Example 3: A Public Database for the Fe-Cr-C Ternary System

```
$
$  Revision history:
$      Created as PDEMO by Pingfang Shi on 2004-10-05
$      Renamed to DFeCrC by Pingfang Shi on 2006-10-25
$
$ FURTHER MODIFICATIONS:
$ ======================
$ pfs: /20041005 (PDEMO)
$      * Retrieved all definitions from PTERN for the Fe-Cr-C ternary !
$
$ pfs: /20061025 (DFeCrC)
$      * Ignore ELEMENT /- definition.
$      * Modify the L(BCC_A2,FE:C,VA;0) [and L(BCC_A2,CR:C,VA;0)]
$        parameters, in order to avoid BCC-appearance (Fe-C)
$        at temperatures higher than 3900 K.
$          $L(BCC_A2,CR:C,VA;0) 298.15 -190*T;          6000 N REF1 !
$           L(BCC_A2,CR:C,VA;0) 298.15 -190*T; 3000 Y 0; 6000 N REF1 !
$          $L(BCC_A2,FE:C,VA;0) 298.15 -190*T;          6000 N REF3 !
$           L(BCC_A2,FE:C,VA;0) 298.15 -190*T; 3900 Y 0; 6000 N REF3 !
$      * Add Cr into HCP_A3 phase, and
$        add all necessary G0/L parameters (according to SSOL2/TCFE3):
$          G(HCP_A3,CR:VA;0)
$          TC(HCP_A3,CR:VA;0)
$          BMAGN(HCP_A3,CR:VA;0)
$          G(HCP_A3,FE:C;0)
$          G(HCP_A3,CR:C;0)
$          L(HCP_A3,CR:C,VA;0)
$          L(HCP_A3,CR,FE:VA;0)
$      * Add "TMM:300/3000" limits to all three binary joins in the
$          ASSESSED_SYSTEM section.
$      * Change the reference indices, e.g., 101 to REF1, in order to
$          always get the reference list correctly.
$      * Re-arrange database format slightly.
$      * Updated the DATABASE_INFO section.
```

$ DATABASE INFORMATION:
$**********************************************************************
$
 DATABASE_INFO                                    DFeCrC '
              TCS Demo Fe-Cr-C Alloy Solutions Database'
       (only for demonstration purposes in TCC-Demo/TCW-Demo)'
    ********************************************************** '
                      (Version 1.2, Oct. 2006) ''
       Copyright @ 2004-2012: Thermo-Calc Software AB, Sweden ''
The DFeCrC database (previously called PDEMO) is the TCS Demo Fe-Cr-C '
Alloy Solutions Database, which is especially designed for primarily '
demonstrating the uses of: '
* TCC-Demo software: BIN, TERN, SCHEIL and some other modules; '
* TCW-Demo software: '
   "Binary" module calculations of phase diagrams and property diagrams'
               in available binary systems; '
   "Ternary" module calculations of phase diagrams (e.g., isothermal'
               sections, monovariant lines involving liquid, liquidus'
               surface projections) and property diagrams in available'
               ternary systems; '
   "Scheil" module simulations of alloy solidifications; and/or '
   "Equilibrium" calculation routines for phase diagrams and property'
               diagrams in available binary or ternary systems. '
It can also be used for other types of calculations/simulations in both'
TCC and TCW software, and in their application programming interfaces.''
It includes critically-assessed data for all possible three binary joins'
(i.e. Cr-C, Fe-Cr and Fe-Cr) and one complete ternary alloy solutions '
within the Fe-Cr-C system. However, due to the fact that experimental'
data for the Fe-C and Cr-C binary joins and Fe-Cr-C ternary system at '
extremely-high temperatures are not sufficient, the available assessed'
data can not be applied to temperature conditions higher than 4000 K.''
Included thermodynamic data are available for various stoichiometric '
and solution phases, e.g. liquid mixture, various alloy solutions and '
intermetallic phases. But the gaseous mixture phase is excluded in this'
```

```
DEMO version.''
The DFeCrC database can be used not only in calculating various types '
of phase diagrams (binary phase diagrams, ternary isothermal sections,'
ternary monovariant lines involving liquid, ternary liquidus surface '
projections, ternary isopleth sections, etc.) and property diagrams '
(the easiest ways are through the BIN and TERN modules), but also in '
simulating alloy solidification processes (with the SCHEIL module) of'
Fe-based or Cr-based alloys (but limited within the Fe-Cr-C ternary '
system in this DEMO version). Many unique features of the TCC/TCW '
software can be demonstrated using this and other specially-designed '
DEMO databases. ''
However, this DFeCrC database (similar to other DEMO and/or PUBLIC TC '
databases) is provided within the TCC-Demo/TCW-Demo software only for '
the purposes of demonstration, testing and evaluation. For R&D projects'
and teaching activities, you are highly encouraged to only use the FULL'
versions of the TCC and/or TCW software together with some commercial '
databases that are appropriate for your specific applications. Please '
contact us for all kinds of details. ''
Release History: Version 1.1 with minor improvements, Oct. 2004 '
               Version 1.2 with minor modifications, Oct. 2006 ''
Edited by: Dr. Pingfang Shi (Thermo-Calc Software, Oct. 2006). ''

About the Database Checker **1539**

Using the Database Checker **1541**

Example of Working with the Database Checker *1541*

About the Database Checker

The Thermo-Calc software package includes a program to check that the syntax of unencrypted database files is correct. The program applies the syntax rules set out in the *Database Manager User Guide* and reports errors and issues warnings. This program is intended for advanced users who develop and manage databases.

Thermo-Calc accepts some deviations from these syntax rules. Although warnings can be ignored, errors must be corrected. Reported errors must be corrected in the TDB file before the database can be loaded by the application. Sometimes the warnings can also reveal the need for additional corrections as shown in the example below.

For example, a warning is generated if a phase name is detected that is also an abbreviation of another phase name in the database. Although allowed, it is not recommended as this can (in some cases) lead to unexpected results because abbreviations are also used when entering commands in the Console and included in macro files. The following shows why in this case an abbreviation is not recommended.

Imagine that a macro file uses the abbreviation `ABC` to refer to a phase in a database that is named `ABCDE`. As long as there is no other phase in the database with the same exact name or initial abbreviation, it works. But if a new phase is added to the database and is actually named `ABC` then the macro can in error refer to the wrong phase. The macro still runs but now refers to the phase `ABC` instead of `ABCDE` because `ABC` is an exact match, *which takes precedence over abbreviations*. The Database Checker displays a warning because this situation can only occur when one phase name is an abbreviation of another.

With respect to using this tool, the executable `DatabaseChecker` file is found in the Thermo-Calc home directory.

The program can also be launched by selecting **Tools** → **Database Checker** from the main menu in Thermo-Calc.

Large amounts of RAM can be required when checking large databases.

The Database Checker application is standalone and available as indicated from the **Tools** menu in Thermo-Calc. However, as required, you can run the `DatabaseChecker.exe` file as a stand-alone program from the file Thermo-Calc installation directory.

Installation Default Directory: Windows, Installation Default Directory: macOS, or Installation Default Directory: Linux

Using the Database Checker

Custom Databases: GES5 and GES6 Calculation Engine Version

As of Thermo-Calc version 2019b, the default calculation engine is set to GES6. For custom database users, you may sometimes see messages in the log indicating that additional preparation is being done by Thermo-Calc prior to a calculation. The preparation is carried out automatically; it is usually fast and only needed the first time a custom database is used after a modification. While databases with warnings are tolerated, databases that contain errors can only be loaded by GES6 after the errors are corrected.

The Database Checker tool uses the same parser as GES6 and can be used to verify the consistency and correctness of databases during development, before the databases are actually used.

Database Checker

To globally set the default from GES6 back to GES5, go to the **Options** window Global General Settings tab and click **Version 5** for the *Preferred Gibbs Energy System* setting. The SET_GES_VERSION Console Mode command is used to change GES versions for a single Thermo-Calc session.

Contact Thermo-Calc Software AB at info@thermocalc.com for more information about the changes or if you encounter any issues you think are related to the new version of the calculation engine.

Using the Database Checker

About the Database Checker

Once you have installed the Thermo-Calc and are familiar with the TDB database file concept you can start working with the file to ensure it does not contain errors that prevent it from working with Thermo-Calc.

Example of Working with the Database Checker

The following shows a couple of the features available when using an unencrypted TDB database file included with Thermo-Calc Console Mode example *tcex11 - Oxidation of Cu_2S with an H_2O/O_2 Gas Mixture*.

Console Mode Examples

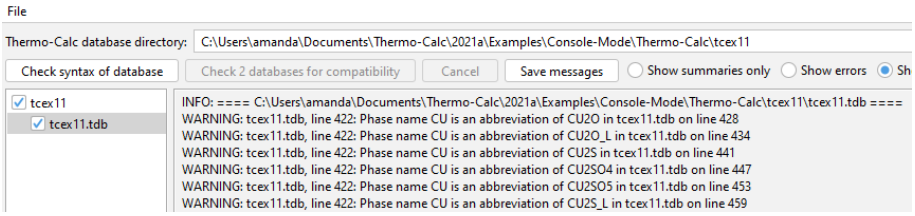
Open a TDB file. This example uses `tcex11.TDB`, which is the user-defined database referred to from the Thermo-Calc macro file `tcex11.TCM`.

1. In Thermo-Calc, from the menu select **Tools→Database Checker**.

2. In the Thermo-Calc Database Checker window, click the **File** button and navigate to a directory with TDB files or a file with a `.TDB` extension.

   If two databases are selected at the same time, these can be tested for compatibility i.e., whether the databases can be appended. The tool generates error messages for database entities e.g., phases, that are not compatible but this does not necessarily mean that the databases cannot be appended, only that the erroneous phases cannot be appended and must be rejected from the system.

3. Click **Select directory or file**.With the file loaded, click **Check syntax of database**. Choose how to show the information: **Show summaries only**, **Show errors**, **Show errors and warnings**, or **Show all messages**. The Database Checker lists the information in the window.



4. Click **Save messages** as needed to save a `.txt` file and use this to help improve your database.

TDB Editor

The TDB Editor is an editing tool for those who develop their own custom databases for use with Thermo-Calc or other applications. The tool speeds up the database editing process by providing immediate feedback through syntax coloring, syntax checking, and by allowing formatting and easy navigation to items of interest in the TDB file.

About the TDB Editor

In order to use this tool, it is important to understand how to work with the standard TDB database format. For example, see Thermodynamic and Kinetic/Mobility Databases, or press F1 in Thermo-Calc and search for *TDB file* in the help.

The TDB Editor is an editing tool for those who develop their own custom databases for use with Thermo-Calc or other applications. The tool speeds up the database editing process by providing immediate feedback through syntax coloring, syntax checking, and by allowing formatting and easy navigation to items of interest in the TDB file.

The advantage to using the TDB Editor compared to a basic text editor includes features such as syntax coloring and checking, formatting of TDB files, and generally easier navigation.

The TDB Editor has two components (see Installing the Code Editor and the TDB Editor for details):

1. As an installed extension to a code editor, which provides the user interface for the TDB Editor. Currently, these code editors are supported:
    - Microsoft Visual Studio Code (VSCode): VSCode is open source and available for free.
    - JetBrains IntelliJ: The full version of IntelliJ is a commercial product but there are also free limited editions available.
    - JetBrains PyCharm: The full version of PyCharm is a commercial product but there are also free limited editions available.
2. A server application that runs invisibly in the background and provides the code editor extension with services specific to the TDB format, such as syntax checking, formatting and the location within the document of various items, such as functions and references.

The syntax checker uses the same text parsing engine as the Database Checker tool and the Thermo-Calc application itself. This means that an edited TDB file (with no errors shown in the TDB Editor) is also accepted by the Thermo-Calc application. For more information see About the Database Checker.

Installing the Code Editor and the TDB Editor

About the TDB Editor

To use the TDB Editor, you install the Code Editor (Visual Studio Code (VSCode), JetBrains IntelliJ, or JetBrains PyCharm) and then in the editor you install the TDB Editor extension, which is included with your Thermo-Calc installation.

> In order to access the most-up-to-date version of the TDB editing functionality, it must be reinstalled every time a *new* version of Thermo-Calc is installed.

System Requirements

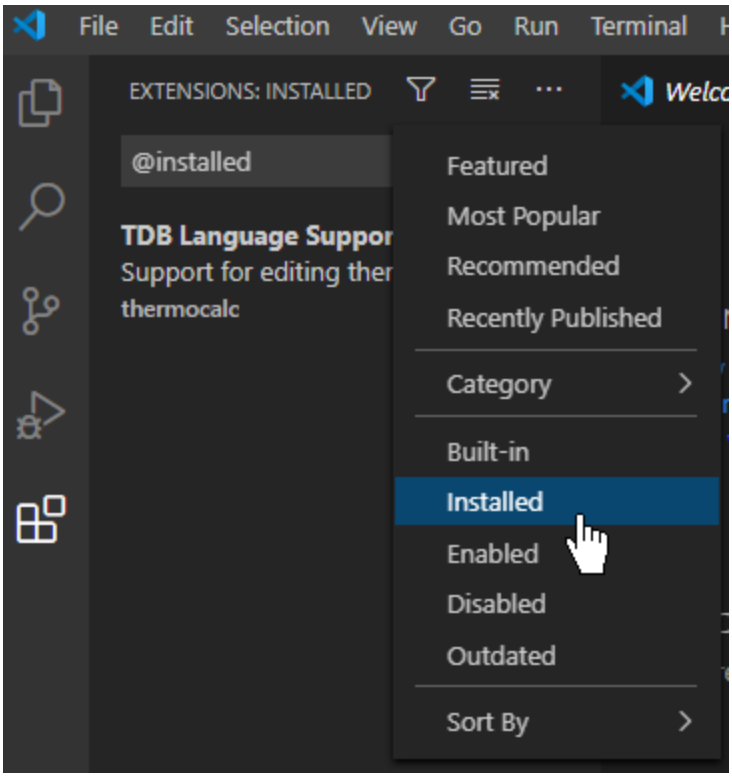
The same system requirements apply to the TDB Editor as to the Thermo-Calc installation.

A full list of system requirements and program availability is found on the Thermo-Calc website. You can also see the roadmap for platform support to use for planning purposes.

Installing the TDB Editor Extension in VSCode

1. Navigate to the Thermo-Calc distribution directory based on your operating system. Locate the file `tdb-language-support.vsix`.
   a. On Windows, the file is typically located under `C:\Program Files\Thermo-Calc-<version>`.
   b. On Linux, the file is typically located under `<user>/Thermo-Calc/<version>`.
   c. On macOS, the file is typically located under `/Applications/Thermo-Calc-<version>/Contents/Resources`.
2. Copy the `tdb-language-support.vsix` file to your desktop.
3. Install VSCode for your platform from https://code.visualstudio.com/download.
4. In VSCode, press Ctrl+Shift+X (or from the menu, select **View→Extensions**). The **Extensions** panel opens.
5. In the upper right corner of the **Extensions** panel, click the three dots (...) **Views and More Actions** button. Select **Install from VSIX** and select the `tdb-language-support.vsix` file on your desktop.

6. Locate **TDB Language Support** in the Extensions panel. For example, click **Filter Extensions → Installed** and the file displays in the panel.



7. Click **TDB Language Support** to see the README file, which includes current version information, known bugs, and limitations.

Installing the TDB Editor Extension in JetBrains IntelliJ and PyCharm

1. Open the **File → Settings** window (Ctrl+Alt+S). All the following settings are done in panels of this window:
2. Open the Editor panel and select **TextMate Bundles**.
3. Click **+** to add a new bundle. Select the bundle by navigating to the **TDBLanguage.tmBundle** located in the Thermo-Calc software distribution directory:
    - On Windows, the distribution directory is typically `C:\Program Files\Thermo-Calc-<version>`.
    - On Linux, the distribution directory is typically `<user>/Thermo-Calc/<version>`.

- On macOS, the distribution directory is typically `/Applications/Thermo-Calc-<version>/Contents/Resources`. You might need to copy the bundle from the installation directory to the desktop before being able to select it.

The editor supports syntax coloring of TDB files.

4. Open the **Plugins** panel and download and install the **LSP4IJ plugin**. Restart the IDE if required.
5. Open the **Languages & Frameworks** panel and select **Language Servers**. Click **+** to add a new server and set the following:
   - Name: **TDB Language Server**
   - Server / Command: `<Thermo-Calc's distribution directory>TDBLanguageServer.<file extension>` where file extension is:
     - Windows: `.exe`
     - Linux: `.sh`
     - macOS: `.command`
   - Mappings / File name patterns:
     - `*.tdb`
     - `Language id: tdb`
6. The editor supports syntax checking, clickable items with jumping and formatting of TDB files. Click the **Language Servers** icon in the left margin of the output pane at the bottom of the screen.

   The TDB Language Server should now be listed.
7. If you want to see details about the communication between the editor and the language server (which might require a restart of the editor), click the entry to configure verbose tracing in the **Debug** tab.
8. Expand the **TDB Language Server** entry to show the server status. If a TDB file is loaded in the editor, the status should display the text *started pid:<number>*.

Notes about the TDB Editor Extension

- The syntax checker cannot resolve references to TDB files with partial database information and gives errors in such cases. Only databases contained in single files can be handled. For syntax checking of multi-file databases, use the stand-alone Database Checker tool. See About the Database Checker.

- If you encounter warning messages that do not match the content in the TDB Editor, a possible solution is to save the file to disk (press Ctrl+S on the keyboard), which reloads the file and restarts the syntax checker.
- Very large files can sometimes cause issues with the language support functionality although the actual editing should be unaffected by this.
    - In VSCode, the default maximum file size can be changed in **Preferences → Settings → Text Editor → Diff Editor → Max File Size**.
    - In IntelliJ and PyCharm, the default maximum size of 2.5 MB can be changed by setting the following custom property under **Help**:
      `idea.max.intellisense.filesize=<the filesize in kB>`.
        - For example enter `2500` for 2.5 MB,
          `idea.max.intellisense.filesize=2500`.

Using the TDB Editor

About the TDB Editor

Once you have installed the TDB Editor and are familiar with the TDB database file concept you can start working with it to edit an existing file or create a new TDB file.

Creating a TDB File

To create a new TDB file, save an empty text file with a `.TDB` extension.

Opening a TDB File

In the code editor, from the menu select **File→Open** and navigate to a file with a `.TDB` extension.

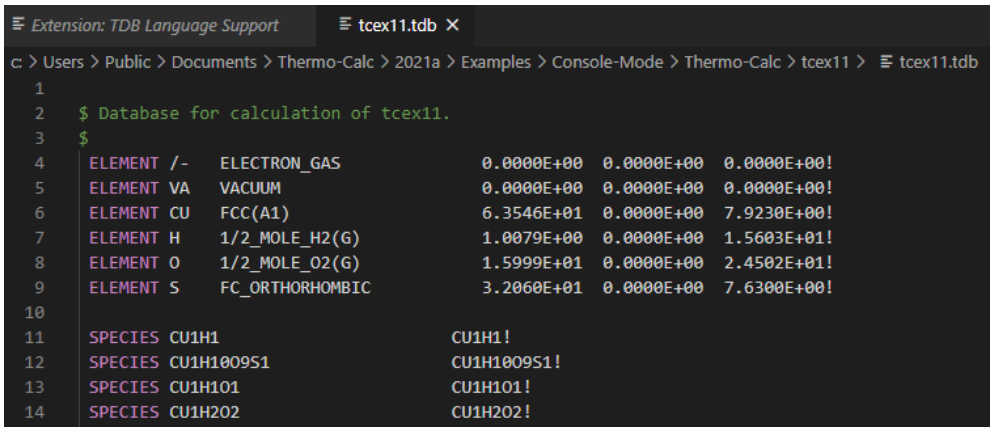
Example of Working with the TDB Editor

The following shows a couple of the features available when using an unencrypted TDB database file included with Thermo-Calc Console Mode example *tcex11 - Oxidation of Cu_2S with an H_2O/O_2 Gas Mixture*.

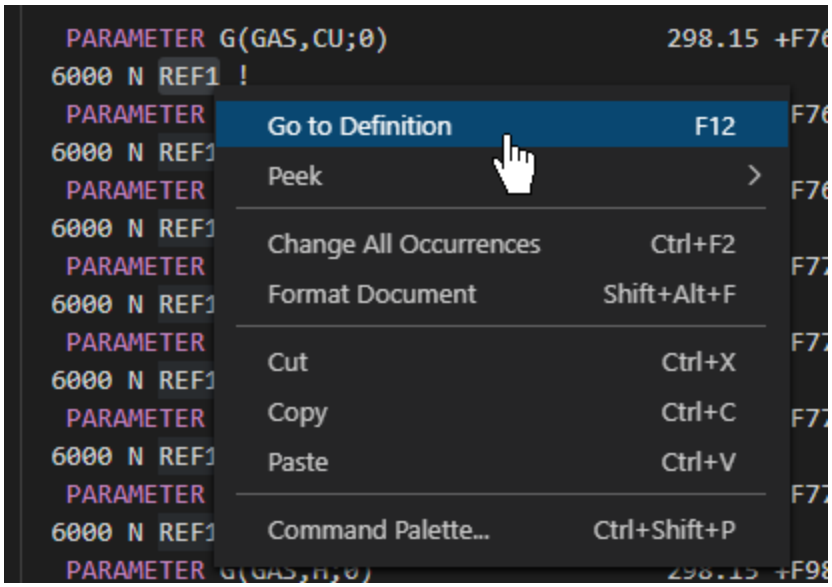
Console Mode Examples

Open a TDB file. This example uses `tcex11.TDB`, which is the user-defined database referred to from the Thermo-Calc macro file `tcex11.TCM`.

The unencrypted database opens in the TDB Editor where you can quickly see the color syntax of the commands making it easy to navigate. The images below show VSCode but the appearance in IntelliJ and PyCharm is similar.



Where there are definitions or references included with the file, you can also navigate quickly to these using **Go To Definition** (ctrl-click or right-click to select from the menu).

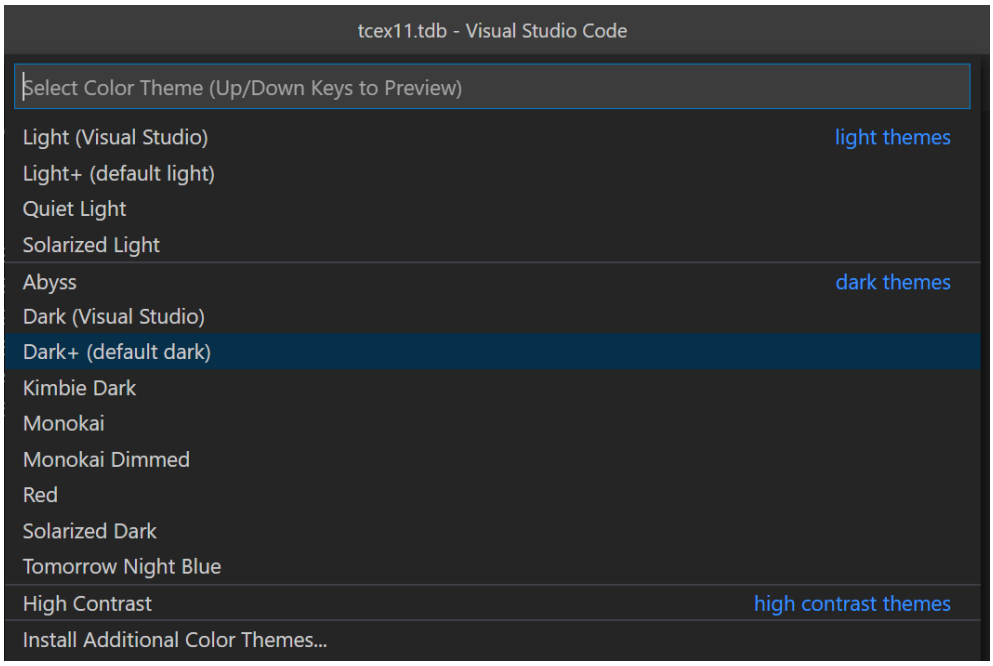


There are many other editor features available that you can learn more about from the respective Help menus. One such item of particular use is to be able to customize the color scheme.

Customizing the Color

The code editors come with a number of pre-defined color themes and additional themes can be downloaded as extensions.

To select a color theme, in VSCode press `Ctrl+K` then `Ctrl+T`. In IntelliJ and PyCharm open the Settings by pressing Ctrl-Alt-S and then select Appearance & Behavior and Appearance.



A preview of each theme is shown. Use the arrow keys to try each and select the theme that best suits your preferences.

DATAPLOT User Guide

The *DATAPLOT User Guide* gives all the details on the graphical language DATAPLOT that a phase diagram or property diagram calculated by Thermo-Calc or a kinetic profile simulated by the Diffusion Module (DICTRA) can be defined. It is applicable to Console Mode only.

Using this Guide

The *DATAPLOT User Guide* gives all the details on the graphical language DATAPLOT that a phase diagram or property diagram calculated by Thermo-Calc or a kinetic profile simulated by the Diffusion Module (DICTRA) can be defined.

This guide

- Discusses the important features of the DATAPLOT language.
- Describes the commands to define PROLOGUE and DATASET.
- Several examples and the standard codes for formatting are provided.

One topic introduces the method of formatting DIGLIB symbols in LaTeX documents, for the purpose of necessarily/appropriately referring to the corresponding LaTeX symbols (closest to those DIGLIB symbols which have been plotted on a diagram using the DATAPLOT Graphical Language) in the texts of LaTeX documents for publications/reports.

About the DATAPLOT Graphical Language

In order to obtain graphical output of any numerical data and informative strings, a graphical language called DATAPLOT was developed in connection with the graphical software DIGLIB. Using this graphical language, you can store information in a normal text file (*.EXP), which can be plotted as graphical symbols, lines, texts or Greek letters on any plot device support by DIGLIB.

You can generate and plot DATAPLOT (*.EXP) files together with various calculation and/or experimental results from, for example, phase and property diagrams calculated with the Thermo-Calc software composition profiles or other diagrams simulated by the Diffusion Module (DICTRA).

An EXP file automatically generated by the POST-processor (using the MAKE_EXPERIMENTAL_DATAFILE command) in the Thermo-Calc software is a DATAPLOT (*.EXP) file and may contain all types of legal DATAPLOT commands and parameters. With a text editor, you can modify or add some DATAPLOT commands and related parameters in an existing EXP file. This is useful when appending experimental information to calculated/simulated plots, and when specifying user-defined texts, symbols, colors, fonts, filled patterns, diagram types, diagram sizes, symbol/character sizes, titles, special characters, etc.

There is another type of experimental data file that is generated in Thermo-Calc when working with the PARROT module. For more information seeExperimental Data Files (*.POP, *.DOP).

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

DATAPLOT Examples

To help you prepare your EXP (experimental) files to use for your plotted diagrams generated by Thermo-Calc simulations, there are examples of EXP files using the DATAPLOT graphical language standard, which are independent of software versions.

DATAPLOT example files are available in a zip file on our Documentation page on our website. Or this is a direct link to download the zip file.

Plotting Experimental Data Files

You can read and plot experimental data files in both Console Mode and Graphical Mode.

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

Graphical Mode

In Graphical Mode, the Experimental File Reader activity can only be created from the top My Project node. This activity allows you to read an experimental data file (*.EXP). This type of file has information specifying a plotted diagram, written in the DATAPLOT graphical language. From this activity node you can plot the EXP file or save a copy of the file to another location.

Plotting an EXP file in Experimental File Reader

1. Right-click **My Project** and from the **Create New Activity** submenu choose **Experimental File Reader**.
2. In the **Configuration** window in the *EXP file* field, enter the name of the EXP file to plot. Or click the **Select Exp file** button to navigate to a location on the computer to add the dataset.
3. Once the .EXP file is added, under **Dataset Selection** you can choose to include or exclude specific datasets. Use the **Select/Deslect all datasets** checkbox as required.
4. Right-click the **Experimental File Reader** node and from the **Create New Successor** submenu choose **Plot Renderer**.

