700/1)
AL-PB(TDB -HCP -BCC
     ;G5 MAJ:LIQ/AL MAJ:FCC/AL:VA C_S:LIQ/PB C_S:FCC/PB:VA ;P3 *)
CR-FE(;G5 C_S:BCC/CR:VA ;P3 STP:.6/1200/1/-2/2)
AG-CU(;G5 MAJ:FCC/AG:VA C_S:FCC/CU:VA ;P3 STP:.3/1000)
C-NB(;P3 STP:.9/1100/1)
C-SI(;P3 *)
CO-CR(;G5 MAJ:FCC/CO:VA C_S:FCC/CR:VA ;P3 STP:.1/1100)
CR-FE(TDB -HCP ;G5 C_S:BCC/CR:VA ;P3 STP:.6/1200/1/-2/2)
CR-NI(;P3 *)
CR-W(;G5 MAJ:BCC/W:VA C_S:BCC/CR:VA
     ;P3 TMM:500/4000 STP:.3/700/1 STP:.3/1800/2 )
CU-FE(TDB -HCP ;G5 MAJ:LIQ/CU MAJ:FCC/FE:VA C_S:FCC/CU:VA
     ;P3 STP:.9/1400)
FE-N(TDB +FE4N ;P3 *)
FE-O(TDB -LIQUID +IONIC ;G5 C_S:ION_LIQ/FE+2:O-2 MAJ:ION_LIQ/FE+2:VA
    ;P3 STP:.2/2000/1 )
FE-S(TDB -LIQUID +IONIC ;G5 C_S:ION_LIQ/FE+2:S MAJ:ION_LIQ/FE+2:S-2 ;P3
*)
AL-MG-SI(;P3 *)
C-CR-FE ;G5 MAJ:BCC/FE:VA C_S:BCC/CR:VA ;P3 *) !
```

The semicolon (`;`) is a part of the `;G5` and `;P3` directives. A long descriptive information can be written in more than one line, such as for the `AL-NI`, `AL-PB` , `CU-FE` and `FE-O` systems shown above.

The directive `;P3 *` is needed if the default start point should be used. If there is no `P3` directive, the BIN or TERN module generates some 20 different start points in order to cover all possible compositions and temperatures (for a binary system) or all possible compositions (for a ternary system under any specific temperature).

CASE and ENDCASE

```
CASE [ELEMENT/SPECIE/PHASE] !
IF (boolean algebra on element, species or phase names) THEN
     [GIBBS/POLY/DATA command] !
ENDCASE !
```

This keyword takes as its argument, a definition on which type of the following Boolean algebra operates. A simple Boolean algebra using `AND` and `OR` with a maximum of four levels of parentheses works. The `CASE` construction must end with the `ENDCASE` keyword. This makes it possible to have additional GIBBS or POLY commands executed depending on the user selection of elements, species or phases. The DATA commands that can be given as secondary keyword to DEFAULT_COMMAND can also be executed.

Example 1

```
CASE ELEMENT !
 IF((CR OR TI OR V) AND N)
 THEN GES AM_PH_DES @ C_S ,, CR MO TI V:C N: !
 ENDCASE !
```

Example 2

```
CASE ELEMENT !
 IF(O) THEN TDB DEFINE_SYSTEM_ELEMENT /- !
 ENDCASE !
```

Example 3

```
CASE ELEMENT !
 IF(AL AND FE)
 THEN TDB DEF_SYS_ELEMENT VA !
 ENDCASE !
```

COMPOUND_PHASE

```
COMPOUND_PHASE [phase name]*24 [data-type code]*8 [constituent] !
```

The keyword is a compact way to simultaneously define a species, a *compound phase* (maximum 24 characters) and its phase-constituent. It is useful for stoichiometric phases with constant compositions. The species name and stoichiometric formula must be identical, i.e. being the given *constituent*. The phase has this species as its only constituent. This keyword allows the database definition file for a large substance database to be more compact; it is a combination of the SPECIES, PHASE and CONSTITUENT keywords.

Example of COMPOUND_PHASE

```
COMPOUND_PHASE AL2O3 % AL2O3 !
COMPOUND_PHASE MAGNETITE %MF FE3O4 !
COMPOUND_PHASE QUARTZ % SIO2 !
```

CONSTITUENT

```
CONSTITUENT [phase name]*24 [constituent description]*2000 !
```

This keyword (and the ADD_CONSTITUENT keyword for large solution phase) defines the phase-constitution as a list of constituents (for a substitutional phase with no sublattice) or of constituent arrays (for a sublattice phase).

The *phase name* (maximum 24 characters) must be a predefined phase (i.e. already through the PHASE keyword).

It is important that if a phase bears a legal phase-type (among G, A, Y, L, I, F and B) in its phase definition (already by the PHASE keyword; such as GAS:G, SLAG:L, LIQUID:L, IONIC_LIQ:Y, SPINEL:I, FCC_L12:F, HCP_D021:F, BCC_B2:B, AQUEOUS:A), such a valid phase-type code must also always be attached to the phase name in the CONSTITUENT keyword (and the ADD_CONSTITUENT keyword).

Specifying the phase name in UPPER-case is recommended. You can define a phase name as a mixture of UPPER-case and lower-case letters in a database, but the DATA module automatically converts all lower-case to UPPER-case because the GIBBS module only recognizes UPPER-case phase names.

The *constituent description* (maximum 2000 characters) is a list of the species that enter a phase. The list starts with a colon (:), indicating the start of the sub-list of species for the first sublattice, and different sublattices are separated by colons. The complete sequence ends with a final colon.

Optionally, each sublattice may specify which species are considered to be major constituents. This is done by adding a percent sign (%) directly to the species name. The start values on the site fractions of the major constituents should sum to 0.99 on a specific sublattice. Thus, the minor constituents (i.e. those without a %) add up to 0.01. A maximum of 2000 characters can be coded in the constituent description, continuing in sequent lines. If the phase has a constituent description longer than 2000 characters, the rest can be coded in one or several ADD_CONSTITUENT keywords.

Example of CONSTITUENT

```
CONSTITUENT BCC_A2 :FE

CONSTITUENT IONIC-LIQ:Y :FE+2 : SB-3: !

CONSTITUENT M23C6 :CR FE :FE CR W MO : C: !

CONSTITUENT AQUEOUS:A :H2O% AG+1 AGF AGCL AGCL2-1 AGI3-2 AGSO4-1
AGC2H4+1

 AGN2H6+1 AGC2N2-1 AGC2H4NO2 AL+3 ALF3 ALO2-1, ... : !