   If the source EXP file is changed, you can also click the **Reload the selected EXP file from disk** button to refresh the data. If you want to save or export the loaded file, click the **Save EXP file** button, then navigate to where you want to save it and give it a file name.

5. In the **Configuration** window click **Perform** or right-click the **Plot Renderer** node and select **Perform**.

Console Mode

In Console Mode you use the QUICK EXPERIMENTAL PLOT command found in the POLY-3 POST module (as well as in the Diffusion Module (DICTRA) POST module) to plot the .EXP files. This command can be used when there is no graphical information to be plotted in the POLY3 workspace. It defines a pair of axes, sets the axis labels to X and Y, and scales both X- and Y-axes between 0.0 and 1.0 unless a prologue is read from the DATAPLOT (*.EXP) data file.

Plotting an EXP file in POST

1. Go to the POLY-3 Module: At the SYS prompt type `Go Poly`.
2. Go to the POST module: At the POLY_3 prompt type `Post`.
3. At the POST prompt, type `Quick`.
4. Enter Prolog and Dataset numbers (if applicable). See QUICK_EXPERIMENTAL_PLOT.
5. AT the POST prompt, type `Plot`.

DATAPLOT File Structure

A DATAPLOT file is a normal text file with the extension `EXP` that can be created with a text editor or by a program. The file must contain one or more `DATASETS` and possibly also one or more `PROLOGUES`. Each `PROLOGUE/DATASET` is an entity that can be individually selected for plotting.

A PROLOGUE/DATASET is identified by a unique positive number in the file. A PROLOGUE normally contains various DATASET commands for defining information about axis scaling, axis text, axis length, title and so on. A PROLOGUE is terminated by another PROLOGUE or by the first DATASET. This means that all PROLOGUES must be placed at the beginning of the file, before the first DATASET.

A DATASET normally contains DATASET commands that are associated to separate data points, as well as with one or more `BLOCKS` of data (calculated or experimental). A DATASET is terminated by another DATASET command or the end of file.

DATAPLOT Language Syntax

The DATAPLOT language consists of commands with or without parameters:

```
COMMAND {parameter(s)}
```

The basic graphical command consists of an X/Y coordinate pair and a Graphical Operation Code (GOC). With other commands, the interpretation of this basic command can be modified. There are separate commands to draw a polygon or a function and ways to get texts in different fonts.

To edit a DATAPLOT file, the graphical commands can be abbreviated.

A command (with parameters) must not exceed 80 characters. If it is too long (normally as writing necessary codes in a command's parameters for a complex expression), two or more lines can be edited.

Coordinate Systems

The DATAPLOT language accepts coordinates in three different coordinate systems, which are called *world*, *virtual* and *normalized*.

- The *world* coordinates are selected to represent any kind of data and be of “any” magnitude.
- The *virtual* coordinate system uses centimeters as units. However, the actual size of one unit is dependent on the implementation of the device driver in DIGLIB. It is not recommended to use this coordinate system if different output devices are used for preliminary and final plots.
- The *normalized* coordinate system goes from zero to one. When plotting, you interactively scale each axis by selecting the minimum and maximum word coordinates on the axis. In the normalized coordinate system, the minimum axis value is represented by zero and the maximum by one. DIGLIB draws a square between the four points (of the X and Y axes) that are determined by the coordinates zero and one in the normalized coordinates.

It is also possible to draw triangular plots as described below. However, in most places, it only references square diagrams. All data points within the minimum and maximum word coordinates are plotted inside this square. DIGLIB also writes tic marks and corresponding word values at such tic marks.

It may be convenient to use normalized coordinates to draw boxes and texts. You can give normalized coordinates outside zero and one if you want to write texts outside the area enclosed by the square. To ensure proper operation outside the normalized box, the clipping must be turned off.

Graphical Operation Codes

The Graphical Operation Code (GOC) determines how the coordinates are interpreted and what is done at the point determined by the coordinates. For an individual data point, its GOC codes must be given. For each data BLOCK, you define a default GOC that is used for the whole BLOCK, unless a GOC is explicitly defined for a specific point.

- If S is omitted, no symbol is plotted. A number selecting the symbol can optionally follow the character S. The DIGLIB software determines which symbol the number represents. See Plotting a Symbol.
- If any of the other characters are omitted, the default defined for the BLOCK is used. Absolute values imply the current coordinates; relative values mean that these are added to the current coordinates. The GOC must be written without any space between various characters, but the order for the characters is irrelevant.
- If no GOC is defined for a BLOCK, the system default is MWA, (Move Word Absolute), i.e., move to the given point that is interpreted as absolute word coordinates. GOC=DNA means draw a line from the current point to the new one interpreting the coordinates as normalized. After each draw or move operation, the so-called current point is the new point.
- The TEXT following the ' command is interpreted and expanded by the DIGLIB software, if it includes any ^ operator or STRING names using the ~ descriptor. To get PostScript outputs, the TEXT must be edited by the LaTeX Text Formatting Program instead (see LaTeX Formatting Codes).

GOC Character Definitions

The GOC is a combination of the following characters:

Character	*Meaning*
W, V or N	To use world (W), virtual (V) or normalized (N) coordinates. W is the default.
A or R	XY are absolute (A) or relative (R) values. A is the default.
M or D	To perform a move (M) or draw (D) operation to XY. M is the default.
B	To apply “soft” splines on a line drawn between the coordinate pairs (used only on BLOCK data).

Character	*Meaning*
`S`	To plot default symbol at XY.
`S#`	To change default symbol to No # symbol and plot it at XY.
`'TEXT`	To plot `TEXT` at XY. It must be the last operation in a GOC code. The TEXT following the ' command is interpreted and expanded by the DIGLIB software, if it includes any ^ operator or STRING names using the ~ descriptor.

Tables or Blocks

In many cases, you have (calculated or experimental) data in the form of tables, and want to plot one or several columns as X-axis and one or more columns as Y-axis. A single table can contain many sets of data records of the same kind of information for a specific data BLOCK. There can be many data BLOCKS in a DATASET.

By enclosing these tables in a data BLOCK, you can select which column(s) is the X-axis and which is the Y-axis. For example,

```
BLOCK X=C1; Y1=C3; Y2=C2; GOC=C4,DAW
```

Where the X-axis values are in column 1, the Y-axis values are in columns 2 and 3, and any GOC codes are in column 4. The default GOC for this BLOCK is Draw Absolute Word. The GOC code inside the table is only necessary if the default GOC is not applicable.

A more elaborate use of the table is shown in this example:

```
BLOCK X=C3; Y=1E3/(C3+273); GOC=C8,MAWS1
```

Where the X-axis values are in column 3, the Y-axis values are in column 1 with some additional calculations applied. Any GOC is in column 8, and the default GOC is Move Absolute Word and plot the symbol no. 1.

Columns in a table must be separated by one or more space characters and do not have to be justified.

It is possible to have tables with mixed text and numbers, but each word followed by a space is counted as one column. The columns used for plotting also must be numerical. An example of a legal line in a table is

```
298.15 This_is_the_second_column 11.5 This_is_the_fourth_column
```

A line in the table must not exceed 80 characters. A BLOCK must be terminated by a line with the BLOCKEND command.

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

Drawing a Polygon

Normally, each point is written on a separate line. But in order to draw a line in a more compact way, use the command DRAWLINE. DRAWLINE is followed by a couple of X/Y number pairs. The X/Y pairs must be separated by a space, and there must be a comma sign between the X and Y values. DRAWLINE makes a move operation to the first pair of X/Y coordinates, and then draws a line among all pairs up to the last one. All pairs must fit on one line of 80 characters, but there can be several consequent DRAWLINE commands.

Example 2 – Draw Polygons and Symbols

Drawing an Analytical Function

Use a BLOCK command to set an axis to a function. It is not necessary to use a value from any column in order to compute the function value to be plotted. Use the FUNCTION command to plot a function with an even increment of the independent variable.

Example 4 – Draw Curves Defined by Functions

Painting of an Enclosed Area

Use the PAINT command to paint or fill an area in a specified pattern in the plot. Available patterns are determined by the DIGLIB software. A related command to PAINT is PCFUNCTION.

Writing a Text

Use the TEXT command to write a text at the current point. You can write a text at any X/Y pair by appending a single quote followed by the text on the same line. For example:

```
1.1 1.0 NAM'This is a text
```

writes `This is a text` at the normalized coordinates (`1.1, 1.0`).

Use the command FONT to select the font used for the text, and CHARSIZE to select the size of the characters. Set this size of the symbols with SYMBOLSIZE.

If a text or a single character should be of a different font than all the other text, or to use subscripts or superscripts in a text, use the ^ operators or STRING command to create the text. The command STRING stores the text in a specified variable that includes all text-formatting information defined by the DIGLIB software.

Example 3 – Using Strings and Various Line Types and Example 5 – Use Included Files for Predefined Symbols.

However, if a graphical output is done on a PostScript device using the PostScript hardcopy fonts, special text formatting codes as LaTeX Formatting Codes should be used and the STRING formatting syntax is then not valid.

Plotting a Symbol

As described in Graphical Operation Codes, a GOC code in a data BLOCK may contain an `S` option to plot a symbol for an X/Y pair or the same symbols for the data BLOCK. A number selecting the symbol can optionally follow the character `S`. You can plot a symbol at any current X/Y position by appending a quote specified by the symbol number in the GOC code (e.g., `1.1 1.0 MANS5'This is a text`).

You can also insert DIGLIB symbols into LaTeX-edited documents.

Example 1 – Draw Lines and Symbols, Example 2 – Draw Polygons and Symbols and Example 8 - DIGLIB Symbols

Other Commands

General

- When plotting symbols representing various experimental data, it is important that the symbols are centered around the coordinate values.
- The dollar sign $ as the first character of a line stands for a comment character, which means the whole line is ignored when plotting.

ATTRIBUTE

Use the ATTRIBUTE command to change the coordinates where text is displayed. The default is the lower left corner of the first character in the text.

CLIP

Use the CLIP command to change the default where all data outside the normalized coordinates zero and one are not plotted.

COLOR

If you are using a color device, use the COLOR command to change color of the lines. On some black and white devices, colors are simulated with different width and dashing of the lines.

INCLUDE

Use the INCLUDE command to create libraries with texts and include these in similar plots.

LINETYPE

Use the LINETYPE command to define line types as solid, long dashed, short dashed or dotted.

Interactive Plotting

The DATAPLOT file is read into the POST module in the workspace with APPEND_EXPERIMENTAL_DATA or QUICK_EXPERIMENTAL_PLOT. These commands ask for the name of the DATAPLOT file and also which PROLOGUE(S) and DATASET(S) are to be plotted.

Press F1 and search the Help for details.

By giving the PROLOGUE/DATASET number as `-1`, you get a list of the available PROLOGUES/DATASETS in the file. Note that if `DATASET 0` is in a DATAPLOT file, its data is always used even if other DATASETS are chosen.

Formatting DIGLIB Symbols in LaTeX Documents

When using the LaTeX editor, you can use the DIGLIB symbols in texts and in figures. This then refers to the corresponding LaTeX symbols (closest to those DIGLIB symbols which are plotted on a plot using the DATAPLOT Graphical Language) in the texts of LaTeX documents for publications/reports.

This topic shows how to generate some DIGLIB symbols in texts, through the attached LaTeX source file and its converted jpg file.

Example 8 - DIGLIB Symbols

DIGLIB_Sym.tex

```
\documentclass[dvips,12pt]{article}
\textwidth 165mm
\textheight 225mm
\oddsidemargin 1mm
\evensidemargin 1mm
\topmargin 1mm
%%\usepackage{amssymb}
%% next replace amssymb and to get udtimes
\usepackage[utopia]{mathdesign}
\usepackage{rotating}
\usepackage[latin1]{inputenc}
\usepackage{graphics}
\usepackage{graphicx,subfigure}% with figures
%\usepackage[draft]{graphicx}% without figures
\usepackage{subfigure}% with figures
\topmargin 1mm
\oddsidemargin 1mm
\evensidemargin 1mm
\begin{document}
{\Large \bf Diglib symbols and their corresponding LaTeX symbols}
\vspace{5mm}
```

The information below gives the closest corresponding LaTeX symbol. All symbols (except +) must be generated in math mode. Most of these require the package `amssymb`, i.e., you need a directive `usepackage{amssymb}` in the preamble. Two of the symbols require the more extensive `mathdesign` that can be included with `usepackage[utopia]{mathdesign}`.

```
\vspace{5mm}
{\Large
\begin{tabular}{llll}
Diglib & Latex & Latex name & Note\\
1& $\vartriangle$& $\backslash$vartriangle & amssymb \\
2& $\square$& $\backslash$square\\
3& {\Huge $\diamond$} & $\backslash$diamond & size $\backslash$Large \\
4& $\udtimes$& $\backslash$udtimes & mathdesign \\

\end{document}
```

LaTeX Formatting Codes

By default when using the LaTeX command, you are in math mode and Thermo-Calc automatically interprets the entered text as math. The above link uses the dollar sign ($) in all the examples but this is NOT required. For example, if you enter `$E=mc^2$` this is displayed including the $ instead of the equation.

LTEXT vs LaTeX Commands for Labels

Symbol or Text Format	*LTEXT*	*LaTeX*
Subscripts in an axis text	S-A-TEXT Y N Mole-fraction Al^DO2O^DO3	S-A-TEXT Y N \latex \textsf{Mole-fraction } Al_2O_3
Label with subscript	add .13 .15 n c-ZrO^DO2$	add .13 .15 n \latex c-ZrO_2
Greek symbol	ADD .05 .50 N ^GRd$	ADD .05 .50 N \latex \delta

PROLOGUE Commands

YTEXT **1588**

YTYPE **1589**

PROLOG

PROLOG is the beginning of a number of consequent lines of user-defined diagram layout commands. The lines are displayed with the `optional text` when using the `-1` option in the POST-processor as prompted for the PROLOG number with APPEND_EXPERIMENTAL_DATA or QUICK_EXPERIMENTAL_PLOT.

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

Syntax	PROLOGUE # optional text
	# is an unsigned integer identifying the PROLOG.

DIAGRAM_TYPE

DIAGRAM_TYPE sets the diagram type to square (the default) or triangular.

Example 6 – Triangular Diagrams for Ternary Systems

Syntax	DIAGRAM_TYPE type plot_3rd_axis clip_along_third-axis
	`type` is a character string reading SQUARE (default) or TRIANGULAR. If `type` reads TRIANGULAR, then two additional parameters are given: `plot_3rd_axis` and `clip_along_third-axis` that are characters strings reading YES or NO.

TIC_TYPE

TIC_TYPE sets the relative length of the tic marks.

Syntax	TIC_TYPE #
	# is a real number. Default value is 1. Negative number gives tics on the inside of the diagram frame. 0 gives no tics.

TITLE

TITLE sets the title text string to be printed above the diagram.

Syntax	TITLE text
	`text` is an arbitrary text string that may contain text-formatting codes

XLENGTH

XLENGTH sets the X-axis length to approximately # centimeters.

Syntax	**XLENGTH #**
	# is a positive real number (the approximate X-axis length in centimeters).

XTEXT

XTEXT sets the X-axis text.

Syntax	XTEXT text
	`text` is an arbitrary text string that may contain text-formatting codes.

XTYPE

XTYPE sets the X-axis type as linear (default), logarithmic or inverse.

Syntax	XTYPE type
	`type` is a character string reading LIN, LOG or INV.

YLENGTH

YLENGTH sets the Y-axis length to approximately # centimeters.

Syntax	Y LENGTH #
	# is a positive real number (the approximate Y-axis length in centimeters).

YSCALE

YSCALE sets the scaling in word coordinates of the Y-axis.

Syntax	YSCALE min max
	`min` and `max` are real numbers.

YTEXT

YTEXT sets the Y-axis text.

Syntax	Y TEXT text
	`text` is an arbitrary text string that may contain text-formatting codes.

YTYPE

YTYPE sets the Y-axis type as linear (default), logarithmic or inverse.

Syntax	Y TYPE type
	`type` is a character string reading LIN, LOG or INV.

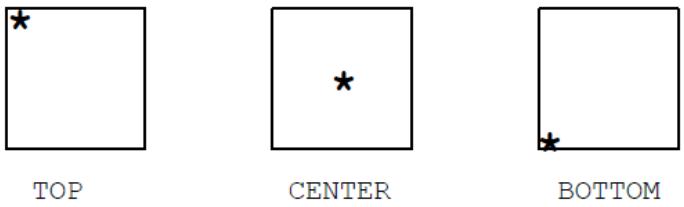
TEXT 1612

ATTRIBUTE

ATTRIBUTE specifies where the current XY position is in the character or symbol plotbox.

Example 2 – Draw Polygons and Symbols, Example 3 – Using Strings and Various Line Types, and Example 5 – Use Included Files for Predefined Symbols

Syntax	ATTRIBUTE
Prompts	`attribute`
	`attribute` may be TOP, CENTER or BOTTOM. ATTRIBUTE CENTER is default for symbols; ATTRIBUTE BOTTOM is default for characters.



BLOCK

BLOCK defines how the following numeric data block shall be interpreted. The definitions of X and Y coordinates may also be expressed as a function of the column values, making it possible to perform transformations.

Syntax	`BLOCK X&=C#; ...; Y&=C#; ...; GOC=C#,@@@...`
	`&'` are optional unsigned integers that make it possible to plot several (maximum 9) X- or Y- axis columns. `#'` are unsigned integers identifying the column numbers. The column number # in "GOC=C#" is the location of any possible GOC codes in the current data BLOCK; @@@ stands for the default Graphical Operation Code (GOC) for the current BLOCK. The GOC code inside the current table is only necessary if the current default GOC is not applicable.

GOC Characters

The GOC is a combination of the following characters:

Character	*Meaning*
`W`, `V` or `N`	To use world (`W`), virtual (`V`) or normalized (`N`) coordinates. `W` is the default.
`A` or `R`	XY are absolute (A) or relative (R) values. `A` is the default.
`M` or `D`	To perform a move (M) or draw (D) operation to XY. `M` is the default.
`B`	To apply "soft" splines on a line drawn between the coordinate pairs (used only on BLOCK data).
`S`	To plot default symbol at XY.
`S#`	To change default symbol to No # symbol and plot it at XY.
`'TEXT`	To plot `TEXT` at XY. It must be the last operation in a GOC code. The TEXT following the ' command is interpreted and expanded by the DIGLIB software, if it includes any ^ operator or STRING names using the ~ descriptor.

BLOCKEND

Use BLOCKEND to terminate the local definition of the graphical operation code defined by the earlier BLOCK command.

CHARSIZE

CHARSIZE redefines the default size of the characters in the plot. The character size has an initial default value, which may vary with the current font setting and the output device (the plot format).

Syntax	CHARSIZE $$
	`$$` must be an unsigned real.

CLIP

CLIP turns clipping on or off. If it is OFF, it allows output outside the ordinary plot area defined by normalized coordinates zero and one.

Example 2 – Draw Polygons and Symbols and Example 9 - DIGLIB Fonts and Lines

Syntax	`CLIP CLP`
	`clp` is a character string reading ON or OFF.

COLOR

Use COLOR to redefine the current color setting. There are 22 legal color codes (from 0 to 21).

Example 7 – Color Codes

Syntax	COLOR code
	`code` is an unsigned integer number (from 0 to 21) identifying the color, or a character string specifying the color.

DIGLIB Color Codes

Code	*Color*	*Equivalent Character*
0	Background	Invisible
1	Black	Normal
2	Red	Very_Thick
3	Green	Thin
4	Blue	Thick
5	Yellow	Very_Thin
6	Magenta	Dashed
7	Cyan	Dotted
8	Purple	
9	Gold	
10	Turquoise	
11	Pink	
12	Gray	

Code	*Color*	*Equivalent Character*
13	Orange-red	
14	Maroon	
15	Plum	
16	Sea green	
17	Olive	
18	Sienna	
19	Orange	
20	Coral	
21	UserDef	
22 and higher	Any digit larger than 21 has the color effect as 1 (black).	

DATAPOINT

DATAPOINT is not a DATASET command, but the basic DATAPLOT command (see synopsis below) performs an action at the current point determined by the specified X/Y- coordinates. A DATASET may contain various data points, in addition to one or more data BLOCKs. Such data points are separated and independent on each other.

Syntax	`X Y GOC`

	X and Y are unsigned real numbers identifying the X/Y-coordinates for the current data point. GOC stands for Graphical Operation Code (GOC) for the current point. Legal GOC characters.
	Example
	`0.7 0.95 N'Example 6`
	`0.5 0.08 MNA'E^FS18^SQ(^SK^FS10A+5#8*C#^FS10 -!a^FS18)^FS11+B^DIa#b#$`

DATASET

DATASET indicates the beginning of a number of consequent lines comprising a set of user-defined data. The DATASET lines are displayed on the terminal along with the `optional text` when using the `-1` option in the POST-processor as prompted for the DATASET number in the APPEND_EXPERIMENTAL_DATA or QUICK_EXPERIMENTAL_PLOT command.

See the Tips and Tricks: How to Plot Experimental Data blog post on our website for useful guidance about this topic.

Syntax	`DATASET # optional text`
	`#` is an unsigned integer identifying this set of data.

DRAWLINE

DRAWLINE draws a line starting at (x1,y1) to (xn,yn) through (x2,y2) → (x(n-1), y(n-1)).

Example 1 – Draw Lines and Symbols and Example 2 – Draw Polygons and Symbols

Syntax	`DRAWLINE x1,y1 x2,y2 .... xn,yn`

`x` and `y` may be reals or integers of any value. This is the same as connecting all points in a table:

```
x1   y1    M
x2   y2    D
...  ...   D
xn   yn    D
```

FONT

FONT redefines the default font setting in the POST-processor.

Example 9 - DIGLIB Fonts and Lines

Syntax	FONT #
	# is an unsigned integer.

Font Numbers

Number	*Font*
1	Bold
2	Normal
3	Italic
5	Bold and Italic
10	Monotype Normal
11	Monotype Italic
12	Monotype Bold
13	Monotype Bold and Italic
14	Narrow Normal
15	Narrow Italic

FUNCTION

FUNCTION defines and plots a user-defined function.

Example 4 – Draw Curves Defined by Functions

Syntax	`FUNCTION Y=f(X); start end number_of_XY_pairs; GOC;` `FUNCTION X=f(Y); start end number_of_XY_pairs; GOC;`
	`f(X)` or `f(Y)` are legal mathematical functions of X or Y, understandable by a FORTRAN program. `start` and `end` are unsigned real numbers, and `number_of_XY_pairs` an unsigned integer. `GOC` is a legal graphical operation code as defined with BLOCK.

GLOBALSIZE

GLOBALSIZE redefines the default global size of the plot. The global size has an initial default value.

Syntax	`GLOBALSIZE $$`
	`$$` must be an unsigned real.

INCLUDE

INCLUDE adds a file into the current input stream.

Example 5 – Use Included Files for Predefined Symbols.

Syntax	`INCLUDE filename`
	`filename` is a legal filename (with its correct path) for the operation system.

LINETYPE

LINETYPE redefines the current linetype in the plot.

Example 3 – Using Strings and Various Line Types, Example 8 - DIGLIB Symbols and Example 9 - DIGLIB Fonts and Lines

Syntax	LINETYPE #
	# must be an unsigned integer. Legal linetypes are (for both normal graphical outputs and for PostScript formats): • Solid (default) • Long dashed • Short dashed • Dotted

Line Types

Number	*Type*
1	Straight line
2	Dashed line
3	Dotted line
4	Dash-Dot line

PAINT

PAINT paints the area enclosed by the current path in the current pattern. The current path starts at the last MOVETO given and includes all subsequent DRAWs. This command only works for the PostScript format (as graphical files or on printed hardcopy).

PCFUNCTION

Syntax	PAINT <code> <video> <mode>
	<> denotes optional parameters. To set a new current pattern, supply any or all of the optional parameters. • `<code>` is a single letter 0-9, A-Z or a-t (if `<code>=t`, also supply a space and a number in the range 0.00-1.00). The default is `0`. • `<video>` is a string reading NORMAL (the default) or INVERSE. • `<mode>` is a string reading TRANSPARENT (the default) or OPAQUE.

PCFUNCTION

PCFUNCTION appends a user-defined function to the current path. It is used with PAINT.

Syntax	`PCFUNCTION Y=f(X); start end number_of_XY_pairs; GOC;` `PCFUNCTION X=f(Y); start end number_of_XY_pairs; GOC;`
	`f(X)` or `f(Y)` are legal mathematical functions of X or Y, understandable by a FORTRAN program. `start` and `end` are unsigned real numbers, and `number_of_XY_pairs` an unsigned integer. `GOC` is a legal graphical operation code as defined with BLOCK.

STRING

STRING defines a string containing a text and operation codes (e.g., to change the default font settings).

Example 3 – Using Strings and Various Line Types and Example 5 – Use Included Files for Predefined Symbols

Syntax	STRING name text_with_each_character_in_^S#^G^F#^U#^D#^R#^L#^N
	`name` is a valid alphanumeric name (variable) to represent the text including all text formatting codes. It is highly recommended that all the characters in the name are in CAPITAL CASE (e.g. ACA2SO4); otherwise, the defined STRING can be incorrectly plotted. `text_with_each_character_in_^S#^G^F#^U#^D#^R#^L#^N` means the text is coded with each of its characters (and/or numeric numbers) that are formatted with various operators (`^S#`, `^G`, `^F#`, `^U#`, `^D#`, `^R#`, `^L#` and/or `^N`). `#'` are unsigned integers. `^` is the caret character and does not mean a control character. Between an `#` (in an operator) and a numeric number (as a part of the text), there must always be a comma sign (`,`) or the number is not plotted in the text, because the `#` with the number is interpreted as another incorrect #. In some of the commands, `#=0` resets the option to previous (or default) value.

String Operation Codes in the DIGLIB Software

For the PostScript hardcopy fonts, these operation codes are not valid; see LaTeX Formatting Codes:

Operator	*Operation*
`^S#`	Set character size to size #
`^G`	Set font to Greek
`^F#`	Set font to font number #
`^U#`	Move up # units
`^D#`	Move down # units
`^R#`	Move right # units

Operator	*Operation*
`^L#`	Move left # units
`^N`	Do not move, remain at current

Examples

```
STRING Alpha1 ^Ga^F0^D0^S8,1^S0^U0
```

is set to α_1

```
STRING M23C6 M^D0^S8,23^S0^U0C^D0^S8,6^S0^U0
```

is set to $M_{23}C_6$

```
STRING ACA2CO3 ^Ga^F0^D0^S8Ca^D0^S4,2^S0^U0^S8CO^D0^S4,3^S0^U0
```

is set to Ca_2CO_3

SYMBOLSIZE

SYMBOLSIZE redefines the current symbol size setting. The symbol size has an initial default value.

Example 3 – Using Strings and Various Line Types, Example 7 – Color Codes and Example 8 - DIGLIB Symbols

Syntax	`SYMBOLSIZE $$`
	`$$` must be an unsigned real.

TEXT

TEXT outputs, at the current position, the text following the keyword TEXT or the text in the string `string_name` that is defined with STRING.

Syntax	`TEXT text` or `~string_name`
	It is possible to mix ^ operators and previously defined string names using the ~ operator.

Example 7 – Color Codes

The macro text below produces the example output. You can copy the text into your own EXP file, or use the example file `DATAPLOT 7 - Color Codes.EXP`.

The DATAPLOT example files are available on the Documentation page on our website. These are found under Current Documentation > Examples > Thermo-Calc Console Mode. Or a direct link to a zip file you can download is here. These examples do not change between releases and relate to working in classic Console Mode.

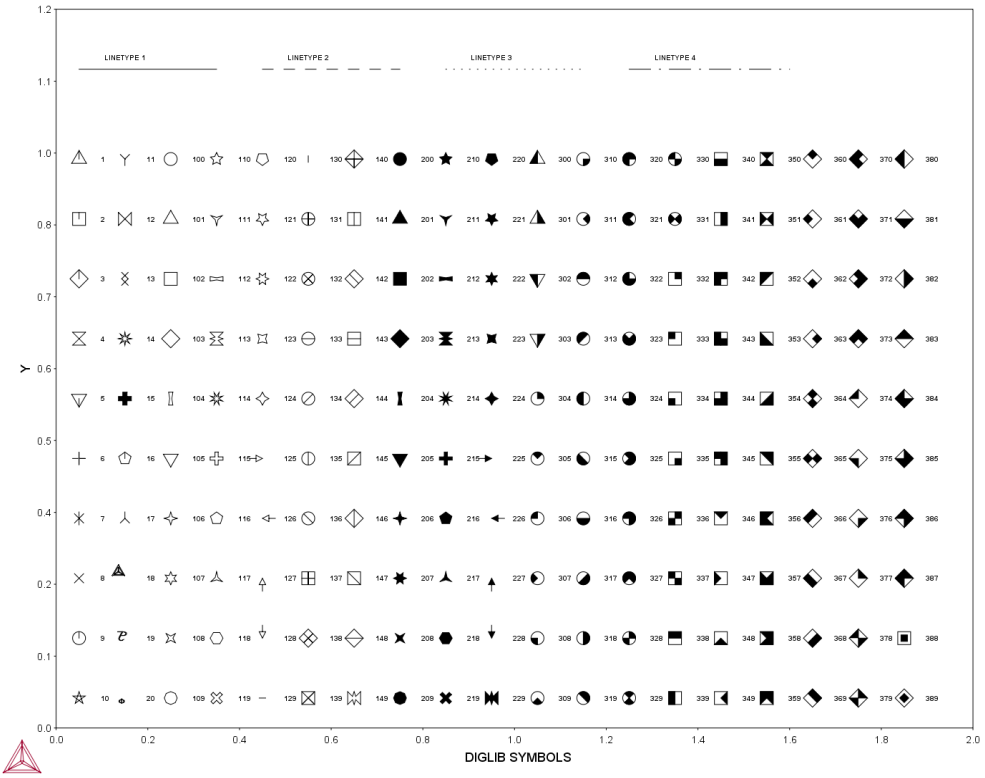
Example 8 - DIGLIB Symbols

The macro text below produces the example output. You can copy the text into your own EXP file, or use the example file `DATAPLOT 8 - DIGLIB Symbols.EXP`.

The DATAPLOT example files are available on the Documentation page on our website. These are found under Current Documentation > Examples > Thermo-Calc Console Mode. Or a direct link to a zip file you can download is here. These examples do not change between releases and relate to working in classic Console Mode.

Output Example



A default symbol is the current symbol in the run of the software (it is usually the No 1 symbol if the POST-processor is switched on for the first time). S (i.e., # is not specified) means that the current symbol is plotted. S0 (i.e., #=0) means that no symbol is plotted.

Add-on Modules and Property Model Libraries

Thermo-Calc Software offers several Add-on Modules that allow users to extend the functionality of the software in your area of specialization. All Add-on Modules are built into the Thermo-Calc platform, so there is no need for additional installation. This also creates a unified workflow and allows data to move seamlessly between the modules.

In order to run the Add-on Modules, it is necessary to have a license for Thermo-Calc and at least one thermodynamic and properties database. Some of the modules also require an additional mobility database.

The following sections have information about these products:

- Additive Manufacturing (AM) Module
- Diffusion Module (DICTRA)
- Precipitation Module (TC-PRISMA)
- Process Metallurgy Module
- Nickel Model Library
- Noble Metal Alloys Model Library
- Steel Model Library
- Titanium Model Library

Additive Manufacturing (AM) Module

The Additive Manufacturing (AM) Module is an Add-on Module in Thermo-Calc that is primarily designed for modeling the powder bed fusion process in additive manufacturing.

Special focus has been to have a unified treatment of alloy dependent material properties and process parameters when solving the multiphysics problem of a moving heat source that melts and solidifies metal powder. The multiphysics simulation involves thermal conduction, fluid flow, evaporation-, radiation- and convective- heat loss. The Module is available in Graphical Mode.

About the Additive Manufacturing (AM) Module

This guide is a supplement to the full Thermo-Calc documentation set. Access the help in Thermo-Calc by pressing F1, or choose **Help** → **Online help**, or click **Online Help** on the main **My Project Configuration** window. See Additive Manufacturing (AM) Module Help Resources to learn other ways to access information.

The Additive Manufacturing (AM) Module (also referred to as the AM Module) is an Add-on Module to Thermo-Calc and it is available in Graphical Mode as the AM Calculator. The aim of the Additive Manufacturing Module is to better understand the laser powder bed fusion (LPBF) process by predicting the temperature distribution and melt pool geometry as a function of process parameters and using material properties from the Thermo-Calc thermodynamic and properties databases. You can also simulate the powder bed fusion-electron beam (PBF-EB) process, commonly called Electron Beam Melting (EBM), using the electron beam heat source. Special focus is to have a unified treatment of alloy-dependent material properties and process parameters when solving the multiphysics problem of a moving heat source that melts and solidifies metal powder. The multiphysics simulation involves thermal conduction, fluid flow, evaporation-, radiation-, and convective-heat loss.

The Module can simulate the transition from conduction- to keyhole-mode. With experimental melt pool data you can calibrate the heat source. The calibrated heat source can be used to predict additional process conditions and/or to construct printability (aka process) maps. It can also predict composition changes caused by evaporation during additive manufacturing.

Furthermore, once you have the temperature distribution, for instance as a function of time and space, you can also use this information for other Thermo-Calc Add-on-Module simulations such as with the Diffusion Module (DICTRA) or the Precipitation Module (TC-PRISMA), or for input to other external finite element programs.

What Can you Evaluate with the AM Module?

Evaluation of the following is possible depending on the calculation type.

Steady-State

- Size of melt pool
- Peak temperature
- Velocity of fluid flow
- Property variations through the melt pool (temperature, viscosity, thermal conductivity, density) or any selected line
- 2D sectioning in any plane
- Heat source calibration
- Thermal gradient and solidification rate
- Keyhole mode (with Gaussian, Core-ring, Top-hat, or Electron Beam heat sources) with or without fluid flow

Transient and Transient with Heat Source from Steady-state

- Temperature vs. time response at selected points of the build and how this changes with process parameters
- Time-dependence of the properties listed above under steady-state
- Thermal gradient and solidification rate
- Connect the above temperature vs. time response with the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA)
- Keyhole mode (with a *Transient with heat source from Steady-state* simulation using a Gaussian, Core-ring, Top-hat, or Electron Beam heat source) with or without fluid flow

Evaporation with Steady-state

- Track the average liquid and gas compositions throughout the build process across successive tracks and layers
- Plot the printed composition and evaporated gas composition
- Track composition change

Overview of the Content

There are Additive Manufacturing (AM) Module Help Resources and Network License Restrictions to consider and access.

Theory is included in a variety of feature topics. Some basic equations pertaining to the logic behind the simulation and settings are discussed in Additive Manufacturing Module Theory, as well as particular details about other features are discussed in About Heat Source Calibration, About the Keyhole Model, About the Absorptivity Model, About the Heat Source Models, and Composition Changes Due to Evaporation.

The workflow for the AM Module is outlined in Setting Up the Additive Manufacturing Simulation and there are two default Additive Manufacturing Templates you can use to start defining your project. You can also add nodes individually to build your own tree. There are two workflows, and in either workflow, defining the AM Calculator involves choosing one of the available simulation types, which are summarized in Additive Manufacturing Simulation Types as well as the Steady-state Calculation Types. Learn about the associated About the AM Plot Types, where there are links to feature-based topics for each calculation or plot type.

Then you can start building the simulation using the activity nodes and depending on which workflow you start with.

This involves the standard **System Definer** and **Scheil Calculator** settings, which are the same as what is used with a standard Thermo-Calc configuration. When you add an Additive Manufacturing Template (and need to generate some materials properties or do not have a material library to use), then some unique default settings for the Scheil Calculator and these particular types of simulations are already set by default. These are discussed in Setting Up the Additive Manufacturing Simulation.

This set of topics specifically includes details about the settings for the AM Calculator and the specialized AM Calculator: Plot Renderer Settings. There are many additional specialized sections related to working with, for example, probe data as well as experimental data files that are used in heat source calibrations and batch calculations.

There are many details related to visualizing the plots discussed in several sections, starting with Working with AM Visualizations and then extended with specialized sections Visualizing Heat Source Calibrations and Visualizing Batch Calculations in the AM Module. The power of the AM Module is that there are many ways visualize both the set up (i.e. you can preview a variety of settings) and then finally examine and work with your results using the AM Visualizations Window Plot Toolbar and many other settings.

There are also several examples included with the installation that are generally discussed and described in the examples section.

Database Availability

For compatibility with the Additive Manufacturing Module, a database needs the following properties added in addition to the thermodynamics: surface tension for liquid, viscosity for liquid, thermal conductivity, molar volume, and a complete gas description.

The Additive Manufacturing Module is currently available together with the following databases, starting with the version indicated:

- Aluminum-based Alloys Database (TCAL9 and newer)
- Copper-based Alloys Database (TCCU6 and newer)
- High Entropy Alloys Database (TCHEA6 and newer)
- Magnesium-based Alloys Database (TCMG6 and newer)
- Molybdenum-based Alloys Database (TCMO1 and newer)
- Nickel-based Superalloys Database (TCNI12 and newer)
- Niobium-based Alloys Database (TCNB1)
- Noble Metal Alloys Database (TCNOBL3 and newer)
- Permanent Magnetic Materials Database (TCPMAG3 and newer)
- Solder Alloy Solutions Database (TCSLD5 and newer)
- Steel and Fe-alloys Database (TCFE13 and newer)
- Titanium and TiAl-based Alloys Database (TCTI5 and newer)

Learn more about the Additive Manufacturing (AM) Module on our website including the details about database compatibility or to watch a webinar. You can also use the Getting Started Guide to learn about the key features available or visit our YouTube channel.

Available Options

The Additive Manufacturing (AM) Module is an Add-on Module to the core Thermo-Calc software.

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. Without a license you are in *Demo Mode* where you can, for example, open and view example set ups, run some examples, add templates and nodes to the Project window, adjust some Configuration settings, and preview some functionality on the Visualizations window.

The Additive Manufacturing (AM) Module is not available with the free Educational version of Thermo-Calc.

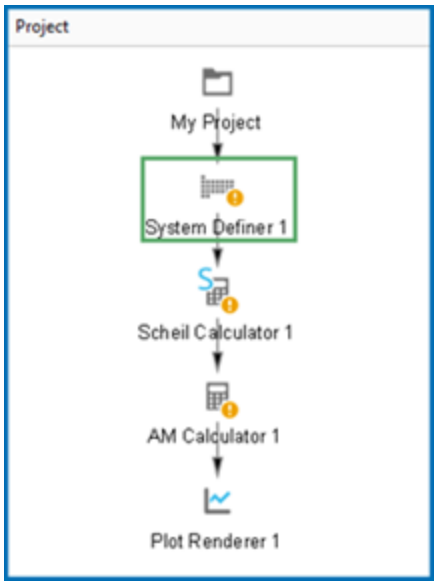
Additive Manufacturing Templates

Two types of **Additive Manufacturing** templates are under **Applications** and these are available to all Thermo-Calc users when in Graphical Mode. If you are in DEMO (demonstration) mode then this is indicated by the addition of **DEMO** text. See Figure 1.

Using the Templates

After opening Thermo-Calc in Graphical Mode, in the templates section under **Applications**, click the **Additive Manufacturing** button to add a *System Definer*, *Scheil Calculator*, *AM Calculator*, and *Plot Renderer* to the **Project** tree.

This template is used when you need to generate and use data from a Scheil calculation.



An alternate template is available when you already have data or can directly use or import a Material Library.

After opening Thermo-Calc in Graphical Mode, in the templates section under **Applications**, and to the right of **Additive Manufacturing**, click the **With Material Library** button to add an *AM Calculator* and *Plot Renderer* to the **Project** tree.

Demonstration (Demo) Mode

The Additive Manufacturing (AM) Module is available in a demonstration (DEMO) mode without an additional AM license. It includes access to the templates, some examples, and some access to the embedded predefined material properties libraries. You also have access to the fluid flow settings and a steady-state calculation can be done. However, there are limitations such as the ability to change settings and to fully run calculations.

What is Included?

- Some examples (i.e. AM_01, AM_02, AM_03, AM_06b) use embedded and predefined Material Properties libraries that are included for all users. Although these examples can be run without a license, you cannot make any changes to the settings. If changes are made, the **Perform** button can still be clicked but the calculation will fail and a message displays above the **Perform Tree** button to inform you of the need for a license. In addition, the **Event Log** displays an error message, `ERROR AM Calculation: AM Calculation in Demo mode has limited functionality`. See Figure 2.

- Generally, when in DEMO mode and using the **With Materials Library** template, you can perform a calculation with default values. You cannot change any setting, including the calculation types (i.e. Steady-state, Transient, or Transient with heat source from Steady-state) as well as the Material Properties library i.e. meaning only Steady-state with the IN625 library is available with the default setup is possible.
- All plot configurations are possible to perform in the above cases.
- All examples except those listed above require a full license to the Additive Manufacturing (AM) Module to run, plus often additional licenses (i.e. for databases or other Add-on Modules). For those without the applicable licenses, you can still open the examples to review the settings and then refer to the documentation for discussions of what it is showing.

You can also view the *Getting Started Guide* on the website, which uses AM_04 in the example.

Figure 1: The templates indicate that you are in DEMO mode and would need an AM license to fully use the templates or run certain examples as listed in the text.

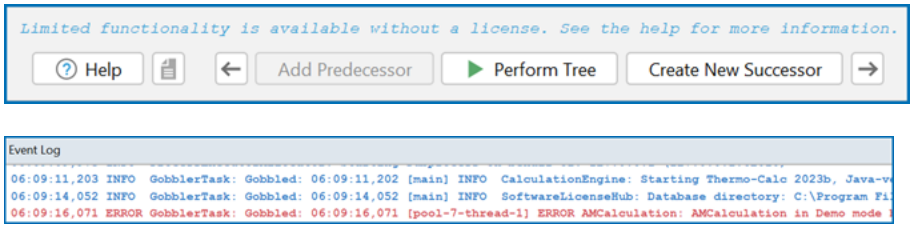


Figure 2: When in DEMO mode and you click on the AM Calculator node, the above note is included at the bottom of the Configuration window to remind you that a license is needed for full functionality. The Perform Tree button is not always available and sometimes even if it is available to click, the calculation itself cannot complete due to lack of a license. There will also be an error message in the Event Log to indicate the need for a license.

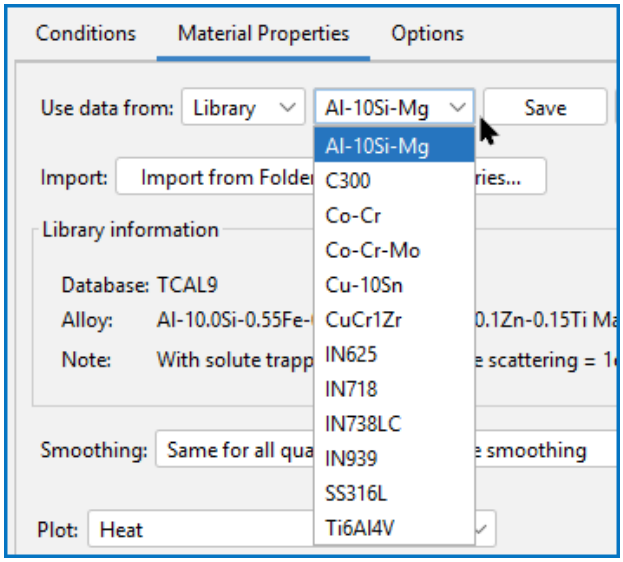
Material Properties and Libraries

All predefined Material Properties libraries are available if you have a license for the Additive Manufacturing (AM) Module, even if you do not have the alloy database it is created with.

Create or Import Your Own Material Library

The use of the Scheil Calculator with an AM Calculator provides you with a way to generate the data you need to feed into any AM calculation. When this Scheil calculation is completed, and if you have a full license, you can save the results to the Material Properties Library for later use. From the AM Calculator there is an option to use either Scheil data (when it is connected to the Scheil Calculator) or predefined library data (as long as you have a license to the Additive Manufacturing (AM) Module the calculations can be run fully). With the applicable license, you can also import your own material library for a particular alloy of interest and then you can just use the AM Calculator (i.e. the **With Material Library** template setup) without needing the additional Scheil calculation step.

Users with a full Additive Manufacturing license can access all the predefined libraries for use in calculations (and also can create and import their own libraries and save these for reuse).



Learn More

Using Data with Other Add-on Modules

When you also have licenses either for the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA), for transient simulations you can additionally include probe data from the AM Calculator in the set up of the thermal profile for diffusion and precipitation calculations, respectively.

See AM Calculator: Working with Probe Data

Additive Manufacturing (AM) Module and TC-Python

When you also have a license for the TC-Python Software Development Kit, you can use the Additive Manufacturing (AM) Module functionality. Some examples are available with just a TC-Python license. Learn more about TC-Python on our website.

Additive Manufacturing (AM) Module Help Resources

The technical content is available in HTML format as an Online Help system that you can access from two locations. Both versions are viewed in your browser.

Local vs Web Help

Go to these locations to access the same content:

- **Locally Installed Help**: When in Thermo-Calc, press F1 to open the current version of the help in a local browser. You can also click **Online Help** from the **My Project** page to open the file. Then search or navigate to the applicable folder to browse the contents. This does not not require an Internet connection.
- **Web Help**: Go to the Documentation page to link to the most recent version of the web help. Then search or navigate to a relevant folder to browse the contents.

Between releases there may be minor updates to the web version compared to the installed version. All updates made to the web version are included in the next installed release version.

There are several resources available on our website to help you learn how to use Thermo-Calc and other Add-on Modules. Go to the Getting Started Guides page and choose one of the guides that provides new users an introduction to setting up simple calculations in Graphical Mode. The information there is also in this help documentation.

Discover more or refresh your skills with an Advanced Lecture Series on Fundamentals of Thermodynamics, created by Professor John Ågren, one of the original developers of Thermo-Calc.

Opening the Web Version of the Help

A web version **specific to only the most recent release version** is available at the following link (copy this):

https://help.thermocalc.com/2026b/content/intro/help-home.htm

Opening the Installed Help: No Internet Needed

There are several ways to access online help in a browser. The content opens in a browser but uses local content so you do not need an Internet connection except for links to external websites.

First open Thermo-Calc, then choose one of these options to go to the local browser version of the help:

- Press <F1> on the keyboard.
- Select **Help** → **Online Help**.
- On the **My Project Configuration** window, click **Online Help**.
- At the bottom of any **Configuration** window, click **Help**.

Additive Manufacturing (AM) Module Specific Information

Learn more about the Additive Manufacturing (AM) Module on our website including the details about database compatibility or to watch a webinar. You can also use the Getting Started Guide to learn about the key features available or visit our YouTube channel.

For more Additive Manufacturing (AM) Module learning resources, visit the video tutorials on our website or our YouTube playlist.

Network License Restrictions

The Additive Manufacturing (AM) Module requires a separate license. If you are using a network client installation of Thermo-Calc, then you may not be able to use it even if you have access to a license server with a valid network license file. The reason for this is because other clients who are part of your network installation may have checked out all instances of the network license allowed to run simultaneously.

For users with a network license, you must exit Thermo-Calc to release the license for other users. The license is checked out as soon as you add an AM Calculator and remains unavailable to other users until you exit the program.

With a network license, and if as per above you temporarily do not have access to a license, you are automatically put into *Demo Mode*. Then the AM Calculator is available.

Search the online help or see the *Thermo-Calc Installation Guide* for more about network licenses.

Additive Manufacturing Module Theory

This section is an overview of the underlying fundamental theory used and applied to the calculations when you are setting up the AM Calculator using one of the Additive Manufacturing Simulation Types.

Energy Equation: The Enthalpy Formulation

The following formulation is based on a simple assumption that each volume element, which may contain several dendrites or a considerable part of a dendrite, is approximated as homogeneous, i.e., it is sufficient to characterize the whole volume with a single set of state variables. This assumption thus excludes the direct account of varying composition caused by microsegregation within the element.

The enthalpy formulation is based on the conservation of energy and is essentially equivalent with Fourier's second law:

[*Eq. 1*] $$\dot{H}_V = -div(J_Q) + \dot{Q}$$

H_V is the enthalpy density and $\dot{H}_V$ is its time derivative.

The enthalpy density is related to the molar enthalpy H_m and molar volume V_m by:

[*Eq. 2*] $$H_V = \frac{H_m}{V_m}$$

div denotes the divergence operator and J_Q is the heat flux given by Fourier's law:

[*Eq. 3*] $$J_Q = -\kappa \ grad(T)$$

where κ is the heat conductivity, $grad$ denotes the gradient operator and T is the temperature. $\dot{Q}$ is a source term and represents the heat added from the outside at a certain point. In modeling of a process like welding or additive manufacturing this is a key term and requires a lot of modeling.

As state functions the enthalpy and the molar volume depend on temperature, state of phase, and composition of the individual phases. In a volume element approximated as homogeneous, one thus has:

[*Eq. 4*] $$H_m = \sum_\beta f^\beta H_m^\beta \left(T, x_k^\beta\right)$$

[*Eq. 5*] $$V_m = \sum_\beta f^\beta V_m^\beta \left(T, x_k^\beta\right)$$

where f^β is the mole fraction of the phase β and x_k^β is the mole fraction of k in β. The time derivatives thus are:

[*Eq. 6*] $$\dot{H}_m = \sum_\beta \dot{f}^\beta H_m^\beta \left(T, x_k^\beta\right) + \sum_\beta f^\beta \left(c_P^\beta \left(T, x_k^\beta\right) + \sum_{k=1}^{n} \frac{\partial H_m^\beta}{\partial x_k^\beta} \frac{\partial x_k^\beta}{\partial T}\right) \dot{T}$$

[*Eq. 7*] $$\dot{V}_m = \sum_\beta \dot{f}^\beta V_m^\beta \left(T, x_k^\beta\right) + \sum_\beta f^\beta \left(V_m^\beta \alpha^\beta \left(T, x_k^\beta\right) + \sum_{k=1}^{n} \frac{\partial V_m^\beta}{\partial x_k^\beta} \frac{\partial x_k^\beta}{\partial T}\right) \dot{T}$$

Here c_P^β is the molar heat capacity of the β phase and α^β its volumetric thermal expansion. For a given volume element the rates can be calculated from Thermo-Calc for the temperature, fraction of phases and their composition with the input of the rates $\dot{f}^\beta$ and $\dot{T}$.

The rate of change of the enthalpy density, i.e., the left-hand side of Eq. 1 thus is obtained as:

[*Eq. 8*] $$\dot{H}_V = \frac{1}{V_m}\left(\dot{H}_m - H_m \frac{\dot{V}_m}{V_m}\right)$$

The first term inside the brackets represents the change for a constant number of atoms due to a change in temperature or phase. The second term represents a change in volume for a constant number of atoms. However, the second term is balanced by a corresponding contribution in the heat flux, which we do not usually account for, and we should thus leave it out.

[*Eq. 9*] $$\dot{H}_V = \frac{\dot{H}_m}{H_m}$$

The fraction of phases sums up to unity and in the case of only one solid phase:

$$\dot{f}^L = -\dot{f}^\beta$$

In most treatments the positive quantity

$$\Delta H_m = \left(H_m^L(T, x_k^L) - H_m^\beta(T, x_k^\beta)\right)$$

treated as constant and referred to as the latent heat. It is also common to neglect the difference in heat capacity between solid and liquid and the variation of ΔH_m with composition. Eq. 6 then is simplified into

[*Eq. 10*] $$\dot{H}_m = \dot{f}^L \Delta H_m + c_P \dot{T}$$

By the same token

$$\Delta V_m = \left(V_m^L(T, x_k^L) - V_m^\beta(T, x_k^\beta)\right)$$

is often approximated as constant and so Eq. 7 is simplified into

[Eq. 11] $$\dot{V}_m = \dot{f}^L \Delta V_m + V_m \alpha \dot{T}$$

where V_m is given by Eq. 5 and yields

$$V_m = f^L V_m^L + (1 - f^L) V_m^\beta = V_m^\beta + f^L \Delta V_m$$

Eq. 9 now becomes:

[Eq. 12] $$\dot{H}_V = \frac{1}{V_m}\left(\dot{f}^L \Delta H_m^L + c_P \dot{T}\right)$$

and Eq. 1 becomes:

[Eq. 13] $$\frac{1}{V_m}\left(\dot{f}^L \Delta H_m^L + c_P \dot{T}\right) = div(\kappa grad(T)) + \dot{Q}$$

The Equivalent Heat Capacity Method Using Thermo-Calc

If it is further assumed that the fraction liquid f^L is a unique function of temperature one has:

[Eq. 14] $$\dot{f}^L = \frac{df^L}{dT}\dot{T}$$

and Eq. 13 may be further simplified to:

[Eq. 15] $$\frac{c_p^{eff}}{V_m}\dot{T} = div(\kappa grad(T)) + \dot{Q}$$

where the effective heat capacity c_p^{eff} is given by:

[Eq. 16] $$c_P^{eff} = \left(\frac{df^L}{dT}\Delta H_m + c_P\right)$$

Eq. 15 is a normal heat-flow equation and the complication of the liquid/solid phase transformation is taken into account by means of an effective heat capacity. This method is referred to as the equivalent heat-capacity method by Rappaz [1989Rap].

It then remains to be discussed how to determine $f^L(T)$. It must be given by some extra information. Traditionally it was taken from experimental information but more recently it has been taken from the Scheil equation. The original equation was based on a number of

approximations which are unnecessary today when thermodynamic and properties databases and efficient software such as Thermo-Calc are available. In fact, when using Scheil in Thermo-Calc one can directly calculate $c_p^{eff}(T)$, referred to as apparent heat capacity, for a given initial composition of the liquid. A possible approach thus is to calculate $c_p^{eff}(T)$ for the alloy under consideration and then store the result as a table and use that in the solution of Eq. 15. The molar volume may be extracted from the same calculation. An example for a 316L type of stainless steel is shown in the plots below.

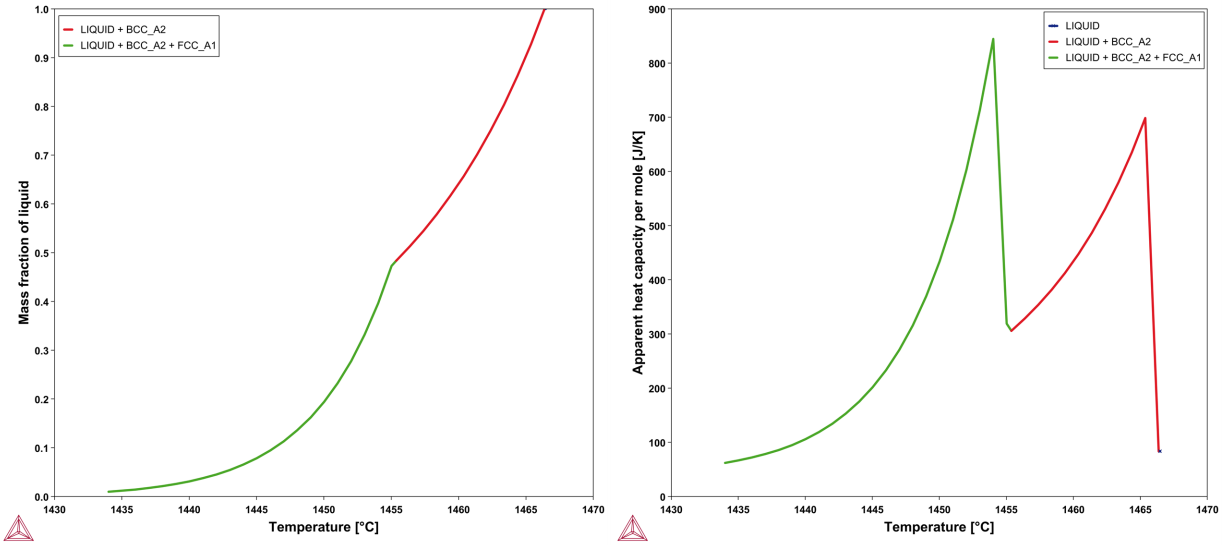

Figure 3: Results of a Scheil simulation of Fe-18Cr-10Ni alloy showing the mass fraction of the liquid (left) and the apparent heat capacity (right) both as a function of temperature.