CONSTITUENT SPINEL:I : AL+3% CR+3 FE+2% FE+3 MG+2% NI+2

                     : AL+3% CA+2 CR+3 FE+2 FE+3 MG+2% NI+2 VA

                     : FE+2 MG+2 VA%

                     : N-3 O-2% :!
```

DATABASE_INFORMATION

```
DATABASE_INFORMATION [text]*10000 !
```

This keyword defines a text for the detailed description of the current database. The text can be listed with the DATA command DATBASE_INFORMATION. An apostrophe (') can be used in the text to indicate a new line; and two apostrophes, ('') can be used in the text to indicate a new line plus an empty line.

The continuous *text* length (each line with max 78 characters) is 10,000 characters.

Example of DATABASE_INFORMATION

```
DATABASE_INFORMATION This is the XXX-Alloy Solution Database '
    in the A-B-C-D-..... System. '
 Developed by TCS, released in May 2001. ''
... more ... !
```

DEFAULT_COMMAND

```
DEFAULT_COMMAND [secondary keyword and parameters] !
```

This keyword specifies commands to be executed by the DATA module at database initialization. The syntax of the available command is currently not the same as the user available DATA commands but the actions are similar. The available *secondary keyword and parameters* in syntax are:

```
DEFINE_SYSTEM_ELEMENT [element names]
DEFINE_SYSTEM_SPECIES [species names]
DEFINE_SYSTEM_CONSTITUENT [phase] [sublattice] [species]
REJECT_SYSTEM_ELEMENT [element names]
REJECT_SYSTEM_SPECIES [species names]
REJECT_SYSTEM_CONSTITUENT [phase] [sublattice] [species]
REJECT_PHASE [phase names]
RESTORE_PHASE [phase names]
```

Example of DEFAULT_COMMAND

```
DEFAULT_COMMAND DEFINE_SYSTEM_ELEMENT FE VA !
DEFAULT_COMMAND REJECT_SYSTEM_CONSTITUENT LIQUID 2 C !
DEFAULT_COMMAND REJECT_PHASE LIQUID !
DEFAULT_COMMAND RESTOR_PHASE GAS !
```

DEFINE_SYSTEM_DEFAULT

```
DEFINE_SYSTEM_DEFAULT [keyword] {G-ref. type index} !
```

This keyword sets the default value to ELEMENT or SPECIES in the DATA command DEFINE_SYSTEM.

For a substance database, it can be appropriate to have ELEMENT as a default value whereas a large solution database can benefit from having SPECIES as a default value. A proper default value is useful for beginners. An advanced user is more likely to use the DATA commands DEFINE_ELEMENT and DEFINE_SPECIES to override the default value.

{G-ref. type index} is an integer indicating the reference state type for an element when entering and listing data in the GIBBS module. The following lists legal numbers and the corresponding meaning (the reference state type for an element):

Number	*Definition*
1	symbol: G
2	symbol: H298
3	symbol: H0

For example:

```
DEFINE_SYSTEM_DEFAULT element 2 !
```

ELEMENT

```
ELEMENT [element name]*2 [ref. state]*24 [mass] [H298] [S298] !
```

The *element name* (maximum two characters) is the one found in the periodic chart but there are no naming restrictions. However, the GIBBS module only recognizes UPPER-case element names (if the `Upper Case Mode` is selected by the GIBBS command REINITIATE), which means that lower-case (if defined in a database) is automatically converted to UPPER-case by the DATA/GIBBS module.

The elements are automatically entered as species using the same names of the elements. If, for example, the species corresponding to FE needs to be named FE1, you can define the species as FE1, which results in an element named FE and a species named FE1. Vacancies (VA) and electrons (denoted either as /- in gaseous, liquid or solid phases, or ZE in an aqueous solution phase), need to be entered as special elements for correct handling by the DATA module.

The *reference (ref.) state* (maximum 24 characters) is the stable phase (at 298.15 K and 1 bar) that should contain this element and be used as the reference state for all element thermodynamic data. The *mass*, given in gram per mole, is used in various calculation programs and should always be given the correct value. *H298* and *S298* denote the enthalpy and entropy difference between 0 and 298.15 K for the element in SI units. If these are unknown, the values can be set to zero. All this information (reference state, H298 and S298) define the SER (Stable Element Reference state).

Example of ELEMENT

```
ELEMENT /- ELECTRON_GAS      0.0 0.0 0.0 !
ELEMENT VA VACUUM            0.0 0.0 0.0 !
ELEMENT ZE UNIT_CHARGE       0.0000000001 0.0 0.0 !
ELEMENT AL FCC_A1            26.98154 4577.296 28.3215 !
ELEMENT C GRAPHITE          12.011 1054.0   5.74 !
ELEMENT FE BCC_A2            55.847 4489    27.28 !
ELEMENT O 1/2_MOLE_O2(G)    15.9994 4341   102.5158 !
ELEMENT TI HCP_A3            47.88  4810    30.648 !
ELEMENT ZR HCP_A3            91.224 5566.27 39.181 !
ELEMENT ZY DUMMY              1        1        1 !
```

FTP_FILE

```
FTP_FILE [filename] !
```

FTP_FILE is a special function random file and the function names correspond to the record numbers where these record names and the functions are stored. The FTP_FILE decreases search time for the associated database in the DATA module. The file is used for large substance databases along with a SEQ sequential or RND0 random file for storage of G0 parameters referring the functions named `FxxxxT` that are stored in the FTP file. The integer number `xxxx` is a search code used by DATA when such files are processed.

No modification of this file type is allowed.

Example of FTP_FILE

```
FTP_FILE TCPATH\DATA\[DATABASE]\FTP-FILE.DATA !
```

FUNCTION

```
FUNCTION [function name]*8 [lowest temp. limit]
[expression 2]; [upper temp. limit 2] Y
[expression 1]; [upper temp. limit 1] Y
[expression 3]; [upper temp. limit 2] Y
 .......... ; ..... Y
[expression n-1]; [upper temp. limit n-1] Y
[expression n]; [upper temp. limit n] N {Ref. Index} !
```

GIBBS can use predefined functions in the expression (TP-Function) of a Gibbs energy parameter or in other functions. This is often used when several parameters (or functions) have a common sub-expression, such as for metastable modifications of elements. This keyword can appear in both files for database definition and sequential storage, but not in FTP files. A valid *function name* can have up to 8 characters.

A function always starts with a lowest temperature limit of its applicability, followed by one or more (up to 10) expressions (TP-Functions) that are coded as mathematical relations of constants, functions of stable variables (T and P) and other entered functions (normally with a # suffix, e.g. +3*GHSERAL#).

ENTER_PARAMETER

The expression is a FORTRAN-like expression and operators +, -, *, = and ** can be used (** only with integer powers). Unary-functions LN or LOG (both for natural logarithm) and EXP (for exponential) can also be used. There is also the GEIN function available for the Einstein Model.

```
GEIN(THETA) = 1.5*R*THETA + 3*R*T*LN(1-EXP(-THETA/T))
```

General Einstein Model

Each expression (TP-Function) should end with a semicolon (;), and be followed by its upper applicable temperature limit and a continuation indicator (Y to continue with the next expression or N to end the function's expression). If there is no continuation after a specific expression (TP-Function), the reference index can optionally be given after the N indicator.

A complete/valid function entry can be written in several continuation lines if the function's expression (TP-Function) is too long or if there is more than one applicable expression (TP-Function), as the maximum length of each line is 78 characters.

It is recommended to always have at least one empty space at the beginning of each continuation line. Otherwise, the DATA module may misunderstand the expression or issue some error messages when reading the function entry. Avoid entering functions like the one below.