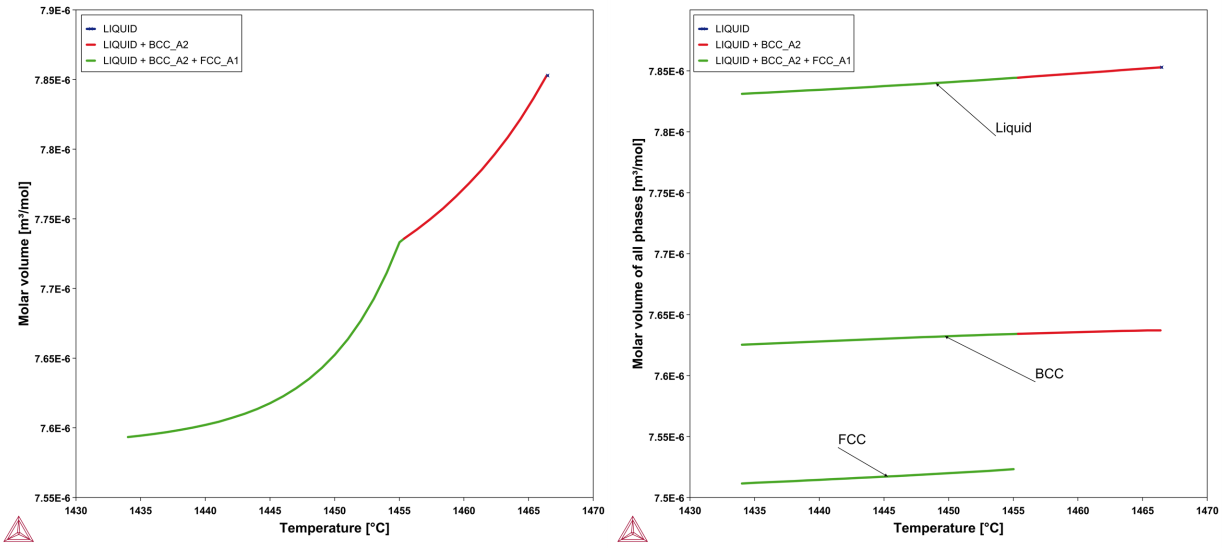

Figure 4: Molar volume from a Scheil simulation of Fe-18Cr-10Ni alloy. The right plot shows all phases as a function of temperature.

The Enthalpy Method Using Thermo-Calc

In the enthalpy method we keep Eq. 1 and use Eq. 9 to write

[*Eq. 17*] $$\frac{\dot{H}_m}{V_m} = -div(J_Q) + \dot{Q}$$

As pointed out by Rappaz [1989Rap] there is no mathematical difference between the enthalpy method and the equivalent heat capacity method because the former is simply the integral of the heat capacity over T. For numerical reasons the cusps in the heat capacity may be disadvantageous and the enthalpy has a nicer behavior as shown in the plot below, where it gives temperature as a unique function of enthalpy.

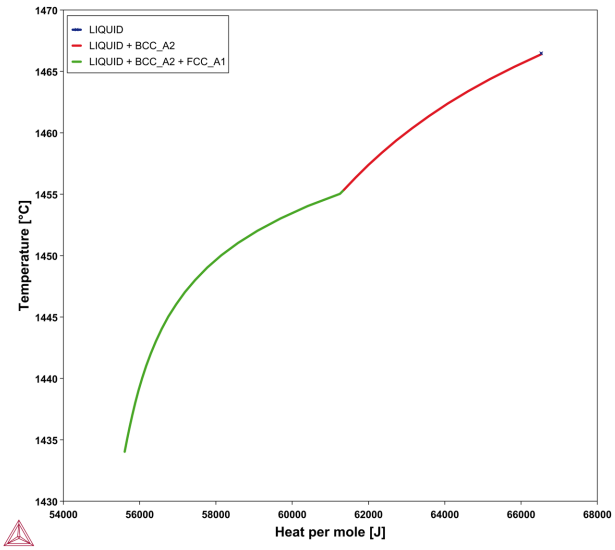

Figure 5: Enthalpy from a Scheil simulation of Fe-18Cr-10Ni alloy.

In the Additive Manufacturing Module, we therefore use Eq. 17 to predict the evolution of temperature during the laser powder bed fusion (LPBF) process for the given material properties and process parameters.

Steady-state Formulation

An important approximation is when one can solve the stationary heat-flow equation for a volume element moving with the heating source. In that case, we neglect the left-hand side of Eq. 17 and add a translation term as follows:

[*Eq. 18*] $$div[\kappa grad(T)] - \frac{v_b}{V_m} grad(H_m) + \dot{Q} = 0$$

Where v_b is the velocity of the heat source. In case of additive manufacturing, v_b is the scanning speed.

Fluid Flow

When there is also fluid flow involved, a fluid transport term has to be added to the heat-flow equation and one obtains:

[*Eq. 19*] $$\frac{\dot{H}_m}{V_m} = div[\kappa grad(T)] - \frac{v}{V_m} grad(H_m) + \dot{Q}$$

where v is the velocity vector field and may be imposed or obtained from the solution of the Navier-Stokes equation:

[*Eq. 20*] $$\rho\dot{v} + \rho(vgrad)v - \mu(divgrad)v = F_V - gradP$$

where ρ is the density related to the molar volume by means of

[*Eq. 21*] $$\rho = \frac{1}{V_m}\sum_k x_k M_k$$

M_k is the molar weight in kg mol^{-1}. μ is the viscosity, F_V is a volume force, e.g., gravitational forces, and P is the internal pressure. The equation is often combined with approximating the liquid as incompressible.

[*Eq. 22*] $$div(v) = 0$$

Large Eddy Simulation Used for Fluid Flow

The use of a subgrid model [1963Sma] relies on the eddy-viscosity assumption and this is applied to account for the unresolved turbulent motions that cannot be directly simulated due to computational limitations. The Smagorinsky model is the default for fluid flow, and it provides a simple way to estimate *Subgrid-scale (SGS)* viscosity in large eddy simulation as,

$$\nu_{SGS} = (C_S\,\Delta)2|\overline{S}|$$

where:

- C_S is the Smagorinsky constant (default value is 0.18).
- Δ represents the filter width (length scale).
- $|\overline{S}|$ is the magnitude of the resolved strain rate tensor.

Numerical Boundary Conditions

In order to obtain temperature distribution during the LPBF process in the Additive Manufacturing (AM) Module, incorporating fluid flow inside the melt pool, we couple energy equations with the Navier-Stokes equations, as explained earlier. In order to accurately reflect the physical process, both of these equations are subjected to a certain set of boundary conditions, which are given as follows.

Boundary Conditions for Energy Equation

The energy equation is subjected to four different boundary conditions. The first boundary condition is defined on the top surface (either the powder bed surface or the solid substrate) and represents the energy lost due to convection and radiation to the surrounding gas.

[*Eq. 23*] $$Q_L = h(T - T_{ambient}) + \epsilon\sigma(T^4 - T_{ambient}^4)$$

where h is the convective heat transfer coefficient, ϵ is the surface radiation emissivity and

$$\sigma = 5.669 \times 10^{-8} W/m^2K^4$$

is the Stefan-Boltzmann constant. $T_{ambient}$ is the ambient temperature or the temperature of the surrounding gas in the build chamber and can be set in the AM Calculator configuration.

The second boundary condition represents the heat lost through the vertical walls of the domain and for simplicity we have chosen adiabatic boundary conditions for these surfaces. The boundary condition for the vertical walls of the computational domain is thus given as:

[*Eq. 24*] $$Q_N = 0$$

The third boundary condition reflects the temperature of the base plate and is therefore applied to the bottom of the computational domain. Here we have assumed that the base plate of the build part is kept at a constant temperature and the boundary condition is therefore given as:

[*Eq. 25*] $$T = T_{baseplate}$$

$T_{baseplate}$ is the base plate temperature and can be set in the AM Calculator configuration.

The fourth and the most important boundary condition is the evaporation boundary condition that represents the heat lost due to evaporation of the material. Evaporation is implemented using a physics-based approach where the heat loss due to evaporation (Q_E) is given as:

[*Eq. 26*] $$Q_E = 0.82 J_E \Delta H_v$$

where J_E is the evaporation flux and ΔH_E is the evaporation enthalpy. For a multicomponent system, the evaporation flux is given as follows:

[*Eq. 27*] $$J_E = \frac{1}{\sqrt{2\pi MRT}}\left(P_o exp(-\frac{\Delta G_v}{RT}) - P\right)$$

where ΔG_v is the driving force for evaporation, M is the molar mass of the gas, P is the gas pressure inside the chamber, P_o is the atmospheric pressure, and R is the universal gas constant. The driving force for evaporation, the evaporation flux, and the molar mass of the

gas are all temperature-dependent material properties which are obtained from Thermo-Calc databases and are included in the material library whereas the gas pressure inside the chamber can be set from the AM Calculator configuration.

Boundary Conditions for Navier-Stokes Equations

For the velocity, a no-slip boundary condition is used for the bottom surface of the computational domain. A no-slip boundary assumes that at a solid boundary, the fluid will have zero velocity relative to the boundary. For the pressure, a pinned boundary condition is used.

For the melted liquid at the top, the symmetry (front - in a steady-state simulation), and the keyhole surfaces, the free-slip boundary is used.

The most important boundary condition in Navier-Stokes setup is the Marangoni boundary condition that reflects the tangential force on the surface and the keyhole surface of the melt pool due to temperature variation of surface tension or the so-called Marangoni effect. In AM, large temperature gradients on the surface of the melt pool, leads to the Marangoni effect and is the primary cause of convective flow inside the melt pool. The Marangoni shear stress (τ) is modeled using the following equation:

[*Eq. 28*] $$\tau = \frac{\partial \gamma}{\partial T} \nabla_s T$$

where γ is the surface tension and ∇_s represents the tangential component of the spatial derivative.

Surface tension is also a temperature-dependent material property which is obtained from Thermo-Calc databases and is included in the material library.

Thermophysical Properties of Powder Material

When the **Use separate material properties for powder** checkbox is selected on the AM Calculator, a different thermal conductivity, density and molar volume is used for the powder material as compared to the solid substrate. The above mentioned properties depend on the porosity (ϕ) of the powder. The density (ρ_{powder}) and molar volume (Vm_{powder}) of the powder are then simply given as follows:

$$\rho_{\text{powder}} = \rho_{\text{solid}}(1-\phi)$$

$$Vm_{\text{powder}} = Vm_{\text{solid}} \frac{1}{1-\phi}$$

For thermal conductivity of powder k_{powder}, an empirical expression is used which was suggested by Xue and Barlow [1991Xue]. The thermal conductivity of powder thus also depends on the conductivity of the surrounding gas. For simplicity, the surrounding gas is assumed to be air. The thermal conductivity of powder is given as follows:

[*Eq. 29*]
$$k_{\text{powder}} = \left(6.3 + 22\sqrt{0.09k_{\text{solid}} - 0.016}\right) \frac{k_{\text{solid}}\ (1-\phi)}{(k_{\text{solid}}\ /k_{\text{air}})(10^{0.523-0.594\phi})-1}$$

where $k_{\text{air}} = 0.05784$.

Additional theory related to specific features is described in such topics as About the Absorptivity Model, Composition Changes Due to Evaporation, or About the Keyhole Model. When in Thermo-Calc press F1 to search the help.

See the theory related to heat sources in About the Heat Source Models and About Heat Source Calibration. Settings information specific to heat sources is also found in AM Calculator Heat Source Settings.

The settings related to this topic are defined for the AM Calculator starting with the AM Calculator Conditions Settings section.

Composition Changes Due to Evaporation

Selective evaporation of volatile elements can become a significant issue during AM printing when processing conditions cause overheating and excessive evaporation, resulting in a printed composition that falls outside the alloy specification limits.

Element evaporation during additive manufacturing occurs to some extent across the entire liquid–gas interface. However, most evaporation takes place in the keyhole region, where temperatures reach or exceed the evaporation temperature of the alloy. This is where you can use the *Evaporation with Steady-state* mode to compute composition changes due to evaporation using a steady-state solution.

The modeling of evaporation-induced composition changes in the Additive Manufacturing (AM) Module follows an approach similar to that described in the References. The main assumptions are that the melt pool and keyhole geometries can be determined from a single steady-state AM simulation, and that these geometries remain unchanged during the printing of multiple overlapping tracks and layers. The average liquid and gas compositions are continuously tracked throughout the build process across successive tracks and layers. The calculation procedure is described in the following sections.

Evaporation Flux at the Liquid/Gas Interface

The evaporation flux at the liquid–gas interface for multicomponent alloys under varying pressure conditions can be expressed as follows:

$$J^0 = \frac{P_0}{\sqrt{2\pi MRT}}\left(\exp\left(-\frac{\Delta G_V}{RT}\right) - P/P_0\right)$$

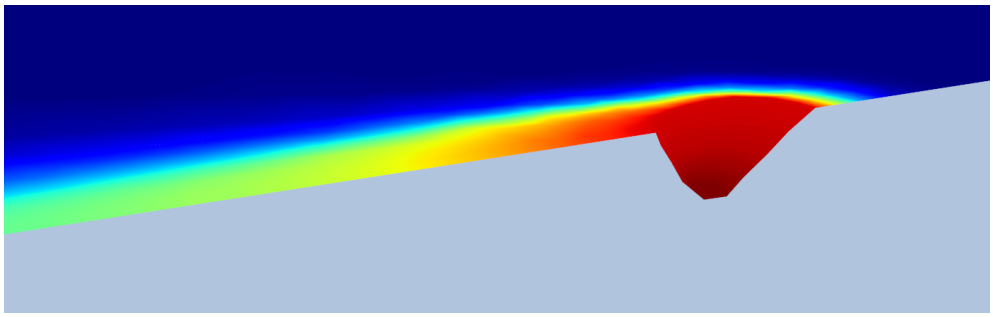
Here, P_0 is the pressure at which the thermodynamic calculation is performed to evaluate the chemical driving force for evaporation, ΔG_V, while P is the pressure at which the evaporation flux is evaluated.

The theoretical evaporation rate may deviate from experimentally measured values. To account for systematic deviations for specific elements, elemental accommodation coefficients, α_i, can be introduced as fitting parameters.

$$J_i = \alpha_i J_i^0$$

The total flux per unit time is then obtained by integrating the evaporation flux over the entire liquid–gas interface:

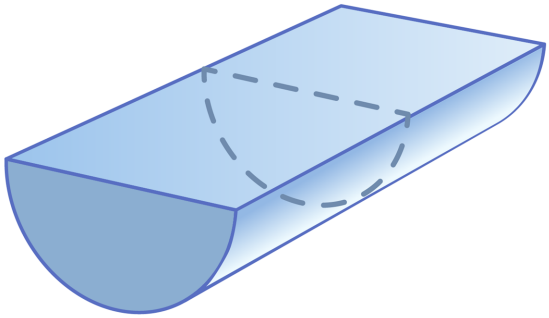
$$m_i = \oint J_i \, dS$$



The liquid–gas interface, including the keyhole region. The color scale represents temperature.

Volume of a Single Track

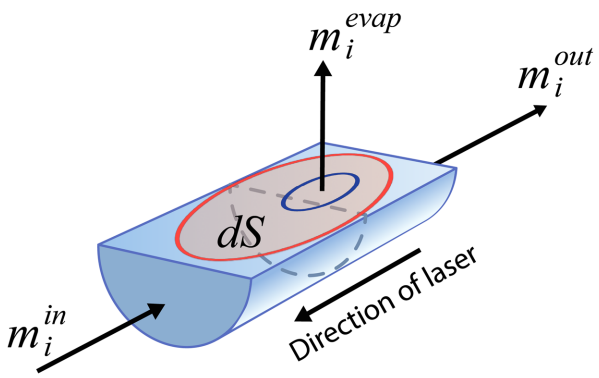
The volume of a single track per unit time can be estimated from the widest cross-section of the melt pool multiplied by the scan speed. In other words, the deposited volume is approximated as the extruded geometry of the melt pool's widest section.



Schematic of the extruded geometry of the widest section.

Composition Changes for Single Track

The average composition change over a unit time interval can now be calculated by performing a mass balance on a control volume moving with the laser, as illustrated in the figure below. The evaporation rate and single-track volume were described in the previous section. The incoming composition to the control volume, m_i^{in}, is assumed to correspond to the initial powder composition. Applying a mass balance over the control volume yields the resulting composition, m_i^{out}, after evaporation.

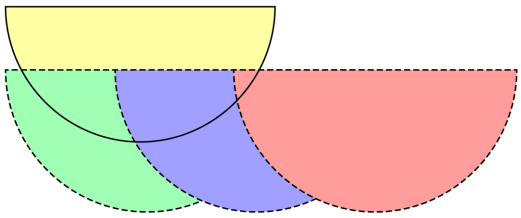


A control volume moving with the laser is considered.

In the figure above, the incoming and evaporated compositions are denoted by m_i^{in} and m_i^{evap}, respectively. A mass balance over the control volume gives the resulting composition after evaporation, m_i^{out}. Mass balance over control volume moving with the laser gives the average printed composition for a single track.

Overlapping Tracks

Calculating the average composition change for overlapping tracks within the same layer and across multiple layers is conceptually similar to the single-track case. However, the average incoming composition to the current track now includes contributions from previous tracks and layers due to melt pool overlap.



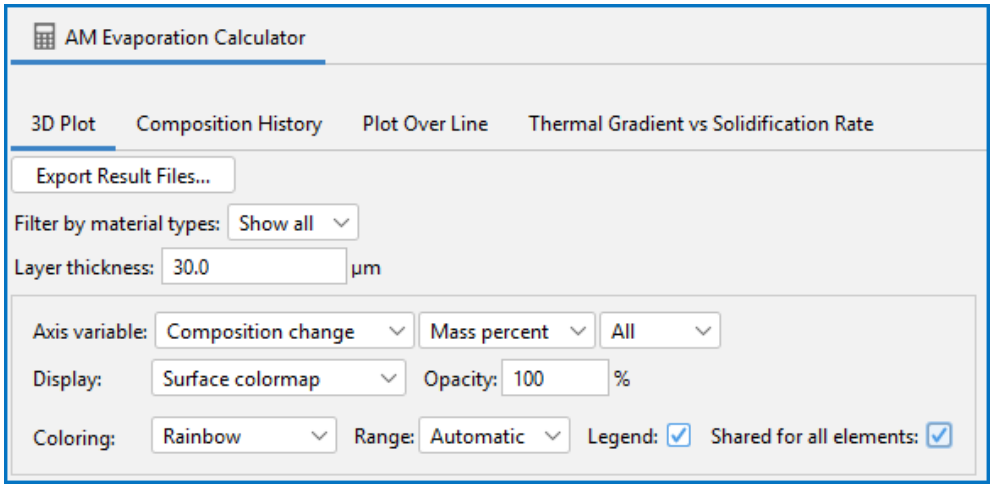
2D schematic illustrating the different regions that must be tracked to evaluate composition changes. In the first layer, the third track overlaps both the first and second tracks. In the second layer, the first track overlaps all three tracks in the underlying layer.

As stated earlier, the multi-track calculations are based on the assumptions that the melt pool and keyhole geometries, as well as the temperature field, can be obtained from a single steady-state AM simulation, and that these characteristics remain unchanged during the deposition of overlapping tracks and layers. The average liquid and gas compositions are

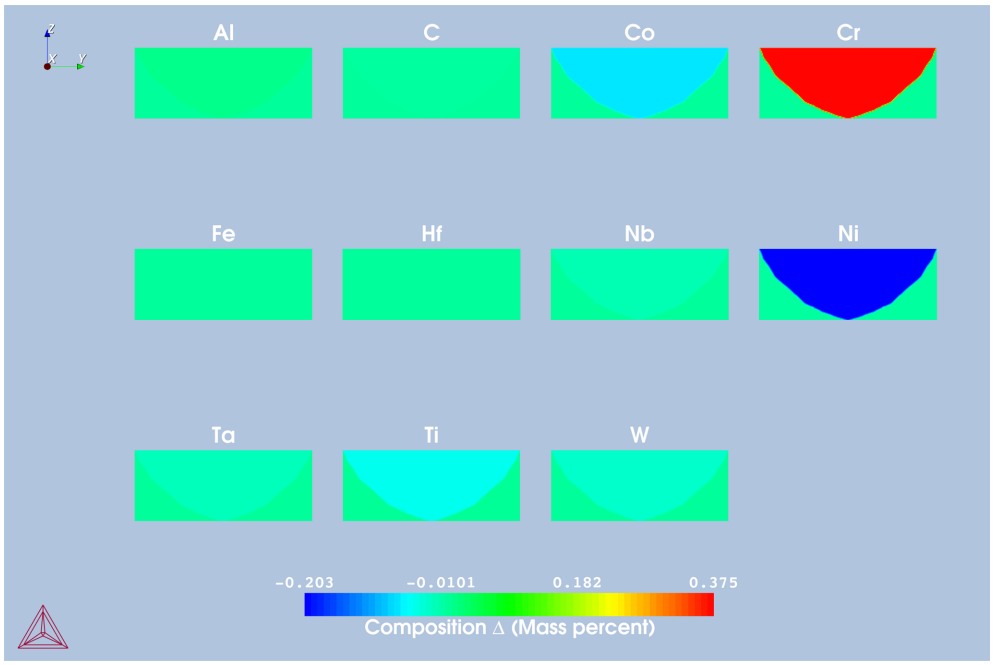
continuously updated throughout the build process across successive tracks and layers. At each step, equilibrium calculations are performed to determine the evaporation driving force and gas composition from the current liquid composition.

Visualization of Composition Changes

The calculated composition change after an evaporation simulation can be visualized in several ways. Below is an example of the composition change of alloy IN939 for a single-track calculation calculated at power 200 W and scan speed 1.8 m/s.



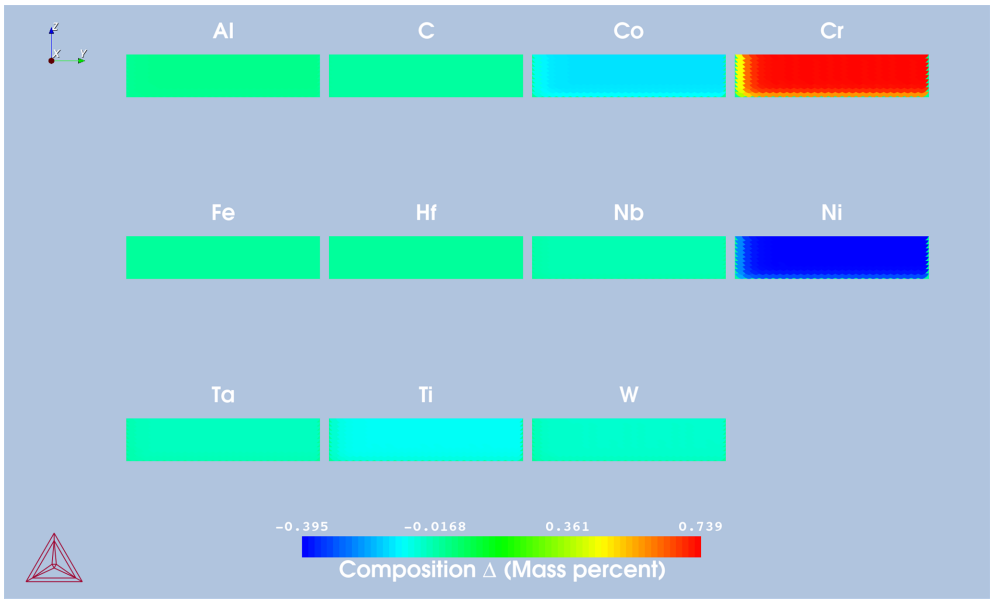
The Plot Renderer Configuration window where settings are entered and the Composition change Axis variable is selected.



Calculated composition change of IN939 for a single-track at power 200 W and scan speed 1.8 m/s.

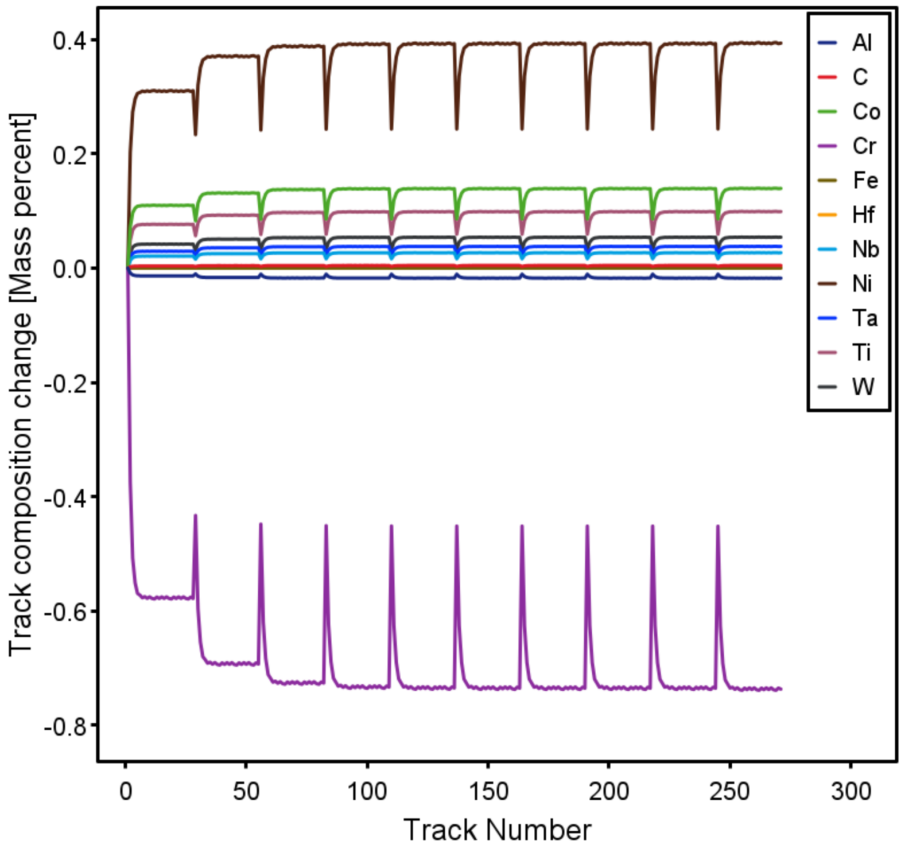
Open and run the installed example, described in AM_16: Composition Change Due to Evaporation, to follow along and compare with these results.

To predict representative composition changes in experimentally printed cubes or larger components, multiple tracks and layers must be simulated until the composition reaches a steady state. Below is an example calculation for IN939 using multiple tracks and layers at a laser power of 200 W and a scan speed of 1.8 m/s. The case consists of 10 layers with 27 tracks each, with a hatch spacing of 50 µm, and a powder layer thickness of 30 µm.

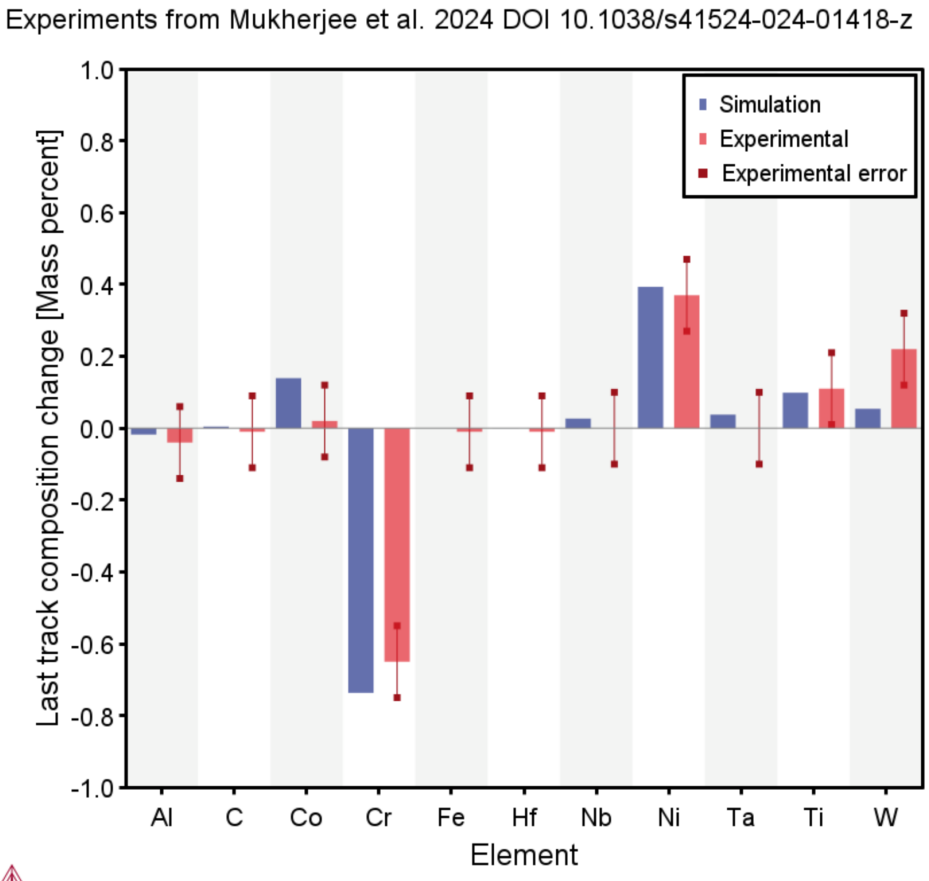


Calculated composition change of IN939 for multiple tracks and layers at power 200 W and scan speed 1.8 m/s. In total 10 layers with 27 tracks each, 50 mm hatch spacing, and 30 mm powder layer.

In the figure below, you can track composition as a function of track number. The largest relative composition change occurs in the first track, which consists solely of melted powder. Subsequent tracks (tracks 2–27) within the same layer partially overlap previously processed material, leading to a gradual evolution of composition. A pronounced change is then observed at the transition to the next layer (track 28). By the final track (track 270), the composition has reached a steady-state and can be considered representative of the average composition in a larger printed part.

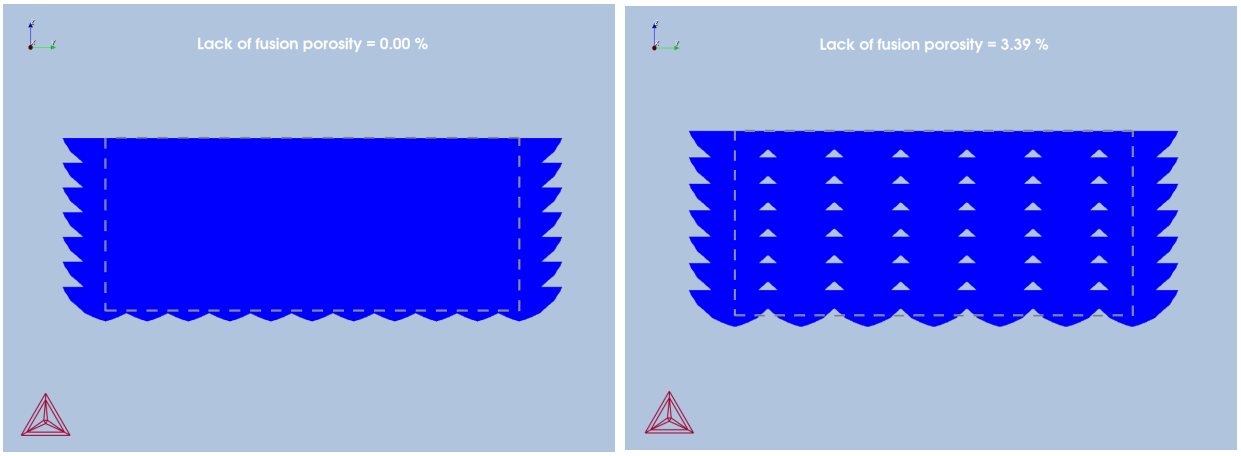


Predicted composition of the alloying elements of IN939 as a function of track number. A total of 10 layers is simulated with 27 tracks on each layer.



Calculated last track composition, number 270, of IN939 compared to experiments by [2024Muk].

Assuming that the melt pool and keyhole geometries remain unchanged during the deposition of overlapping tracks and layers, it becomes possible to calculate and visualize the average lack-of-fusion porosity. To avoid edge effects, the calculation excludes the boundaries of the printed region, as shown in the figure below.



IN939 at power 200 W and scan speed 1.8 m/s. (left) Zero Lack-of-fusion porosity for 50 µm hatch distance. (right) 3.39% Lack-of-fusion porosity for 75 µm hatch distance.

For an installed example using this simulation mode, see AM_16: Composition Change Due to Evaporation.

About the Heat Source Models

It is crucially important to correctly model the heat source in AM simulations since the heat source not only affects the size of the melt pool but also determines the temperature gradients around the melt pool. In the Additive Manufacturing (AM) Module, these heat source models are available: **Gaussian**, **Core-ring**, **Top-hat**, **Electron Beam**, **Double-ellipsoidal**, and **Conical**.

The **Configuration** window settings for each of these heat sources are further described in both the AM Calculator Conditions Settings and AM Calculator Heat Source Settings topics. There is a variety of additional background theory topics available based on the selected heat source.

Topic	*Heat Source Models*	*Link to Theory*

Keyhole model	Gaussian, Core-ring, Top-hat, and Electron Beam	About the Keyhole Model
Absorptivity	Gaussian, Core-ring, Top-hat, and Electron Beam	About the Absorptivity Model
Heat source calibrations	Gaussian, Double-ellipsoidal, and Conical	About Heat Source Calibration

Gaussian Heat Source

The **Gaussian** model is a surface heat source model which was initially proposed by Pavelic et al. [1969Pav]. By surface heat source model, it is meant that the power input from the heat source is only defined on the top surface of the workpiece, as a Neumann boundary condition on the computational domain, and the heat energy then diffuses into the workpiece depending on the thermal diffusivity of the selected material. As suggested by Pavelic et al., the heat flux (W/m^2) is defined as Gaussian distribution around the center of the heat source, deposited on the top surface of the domain, as given in the equation below. A schematic representation of the heat flux, as defined by Gaussian heat source is shown in Figure 6.

[*Eq. 1*]
$$Q = \frac{2\epsilon P}{\pi r^2} exp\left[-2\frac{(x-X_p)^2+(y-Y_p)^2}{r^2}\right]$$

Where Q is the power density deposited on the top surface (W/m^2), ϵ denotes absorptivity of the laser beam, P is the power of the heat source (W), r is the laser spot radius, and x and y denote coordinates of the computational domain while X_p and Y_p represent the location of the heat source.

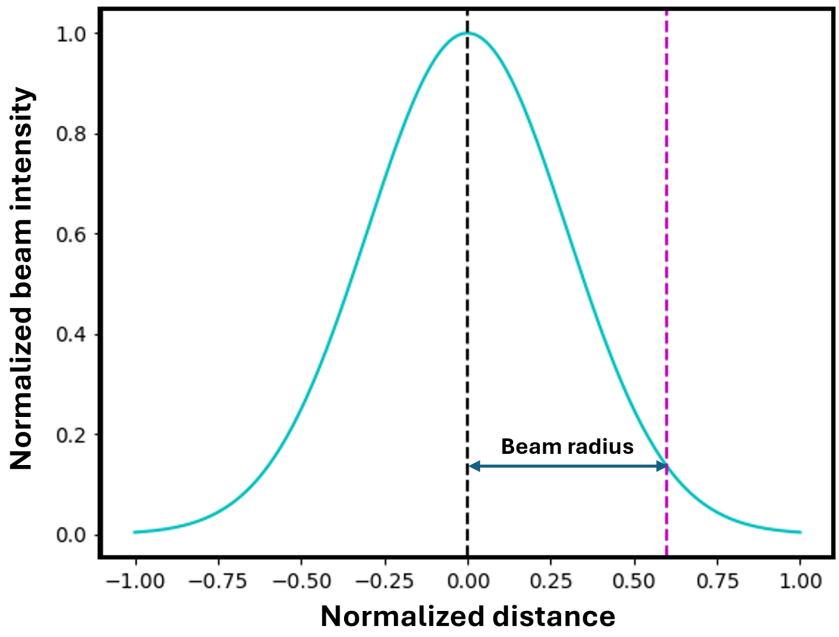

Figure 6: Schematic representation of energy distribution in Gaussian heat source model.

There are various examples using this heat source, i.e. AM_04: Scheil Transient Steady-state and AM_08a: Grid Calculation for a Ti64 Alloy.

Also see additional theory related to using a Gaussian heat source with the keyhole option in About the Keyhole Model.

Core-ring Heat Source

Gaussian beam distribution in additive manufacturing often leads to high energy intensity peaks and strong thermal gradients causing manufacturing defects such as keyhole porosity and suboptimal material processing performance. To overcome these challenges, spatial beam shaping is available as an alternate method to customize energy distribution and control the

resulting thermal field [2023Bi; 2025Bir]. One of the alternative beam shapes is the **Core-ring** profile where energy is distributed between a central core and an outer ring.

AM_13: Using the Core-ring Beam Shape

From a production point of view, the primary benefit of **Core-ring** and **Top-hat** beam shapes is that there is a much wider and more stable melt pool. This means that you can increase the productivity of the process so that it prints faster, consequently saving on printing costs [2021Grü].

The alternative beam shape, **Top-hat**, is described in the next section.

A **Core-ring** heat source, like a Gaussian heat source, is a surface heat source model, which means that the power input from the heat source is only defined on the top surface of the workpiece, as a Neumann boundary condition. The intensity of a core-ring heat source can be modeled as a combination of a central Gaussian core beam and an outer ring beam [2024Gal].

The intensity of the core beam, as shown in Eq. 1, is given as follows:

[*Eq. 2*] $$Q_{\text{core}} = \frac{2\epsilon P}{\pi r_{\text{core}}^2} \exp\left[-2\frac{(x-X_p)^2+(y-Y_p)^2}{r_{\text{core}}^2}\right]$$

Where

- Q_{core} is the power density of the Gaussian core (W/m^2),
- ϵ denotes the absorptivity of the laser beam,
- P is the power of the heat source (W),
- r_{core} is the $1/e^2$ radius of the core beam,
- x and y denote coordinates of the computational domain, and
- X_p and Y_p represent the location of the heat source.

The intensity of the ring beam is derived by assuming the conservation of the total laser power,P, and is given as follows:

[*Eq. 3*] $$Q_{ring} = \frac{\epsilon P}{2\pi\omega} \exp\left[-2\frac{(r-w_{ring})^2}{r_{ring}^2}\right]$$

Where

- ϖ is the factor that ensures conservation of the total laser power,
- w_{ring} is the radial distance of the outer ring beam from the center of the heat source, and
- r_{ring} is the $1/e^2$ radius of the ring beam.

Assuming that the total power remains constant, ϖ takes the following form:

$$\varpi = -\frac{\sqrt{2}w_{ring}r_{ring}}{8}\left(-2\sqrt{\pi}\left(2-erfc\left(\frac{\sqrt{2}w_{ring}}{r_{ring}}\right)\right)-\frac{\sqrt{2}r_{ring}e^{-2\frac{w_{ring}^2}{r_{ring}^2}}}{w_{ring}}\right)$$

Finally, r is given as follow:

$$r=\sqrt{(x-X_p)^2+(y-Y_p)^2}$$

The total intensity of the core-ring beam is then given as:

$$Q=\alpha\ Q_{ring}+\ (1-\alpha)\ Q_{core}$$

Where α denotes the fraction of power in the ring beam and $1-\alpha$ consequently expresses the fraction of power in the core beam.

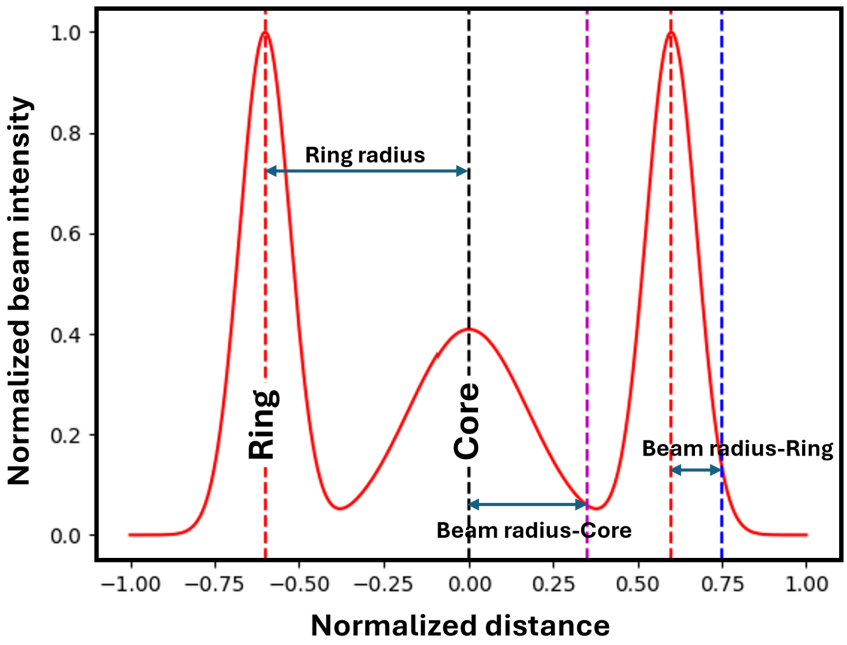

Figure 7: A schematic of the intensity profile of a core-ring heat source.

Index Mode (Core-ring)

The intensity of the core-ring beam depends on different radii and the distribution of power between the core beam and the ring beam. For most users, these radii are not known since they are selected by the laser optics system of the additive manufacturing (AM) machine being used. The **Index Mode** is is available with the **Core-ring** heat source to guide the selection of settings for the **Beam radius-Ring**, **Ring radius**, and **Amount of power in ring**, based on the **Beam radius-Core** and **Index** number. The AM Module incorporates configurations commonly provided by AM machines and laser optics systems as described below.

The ratio between the **Beam radius-Core** and the outer radius i.e. **Beam radius-Ring** + **Ring radius** is assumed to be constant and is equal to 0.38. Furthermore, **Beam radius-Ring** is assumed to be a function of the **Beam radius-Core**. For instance, for a **Beam radius-Core** of 50 µm (i.e. diameter of 100 µm), the **Beam radius-Ring** would be 33 µm and the **Ring radius** would then be 98.58 µm. Similarly, for **Beam radius-Core** of 100 µm, the other Beam radii would also scale accordingly, such that the **Beam radius-Ring** would become 66 µm and the **Ring radius** would be 197.16 µm.

For the **Index Mode**, you provide the **Beam radius-Core** and select the **Index** number and the rest of the heat source parameters are set as described above.

The **Amount of power in ring** depends on the selected **Index** number and is set as follows:

Index	*0*	*1*	*0*	*3*	*4*	*5*	*6*
Amount of power in ring	7%	25%	35%	50%	70%	80%	90%

Custom Mode (Core-ring)

The **Custom Mode** for the **Core-ring** heat source allows you to manually enter all the parameters of the heat source. This requires an awareness of all the radii, either from the optics system of the AM machine in use, or from the calibration measurements of the laser beam.

If you plan to use the beam radii from the **Index Mode** but perhaps require a different power distribution in the core/ring, you can first select the **Index Mode**, enter the **Beam radius-Core**, then change to **Custom Mode** and enter the user-defined **Amount of power in ring**.

Top-hat Heat Source

In addition to the Core-ring beam shape as an alternative to the Gaussian heat source, the **Top-hat** heat source is available with a flat and uniform energy distribution within a circular region and drops to zero outside the region.

AM_14: Using the Top-hat Beam Shape

A **Top-hat** heat source is also called a *flat-top* and is considered a surface heat source model. In the AM Module, the top-hat heat source is approximated with a super-Gaussian beam, which means that the intensity of the beam at the edges decays softly but more steeply than a Gaussian beam, resulting in a flatter peak and sharper edges.

The intensity of such a beam is given as follows [1996Lu]:

[*Eq. 4*] $$Q = Q_0 \exp\left(-2\left(\frac{r}{r_{tophat}}\right)^{2n}\right)$$

Where

- r_{tophat} is the $1/e^2$ radius of the top-hat beam and

  $$r = \sqrt{(x - Xp)^2 + (y - Yp)^2}$$

- n is the order of the super Gaussian beam, which determines the steepness of the beam edges. To get a better approximation of the top-hat beam, Thermo-Calc uses $n = 5$.

- Q_0 is the peak intensity of the top-hat beam, and given the conservation of the total power, it takes the following form:

  $$Q_0 = \left(\frac{\epsilon n P}{\pi r_{tophat}^2}\right) \cdot \frac{2^{1/n}}{\Gamma\left(\frac{1}{n}\right)}$$

  where $\Gamma\left(\frac{1}{n}\right)$ represents the Gamma function evaluated at $\frac{1}{n}$, ϵ denotes the absorptivity of the laser beam, and P is the power of the heat source (W).

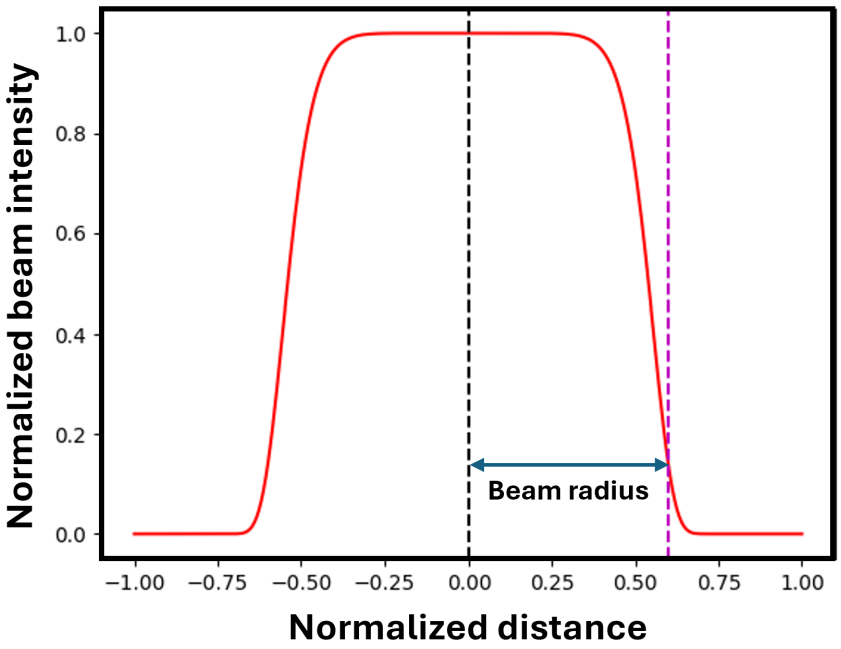

Figure 8: A schematic of the intensity profile of a top-hat heat source.

Electron Beam Heat Source

Electron Beam Melting (EBM) is an additive manufacturing process in which a high-energy electron beam selectively melts metal powder layer-by-layer inside a vacuum chamber. The powder bed is preheated to a high temperature throughout the build, resulting in low residual stresses.

A major advantage of EBM over Laser Powder Bed Fusion (LPBF) is its ability to process materials that are prone to cracking when exposed to the steep thermal gradients of laser-based melting. The high build temperature, vacuum conditions, and efficient energy absorption of the electron beam make EBM suitable for alloys that are difficult to print with lasers, such as gamma titanium aluminides and certain nickel-based superalloys.

In the AM Module, the heat source for the EBM process is approximated by a Gaussian profile, which means that the heat intensity applied on the top surface of the domain is described as follows:

$$Q = \frac{2 \cdot A \cdot P}{\pi r^2} \exp\left[-2\frac{(x-X_p)^2+(y-Y_p)^2}{r^2}\right]$$

Where Q is the power density (W/m^2), A denotes the absorptivity of the electron beam, P is the power of the electron beam given as the product of the beam current and acceleration voltage, r is the $1/e^2$ radius of the electron beam, and x and y denote coordinates of the computational domain while X_P and Y_P represent the location of the heat source.

Examples using this heat source: AM_12: Using AM Calculator Probe Data with the Precipitation Module (TC-PRISMA) and AM_15: Electron Beam Melting in an IN718 Alloy.

Double Ellipsoidal (Goldak) Heat Source

The **Double ellipsoidal** heat source model is a volumetric heat source model which was first proposed by Goldak et al. [1984Gol], and is now commonly used in LBPF simulations. In contrast to the surface heat source model, in the volumetric heat source model, the power input is defined not only on the surface of the workpiece but also inside the powder bed, along the depth of the powder bed. The heat distribution in the double-ellipsoidal heat source model is given by a combination of two ellipsoids; one in the front quadrant of the heat source and the other in the rear quadrant, as shown in the figure below. The power density is thus given by two different expressions, one for each quadrant of the heat source.

[*Eq. 5*]
$$Q_f = f_f \frac{6\sqrt{3}\varepsilon P}{\pi^{\frac{3}{2}} a_f bc} \exp\left[-2\frac{(x-X_p)^2}{a_f^2} + \frac{(y-Y_p)^2}{b^2} + \frac{(z-Z_p)^2}{c^2}\right]$$

$$Q_r = f_r \frac{6\sqrt{3}\varepsilon P}{\pi^{\frac{3}{2}} a_r bc} \exp\left[-2\frac{(x-X_p)^2}{a_r^2} + \frac{(y-Y_p)^2}{b^2} + \frac{(z-Z_p)^2}{c^2}\right]$$

Where Q_f and Q_r are the power densities (W/m^3) in the front and rear quadrant of the heat source, while a_f and a_r are the semi-axes of the front and rear ellipsoids, respectively. b and c are the semi-axes along the width and depth of the melt pool. f_f and f_r are the proportional coefficients for the front and rear ellipsoid of the heat source, with the condition $f_f + f_r = 2.f_f$ is then given as follows:

[*Eq. 6*]
$$f_f = \frac{2a_f}{a_f + a_r}$$

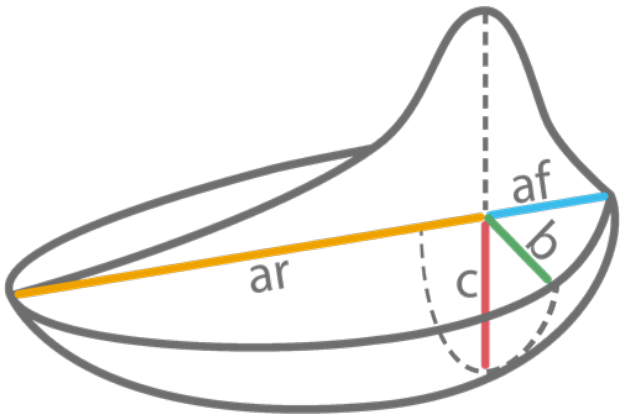

Figure 9: Schematic representation of energy distribution in double ellipsoidal heat source model.

For examples using this heat source, see AM_01: Transient Simulation of a Single Track and AM_02: Transient and Steady-state Simulations of a Single Track.

Conical Heat Source

The **Conical** heat source model is also a volumetric heat source model, which was first employed for welding simulations but due to inherent similarities between welding and LPBF processes, this model is also commonly used for AM simulations. The conical heat source model is defined by a Gaussian heat distribution on the top surface of the workpiece and a conical distribution along the depth of the powder bed. A schematic representation of the energy distribution for conical heat source model is shown below.

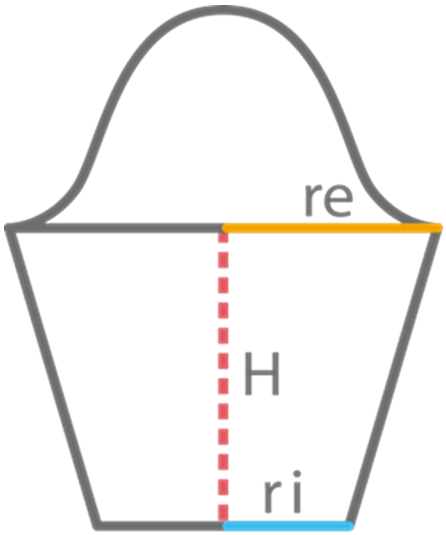

Figure 10: Schematic representation of energy distribution in conical heat source model.

The power density for the conical heat source is given as follows [2019Zha]:

[*Eq. 7*] $$Q = \frac{6\varepsilon P}{\pi H\left(r_e^2 + r_e r_i + r_i^2\right)} \exp\left[-2\frac{(x-X_p)^2+(y-Y_p)^2}{r_o^2}\right]$$

with

$$r_o = r_e + (z - ZP)\frac{(r_e - r_i)}{H}$$

where r_e and r_i are the cone radius at the top and bottom, respectively, while H is the height of the cone.

About Heat Source Calibration

There are models available to define the heat source in the AM process and that are also available with the **Heat Source Calibration** *Calculation Type*: **Gaussian**, **Double ellipsoidal**, or **Conical**. All these heat sources rely on different sets of parameters to fully define the heat input to the powder and solid substrate.

The keyhole model is available for Gaussian, Core-ring, and Top-hat heat sources. See About the Keyhole Model for some additional information.

Defining the Heat Source Models

The standard Gaussian heat source model (a **Single Point** *Calculation Type*) requires defining the **Absorptivity** and the **Beam radius** on the **AM Calculator Configuration** window. The keyhole model takes into account the effect of evaporation recoil pressure that produces a keyhole, if present for the given processing conditions. Multiple reflections are also included in the keyhole model to improve the calculation of the keyhole shape. The absorptivity of the liquid can be calculated but often requires correction due to uncertainty in the model, surface oxides, and so forth. The beam radius of the heat source of the printer is, however, most often known but does not always match the definition of the beam size for the Gaussian heat source used in the simulation. Leveraging the experimental melt pool data and the relation between melt pool size and energy density can help to calibrate the absorptivity and beam radius for the Gaussian heat source model.

For information about using calculated or constant absorptivity with a Gaussian Heat Source Calibration, there is additional theory in About the Absorptivity Model. The associated settings for this type of calibration is in the subsection Heat Source Calibration.

Similarly, for volume heat sources, i.e. **Double ellipsoidal** and **Conical**, it is necessary to enter four and three parameters, respectively, along with the absorptivity. Since volume heat sources are a numerical way to correctly capture the shape of the melt pool, it is not always possible to know the values of these parameters for the processing conditions.

However, according to the literature [2021Gra] you can find a relationship between the size i.e., width and depth of the melt pool, and the energy density (defined as the ratio of power and scanning speed) and based on that, you can also find a relationship between the heat source parameters and the energy density.

See Additive Manufacturing Module Theory for a general overview including details about the heat sources.