```
FUNCTION GHSERXY 298.15
-1000+1058*T-38.9*T*LOG(T)+GFUNXY#; 6000 N !
```

Such a function is read by the DATA module as

```
1000+1058*T-38.9*T*LOG(T)+GFUNXY#
```

rather than

```
-1000+1058*T-38.9*T*LOG(T)+GFUNXY#
```

This is because the DATA module concatenates all lines and removes extra spaces before trying to enter the function in the GIBBS workspace. Thus, the - sign is taken as a delimiter between 298.15 and 1000, and the function incorrectly becomes:

```
FUNCTION GHSERXY 298.15 1000+1058*T-38.9*T*LOG(T)+GFUNXY#; 6000 N !
```

Avoid this mistake by giving at least one empty space as the first character of a new line, such as

```
FUNCTION GHSERXY 298.15
-1000+1058*T-38.9*T*LOG(T)+GFUNXY#; 6000 N !
```

which is read correctly as

```
FUNCTION GHSERXY 298.15 -1000+1058*T-38.9*T*LOG(T)+GFUNXY#; 6000 N !
```

The lowest-temperature limit (in Kelvin) for the applicability of the (first) TP-Function in a function is normally set by default as 298.15 K, in most cases. However, you can set another limit when it is applicable (according to experimental data and assessments).

An upper-temperature limit (in Kelvin; followed by a Y or N sign) for the applicability of each TP-Function in a function must be given after the semicolon (;) immediately following the specific TP-Function. The highest-temperature limit (in Kelvin) for the applicability of the current function is always followed by the N sign. If a negative number is given as the lowest-temperature limit, it assumes there are breakpoints in pressure for this function. In these cases, it is interpreted as the lowest-pressure limit (in Pascal), and the other limits in the current function is also taken as pressure limit values (in Pascal).

The temperature/pressure limits for the functions are checked during calculations. An indicator is set if the actual temperature/pressure condition is below the lowest temperature/pressure limit or above the highest temperature/pressure limit. In these cases, an extrapolation is done using the TP-Function valid in the nearest temperature/pressure range.

The optional reference index *{Ref. Index}* is an integer number indicating where to find the particular function in a special reference file. The references are listed when doing the GET_DATA command in the DATA module. They can also be listed in the GIBBS module with the command LIST_DATA with the option R.

For accounting for the reference indices, also see the keyword REFERENCE_FILE.

The reference index field can also be an abbreviation (such as REF:250, REF_002, or REF-SGTE) which denotes the original reference. In this case, the reference cannot be obtained when issuing the DATA command GET_DATA or the GIBBS command LIST_DATA (with the option R).

However, the references directly coded in the database definition file (***setup.TDB) starting with a letter can be shown when issuing the DATA command GET_DATA or the GIBBS command LIST_DATA (with the option N or R). Normally, such references must be located after the LIST_OF_REFERENCE keyword. It is recommended to use reference code names such as REF001, REF018, etc. The reference list, which is generated by the GIBBS command LIST_DATA <file> with the N or R option, is also possible to be directly read by the DATA module.

The DATA module can selectively retrieve functions which are necessary for a defined system from a database that has functions stored in its setup file or SEQ sequential function file, while all other functions irrelevant for the defined system are ignored and are not saved in associated GIBBS and POLY workspaces. Previously, this can only be done for large databases that have functions stored in RND1 random or FTP function files.

Example of FUNCTION

```
FUNCTION GFREE 298.15 1000+GFUNXY#; 6000 N !
FUNCTION GFUNXY 298.15 -1000+200*T+30*T*LOG(T); 6000 N 505 !
FUNCTION G0_CAO 298.15 -663538.11+352.67749*T-57.7533*T*LN(T)
      +5.3895E-03*T**2-8.879385E-07*T**3+575530*T**(-1);
   1400.00 Y -625196.99+78.896993*T-20.40145*T*LN(T)
      -1.112923E-02*T**2+5.1896733E-07*T**3-6917350*T**(-1);
   2900.00 Y -499226.55-490.37695*T+51.95912*T*LN(T)
     -2.961051E-02*T**2+1.4033905E-06*T**3-48114685*T**(-1);
   3172.00 Y -587711.89+375.04117-62.76*T*LN(T);
```

```
6000.00 N REF020 !
```

LIST_OF_REFERENCE

```
LIST_OF_REFERENCE
NUMBER SOURCE
[REFxxx] '[Detailed reference]'
..........
.......... !
```

This keyword starts a reference list that is directly coded in the database definition file (`***setup.TDB`). Its argument begins on the following line, and normally has an explanation line (NUMBER SOURCE) that is followed by various reference codes. Each reference code may occupy one or more lines (each line with maximum 78 characters), but must have a reference code name (that starts with a letter) and the detailed reference information (that is written within two single-quotation marks, `''`). It is recommended to use reference code names such as `REF001`, `REF018`, etc. A maximum of 400,000 characters after the keyword is allowed until the exclamation mark (`!`).

Such a reference list can be shown when issuing the DATA command GET_DATA or the GIBBS command LIST_DATA (with the `R` option). The reference list, which is generated by the GIBBS command LIST_DATA `<file>` with the `N` option, has this structure, and is thus possible to be directly read by the DATA module.

Example of LIST_OF_REFERENCE

```
LIST_OF_REFERENCES
 NUMBER SOURCE
 REF283 'Alan Dinsdale, SGTE Data for Pure Elements,
        Calphad Vol 15(1991) p 317-425,
        also in NPL Report DMA(A)195 Rev. August 1990'
 REF224 'P-Y Chevalier, Thermochimica Acta, 130 (1988) p 33-41; AG-SI'
 !
```

OPTIONS

```
OPTIONS /[alloy name]([composition limitations for all alloying
elements]) !
```

This keyword defines an alloy in a database. An alloy has a name, a major component and a number of alloying elements. The purpose for defining an alloy is to be able to tell you about applicable composition limits of the current database in applications to that particular type of alloy. It is possible to have several alloys in the same database. The alloys are given after the keyword in the database.

The alloy name must be proceeded by a slash (`/`) and terminated by the opening parenthesis, with no spaces are allowed in between.

- The alloy name is maximum 8 characters.
- After the parenthesis, follows the major element and a parenthesis with its minimum mass and minimum mole percent given inside.
- Then, the alloying element names, each with its maximum mass and mole percent are given within parenthesis.
- There must a space between definitions for each alloying element.
- The alloy definition is terminated by a closing parenthesis, and the whole OPTIONS keyword by the exclamation mark (`!`).

Example of OPTIONS

```
OPTIONS /SSteel(Fe(60,60) CR(30,30) NI(15,15) SI(1,1) N(.1,1)) !
```

PARAMETER

```
PARAMETER <parameter name> [lowest temp. limit]
[expression 1]; [upper temp. limit 1] Y
[expression 2]; [upper temp. limit 2] Y
[expression 3]; [upper temp. limit 2] Y
 .......... ; ..... Y
[expression n-1]; [upper temp. limit n-1] Y
[expression n]; [upper temp. limit n] N {Ref. Index} !
```

This keyword can appear in both files for database definition and sequential storage, but not in FTP files. After the keyword, a valid < *parameter name*> in some cases should be given.

It is used to define standard Gibbs energies (i.e. the G parameters for Gibbs energy of formations) of all valid end-members of various stoichiometric and solution phases, and excess Gibbs energies (i.e. the L parameters for Gibbs energy of interactions) of all binary, ternary, quaternary or higher-order interactions in various solution phases; both standard Gibbs energies and excess energies can also have parameters for contributions from PT-depended volume variations (i.e. the V0, VA, VC and VK parameters for molar volume, thermal expansivity, bulk modulus, isothermal compressibility and high-pressure fitting parameter), magnetic ordering (i.e. the TC and BM parameters for Curie temperature and Bohr magneton number) and hypothetical electrostatic interactions (i.e. BM parameter for Born functions $\omega_{Pr,Tr}$ of aqueous solute species).

The general form of a parameter is:

```
<identifier>(<phase>, <constituent array>; <digit>) <xxx> <expression>
<yyy> <keyword Y or N> <zzz> !
```

General Form

Name	*Description*
identifier	The parameter type.
phase	The phase name (maximum 24 characters).
constituent array	The specific constituent array in the phase.

Name	*Description*
digit	The degree of composition-dependent interaction contribution (an integer number from 0 to 9), that is only for excess energy (L), Curie temperature (TC) and Bohr magneton number (BMAGN), as well as for volume-related parameters (V0 or VA or VB or VC or VK); if it is valued as zero, or if it is for the standard Gibbs energy (G) for which the degree is always zero, it can be omitted.
expression	The mathematical relation to describe the parameter.
xxx and yyy	The low and high temperature limits respectively for the applicable temperature range of the parameter expression
keyword Y or N	The indicator on if there is continuation for the parameter expression or not
zzz	The reference index/number for the assessment of this parameter;
!	The exclamation mark is used to indicate that the current parameter definition is ended

GIBBS Parameter Name

The GIBBS parameter name has a general form of:

```
<identifier>(<phase>,<constituent array>;<digit>)
```

GIBBS Parameter Type-Identifier and Definition

The GIBBS parameter name consists of several parts. The first is a *type-identifier*. The following type-identifiers are legal:

Type-Identifier	*Definition*
G	Standard energy parameter (Gibbs energy of formation)
L	Excess energy parameter (Gibbs energy of interaction)
TC	Curie temperature for magnetic ordering

Type-Identifier	*Definition*
BMAGN or BM	Bohr magneton number for magnetic ordering (or Born function ω Pr,Tr for aqueous solute species).
LNTHETA1, LNTHETA2, LNTHETA3, LNTHETA4, and LNTHETA5	$ln(\Theta)$ where Θ is the Einstein temperature. Used by the general Einstein model and together with a corresponding THETAF parameter with the same number. See General Einstein Model in the *Database Optimization User Guide*. This parameter is only available with GES6.
THETAF1, THETAF2, THETAF3, THETAF4, and THETAF5	A weight function used together with a corresponding LNTHETA parameter with the same number. Used by the general Einstein model. See General Einstein Model in the *Database Optimization User Guide*. This parameter is only available with GES6.
V0	Molar volume at 298.15 K and 1 bar (a numeric value only)
VA	Integrated thermal expansivity $\int_{298.15}^{T} \alpha(T)dT$
VC	High-pressure fitting parameter
VK	Isothermal compressibility
VISC	RT*ln(η) where η is the dynamic viscosity
ELRS	Electric resistivity
THCD	Thermal conductivity
SIGM	Surface tension of a liquid end-member
XI	Surface tension dampening factor/interaction for one constituent in a two-constituent combination. See the examples for how to use these parameters
ECij	Elastic constant parameter
ECijMAG	Scaling factor for magnetic contribution to elastic constants

Examples

Parameter	*Definition*
G(GAS,C1O2)	The Gibbs energy of formation of a CO2 molecule in gas.
G(FCC,FE:VA)	The Gibbs energy of formation of fcc Fe with interstitials.
L(LIQ,Fe,Cr;0)	The regular solution parameter for Fe and Cr in liquid.
L(LIQ,Fe,Cr;1)	The sub-regular solution parameter.
TC(BCC,Fe:Va)	The Curie temperature of bcc Fe.
BMAGN(BCC,Fe:Va)	The Bohr magneton number parameter of bcc Fe.
SIGM(LIQUID,AL;0)	Surface tension of Al in LIQUID. Constant value or linear temperature dependence.
XI(LIQUID,AL,CU;0)	Surface tension dampening factor for Al in the Al-Cu combination in LIQUID. Constant value.
XI(LIQUID,AL,CU;1)	Surface tension dampening factor for Cu in the Al-Cu combination in LIQUID. Constant value.
EC11(HCP_A3, TI:VA;0)	The regular solution parameter for elastic constant C11 of HCP Ti with interstitials.
EC11MAG(BCC_A2, FE:VA;0)	The scaling factor for the magnetic contribution to elastic constant C11 for BCC Fe with interstitials.

You can also use G for interaction parameters; and on output list (performed by the GIBBS command LIST_PARAMETER or LIST_PHASE_DATA) the type-identifier L is always used for interaction parameters. Note that the type-identifier BM is also used for Born functions $\omega_{Pr,Tr}$ of aqueous solute species.

The identifier must be followed by an opening parenthesis, a phase name, a comma and a constituent array. Optionally, the constituent array can be followed by a semicolon and a digit. The parameter name is terminated by a closing parenthesis.

It is important that if a phase bears a legal phase-type (among G, A, Y, L, I, F and B) in its phase definition (already by the PHASE keyword; such as GAS:G, LIQUID:L, SLAG:L, IONIC_LIQ:Y, SPINEL:I, FCC_L12:F, HCP_D021:F, BCC_B2:B, AQUEOUS:A), such a valid phase-type code should not be attached to the phase name in the PARAMETER keyword.

Specifying the phase name in UPPER-case is recommended. You can define a phase name as a mixture of UPPER-case and lower-case letters in a database, but the DATA module automatically converts all lower-case to UPPER-case because the GIBBS module only recognizes UPPER-case phase names.

The *constituent array* consists of a list of constituent names. Interaction parameters have two or more constituents from the same sublattice separated by a comma. If the phase has sublattices, at least one constituent in each sublattice must be specified. The exception is if the phase is ionic liquid (specified with the "phase bit" :Y), then neutral endmember and interaction parameters are written as if the first sublattice does not exist, e.g. PARAM G (IONIC_LIQ,FEO3/2;0), i.e. the constituent array does not contain any constituents from the first (cation) sublattice.

For more ionic liquid specific parameters, see Parameters for the Two Sublattice Ionic Liquid Model.

The constituents in different sublattices must be given in sublattice order and are separated by a colon.

After the component array, a sub-index digit can be specified after a semicolon. This digit must be in the range 0 to 9. The interpretation of the sub-index depends on the excess energy model used for the phase. If no semicolon and digit are given, the sub-index value is assumed to be as zero.

The excess energy parameters, e.g. the regular/subregular (binary) parameter or ternary parameters, are multiplied with two or more fractions of the constituents from the same sublattice of the solution phase. These additional constituents must be given as interacting constituents.

Be careful about the sign of odd terms, for example, L(BCC, B, A:VA;1) is treated as L(BCC,A,B:VA;1), i.e. it is always put into alphabetical order.

Solution phases with sublattices may have interacting constituents in each sublattice.

You can use an asterisk (*) to denote that the excess interaction parameter is independent of the constituents of a specific sublattice. For example, L(FCC_L12,AL,NI:*) means that the interaction parameter is for the binary interaction between constituents AL and NI on the first sublattice in the FCC_L12 solution phase, while it is independent of all constituents on the second sublattice. A interaction parameter in the list of constituents is always added to the Gibbs energy and the asterisk (*) is calculated with the term of [1-∑y(specified constituents)], which implies that in an A-B binary system the following three L parameters are identical (but in higher-order systems, they are different):

- `L(phase,A,B)` is multiplied with `X(A)*X(B)`
- `L(phase,A,*)` is multiplied with `X(A)*(1-X(A))`
- `L(phase,B,*)` is multiplied with `X(B)*(1-X(B))`

A parameter always starts with a lowest temperature limit of its applicability, followed by one or more (up to 10) expressions (TP-Functions) coded as mathematical relations of constants, functions of stable variables (T and P) and entered functions (normally with a # suffix, e.g. +3*GSERAL#).

The expression is a FORTRAN-like expression and operators +, -, *, = and ** can be used (** only with integer powers). Unary-functions LN or LOG (both for natural logarithm) and EXP (for exponential) can also be used.

There is also the Einstein function GEIN available:

```
GEIN(THETA) = 1.5*R*THETA + 3*R*T*LN(1-EXP(-THETA/T))
```

General Einstein Model

Each expression (TP-Function) should ends with a semicolon (;) and be followed by its upper applicable temperature limit and a continuation indicator (Y to continue with the next expression, or N to end the parameter's expression). If there is no continuation after a specific expression (TP-Function), the reference index can be optionally given after the N indicator.

A complete/valid parameter entry can be written in several continuation lines if the parameter's expression (TP-Function) is too long or if there is more than one applicable expression (TP-Function), as the maximum length of each line is 78 characters.

It is recommended to always have at least one empty space at the beginning of each continuation line. Avoid entering parameters such as:

```
PARAMETER G(LIQUID,A,B) 298.15
-2000+4568*T+2*GFUNAB#; 6000 N !
```

Such a parameter is read by the DATA module as 2000+4568*T+2*GFUNAB#, rather than as -2000 +4568*T+2*GFUNAB#.

Avoid this mistake by giving at least one empty space as the first character of a new line, such as

```
PARAMETER G(LIQUID,A,B) 298.15
-2000+4568*T+2*GFUNAB#; 6000 N !
```

The lowest-temperature limit (in Kelvin) for the applicability of the (first) TP-Function in a parameter is normally set by default as 298.15 K, in most cases; however, you can set another limit when it is applicable (according to experimental data and assessments). An upper-temperature limit (in Kelvin; followed by a Y or N sign) for the applicability of each TP-Function in a parameter must be given after the semicolon (;) immediately following the specific TP-Function; and the highest-temperature limit (in Kelvin) for the applicability of the current parameter is always followed by the N sign. If a negative number is given as the lowest-temperature limit, it is assumed that there are breakpoints in pressure for this parameter. In such cases, it is interpreted as the lowest-pressure limit (in Pascal), and the other limits in the current parameter are also taken as pressure limit values (in Pascal).

The temperature/pressure limits for the parameters are checked during calculations. An indicator is set if the actual temperature/pressure condition is below the lowest temperature/pressure limit or above the highest temperature/pressure limit. In these cases, an extrapolation is done using the TP-Function valid in the nearest temperature/pressure range.

The optional reference index *{Ref. Index}* is an integer number indicating where to find the particular parameter in a special reference file. The references are listed when doing the GET_DATA command in the DATA module. These can also be listed in the GIBBS module with the command LIST_DATA and the option R or N.

For accounting the reference indices, also see the keyword REFERENCE_FILE.

The reference index field can also be an abbreviation (such as REF:250, REF_002, or REF-SGTE) denoting the original reference. In this case, the reference cannot be obtained when issuing the DATA command GET_DATA or the GIBBS command LIST_DATA (with the option R or N).

However, the references directly coded in the database definition file (***setup.TDB) that starts with a letter can be shown when issuing the DATA command GET_DATA or the GIBBS command LIST_DATA (with the option R or N). Normally, such references must be located after the LIST_OF_REFERENCE keyword. It is recommended to use reference code names such as REF001, REF018, etc. The reference list, which is generated by the GIBBS command LIST_ DATA <file> with the N option, is thus also possible to be directly read by the DATA module.

Examples

```

```

Parameters for the Two Sublattice Ionic Liquid Model

For the two sublattice ionic liquid model (specified with the "phase bit" :Y in the phase declaration), there are some additional requirements on the allowed parameters. While in the regular case all combinations of a phase's constituents are allowed as end-members, there are some constraints on the allowed parameters for ionic liquid.

In the ionic liquid model, the vacancy has been given an "induced" charge -Q, where Q is the average charge of the first (cation) sublattice.

All allowed parameters are listed below. The following notations are used:

- `C`= Cation
- `C1`= Cation 1 if more than one. Similar for anions and neutrals.
- `A`= Anion
- `VA`= Vacancy
- `N`= Neutral
- `D`= Anion or vacancy or neutral (i.e. anything on the second sublattice)

The phase description is:

```
(C1,C2…Ci)P(A1,A2...Ai,VA,N1, N2...Ni)Q
```

In the ionic liquid model,the Vacancy has been given an "induced" charge -Q, where Q is the average charge of the first (cation) sublattice.

Allowed end-members, assuming the phase name is IONIC_LIQ:

```
G(IONIC_LIQ,C:A;0)
G(IONIC_LIQ,C:VA;0)
G(IONIC_LIQ,N;0)
```

(The last line is an exception to the case that the constituent array must contain constituents from all sublattices)

This leaves one not allowed end-member:

```
G(IONIC_LIQ,C:N;0)
```

Allowed binary interaction parameters, where i is the interaction order in a Redlich-Kister expansion.

```
G(IONIC_LIQ,C1,C2:A;i)
G(IONIC_LIQ,C1,C2:VA;i)
G(IONIC_LIQ,C:VA,N;i)
G(IONIC_LIQ,N1,N2;i)
G(IONIC_LIQ,C:A1,A2;i)
G(IONIC_LIQ,C:A,VA;i)
G(IONIC_LIQ,C:A,N;i)
```

No other binary interactions are allowed.

Allowed ternary interaction parameters. The interaction is composition independent if there is one parameter with i = 0. It is composition dependent if there are three parameters with i = 0, 1 and 2. There can only be one or three parameters for one combination of constituents

```
G(IONIC_LIQ,C1,C2,C3:A;i)
G(IONIC_LIQ,C1,C2,C3:VA;i)
G(IONIC_LIQ,N1,N2,N3;i)
G(IONIC_LIQ,C1,C2:VA,N;i)
G(IONIC_LIQ,C:VA,N1,N2;i)
G(IONIC_LIQ,C:A,D1,D2;i)
G(IONIC_LIQ,C1,C2:A,D;i)
```

No other ternary interactions are allowed.

PHASE