This means that if a set of experimental data for an alloy can be provided in the form of power, scanning speed, width of the melt pool, and depth of the melt pool, then you can perform a heat source calibration to calibrate the heat source parameters for the given material. This is done by running an optimization algorithm for the selected experimental data and then choosing an appropriate function for each heat source parameter. As a result, the output includes expressions of the given parameters as a function of the energy density, which can be saved and is available later in heat source list as a **Users heat source**. This is for any given process parameter (i.e. the saved heat source can be used for any process parameter).

When a **Users heat source** option is available to choose in the heat source list, then only the **Power** of the heat source needs to be entered and the rest of the parameters, including the absorptivity, are automatically included in the simulation based on the selected expressions when originally saving the heat source calibration data.

In order to set up the calibration of the heat source, you select the **Steady-state** simulation type and then select **Heat Source Calibration** as the *Calculation Type*. The calibration is performed assuming steady-state conditions so most of the configurations are done in the same way as the **Single Point** Steady-state simulation. The difference is that you need to choose which heat source to use, i.e. **Gaussian**, **Core-ring**, **Top-hat**, **Double ellipsoidal**, or **Conical**.

For more details about including the **Heat Source Calibration** *Calculation Type* during the simulation set up, go to AM Calculator Conditions Settings. Then go to Visualizing Heat Source Calibrations for details about navigating the various previews and results.

Heat Source Calibration with Experiment Data

When the **Heat Source Calibration** is selected in the **Steady-state** simulation type, there is an option to import a file with experimental data points that can be used in the simulation. Data can also be entered directly into the table on the AM Calculator Configuration window. However, if an **Experiment file** is imported it needs to be set up in a certain way so that the software can read the data.

AM Calculator Experiment File Requirements

Once the experiment data is entered, you can view the plot of melt pool dimensions vs. energy density (P/v) in the **Visualizations** window, and make a selection of the experiments to be used for calibration by checking the corresponding checkbox in the **Use** column. When this is done, click **Perform Tree** to perform the calibration.

If you select **Depth** from the **Calibrate for** list, then the experimental values for only the melt pool depth is needed.

Examples Related to Heat Source Calibration

There are two examples included with the installation to help you understand how to calibrate a heat source and then use the calibration in simulations.

AM_06a: Calibrating a Heat Source for a 316L Steel: This example demonstrates the calibration of the heat source using the **Gaussian** and **Double ellipsoidal** heat sources.

AM_06b: Using the Calibrated Heat Source for a 316L Steel: The purpose of this example is to use the saved heat sources from AM_06a and then validate the results by comparing the melt pool size from the simulations with the experimental melt pool dimensions. It also uses the keyhole model.

About the Keyhole Model

In additive manufacturing a laser beam melts the powder, and at high energy density of the laser also evaporation of the liquid metal occurs. The evaporation causes transfer of momentum from the metal to the vapour, i.e. a recoil. The conservation of total momentum then leads to a recoil pressure that pushes down the liquid/gas interface to form a cavity, also known as a keyhole. However, this free surface is computationally expensive to calculate due to the very dynamic movements of the keyhole. To reduce the complexity, the Additive Manufacturing (AM) Module has an analytic model based on [1994Kap] to pre-compute the keyhole shape and the corresponding mesh.

Background

The analytical keyhole model approximates the heat conduction by a moving line source where the keyhole shape is obtained by heat balance at the keyhole wall using average material properties. A point-by-point scheme compares absorbed power and conduction losses to obtain the local inclination angle of the keyhole walls.

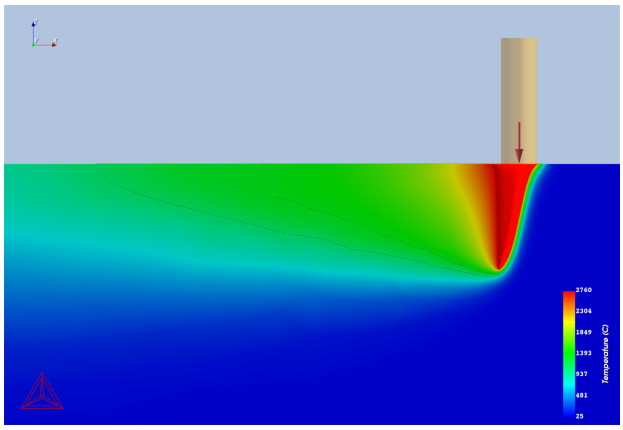

Figure 11: Side-view of a keyhole and melt pool for the material SS316L with Gaussian beam radius of 40 µm and the absorptivity set to 40%.

When a keyhole is formed, the energy is transmitted into the material through numerous reflections within the keyhole (see Figure 12).

For metals with an absorption factor of around 30% the reflections can increase the effective absorption to values around 90% or higher of the total laser beam energy. In the Additive Manufacturing (AM) Module, multiple reflections are implemented in the analytical keyhole mode according to the Coviello publication [2022Cov]. This strategy allows for computation of a keyhole shape, including multi reflections using ray tracing.

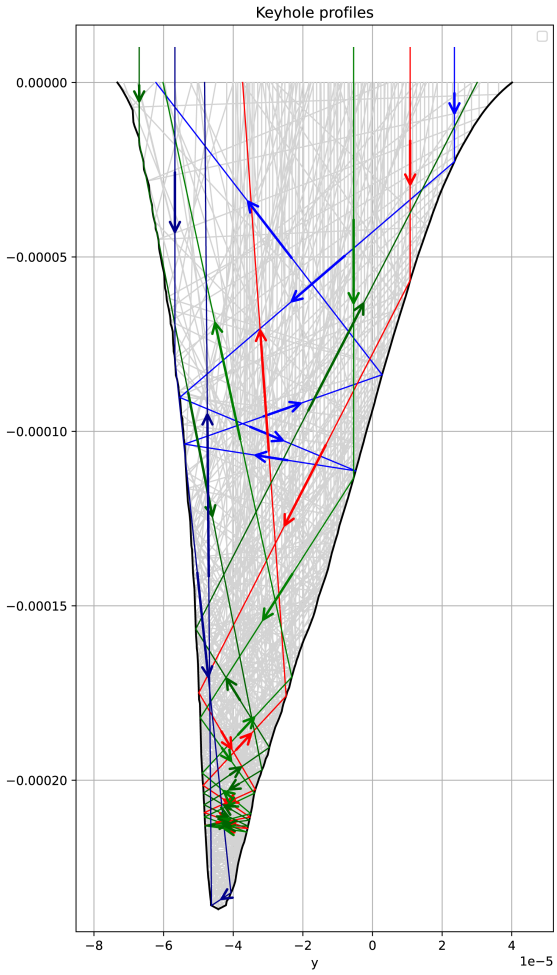

Figure 12: Ray tracking of the laser beam reflected at the wall of the keyhole. Blue, green and red lines highlight the path for three rays. Gray lines represent a fraction of all the reflected rays.

Availability

The keyhole model is limited to the surface heat sources (Gaussian, Core-ring, Top-hat, and Electron Beam). An additional input is the beam quality factor M^2 of the laser beam where the default value is 1.0. The beam quality factor is a measure of laser beam quality, it relates the beam divergence of a laser beam to the minimum focused spot size that can be achieved.

By default, the **Use keyhole model** checkbox is selected. To make changes to this setting, go to AM Calculator Heat Source Settings for additional information.

Multiple Reflections in the Keyhole

When using an **Electron Beam** heat source, the electron beam interacts with the material differently than a laser. When a laser hits the surface, part of the light reflects and continues traveling until it reaches another surface. Accounting for these multiple laser reflections in the keyhole is therefore essential for a laser heat source.

In EBM, high-energy electrons have low reflectivity and mainly undergo inelastic collisions with the material. Some of the non-absorbed energy is emitted as X-rays, while the rest appears as back-scattered electrons that spread in many directions with varying energies. Because this scattered energy is diffuse and relatively small, secondary reflections are ignored with the EBM heat source and the keyhole model.

For additional theory, see Electron Beam Heat Source.

About the Absorptivity Model

The absorptivity of a flat metal surface is a function of the alloy composition, temperature, the wavelength of the heat source, and the angle of incidence.

The absorptivity of a metallic powder is more complex. Most metallic powders are oxidized at the surface where a thin layer of oxide often increases absorptivity. Multiple reflections of the laser rays also increases the effective absorptivity, e.g. at surface roughness or between the particles within the powder layer. The additional complications of the metallic powder are neglected in this model, which focuses on an ideal flat surface of the liquid phase after the powder has melted. This simplification can be justified at steady-state conditions when a melt pool is established and most laser rays hit the liquid surface in the melt pool.

Additional related theory topics include: Additive Manufacturing Module Theory, About the Heat Source Models, and About the Keyhole Model.

Laser Beam Reflection

A fraction of the energy of a laser ray (E) is absorbed when it strikes a surface, the rest of the energy is reflected (R), i.e. the absorptivity is given by $A = (1 - R) * E$.

The Fresnel equation describes how the absorptivity depends on the angle of incidence α.

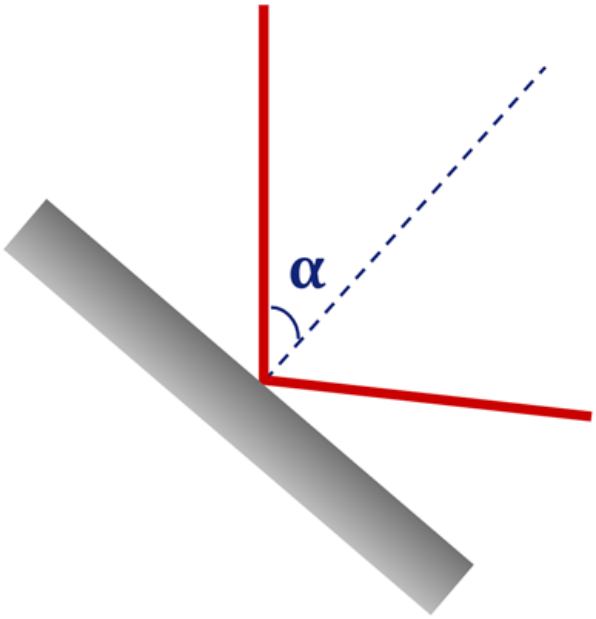

Figure 13: A laser ray strikes a surface at the incident angle α.

For an unpolarized laser beam, the reflection coefficient R is the average of the parallel and perpendicular component, denoted by R_s and R_p:

$$R = (R_s + R_p)/2$$

Both components of R are given by the Fresnel equations:

$$R_s = \left| \frac{cos\ \alpha - \sqrt{\hat{n}^2 - sin^2\alpha}}{cos\ \alpha + \sqrt{\hat{n}^2 - sin^2\alpha}} \right|^2$$

$$R_p = \left| \frac{\hat{n}^2 cos\ \alpha - \sqrt{\hat{n}^2 - sin^2\alpha}}{\hat{n}^2 cos\ \alpha + \sqrt{\hat{n}^2 - sin^2\alpha}} \right|^2$$

The refraction index $\hat{n}$ is a complex number $\hat{n} = n - ik$ where k corresponds to the extinction coefficient.

The refractive index is directly related to the electric permittivity, $\hat{\epsilon} = \varepsilon_r - i\varepsilon_i$:

$$n = \frac{1}{\sqrt{2}} \left[\left(\epsilon_r^2 + \epsilon_i^2 \right)^{1/2} + \epsilon_r \right]^{1/2}$$

$$k = \frac{1}{\sqrt{2}} \left[\left(\epsilon_r^2 + \epsilon_i^2 \right)^{1/2} - \epsilon_r \right]^{1/2}$$

About the Lorentz-Drude (LD) Model

The Lorentz-Drude model (LD) relates the electric permittivity with the electric resistivity [2021Yan].

The electric resistivity thermophysical property is included in many Thermo-Calc databases. For a list of databases that include it, see the Properties that Can Be Calculated brochure on the website or refer to the specific database documentation.

The LD model only considers the intraband absorption and is neglecting the interband part. The interband part of absorption is, however, often less dominant for wavelengths larger than 1 µm; for smaller wavelengths the model shows larger deviations when compared to experimental data.

For additive manufacturing lasers, the most common wavelength used is 1.06 µm.

The LD model is used as a first approximation of the dielectric constants of an alloy. The model is then further calibrated against the available experimental information of dielectric constants, refraction index, and absorptivity of liquid metal, i.e. the correction functions f^r and f^i are modeled:

$$\epsilon_r = \epsilon_r^{LD} \cdot \left[\sum_{i \in n} x_i \cdot f_i^r(\lambda, T) + \sum_{i \in n j \in n} \sum_i x_i \cdot x_j \cdot f_{i-j}^r(\lambda, T)\right]$$

$$\epsilon_i = \epsilon_i^{LD} \cdot \left[\sum_{i \in n} x_i \cdot f_i^i(\lambda, T) + \sum_{i \in n j \in n} \sum_j x_i \cdot x_j \cdot f_{i-j}^i(\lambda, T)\right]$$

where

- x_i is the mole-fraction of element i
- λ the laser wavelength, and
- T the temperature.

The correction improves the model accuracy for the entire wavelength spectrum.

Following the work by Yang [2021Yan], the LD model obtains the real and imaginary parts of the electric permittivity:

$$\epsilon_r^{LD} = 1 - \frac{\omega_p^2}{f_L^2+\gamma^2}$$

$$\epsilon_i^{LD} = \frac{\gamma}{f_L} \cdot \frac{\omega_p^2}{f_L^2+\gamma^2}$$

where

- ω_p is the plasma frequency,
- f_L is the laser frequency, and
- γ is the damping frequency.

The plasma frequency is given by:

$$\omega_p = \sqrt{\frac{N_e q_e^2}{m_e \epsilon_0}}$$

where

- N_e is the number density of free electrons,
- q_e the absolute value of elementary charge, $q_e = 1.6 \times 10^{-19} C$,
- m_e is the electron mass, $m_e = 9.11 \times 10^{-31} kg$, and
- ϵ_0 is the vacuum permittivity, $\epsilon_0 = 8.85 \times 10^{-12} Fm^{-1}$.

The damping frequency can be expressed as:

$$\gamma = \omega_p^2 \cdot \epsilon_0 \cdot \rho(T, x)$$

where

- $\rho(T, x)$ is the temperature- and composition-dependent electrical resistivity.

The laser frequency can be expressed as:

$$f_l = 2\pi \cdot \frac{c}{\lambda}$$

where

- c is the speed of light in vacuum, and
- λ is the wavelength of the laser.

The free electron density N_e is assumed to be given directly by the atomic mass and mass density:

$$N_e = N_A \cdot \rho_m \sum_{i \in N} \frac{x_i Z_i}{m_i}$$

where

- N_A is the Avagadros constant,
- ρ_m is the mass density of the alloy,
- m_i is the atomic weight of element i, and
- Z is the number of valence electrons per atom of element i.

Heat Sources and Absorptivity

The LD model for liquid absorptivity describes a material property and is applicable to the **Gaussian**, **Core-ring**, and **Top-hat** heat sources where the energy is added to the surface of the material.

The LD model for absorptivity is not applicable to the volume heat sources **Double ellipsoidal** and **Conical**. Volume heat sources assume an effective absorptivity that indirectly can include the effect of keyholing by increasing the absorptivity as a function of energy density.

Surface Heat Sources

The angle of incidence for a laser ray is zero when no keyhole forms. The angle of incidence varies greatly within the keyhole and the full angle dependent absorptivity model is used.

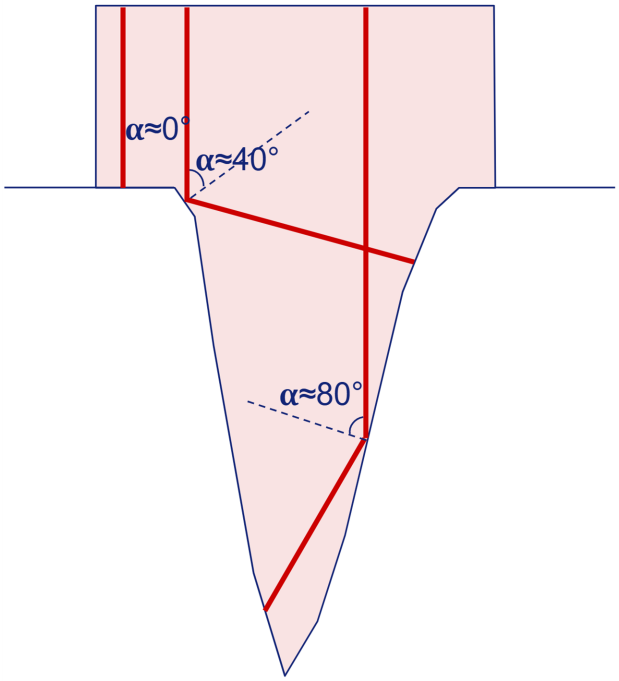

Figure 14: A schematic keyhole where three individual laser rays hit the surface at different incident angle α. The keyhole model in the AM Module accounts for multiple reflections, but only the first reflection for each ray is shown for clarity.

The absorptivity model takes the wavelength of the heat source as input together with a prefactor that can scale the calculated absorptivity up or down. The scaling can be required to calibrate the simulations against experiments.

The following absorptivity settings are described in the AM Calculator Heat Source Settings. The examples use Gaussian, but Core-ring and Top-hat area also available. It is also available with the Electron Beam heat source, although the settings are slightly different and described in the settings section.

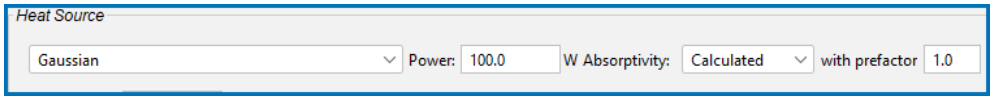

Figure 15: Gaussian Heat Source using the Calculated Absorptivity. The calculated value is scaled with the value of "prefactor" where the default is 1.0, i.e. to use the calculated value as-is.

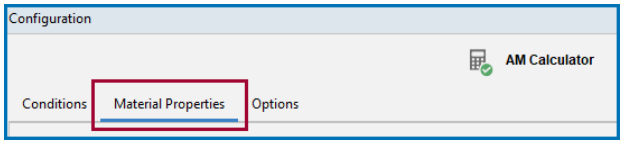
Figure 16: Gaussian Heat Source with User-defined function of the absorptivity.

The resulting absorptivity (given the wavelength and prefactor) can be visualized from the **Material Properties** tab on the **AM Calculator Configuration** window.



The following absorptivity options are described in AM Calculator Heat Source Settings.

From the **Plot** list, select:

- **Absorptivity** to visualize the temperature dependent absorptivity for the liquid phase of the selected material (Figure 17).
- **Absorptivity vs angle** to visualize the angle dependent absorptivity at liquidus and the evaporation temperature (Figure 18).
- **Electric resistivity** to visualize it as a function of temperature (Figure 19).

The electric resistivity is not directly used in the AM simulations, only indirectly through the absorptivity model that uses the electric resistivity when modeling the composition, temperature, and angle dependent absorptivity.

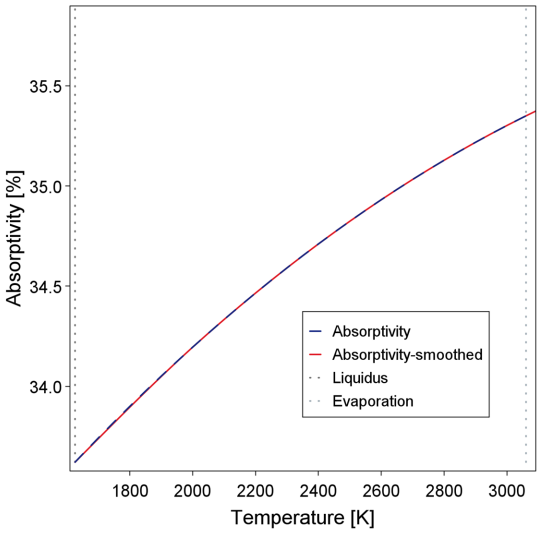


Figure 17: The calculated absorptivity as a function of temperature for the alloy IN738LC.

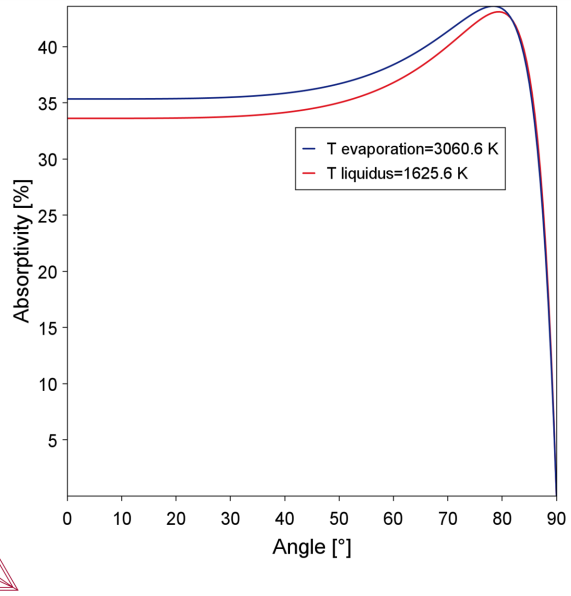

Figure 18: The calculated absorptivity as a function of angle of incidence for the alloy IN738LC. The red curve shows the absorptivity at the liquidus temperature and the blue curve the corresponding absorptivity at the evaporation temperature.

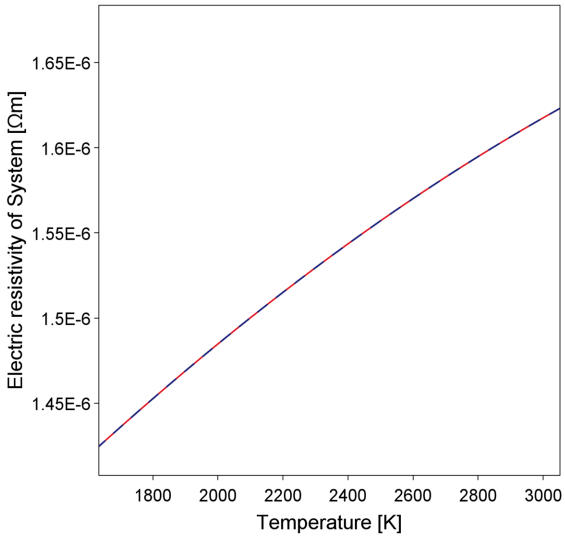

Figure 19: The electric resistivity of the liquid phase for the alloy IN738LC. The electric resistivity is used in the model for absorptivity for the liquid phase.

Absorptivity of the Electron Beam Heat Source

The back-scattering coefficient η, of the electron beam on pure elements, can be described using various empirical equations [1989Aug], expressed as a function of the element's atomic number, the electron beam energy (keV), and the incident angle. Absorptivity is then given by

$$A = 1 - \eta$$

A model of back-scattering as a function of beam energy and incident angle was assessed using experimental backscatter constants collected from the literature for 48 elements.

An example of the back-scattering constant for Ti is shown below. This dataset reveals trends that apply to all elements: electron back-scattering increases with the incident angle, meaning absorptivity decreases. In contrast, for a laser heat source, absorptivity often increases with the incident angle. That means that a keyhole will be shallower for EBM when including this angle of incidence effect.

Another trend is that the back-scattering constant decreases at very low and very high electron acceleration voltages, which the empirical model [1989Aug] does not capture. However, typical EBM beam energies (60–160 keV) fall within the range where the model [1979Hun] is generally reliable. The empirical model is used for elements without experimental data.

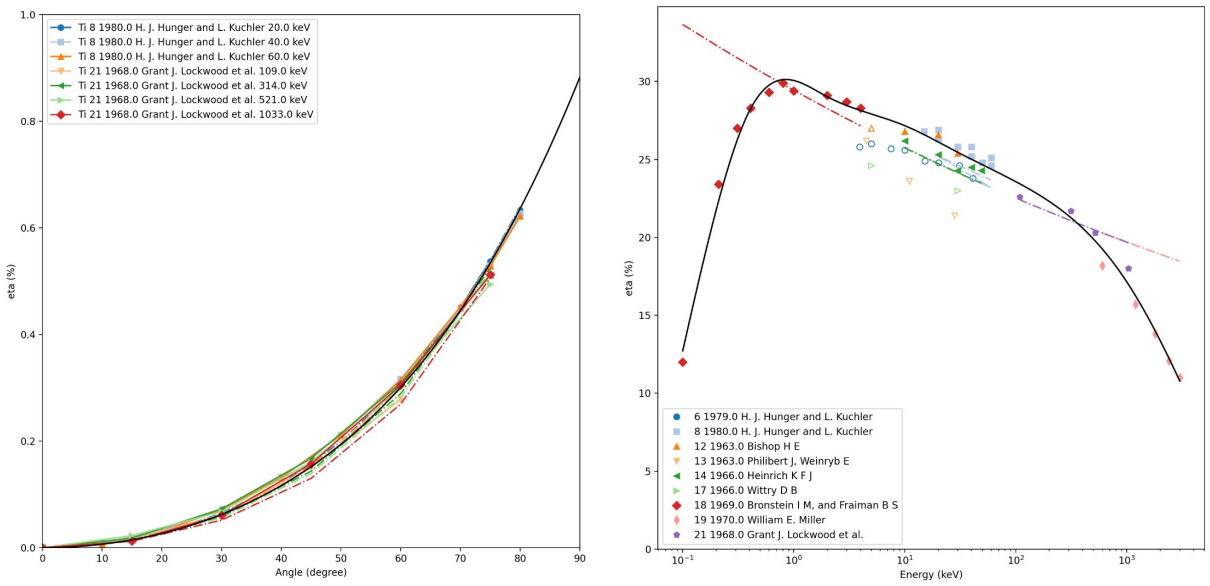

Figure 20: Back scatter constant for Ti, as function of incident angle (left) and as a function of electron beam energy (right). The dash dotted line shows August Wernisch model [1989Aug].

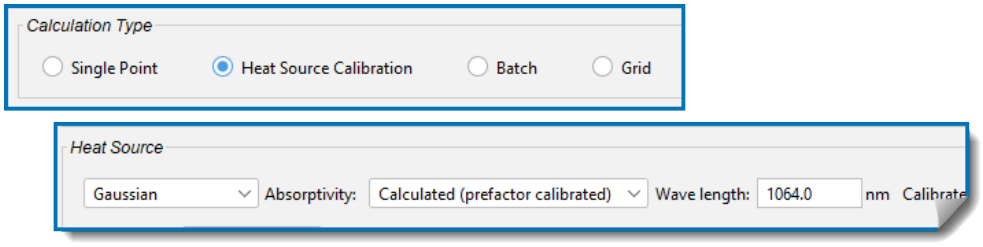
Heat Source Calibration

Additional settings are described in the AM Calculator Conditions Settings topic.

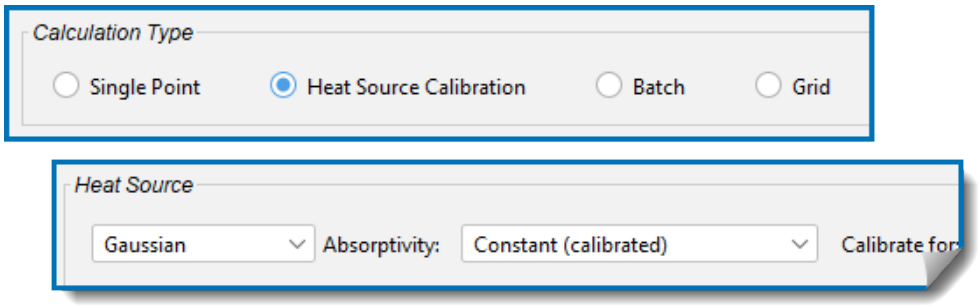
AM_06a: Calibrating a Heat Source for a 316L Steel

For **Gaussian***Heat Source Calibration* calculations, you can use the temperature and angle dependent calculated absorptivity and calibrate the scaling prefactor to match the given experimental data. The settings are on the **AM Calculator Configuration** window.