```
PHASE [phase name]*24 [data-type code]*8 [numb. subl.] [sites in subl.
1] [sites in subl. 2] etc... {auxiliary text string} !
```

This keyword defines a phase and its properties (except for what species are allowed to enter it and for its parameters).

The *phase name* (maximum 24 characters) must be unique; otherwise the DATA module sees it as an attempt to redefine a previously defined phase. This causes DATA to display an error message and ignore the rest of the line. A phase name can be suffixed by an underscore (_and letters to identify the physical state(s) or structure type(s) of the phase.

Examples of Recommended Suffixes

The *phase name* can also be attached with a colon sign (:) and a letter for a legal GIBBS phase-type code (e.g. `IONIC_LIQ:Y` and `GAS:G`).

Suffix	*Definition*
`ABC_S`	The ABC phase in solid state.
`ABC_S2`	The ABC phase in solid state 2.
`ABC_S3`	The ABC phase in solid state 3.
`ABC_LT`	The ABC phase in solid state at low temperatures.
`ABC_HT`	The ABC phase in solid state at high temperatures.
`ABC_L`	The ABC phase in liquid state.
`ABC_LIQ`	The ABC phase in liquid state.
`FCC_A1`	The FCC phase in disordered structure type A1.
`FCC_L12`	The FCC phase in ordered structure type L12.

GIBBS Phase-type Codes

Code	*Definition*
G	Bit set for a gaseous mixture phase.
A	Bit set for an aqueous solution phase.
Y	Bit set for an ionic liquid solution phase (specially treated by the Ionic Two-Sublattice Liquid Model).
L	Bit set for a liquid solution phase (but not A (aqueous) or Y (ionic liquid)).
I	Bit set for a phase with charged species (but not G (gaseous), A (aqueous) or Y (ionic liquid)).
F	Bit set for an ordered FCC or HCP solution phase using the *Four Substitutional-Sublattice Ordering Model* (additionally, such a phase can also have interstitial sublattices).
B	Bit set for an ordered BCC solution phase using the *Four Substitutional-Sublattice Ordering Model* (additionally, such a phase can also have interstitial sublattices).

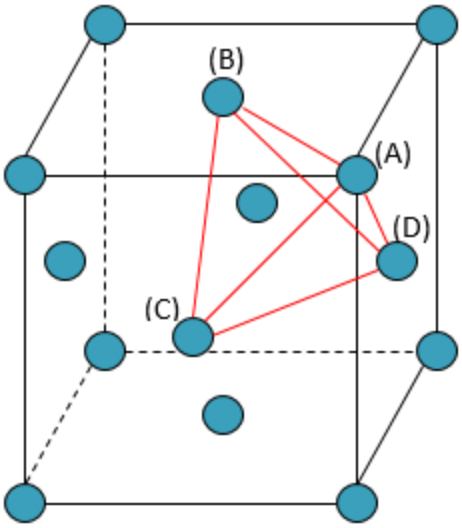
Other invalid characters (e.g. M or P) are eventually treated, together with the colon (:) as a part of a phase name.

A G phase (gaseous mixture) or an A phase (aqueous solution) is usually treated as a substitutional phase without sublattice, and an L phase (ordinary liquid solution) is normally (but not always) modeled as a substitutional phase without sublattice, too.

For ordered FCC or HCP phases, these four substitutional sublattices represent four corners of the regular tetrahedron on these lattices, all of which are the nearest neighbours, as shown.

FCC Unit Cell Example

An FCC unit cell with the lattice positions indicated that correspond to the G (FCC,A:B:C:D) end member. All lattice positions are equivalent for a four substitutional-sublattice ordering model.



A *Normal 4-Sublattice Model* requires that all the `G` parameters for each of the end-members with the same elements but distributed on different sites be given separately. However, as these corners are identical lattice points, the phase-type option `F` means that the `G` parameters need be given only once. The possible permutations are handled automatically.

Additional Clarification

An `A-B` binary solution phase (with the element A located on one sublattice site and `B` on the other three sublattice sites) treated by the Normal 4-Sublattice Model has to have four `G` parameters for four end-members, i.e.

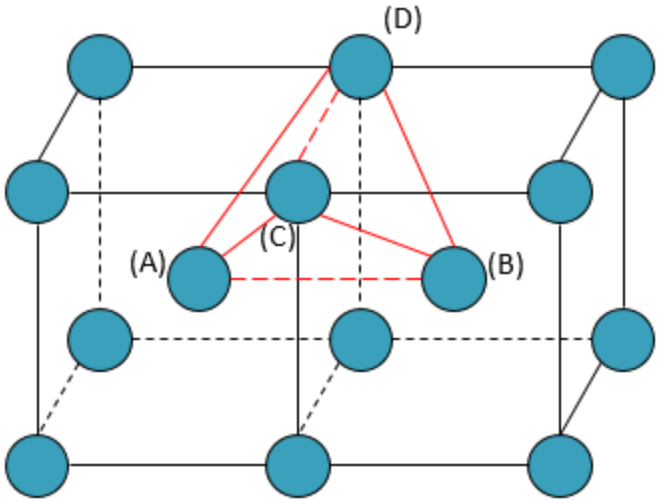
- G(phase,A:B:B:B)
- G(phase,B:A:B:B)
- G(phase,B:B:A:B, and
- G(phase,B:B:B:A)

This is because in the general case these `G` parameters can be different from each other. But for the FCC and HCP orderings, they are identical and thus all `G` parameters of such end-members need to be given only once, and the possible permutations are then automatically handled by the GIBBS module. Also, only one of the identical permutations is listed; in this example, `G(phase,A:B:B:B)` where it is alphabetically the first in the list of permutations. This significantly simplifies the usage of this model (*Four Substitutional-Sublattice Ordering Model*) in multicomponent alloys.

For ordered BCC phases, the phase-type option `B` means the same thing but it is more complicated since the 4-substitutional-sublattice ordering phase represents an irregular tetrahedron with two pairs of sites that are next nearest neighbours as shown:

BCC Unit Cell Example

Two BCC unit cells with the lattice positions indicated that correspond to the G (BCC,A:B:C:D,0) end member. Lattice positions (A) and (B) are equivalent, as are lattice positions (C) and (B) for a four substitutional-sublattice ordering model.



For an end member described by the parameter `G(phase,A:B:C:D)` A and B are next nearest neighbours, as are C and D. And the nearest neighbours of A (or B) are C and D. Thus, for an `A-B` binary solution phase (with the element A located on two sublattice sites and `B` on two sublattice sites) treated by the Normal 4-Sublattice Model, the end-member described by the `G(phase,A:A:B:B)` term has four nearest neighbour bonds between A and B atoms, whereas the end-member described by the `G(phase,A:B:A:B)` term has two nearest neighbour bonds between A and B atoms and three next nearest neighbour bonds.

The first end-member (described by the `G(phase,A:A:B:B)` term) represents B2-ordering and the second (described by the `G(phase,A:B:A:B)` term) stands for B32-ordering. There are two permutations of the `G(phase,A:A:B:B)` term and four permutations of the `G(phase,A:B:A:B)` term, automatically conducted in the *Four Substitutional-Sublattice Ordering Model*. If you enter the unary, binary, ternary and quaternary parameters you are dealing with 1, 6, 21, 55 parameters for BCC:B, 1, 5, 15, 35 parameters for FCC:F and 1, 16, 81, 256 parameters for phases without F/B.

An additional feature with the phase-type options `F` and `B` is that a composition set that represents the solution phase has a suffix (indicating what ordering the phase has) that is automatically added to its phase name in some listings of equilibrium calculations (when performing either single-point or stepping or mapping calculations, and when plotting the calculated property diagrams or phase diagrams).

Such suffix indications can be:

Solution Phase	*Suffix for Disordered Phase*	*Suffix for Ordered Phase*
`FCC PHASE`	`FCC_A1`	`FCC_L12`
		`FCC_L10`
`BCC PHASE`	`BCC_A2`	`BCC_B2`
		`BCC_B32`
		`BCC_D03`
		`BCC_L21`
`HCP PHASE`	`HCP_A3`	`HCP_D019`
		`HCP_B19`

If you want to convert an existing database TDB file to use the F/B feature, add the phase-type code to the corresponding phase name in the PHASE and CONSTITUENT commands in the TDB-file, then when running the LIST_DATA command in the Gibbs (GES) module. The created database file is in this less verbose format.

The *data-type code* consists of 1 to 8 characters where each character must stand for an action, which is to be coupled to this phase. The keyword TYPE_DEFINITION, described below, must be used in the current database to specify what action should be taken by DATA for each character code.

The data entries `[numb. subl.] [sites in subl. 1] [sites in subl. 2]` etc., specify the total number of sublattices (always as an integer digit) and the sites (i.e. stoichiometric coefficients) of each of the sublattices (given in either integer digits or real numerical factors) for the phase.

Optionally, an *auxiliary text string* (maximum 10,000 characters) can be given after the last [sites in sublattice #] but before the exclamation mark `!`. This string displays in connection with the phase name in some listings within the DATA module.

PHASE Examples

```
PHASE GAS:G % 1 1.0 !
PHASE LIQUID:L %ZCDQ 2 1.0 1.0
> Metallic liquid solution, modeled by CEF Model. !
PHASE IONIC-LIQ:Y %ZCDQ 2 1.0 1.0
> Ionic liquid solution, modeled by Ionic Two-Sublattice Model. !
PHASE SPINEL:I   %ZA  4  1 2 2 4
> Complex Spinel Solution, by CEF model with ionic constraints. !
PHASE M23C6 % 3 20.0 3.0 6.0 !
PHASE FCC_A1   %&A 2 1 1
> Disordered FCC phase; also as MX carbides/nitrides. !
PHASE FCC_L10  %&AX 3 0.75 0.25 1
> Ordered FCC phase, modeled by 2-Sublattice Model for Ordering. !
PHASE FCC_L12:F %&AX 5 0.25 0.25 0.25 0.25 1.0
> Ordered FCC phase, modeled by 4-Sublattice Model for Ordering. !
PHASE AQUEOUS:A %HIJMR 1 1.0
> Aqueous Solution: using the Complete Revised HKF Model. !
```

REFERENCE_FILE