For **Absorptivity** select **Calculated (prefactor calibrated)** then enter the **Wavelength** of the heat source or use the default value.



In order to use a constant **Absorptivity**, you can instead select **Constant (calibrated)**, which uses a constant value of absorptivity i.e. it is not dependent on temperature or incidence angle. Then you can calibrate that value to match the given experimental data.



For both **Absorptivity** options (**Calculated (prefactor calibrated)** or **Constant (calibrated)**) you can also either calibrate the **Beam radius** along with the absorptivity or the prefactor (choose **Calibrated**), or use a fixed value of **Beam radius** and calibrate only the absorptivity (choose **User-defined**).

Another setting available with the Gaussian Heat Source Calibration, is to calibrate for both the **Width and depth** of the melt pool from the experimental data or use only the **Depth** of the melt pool for the calibration. If you choose **Width and depth**, the *Experiment Data* values in the table require both the width and depth of the melt pool whereas if you only calibrate the depth then the data file needs to only include the information for the depth of the melt pool.

Setting Up the Additive Manufacturing Simulation

Setting up an Additive Manufacturing (AM) Module simulation can be done in one of two workflows.

General Overview

The general procedure of a simulation using the Additive Manufacturing Module is the following:

1. Define the system (Workflow 1 only):
    a. Choose a database.
    b. Select elements and composition.
2. Retrieve the materials data (Workflow 1 or 2):
    a. Either with a Scheil calculation (Workflow 1) or using the materials property data library (Workflow 2).
    b. Apply data smoothing.
3. Set up the AM Calculator (Workflow 1 or 2):
    a. Choose a simulation type (mode) *Steady-state*, *Transient*, *Transient with heat source from Steady-state*, or *Evaporation with Steady-state*.
    b. For *Steady-state* you can also choose different *Calculation Type* options such as a *Heat Source Calibration* to calibrate a heat source based on the provided experimental data instead of using just a *Single point* calculation. *Batch* and *Grid* types are also available.
    c. For *Steady-state*, *Transient with heat source from Steady-state*, or *Evaporation with Steady-state* simulations plus a Gaussian, Core-ring, Top-hat, or Electron Beam heat source, choose to include a *keyhole model* with or without *fluid flow*.
    d. Set the simulation conditions.

4. Run the simulation and visualize the results (Workflow 1 or 2) based on the settings, for example:
    a. *3D Plot*: Various display options such as Surface colormap, Slice, Contour, Isosurface, Arrow, 2D Glyph, Cone, and Line.
    b. *Plot Over Line* or *Thermal Gradient vs Solidification Rate* (2D). Once the plot is performed you can also switch to view it in a table.
    c. *Probe* (2D) plot at a probe position (only available for transient calculations). You can also use and plot probe data with the Add-on Diffusion Module (DICTRA) and/or Precipitation Module (TC-PRISMA). Once the plot is performed you can also switch to view it in a table.
    d. *Heat Source Calibration Parameters* and *Melt Pool Dimensions*: These plots are available for Heat Source Calibration calculations.
    e. *Printability Map*, *Parity Plot*, and *Melt Pool vs Energy Density*: These plots are available for Batch and Grid calculations. This can also be viewed as a table.
    f. *Composition History* (2D) is available for Evaporation with Steady-state calculations.

Workflow 1: When You Need the Material Properties Data

Use this workflow when you need to get the material properties data to do the calculation. Use a System Definer and Scheil Calculator to extract some Scheil data, then feed the data into the AM Calculator. Then add the Plot Renderer to define the specific AM Calculator Plot Renderer features and visualize the results. In this workflow, you can also save the results from the Scheil Calculator into the Material Library and reuse this data in the future.

When you also have licenses either for the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA), for transient simulations you can additionally include probe data from the AM Calculator in the set up of the thermal profile for diffusion and precipitation calculations, respectively.

Workflow 2: When You Already Have Material Properties Data

When you know you have the available material library data available, either by using the provided libraries, importing your own external data, or by saving your own material library after running a Scheil calculation, then you can directly start defining the AM Calculator and

add and define one or more plots to visualize the results.

The Scheil Calculator and System Definer function the same as with a regular Thermo-Calc simulation. There are features available on the Scheil Calculator that are particularly useful to these types of calculations. The Plot Renderer is also unique to this calculator but is still based on the standard activity node.

The various activity nodes for each workflow are briefly described below.

System Definer (Workflow 1)

The first step of the set-up is to select which database to use and define the material for the simulation. This is done in the System Definer.

In a **System Definer** activity, you select the database to use to retrieve thermodynamic data and define which elements the system has as components. You can also select the species to include as well as change the reference temperature and pressure for your components.

A **System Definer** node can be added either directly to the **My Project** node or by default when the **Additive Manufacturing** template is added.

See System Definer and then to learn more about the many settings go to Configuration Window Settings.

Scheil Calculator (Workflow 1)

Once you have defined your system, you need to retrieve the materials data necessary for the AM calculations. This is done using the Scheil Calculator when you are working in Workflow 1.

A **Scheil Calculator** node can be added either directly to the **System Definer** node or by default when the **Additive Manufacturing** template is added.

About the Scheil Calculator Settings

The Scheil Calculator in the Additive Manufacturing Module template is configured to generate the data necessary for the AM calculation. It is configured to start the simulation at a temperature of 5000 degrees and capture the evaporation and calculate the material properties down to room temperature. If you add a Scheil Calculator manually from the System Definer, you need to change these settings yourself. If you are working with different materials, different settings might be more suitable to your material.

Materials Properties Library (Workflow 1 or 2)

A Scheil calculation using the Scheil Calculator (Workflow 1) can be saved for reuse in the Materials Libraries. Alternatively, if there is external data available to use, you can skip the Scheil Calculator and just use a library (Workflow 2). There are also some predefined materials libraries included with the installation that can be used, and are used, in the examples (e.g. AM_01, AM_02, and AM_03 and others) so that users without an AM license and necessary databases can see how this works.

Available Options

AM Calculator (Workflow 1 or 2)

Add an **AM Calculator** node to the Scheil Calculator. If you used the **Additive Manufacturing** template (on the **My Projects Configuration** window under **Applications**), click the node to display the **Configuration** settings window.

Transient simulations currently support only cuboid geometries. Both Steady-state and Transient models use adaptive mesh refinement to decrease computational cost. You have the option to either choose from the predefined mesh settings that defines the maximum and minimum element size based on the process parameters, or specify the maximum and minimum element size yourself.

You can use this either with or without the Scheil and System Definer if you already have the materials properties calculation you want.

AM Calculator, AM Calculator Conditions Settings, and AM Calculator Heat Source Settings

Choose Materials Data Source

Once the Scheil simulation is complete, click on the AM Calculator 1 node and then the Materials Properties tab to see the material property data obtained from the Scheil calculation. In the Material Properties tab, you can plot the properties required for the AM simulation. This is also where you select the data source that will be used in the simulation. In the Use data from: drop-down list you can choose either Scheil Calculator or Library. The

Scheil Calculator option uses the Scheil results that you just calculated, while the Library option uses the data that was shipped with the software or previously calculated data that you have saved to the Library.

Visualizations Window

Working with AM Visualizations

Apply Data Smoothing

Before you run the AM Calculator, it is important that the data you will base the AM calculation on does not have any sharp peaks or curves to be able to solve the numerical problem. To avoid this, you can apply smoothing to your data. The default setting is **Little smoothing** but this can be changed depending on your simulation.

To determine how much smoothing to apply, you can plot the different properties. In the plot drop-down list you can select which property you want to plot to check the data and if there are any sharp peaks or curves in the plot. The plot appears immediately when you select a property. It is recommended to try running the simulations with only applying **Little smoothing**. If the calculation fails, you can increase the smoothing and try again. It is also possible to apply different levels of smoothing on different properties.

Additive Manufacturing Templates

There are two templates you can use to access the Additive Manufacturing Module settings and features in Thermo-Calc.

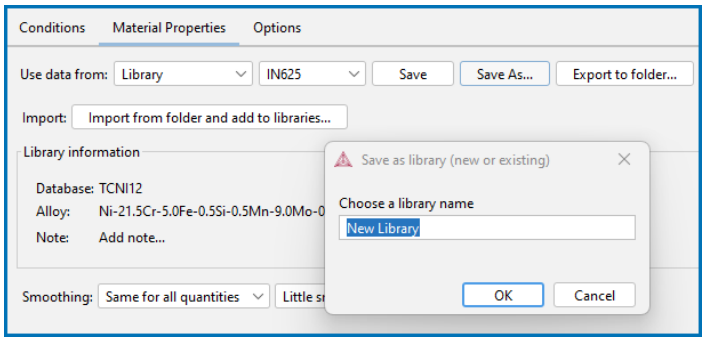
You can also add nodes individually to build your own tree.

When you also have licenses either for the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA), for transient simulations you can additionally include probe data from the AM Calculator in the set up of the thermal profile for diffusion and precipitation calculations, respectively.

Additive Manufacturing Template

On the main **Project Configuration** window, under **Applications**, click the **Additive Manufacturing** icon. This adds the following activity nodes as a tree in the Project window – **System Definer**, **Scheil Calculator**, **AM Calculator**, and **Plot Renderer**. When you add this Additive Manufacturing template (and need to generate some materials properties or do not have a material library to use), then some unique default settings for the Scheil Calculator and these particular types of simulations are already set by default. Then you continue defining the AM Calculator by choosing one of the available simulation types: Steady-state, Transient, or Transient with heat source from Steady-state.

There is also an option on the AM Calculator to save the material properties in a material library, and use these later for a new AM Calculator where you want to make calculations related to the same alloy.



With Material Library Template

Click **With Material Library** to create an activity tree that only includes the **AM Calculator** and **Plot Renderer** nodes. The tree setup does not need the System Definer or Scheil Calculator. Instead you can select (or import) pre-saved Materials Properties data from a library and use these for your AM calculations. For example, if you have already run calculations for the Scheil Calculator for your alloy, and you want to perform a different AM calculation for the same alloy, this data can now be reused where you start the AM Calculator using the second option and use the material property data from the material library.

Additive Manufacturing Simulation Types

There are these simulation types (modes) available on the AM Calculator – *Steady-state*, *Transient*, *Transient with heat source from Steady-state*, and *Evaporation with Steady-state*. This topic gives a general overview of these modes, where detailed theory and settings information is included throughout the content.

Steady-state

For **Steady-state** simulations, you can also choose to run different Steady-state Calculation Types.

In the *Steady-state* mode it is assumed that the temperature distribution and the fluid flow around the heat source is in steady state and does not change with time. This is useful to get an estimation of the temperature distribution and size of the melt pool when you assume that the heat source is moving at a constant speed in a given path. In the single-track experiments, temperature distribution around the heat source and fluid flow inside the melt pool reach a steady state very quickly, and you should then perform steady-state simulations to predict melt pool geometry and cooling rates around the melt pool. In a sense, steady-state simulations give you an overall picture of the process but in order to get more precise details and predict temperature distribution in a multi-layer build, as a function of time, you should perform transient simulations. The benefit of the steady-state option is that these simulations are quick, and you get a solution typically within 1-5 minutes, depending on the process parameters and your computational resources. For the steady-state simulations, you can include or exclude fluid flow inside the melt pool due to the Marangoni effect. For the given processing conditions, if convection is the dominant mode of heat transfer, inclusion of fluid flow is crucial to enhance the accuracy of the model by correctly capturing the underlying physical behavior of melting and solidification of material. Furthermore, you can also perform simulations with a powder layer on the top of the substrate having different material properties than the bulk material. The steady-state simulations are performed on a symmetric domain where you specify only the height of the substrate and the thickness of the powder layer, if present. The length and width of the computational domain are determined automatically based on the process parameters. The temperature distribution is computed using the energy equation while the fluid flow is modeled using the Navier-Stokes equation.

Transient

In the *Transient* mode, you can perform full-scale transient simulations in a 3D rectangular build part and have the possibility to specify a scanning strategy comprising multiple tracks and multiple layers. Here you can enter the height, width, and length of the entire build part or a representative segment of the build part and configure a scanning strategy either for a single track or for multiple tracks (bidirectional or unidirectional). You can also add multiple layers of powder and rotate the scanning pattern between layers.

Similar to the *Steady-state* mode, you can also choose to include fluid flow inside the melt pool to correctly capture the underlying physical phenomena of melting and solidification of the material and thereby increasing the accuracy of the model. The inclusion of fluid flow requires coupling the Navier-Stokes equations together with the energy equation which comes at the cost of increased numerical complexity resulting in longer simulation times.

Transient with Heat Source from Steady-state

In order to perform full scale 3D simulations in an efficient manner, with multitracks and multilayers, including fluid flow in the melt pool or with powder layer(s) having different properties than the solid material, you can use the *Transient with heat source from Steady-state* mode. This mode develops a novel approach where the effect of fluid flow due to Marangoni convection in the melt pool is incorporated without solving for Navier-Stokes equations in the full-scale 3D domain.

The concept involves the assumption that the temperature distribution and fluid flow inside the melt pool instantly reach steady state. First you solve for temperature distribution, using the energy equation and fluid flow due to Marangoni convection, using the Navier-Stokes equations for the given process parameters in the Steady-state mode. Once you have the steady state solution, use this solution inside the melt pool and map it as a “heat source” in the transient simulations. Using this approach, you do not have to solve for the complicated Navier-Stokes equations at each time step in the transient simulation, yet it still captures the effect of fluid flow on the shape of the melt pool. Furthermore, it also reduces the computational time by solving for the most non-linear region in the energy equation i.e., inside the melt pool, only once, and then reusing the solution as a boundary condition in the transient simulations. This approach considerably decreases the numerical complexity of the full-scale transient simulations, which consequently reduces the simulation time without making a significant compromise on the accuracy of the solution.

Evaporation with Steady-state

Selective evaporation of volatile elements can become a significant issue during AM printing when processing conditions cause overheating and excessive evaporation, resulting in a printed composition that falls outside the alloy specification limits.

Element evaporation during additive manufacturing occurs to some extent across the entire liquid–gas interface. However, most evaporation takes place in the keyhole region, where temperatures reach or exceed the evaporation temperature of the alloy. This is where you can use the *Evaporation with Steady-state* simulation to compute composition changes due to evaporation using a steady-state solution.

The main assumptions are that the melt pool and keyhole geometries can be determined from a single steady-state AM simulation, and that these geometries remain unchanged during the printing of multiple overlapping tracks and layers. The average liquid and gas compositions are continuously tracked throughout the build process across successive tracks and layers.

Learn More

Theory related to these simulation types is available see Additive Manufacturing Module Theory, About the Heat Source Models, and Composition Changes Due to Evaporation as starting points. When in Thermo-Calc, press F1 to search the help as needed.

The **keyhole model** is available when **Gaussian**, **Core-ring**, **Top-hat**, or **Electron Beam** heat sources are used for either the *Steady-state* or *Transient with heat source from Steady-state* types of simulation (see About the Keyhole Model. It is available with or without fluid flow.

Steady-state Calculation Types

When setting up a **Steady-state** simulation on the **AM Calculator**, you can also select different *Calculation Types*.

Single Point

The standard steady-state calculation for a single set of processing parameters. This is available with all heat sources.

See Calculation Type (Steady-state) for settings information on the AM Calculator.

Heat Source Calibration

To calibrate a heat source based on the imported or entered experimental data instead of performing a single point calculation. This is available with **Gaussian**, **Double ellipsoidal**, or **Conical** heat sources.

See Calculation Type (Steady-state) for settings information on the AM Calculator. For information about previewing configuration settings (on the AM Calculator) as well as plot results (on the Plot Renderer), see Visualizing Heat Source Calibrations.

Batch

To include power and scan speed data, which is read from a file such as a spreadsheet. You can optionally include experimental melt pool width and depth (if there is data), and compare this to the calculated results using a Parity plot on the Plot Renderer. This is available with all heat sources.

For settings information on the AM Calculator, see Calculation Type (Steady-state). For information about previewing configuration settings (on the AM Calculator) as well as plot results (on the Plot Renderer), see Visualizing Batch Calculations in the AM Module.

Grid

To evaluate two axis variables of power and scanning speeds in the specified range and number of steps. This is available with all heat sources.

For settings information on the AM Calculator, see Calculation Type (Steady-state). For Plot Renderer Configuration settings, see AM Calculator: Plot Renderer Settings.

Learn More

Additive Manufacturing Simulation Types and for overall general theory, see Additive Manufacturing Module Theory.

For background theory related to Heat Sources, see About the Heat Source Models and About the Absorptivity Model. For *Gaussian*, *Double ellipsoidal*, and *Conical* heat sources, also see About Heat Source Calibration for additional details.

AM Calculator

Depending how you set up your simulation, the **AM Calculator** can either be part of the workflow after a **Scheil Calculator** or directly at the root below the **My Project** node.

There is an **Additive Manufacturing** template available under **Applications** that you can use to quickly set up either one of these workflow options for the AM simulation. See Additive Manufacturing Templates and Setting Up the Additive Manufacturing Simulation.

Configuration Window

Once you have added an AM Calculator, the **Configuration** window has these tabs where there are many available features to set on the **Conditions**, **Materials Properties**, and **Options** sections and with the specialized **Plot Renderer** and toolbar on the **Visualizations** window.

There are these simulation type pathways to choose: **Steady-state**, **Transient**, **Transient with heat source from Steady-state**, or **Evaporation with Steady-state**.

In cases where convection is the dominant mode of heat transfer, fluid flow inside the melt pool plays a significant role in determining the correct shape of the melt pool.

For more details about these see Additive Manufacturing Simulation Types. Also review the Additive Manufacturing Module Theory plus related theory sections as needed.

- **Steady-state**: Compute temperature distribution in a steady-state environment, either on a bare metal substrate or with a powder layer on the top, with the possibility to add fluid flow inside the melt pool. For this simulation type, you can also choose the following *Calculation Types*:

    - **Single Point**, which is the standard steady-state calculation for a single set of processing parameters.
    - **Heat Source Calibration** to calibrate a heat source based on the imported or entered experimental data instead of performing a single point calculation. This is available with **Gaussian**, **Double ellipsoidal**, or **Conical** heat sources.
    - **Batch** to include power and scan speed data, which is read from a file such as a spreadsheet. You can optionally include experimental melt pool width and depth (if there is data), and compare this to the calculated results.
    - **Grid** to evaluate two axis variables of power and scanning speeds in the specified range and number of steps.

- **Transient**: Compute temperature distribution in a transient case with the given scanning strategy including multiple paths and layers and the possibility to add fluid flow inside the melt pool.
- **Transient with heat source from Steady-state**: Compute temperature distribution in a transient case with the given scanning strategy including multiple paths and layers. A volume heat source is used in the transient simulations. This is based on the solution of a steady-state calculation.
- **Evaporation with Steady-state**: Compute composition changes due to evaporation using a steady-state solution.

For **Gaussian**, **Core-ring**, **Top-hat**, or **Electron Beam** heat sources (*Steady-state*, *Transient with heat source from Steady-state*, or *Evaporation with Steady-state*) you can also include a **Keyhole model**. This is available with or without fluid flow, or if you use separate material properties for powder.

There are several settings and these are described separately.

- AM Calculator Conditions Settings
- AM Calculator Heat Source Settings
- AM Calculator Materials Properties Settings
- AM Calculator Options Settings

Plot Renderer as a Successor

Also as a successor to the **AM Calculator**, you can right-click the node to add one or more **Plot Renderer** nodes to visualize your results. Although the node works the same as with the other calculators in Thermo-Calc, there are additional features and settings unique to this Module. Useful information is included throughout the documentation. See About the AM Plot Types and AM Calculator: Plot Renderer Settings as starting points.

When setting up an AM simulation, the **Visualizations** window shows both active configuration changes and other design states as set up on the **AM Calculator** as well as the results generated by the **Plot Renderer** calculations. There are several related topics to visualize results as well as when you are setting up the simulations. See Working with AM Visualizations as a starting point to learn more.

AM Calculator Conditions Settings

Once you have added an AM Calculator, the **Configuration** window has these settings tabs where there are many available conditions to set on the **Conditions**, **Materials Properties**, and **Options** tabs and with the specialized **Plot Renderer**.

This topic describes the available main settings on the **Conditions** tab.

Gas Pressure

Pressure is used to calculate the heat loss due to evaporation from the top surface of the given material.

Gas pressure: The pressure of the gas inside the build chamber. The default is 100000 **Pascal**. Select **Atmospheres** or **Bar**.

When you select a different unit the default value does not change.

Enter a different value in the field.

Temperature Settings

Temperature Unit

Temperature unit: Select a unit **Kelvin**, **Celsius**, or **Fahrenheit**.

Base Plate Temperature

If you change the **Temperature unit** then double check that the value in this field is also updated or correct as expected if you are keeping the default. This field does not update automatically when the unit changes.

Base plate temperature: The base plate of the build part is assumed to have a constant temperature. This temperature is used as a boundary condition for the base of the computational domain.

The default is 303.15 K.

Ambient Temperature

The **Ambient temperature** is used to calculate the heat loss from the top surface due to radiation, convection, and evaporation.

This setting is the temperature of the air in the immediate surrounding environment.

If you change the **Temperature unit** then double check that the value in this field is also updated or correct as expected if you are keeping the default. This field does not update automatically when the unit changes.

Fluid Flow Including Marangoni Effect

The use of the **Fluid flow including Marangoni effect** checkbox in combination with separate material properties for powder and the keyhole model is dependent on the simulation type.

Choose to use **Fluid flow including Marangoni effect** if you want to calculate and include for the effect of fluid flow due to gradient of surface tension in the melt pool. The checkbox is selected by default. This solves the Navier-Stokes equation to include fluid flow inside the melt pool due to the Marangoni effect.

Also see the theory section, Fluid Flow and if also using the keyhole model, see About the Keyhole Model.

Feature Checkbox Availability: Fluid flow, Separate Material Properties with Powder, and Keyhole Model

Use Separate Material Properties for Powder

The use of the **Use separate material properties for powder** checkbox in combination with fluid flow and the keyhole model is dependent on the simulation type.

The **Use separate material properties for powder** checkbox is selected by default to use different density and thermal conductivity for the powder layer; otherwise by default the same properties as for the solid are used. Enter a **Powder density** as a percentage (0-100%) of the solid material. The default is 80 % of the solid material.

Feature Checkbox Availability: Fluid flow, Separate Material Properties with Powder, and Keyhole Model

Geometry

For a **Steady-state** simulation you only need to enter the height. For **Transient**, **Transient with heat source from Steady-state**, or **Evaporation with Steady-state** these are volumetric and you also define the width and length. For all simulation types you define the coarseness of the mesh.

Height for Steady-state Simulation

Height: Enter the build height (mm). Length and width of the computational domain is automatically chosen as a function of the heat source parameters and the scanning speed.

Height, Width, and Length for Transient or Evaporation Simulations

- **Height**: Enter the initial build height (mm). Powder layer(s) with the given layer thickness will be added on the top. In mm.
- **Width**: Enter the build width (along y direction). In mm.
- **Length**: Enter the build length (along x direction). In mm.

Mesh

Mesh: The initial mesh size —**Coarse**, **Medium**, **Fine**, or **Custom**. It is adaptive and refined as required.

If **Custom** is selected, enter the maximum and minimum element sizes:

- **Maximum element size:** The initial element size (in µm) in the mesh.
- **Minimum element size**: The minimum element size (in µm) that the adaptive mesh can refine to.

Heat Source

The heat source settings are described in a separate topic: AM Calculator Heat Source Settings. The theory is also described in About the Heat Source Models.

Scanning Strategy

The scanning strategy determines the build geometry for one or multiple layers. Green layer on the top of the geometry is the powder and the grey part is the solid substrate.

For **Steady-state** simulations, you only need to define the **Scanning speed** and **Layer thickness**.

Scanning Speed

Enter a **Scanning speed**, which is the velocity of the moving heat source. The default is 1000 mm/s.

Layer Thickness

Enter a **Layer thickness**, which is the thickness of the powder layer. The default is 40 mm. When you change the layer thickness, the meshing size changes too.

Pattern

Select the scanning **Pattern**—**Single track**, **Bidirectional**, or **Unidirectional**.

- Select **Unidirectional** to use same scanning direction of the heat source for all tracks.
- Select **Bidirectional** to flip scanning direction of the heat source between alternate tracks.

Single Track

- **Margin**: Offset of the laser scanning path from the sides of the computational domain. In case of Single track, offset is placed from the sides transverse to the scanning direction, whereas the scanning path is always in the middle of the domain going along the length of the workpiece.
- **Number of layers**: Enter the number of layers or scroll using the arrows.
- **Powder fill time**: Powder recoating time (unit = s) between two consecutive layers. This does not include lift time. This field is available when more than 1 is entered in the **Number of layers** field.
- **Cooling time**: Enter a cooling time (unit = s) This is the time for which the material is left to cool down after the scanning is completed. During cooling time, the heat source is completely turned off.

Bidirectional and Unidirectional

- **Margin**: Offset of the laser scanning path from the sides of the computational domain.
- **Hatch spacing**: Separation (unit = mm) between two consecutive tracks.
- **Lift time**: Time (unit = s) between two tracks where the heat source is inactive.
- **Number of layers**: Enter the number of layers or scroll using the arrows.
- **Powder fill time**: Powder recoating time (unit = s) between two consecutive layers. This does not include lift time.
- **Rotation between layers**: Rotation (unit = degrees) of the scanning direction between two consecutive layers. The scanning pattern of the first layer is always aligned to the X axis then the second layer will be rotated (if you choose this setting) with the specified angle then the next layer will be rotated at the same angle as compared to the previous layer and so on. This way you can change the rotation of the layers.
- **Cooling time**: Enter a cooling time (unit = s) This is the time for which the material is left to cool down after the scanning is completed. During cooling time, the heat source is completely turned off.

Top Boundary Conditions

Numerical Boundary Conditions and Composition Changes Due to Evaporation in the theory sections.

Radiation Emissivity

Enter a **Radiation emissivity** to include the effect of radiation from the top surface to the surrounding gas. Enter a value between 0 and 1. If you want to neglect the heat loss, then enter 0 to disable radiation.

Convective Heat Transfer Coefficient

Enter a **Convective heat transfer coefficient** for the top surface to the surrounding gas. If you want to ignore this then enter 0 to disable convective heat transfer. The default is 20 W/m^2.

Evaporation

Select the **Evaporation** checkbox to include the effect of evaporation heat loss due to heating of the powder layer or the metallic surface close to the evaporation temperature.

The **Evaporation** heat loss is calculated based on the settings on the **Materials Properties** tab, i.e. evaporation enthalpy per mole, the driving force for evaporation per mole quantity and the molar mass of gas. These are also calculated by the databases.

Calculation Type (Steady-state)

Single Point

By default for **Steady-state** calculations, **Single point** is selected, which by default uses the **Gaussian***Heat Source*. In addition to settings described in this topic, you can also find more details in AM Calculator Heat Source Settings. This is available with all heat sources.

Heat Source Calibration

For some background, see About Heat Source Calibration. Also see Visualizing Heat Source Calibrations for various options related to visualizing the calibration settings.

Select **Heat Source Calibration** to calibrate a heat source based on the imported or entered experimental data instead of performing a single point calculation. All types of heat sources can be used. See below for additional information to enter the *Experiment Data*. This is available with **Gaussian**, **Double ellipsoidal**, or **Conical** heat sources.

Experiment Data (Heat Source Calibration)

It is important to prepare the experiment data file correctly so the simulation performs smoothly. See AM Calculator Experiment File Requirements.

This section is available when **Heat Source Calibration** is selected as the *Calculation Type*.