```
REFERENCE_FILE [file name] !
```

This keyword takes a reference file name as its argument. This reference file (that must be edited in a restrictive way and be saved as a blocked file with a fixed line-length for each line in the file, as described below) contains a complete list of the references for the various parameters (and sometimes functions) in the database. The file must have a fixed record structure: each reference entry with one or several records, and each record with exactly 78 characters written in one single blocked line; and no empty space is allowed at the beginning of all lines in the file. If there are more than one record entered for a reference entry, all the continuation lines must start with an ampersand (&). The line number of the first record for a specific reference entry is then accounted as the unique integer for that specific reference, which is referred when a parameter or function calls this integer as the optional *{Ref. Index}*.

Keywords PARAMETER or FUNCTION have information about specifying a reference index.

Example of REFERENCE_FILE

```
/-1<G>           T.C.R.A.S. Class 1
AG1.64TE1        THERMODATA 01/93
&28/01/93
&SILVER 1.64-TELLURIDE. Solid Standard State.
AG1              HULTGREN SELECTED VAL.       SGTE **
&AT.WEIGHT 107.870,STANDARD STATE:CODATA KEY VALUE.MPT=1234.93K. &--
U.D. 30/10/85.
AG1<G>           T.C.R.A.S Class: 1
AG1/+1<G>        T.C.R.A.S Class: 1
AG1BR1           N.P.L.                       SGTE **
&Tfusion uncertain and heat vaporization estimated.
AG1BR1<G>        THERMODATA 01/93
&28/01/93
&Gaseous Standard State.
AG1BR1O3         BARIN & KNACKE.SUPPL.REF:62,* SGTE **
&AGO3BR        SILVER OXYTRIBROMIDE
```

In the example, the unique integers of related references (for assessed elements, species, phases, interactions, etc.) are:

```
1/-1<G>
2AG1.64TE1
5 AG1
8AG1<G>
9AG1/+1<G>
10AG1BR1
12AG1BR1<G>
15AG1BR1O3
```

SPECIES

```
SPECIES [species name]*24 [stoichiometric formula] !
```

This keyword defines species in the data structure. Every *species name* (maximum 24 characters) must be unique. The species are built from the predefined set of elements in the stoichiometric formula. If an undefined element is referenced, DATA displays an error message and the data structure is probably damaged.

The species names do not have to be the same as the stoichiometry formula, although in general this is recommended. The elements are automatically entered as species using the same names of the elements.

You can define a species name as a mixture of UPPER-case and lower-case letters in a database, but the DATA module automatically converts all lower-case to UPPER-case because the GIBBS module only recognizes UPPER-case species names.

When naming the species in a database, use special characters (such as +, -, _, / and .) in species names. Avoid using other special characters (such as `(` and `)`).

The *stoichiometric formula* is written with a simplified chemical notation, in which the chemical elements should always be given in UPPER-case and in any preferred order, and the stoichiometric coefficients are written in either real numerical factors or integer digits.

It is important that the numerical factor of `1` is not left out. Subgroups are not allowed in a stoichiometry formula; however, while specifying the stoichiometry formula for a specific species in a database, you can specify it in a way that some elements (always together with the corresponding partial stoichiometric coefficients) are repeated (as in the examples below).

Example of SPECIES

```
SPECIES AL2O3     AL2O3 !
SPECIES Silica    SI1O2 !
SPECIES NaSb_6OH  NA1SB1O6H6 !
SPECIES FE+2       FE/+2 !
```

```
SPECIES SB-3       SB/-3 !
SPECIES AlCl2/3           AL.33333CL.666667 !
SPECIES AL1CL1H2O2        AL1CL1H2O2 !
SPECIES AlCl3_3H2O        AL1CL3H6O3 !
SPECIES AlO2H2Cl.H6O3     AL1O2H2CL1H6O3 !
SPECIES AlCl2-OH.3H2O     AL1CL2O1H1H6O3 !
SPECIES AlCl2OH.3Water    AL1O1H1CL2H6O3 !
```

TABLE

It is recommended to always have at least one empty space at the beginning of each continuation line. Otherwise, the DATA module may issue some error messages when reading the table entry.

```
TABLE [name]*8 [start temp] [end temp] [delta temp] [table values] !
```

This keyword can appear in both files for database definition and sequential storage, but not in FTP files. It makes a table of Gibbs energy as a function of temperature where the values are given from the start temperature to the end temperature, at a step of the delta temperature.

Example of TABLE

```
TABLE DEMTAB 1000.0 1500.0 100.0 -2912.9008 -2834.2416 -2755.5824
             -2677.7600 -2600.7744 -2524.2072 !
```

TEMPERATURE_LIMITS

```
TEMPERATURE_LIMITS [lower limit] [upper limit] !
```

This keyword sets the default upper and lower temperature limits used by the GIBBS module for Gibbs energy parameters and functions. It can be used only once in one database definition file and all its sequential files.

Example of TEMPERATURE_LIMITS

```
TEMPERATURE_LIMITS 500.0 1800.0 !
```

TYPE_DEFINITION

```
TYPE_DEFINITION [data-type code]*1 [secondary keyword with parameters]
!
```

This keyword couples phases to an action performed by the DATA module when the DATA command GET_DATA is executed.

Secondary Keywords

The secondary keywords and associated parameters in syntax are:

```
SEQ [filename]
RND# [filename]
GES [valid GIBBS command with parameters]
POLY3 [valid POLY command with parameters]
TDB [valid DATA command with parameters]
IF [conditional statement] THEN [keyword with parameters]
AFTER [valid GIBBS command with parameters]
```

The secondary keyword `SEQ` specifies a sequential file that stores parameters belonging to the phases using the associated data type code (which is defined by this keyword). A special case where the filename is given as an asterisk (`*`) implies that the database definition file also acts as a sequential data storage file. This case makes it possible to have a single file for a small database, which is especially suited for personal databases.

The secondary keyword `RND` should be concatenated with a positive integer `#` to indicate the type of the random file. Currently, there are these types of random files:

- `RND0`, the default, is used for complete Gibbs energy expressions (G0 parameters), where the search field is the unabbreviated parameter name.
- `RND1` is designated for functions, where the function name is used as the search field.
- `RND2` is reserved for binary interaction parameters, where its search field is also the unabbreviated parameter name without any interaction order notation.

Ternary and higher order interaction parameters must be specified on a sequential file. Moreover, the internal structures of these random files are subject to changes with different versions of DATA, and with implementations of DATA on various computer systems. For more information, see the FORTRAN program TDBSORT, which is available from Thermo-Calc Software AB.

The secondary keywords `GES`, `POLY3`, or `TDB` specifies a modification of, or addition to, phases having the associated data type code, such as magnetic contribution, another excess model, or any other valid GIBBS/POLY/DATA command that applies to a certain phase. By implementing this as a call to the interactive GIBBS/POLY/DATA module, flexibility is achieved. If a new type of addition is implemented in a GIBBS/POLY/DATA module, it can be immediately used in the database definition file without reprogramming the DATA module.

In several examples below, the use of the at (`@`) sign indicates any phase to which the relevant type definition (e.g. `A`, `B`, `4`, or `E`) applies.

The secondary keywords `IF` and `THEN` allow specification of a conditional statement structured with respect to the phase constitution that controls the execution of a following type-definition (keyword with parameters) string. See the last four examples.

The secondary keyword `AFTER` is similar to the GES keyword except the defined GIBBS command is executed after all parameters are entered. The reason for this is that the command has no effect unless there is a parameter. Following the `AFTER` keyword, a GIBBS command must be given and it is executed after entering the parameters of the phase.

The data-type code (always as one string) can be any normal or special character, e.g. `0`, `5`, `A`, `F`, `M`, `%`, `&`, and so forth, and is referred in the definition keywords PHASE, COMPOUND_PHASE and ALLOTROPIC_PHASE for various phases.

A phase can have several ADDITIONAL parts of different types (that are enforced by certain TYPE_DEFINITIONS which call the GIBBS command AMEND_PHASE_DESCRIPTION for describing various contributions to Gibbs energy). However, the DATA/GIBBS module automatically deletes any early-defined ADDITIONAL part(s) of the same type.

The DATA module can selectively retrieve functions that are necessary for a defined system from a database that has functions stored in its `setup` file or `SEQ` sequential function file, while all other functions irrelevant for the defined system are ignored and are not saved in associated GIBBS and POLY workspaces.

Example of TYPE_DEFINITION

```
TYPE_DEF % SEQ TCPATH\DATA\[DATABASE]\PARAMETERS.TDB !
TYPE_DEF I SEQ TCPATH\DATA\[DATABASE]\INTERACTION-PARAMS.TDB !

```

Ordered Phase Restores Disorder Contribution

When an ordered phase with disordered contribution is restored, the disordered contribution is automatically restored as well. You can also restore the disordered phase *without* restoring the ordered phase.

However the DIS_PART TYPE_DEFINITION must always be set on the ordered phase. It is important that the disordered phase is declared *before* the ordered phase. Otherwise it causes an error when DIS_PART TYPE_DEFINITION is executed and then either the ordered or disordered phase is rejected.

Example

```
TYPE_DEFINITION & GES A_P_D FCC_A1 MAGNETIC -3.0   2.80000E-01 !
PHASE FCC_A1 %& 2 1  1 !
  CONSTITUENT FCC_A1 :CR,NI% : C%,VA : !
$ THIS PHASE HAS A DISORDERED CONTRIBUTION FROM FCC_A1
TYPE_DEFINITION ' GES AMEND_PHASE_DESCRIPTION FCC_L12 DIS_PART FCC_
A1,,,!
TYPE_DEFINITION ( GES A_P_D FCC_L12 MAGNETIC -3.0   2.80000E-01 !
PHASE FCC_L12 %'( 3 .75  .25  1 !
  CONSTITUENT FCC_L12 :CR,NI% : CR,NI% : C,VA% : !
```

For example a GES command such as the following only affects phases defined above or at the phase with this TYPE_DEFINITION in the TDB file:

```
TYPE_DEFINITION ( GES A_P_D FCC_L12 DIS_PART FCC_A1,,, !
```

For example a TDB command such as the following only affects phases defined *below* the phase with this TYPE_DEFINITION in the TDB file:

```
TYPE_DEFINITION ( TDB RESTORE_PHASE FCC_A1 !
```

VERSION_DATA

```
VERSION_DATE [string]*78 !
```

The string is denoted as the version/revision date and database manager of the database. Nowadays, this directive is used mainly for the purpose of keeping the development and revision history mostly updated.

Example of VERSION_DATA

```
VERSION_DATE Last update and adjustment: Database Manager, 2015-09-25 !
```

Working with the Mobility Databases

Topics to Explore >

Extensions to Database Definition File Syntax **1513**

DIFFUSION **1514**

Valid Model Keywords *1514*

Example of DIFFUSION *1514*

PARAMETER **1515**

ZEROVOLUME_SPECIES **1516**

Extensions to Database Definition File Syntax

Software packages for simulation of diffusional phase transformations, such as the Diffusion Module (DICTRA) and Precipitation Module (TC-PRISMA), need both thermodynamic data and kinetic data (i.e. diffusivities or mobilities). Naturally, the handling and storage of kinetic data also benefits from the use of some kind of database management. Thus, the TDB database definition file syntax has been extended to incorporate some keywords needed for storing kinetic data - PARAMETER, DIFFUSION, and ZEROVOLUME_SPECIES .

DIFFUSION

```
DIFFUSION [model keyword] [phase name] [additional parameter(s)] !
```

This keyword specifies the type of diffusion model to use for a phase if the default model is not desired. The default model calculates the full diffusion matrix. A diffusivity is calculated from the different mobilities and the thermodynamic factors. The former ones are calculated as:

```
M = exp (∑MF/RT) exp (∑MQ/RT) / RT
```

where ∑ stands for a weighted summation of the different MF's and MQ's plus possibly a Redlich-Kister term.

Valid Model Keywords

Keyword	*Description*
NONE	No diffusion in this phase
DILUTE	Constitution list of dependent species in each sublattice must be given as an additional parameter. Only the diagonal terms in the diffusion matrix are calculated. D = exp (∑ DF/RT) exp (∑DQ/RT).
SIMPLE	Constitution list of dependent species in each sublattice must be given as additional parameter. Only the diagonal terms in the diffusion matrix are calculated. D = ∑ DF + ∑ DQ.
MAGNETIC	The so-called ALPHA and ALPHA2 parameters must be given as additional parameters. ALPHA is for the substitutional magnetic model and ALPHA2 for the interstitial one. By appending an & sign and a species name after the alpha keyword one can supply individual values for the different species. The full diffusion matrix is calculated.

Example of DIFFUSION

```
DIFFUSION NONE SIGMA !
DIFFUSION DILUTE CEMENTITE : FE : C : !
DIFFUSION MAGNETIC BCC_A2 ALPHA=0.3 ALPHA2&C=1.8 ALPHA2&N=0.6 !
```

PARAMETER

```
PARAMETER [special GIBBS parameter name] [low temp. limit]
[expression 1]; [upper temp. limit 1] Y
[expression 2]; [upper temp. limit 2] Y
[expression 3]; [upper temp. limit 2] Y
 .......... ; ..... Y
[expression n-1]; [upper temp. limit n-1] Y
[expression n]; [upper temp. limit n] N {Ref. Index} !
```

This keyword allows you to enter all types of normal GIBBS parameters for thermodynamic data as well as five special extensions suitable for kinetic data used in the Diffusion Module (DICTRA).

Valid extensions to special GIBBS parameter names are:

- `MQ`: Activation enthalpy for mobility equation.
- `MF`: Pre-exponential factor for mobility equation.
- `DQ`: Activation enthalpy for diffusivity equation.
- `DF`: Pre-exponential factor for diffusivity equation.
- `VS`: Volume counted per mole of volume carrying species.

See the TDB file for DICTRA example *exa4: Carburization of binary Fe-C alloy: Comparison to an analytical erf solution*. Press F1 in Thermo-Calc to search the help for more information.

```
$============== D I F F U S I O N   D A T A ====================
$
 ZEROVOLUME_SPECIES C VA !

PARA DQ(FCC_A1&C,*:*),,  -148000+32.8*T+R*T*LOG(4.53E-7);,,N!
PARA DQ(FCC_A1&FE,*:*),, -286000+R*T*LOG(0.700E-4);,,N!
```

ZEROVOLUME_SPECIES

```
ZEROVOLUME_SPECIES [list of species] !
```

In the Diffusion Module (DICTRA), the assumption that the volume is carried by the substitutional elements only is applied. The interstitial elements are assumed to have zero molar volumes. This keyword uses a list of which species are to be considered as zero volume ones for an argument.

There is no underscore (_) between *Zero* and *Volume*.

For example

```
ZEROVOLUME_SPECIES VA C N !
```