In the **Experiment file** field, either enter a file path or click the file button ( ) to navigate to a data file such as an Excel spreadsheet (with *.xls or *.xlsx extensions) or a *.csv file. You can also use other programs (e.g. Google Sheets) to enter data and export to a CSV format that can be read by the software.

Click **Open** to import the data. In the **Experiment file** field you can see the file path to the selected file. The next time you click the file button ( ) the program remembers the last location from where the file is opened.

Choose the delimiter—**Comma** (,), **Colon** (:), **Equals sign** (=), **Semicolon** (;), or **Tab**—that matches the delimiter in the experiment file and click the **Reload** ( ) button.

Batch

Select **Batch** to include power and scan speed data, which is read from a file such as a spreadsheet and entered or imported to the *Batch Experiment Data* table. You can optionally include experimental melt pool width and depth (if there is data), and compare this to the

calculated results using a **Parity plot** on the Plot Renderer.

This is available with all heat sources.

In addition to settings described in this topic, you can also find more details in AM Calculator Heat Source Settings and Visualizing Batch Calculations in the AM Module.

Batch Experiment Data

It is important to prepare the experiment data file correctly so the simulation performs smoothly. See AM Calculator Experiment File Requirements.

This section is available when **Batch** is selected as the *Calculation Type*.

In the **Experiment file** field, either enter a file path or click the file button ( ) to navigate to a data file such as an Excel spreadsheet (with *.xls or *.xlsx extensions) or a *.csv file. You can also use other programs (e.g. Google Sheets) to enter data and export to a CSV format that can be read by the software.

Click **Open** to import the data. In the **Experiment file** field you can see the file path to the selected file. The next time you click the file button ( ) the program remembers the last location from where the file is opened.

Choose the delimiter—**Comma** (,), **Colon** (:), **Equals sign** (=), **Semicolon** (;), or **Tab**—that matches the delimiter in the experiment file and click the **Reload** () button.

Grid

Select **Grid** to evaluate two axis variables of power and scanning speeds in the specified range and number of steps. Then continue with the *Grid Definitions*. In addition to settings described in this topic, you can also find more details in AM Calculator Heat Source Settings.

This is available with all heat sources.

Grid Definitions

This section is available when **Grid** is selected as the *Calculation Type*.

For the **Grid** calculation type, define the two axes variables using the fields and menus: **Quantity**, **Min**, **Max**, and **Number of steps**. The number of steps along with the minimum and maximum values for the axes define a grid. For each grid point the selected models are evaluated.

Enter a **Min**, **Max**, and **Number of steps** for:

- **Power (W)** for the selected *Heat Source* model.
- **Scanning speed (mm/s)** for the velocity of the moving heat source.

Probe Positions (Transient Simulations Only)

It is important to add the probes locations before the simulation is run or the action is not recorded.

You can add probes in the domain that record temperature and all other temperature related properties when the simulation is being run.

Click the **Add** and **Remove** buttons to add each probe and then you can either manually enter the probe coordinates (enter the **x**, **y**, and **z** coordinates in the fields) or click **Pick coordinate** to choose each of the points specifically on the **Geometry** tab in the **Visualizations** window.

Some advance options can be selected from a popup menu;

- Double-click on the geometry to pick a coordinate
- Hold Ctrl key to pick a probe in the middle of a layer
- Hold Shift key to map the picking position with a scanning path, i.e. you can pick a probe that snaps to a nearest scanning path
- Hold Shift+Alt keys to map the picking position to the middle of two scanning paths, i.e. pick a probe in the middle of the two nearest scanning paths.

AM Calculator: Working with Probe Data

Using Probe Data in Diffusion and Precipitation Calculations

When you also have licenses either for the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA), for transient simulations you can additionally include probe data from the AM Calculator in the set up of the thermal profile for diffusion and precipitation calculations, respectively.

Learn More

AM Calculator Materials Properties Settings, and AM Calculator Options Settings

Feature Checkbox Availability: Fluid flow, Separate Material Properties with Powder, and Keyhole Model

Depending on what you want to simulate, there are some setting combinations that are available based on the different simulation types. The details are relevant to using the **Fluid flow including Marangoni effect**, **Use separate material properties for powder**, and **Use keyhole model** checkboxes in a variety of combinations. The software automatically guides your choices. However, it can be useful to know in advance what is available to better design your simulation.

Simulation Type	*Feature (checkbox) Availability*		
	Use Separate Material Properties for Powder	*Fluid Flow including Marangoni Effect*	*Use Keyhole Model (Heat Source setting)*
Steady-state	available	available	available
Transient (with fluid flow)	not available	available	not available
Transient (without fluid flow)	available	not available	not available
Transient with heat source from Steady-state (Single-track scanning strategy)	available	available	available
Transient with heat source from Steady-state (Bidirectional or Unidirectional scanning strategies).	not available In this case, you can select the checkbox but the **Perform** button is unavailable.	available	available
Evaporation with Steady-state	available	available	available

AM Calculator Heat Source Settings

These settings are found on the AM Calculator Conditions tab. The other settings are described in AM Calculator Conditions Settings.

Choose the heat source model: **Gaussian**, **Core-ring**, **Top-hat**, **Electron Beam**, **Double ellipsoidal**, or **Conical**. When available you can also choose predefined *Users heat sources* from the list.

Gaussian Heat Source

Gaussian is a surface heat source, and it is applied to the top surface of the domain. Then the heat is diffused based on the diffusivity of the material. This is most commonly used heat source in the industry.

- Settings below: Power, Absorptivity (incl prefactor, Wave length), Beam radius, Use keyhole model, Beam quality factor M^2.

For specific theory see Gaussian Heat Source.

Core-ring Heat Source

A **Core-ring** heat source, like a Gaussian heat source, is a surface heat source model which means that the power input from the heat source is only defined on the top surface of the workpiece, as a Neumann boundary condition. The intensity of a core-ring heat source can be modeled as a combination of a central Gaussian core beam and an outer ring beam.

- Settings below: Power, Absorptivity (incl prefactor, Wave length), Beam radius-Core, Beam radius-ring, Ring radius, Amount of power in ring, Use keyhole model, Beam quality factor M^2, Mode (Index or Custom).

For specific theory see Core-ring Heat Source.

Top-hat Heat Source

A **Top-hat** heat source is also called a *flat-top* and is considered a surface heat source model. In the AM Module, the top-hat heat source is approximated with a super-Gaussian beam, which means that the intensity of the beam at the edges decays softly but more steeply than a Gaussian beam, resulting in a flatter peak and sharper edges.

- Settings below: Power, Absorptivity (incl prefactor, Wave length), Beam radius, Use keyhole model, Beam quality factor M^2, Mode (Index or Custom).

For specific theory see Top-hat Heat Source.

Electron Beam Heat Source

The heat source for the **Electron Beam** melting process is modeled as a Gaussian heat source. The heat is applied on the top surface of the domain, which is then diffused into the material based on the diffusivity of the material and absorptivity of the electron beam.

- Settings below: Power, Acceleration voltage, Absorptivity (incl prefactor), Beam radius, Use keyhole model.

For specific theory see Electron Beam Heat Source.

Double Ellipsoidal Heat Source

The **Double ellipsoidal** heat source, also referred to as Goldak, is a volume model where the heat intensity is in the front and the back of the heat source is defined with the help of two different ellipsoids. The axis of the each ellipsoid is needed.

- Settings below: Power, Absorptivity (% only), ar, af, b, c.

For specific theory see Double Ellipsoidal (Goldak) Heat Source.

Conical Heat Source

The **Conical** option is also a volumetric heat source where heat intensity is described as Gaussian distribution at the top surface, defined by a top radius, that varies linearly in the depth of the workpiece until it reaches a bottom radius within the prescribed depth.

- Settings below: Power, Absorptivity (% only), re, ri, H.

For specific theory see Conical Heat Source.

Heat Source Settings

Power

For a **Single Point** calculation, enter the **Power**. The default is 200 W.

Absorptivity (Gaussian, Core-Ring, Top-Hat, Electron Beam)

The **Absorptivity** settings are based on the *Heat Source* and *Calculation Type* selected.

For a **Single Point**, **Batch**, or **Grid** *Calculation Type*:

- **Gaussian**, **Core-Ring** or **Top-Hat**:
    - Select **Calculated** (the default) to use the alloy's liquid resistivity to calculate the absorptivity as a function of temperature. To adjust this calculation, enter a different prefactor than the default (`1.0`) in the **with prefactor** field.
    - Choose **User-defined** to enter absorptivity in **%** where you also can enter this as a function of temperature (T) i.e. `-1.6e-7*T*T+2.5e-3*T+31`.
- **Electron Beam**:
    - Select **Calculated** (the default) to evaluate a back-scattering coefficient (η) for the given alloy chemistry as a function of acceleration energy and angle of incidence. Absorptivity is then given as $(1-\eta)*100$.
    - To adjust this calculation, enter a different prefactor than the default (`1.0`) in the **with prefactor** field.
    - Choose **User-defined** to enter absorptivity in **%**.

For a **Heat Source Calibration** *Calculation Type* the absorptivity is calibrated separately for each row in the **Experiment Data** table. Select an option to calibrate absorptivity:

- **Calculated (prefactor calibrated)** (the default) to use the calculated absorptivity and calibrate the prefactor.
- **Constant (calibrated)** to calibrate the absolute value of absorptivity.

About the Absorptivity Model and the section Heat Source Calibration for more.

Absorptivity (Double Ellipsoidal, Conical)

The **Absorptivity** settings are based on the *Heat Source* and *Calculation Type* selected.

For this heat source and with a **Single Point**, **Batch**, or **Grid** *Calculation Type* enter the absorptivity **%** for the selected heat source model. The default is 60 %. For **Heat Source Calibration** calculations there are no further settings.

Acceleration Voltage (Electron Beam)

Enter an **Acceleration voltage** of the electron beam in kV.

Wave Length (Gaussian, Core-Ring, Top-Hat)

This field is available:

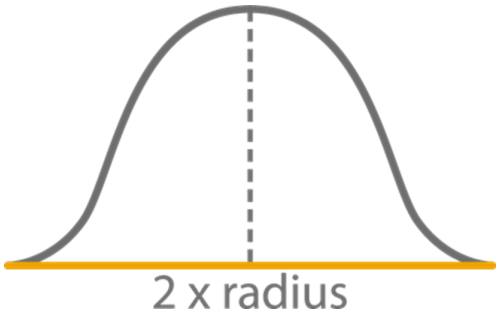
- For a **Single Point**, **Batch**, or **Grid** *Calculation Type* and when **Calculated** is selected as the **Absorptivity**.
- For a **Heat Source Calibration** *Calculation Type* and when **Calculated (prefactor calibrated** is selected as the **Absorptivity**.

About the Absorptivity Model and the section Heat Source Calibration for more.

Enter the **Wave length** in nm.

Beam Radius (Gaussian/Electron Beam)

The beam radius is where the power reduces to $1/e^2$ as compared to its peak value. This is only applied on the top surface and then heat is diffused into the material based on the diffusivity of the material.



For a **Single Point**, **Batch**, or **Grid** *Calculation Type* enter the **Beam radius** size for the **Gaussian** or **Electron Beam** heat source model. The defaults are 40 µm (Gaussian) or 200 µm (Electron Beam). Hover over the field in the GUI to view the example of it as below.

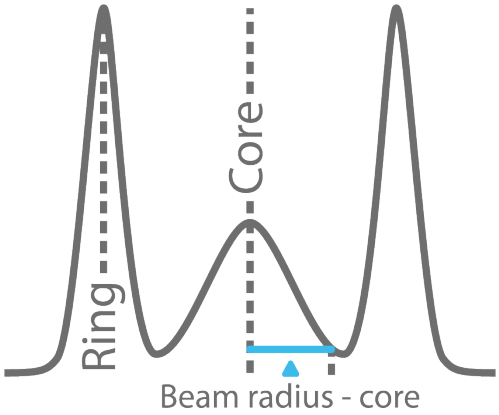
For a **Heat Source Calibration** *Calculation Type* and when **Calculated (prefactor calibrated** is selected as the **Absorptivity**.

- Select **Calibrated** to calibrate the beam radius and the absorptivity or **User-defined** to enter a specific beam radius in the field (unit = µm) and only calibrate the absorptivity.
- Then choose what to **Calibrate for**. Select **Width and depth** of the melt pool, or **Depth** to calibrate using only the depth of the melt pool.

About the Absorptivity Model and the section Heat Source Calibration for more.

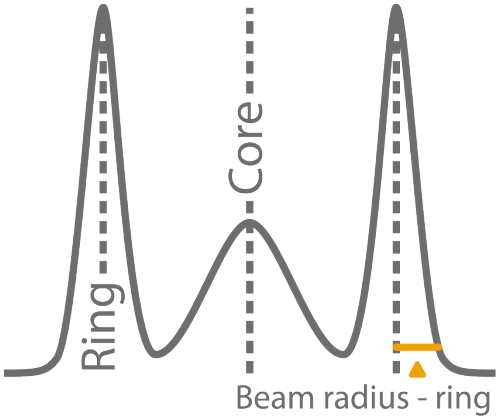
Beam Radius-Core (Core-ring)

The **Beam radius-Core** for a **Core-ring** heat source is the $1/e^2$ radius of the core beam where the power reduces to $1/e^2$ as compared to its peak value. Also see the equations in Core-ring Heat Source.



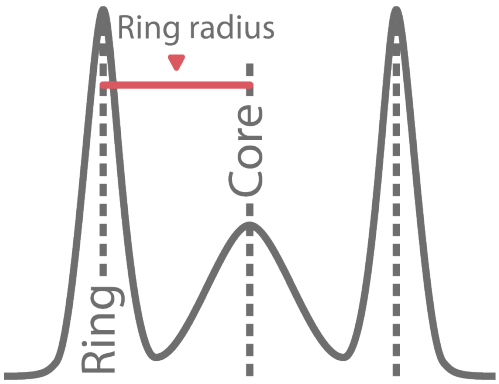
Beam Radius-Ring (Core-ring)

The **Beam radius-Ring** for a **Core-ring** heat source is the $1/e^2$ radius of the ring beam. Also see the equations in Core-ring Heat Source.



Ring Radius (Core-ring)

The **Ring radius** for a **Core-ring** heat source is the ring radius i.e. the distance between the center of the core beam to the center of the ring beam. Also see the equations in Core-ring Heat Source.



Amount of Power in Ring (Core-ring)

Enter a value for the percent (%) of **Amount of power in ring**. This is the % of power for the ring beam. When using the **Index Mode**, the amount of power in the ring is set based on the selected index value (0-6).

Index Mode (Core-ring)

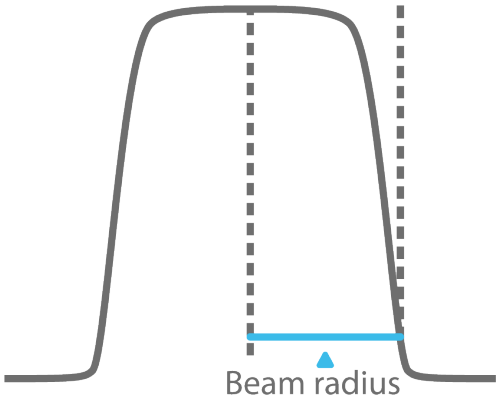
Mode (Core-ring)

Select a **Mode**:

- **Custom** to manually enter all parameters (the Beam radius-Core, Beam radius-Ring, Ring radius, and Amount of power in ring). See Custom Mode (Core-ring) in the theory section for more details.
- **Index** to select the index value (0, 1, 2, 3, 4, 5, or 6). Enter a value for **Beam radius-Core** and then preset values for Beam radius-Ring, Ring radius, and Amount of power in ring are based on this selection. See Index Mode (Core-ring) in the theory section for more details.

Beam Radius (Top-hat)

The **Beam radius** for a **Top-hat** heat source is the $1/e^2$ radius of the top-hat beam i.e. where the power reduces to $1/e^2$ as compared to its peak value. Also see the equations in detailed in Top-hat Heat Source.



Keyhole Model

About the Keyhole Model

The use of the **Use keyhole model** checkbox in combination with fluid flow and separate material properties for powder is dependent on the simulation type.

The **Use keyhole model** checkbox is selected by default and available for a **Gaussian** , **Core-ring**, **Top-hat**, or **Electron Beam***Heat Source*.

Feature Checkbox Availability: Fluid flow, Separate Material Properties with Powder, and Keyhole Model

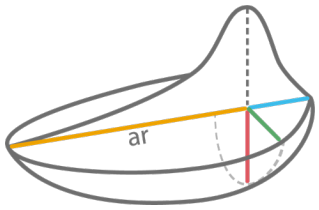
Beam Quality Factor M^2

Enter the **Beam quality factor M^2** of the laser beam.

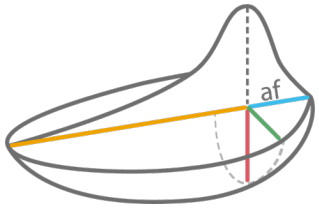
ar, af, b, and c (Double Ellipsoidal)

For **Double ellipsoidal**, also enter the following. For each field you can hover over it in the GUI to see these images that show you the location.

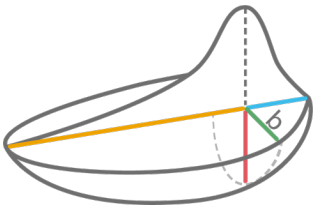
- **ar** (default is 70 µm).



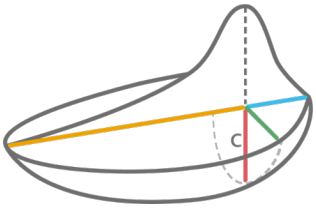
- **af** (default is 70 µm).



- **b** (default is 85 µm).



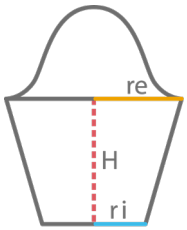
- **c** (default is 200 µm).



re, ri, h (Conical)

For **Conical**, also enter the following. For each field you can hover over it in the GUI to see these images that show you the location.

- **re** (default is 100 µm).
- **ri** (default is 60 µm).
- **H** (default is 100 µm).



Learn More

For background theory related to Heat Sources, see About the Heat Source Models and About the Absorptivity Model. For *Gaussian*, *Double ellipsoidal*, and *Conical* heat sources, also see About Heat Source Calibration for additional details.

When a **Users heat source** option is available to choose in the heat source list, then only the **Power** of the heat source needs to be entered and the rest of the parameters, including the absorptivity, are automatically included in the simulation based on the selected expressions when originally saving the heat source calibration data.

The **Core-ring**, **Top-hat**, and **Electron Beam** heat sources are not available with **Heat Source Calibration** calculations.

Feature Checkbox Availability: Fluid flow, Separate Material Properties with Powder, and Keyhole Model

Depending on what you want to simulate, there are some setting combinations that are available based on the different simulation types. The details are relevant to using the **Fluid flow including Marangoni effect**, **Use separate material properties for powder**, and **Use keyhole model** checkboxes in a variety of combinations. The software automatically guides your choices. However, it can be useful to know in advance what is available to better design your simulation.

AM Calculator Experiment File Requirements

The following describes the requirements for importing experimental file data to be used with an **AM Calculator** either for a **Heat Source** or **Batch** *Calculation Type* and when setting it up on the **Configuration** window.

AM Calculator Conditions Settings

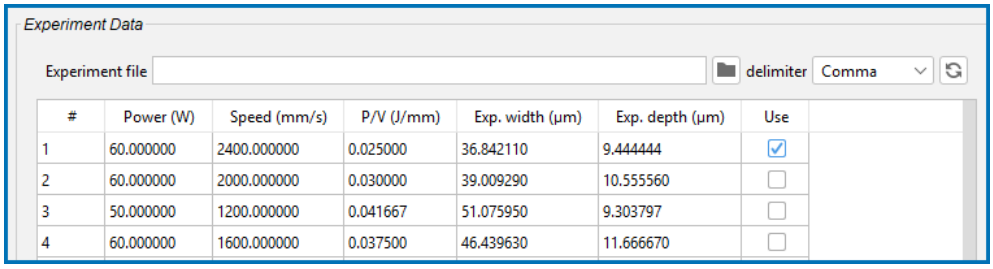
It is important that the experiment data file contents are correctly entered in order for the calculation to perform smoothly.

Heat Source Calibration Calculations

When the **Heat Source Calibration** *Calculation Type* is selected in the **Steady-state** mode, there is an option to import a file with experimental data points that are used to calibrate the heat source.

Data can also be entered directly into the table on the **AM Calculator Configuration** window. However, if an **Experiment file** is imported it needs to be set up in a certain way so that the software can read the data.

These examples use experiment data, key holing, and heat source calibration: AM_06a: Calibrating a Heat Source for a 316L Steel and AM_06b: Using the Calibrated Heat Source for a 316L Steel.



#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp. width (µm)	Exp. depth (µm)	Use
1	60.000000	2400.000000	0.025000	36.842110	9.444444	☑
2	60.000000	2000.000000	0.030000	39.009290	10.555560	☐
3	50.000000	1200.000000	0.041667	51.075950	9.303797	☐
4	60.000000	1600.000000	0.037500	46.439630	11.666670	☐

Figure 21: From example AM_06a, this shows the data imported from an experiment file into the table. The "Use" column allows you to choose the points to include or exclude for the simulation. Here row (experiment) #1 is selected to show the data point. Further down in this list, rows 9, 14, 20, and 21 are also selected to be included.

Batch Calculations

When the **Batch** *Calculation Type* is selected in the **Steady-state** mode, there is an option to import a file with experimental data points.

Data can also be entered directly into the table on the **AM Calculator Configuration** window. However, if an **Experiment file** is imported it needs to be set up in a certain way so that the software can read the data.

These examples use Batch calculations AM_07: Batch Calculations for an IN718 Alloy, AM_08b: Batch Calculations for a Ti64 Alloy, and AM_09b: Batch Calculations for an SS316L Alloy.

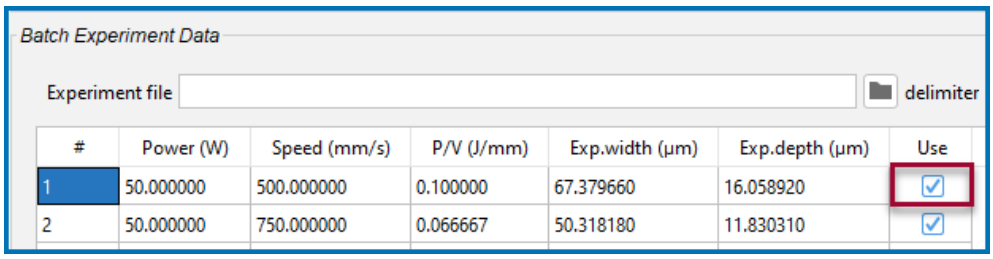


Figure 22: From example AM_08b, this shows the data imported from an experiment file into the table. Here the "Use" checkbox for Experiment 1 is about to be deselected to exclude the data point after previewing it on the Visualizations window.

Experiment File Requirements

Only the columns described here are read / used in the calculation. It is important to enter the information exactly as described. All header text (the first line in the file) must also be written in English, i.e. no translations into other languages will be read correctly by the experiment file.

The experiment file is set up as follows.

- The first row in the file is the header.
- Include only four columns in the file and these must be in the following order and must use the indicated units.

> Default Global units (i.e. set via the **Tools → Options** menu) are not applicable. The data must be in the indicated units.

  - **Power** (unit = W)
  - Scanning **Speed** (unit = mm/s)
  - **Width** of the melt pool (unit = µm)
  - **Depth** of the melt pool (unit = µm)

- All of the values entered or imported to the table must be positive and greater than zero.

> If you select **Depth** from the **Calibrate for** list, then the experimental values for only the melt pool depth is needed.

Do not include the following in the file:

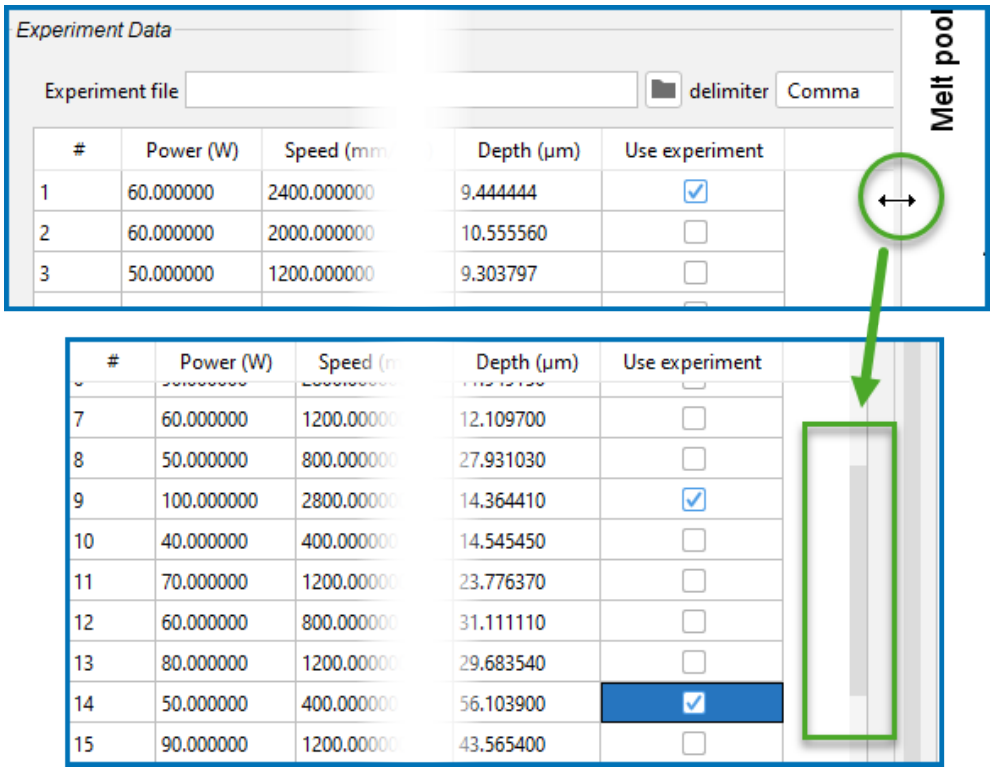
- **#** this is the experiment number that is automatically associated to each imported or entered set of data. It is used to identify the applicable rows by a unique number so that you can easily identify these points (i.e. points are identified by labels on the plots), or when choosing to include or exclude the experiment point from the simulation or later from a plot.
- **P/v (J/mm)**. This is the energy density and is defined as the ratio of power and scanning speed. This is not included in any data file. This is automatically calculated based on the **Power** and **Speed** entered or included in the file (i.e it is defined as the ratio of power and scanning speed).
- **Use**. This column is not part of the text file, it is available once the data is imported or entered in the table. Then you can choose to include or exclude specific data points as you examine this output in the **Visualizations** window.

	A	B	C	D
1	Power	Speed	Width_avg	Depth_avg
2	50	800	57.27	27.93
3	100	2800	47.82	0
4	40	400	58.46	14.55
5	60	800	68.42	31.11

#	Power (W)	Speed (mm/s)	P/v (J/mm)	Width (µm)	Depth (µm)	Use experiment
1	50.000000	800.000000	0.062500	57.270000	27.930000	☑
2	100.000000	2800.000000	0.035714	47.820000	0.000000	☑
3	40.000000	400.000000	0.100000	58.460000	14.550000	☑
4	60.000000	800.000000	0.075000	68.420000	31.110000	☑

Figure 23: An example of the original experiment data file, with the four headings in the correct order and these do not need the units included here. When the file is imported, there is a standard header that is kept, plus the additional columns (i.e. #, P/V, and Use experiment), which are automatically available and updated as needed.

Once a set of data is imported to the table (or entered manually), expand the **Configuration** window to reveal the scroll bars. Then you can scroll up or down, left or right, within the table to select checkboxes for the relevant data points you want to include or exclude. This is applicable to the tables found on the AM Calculator as well as those on the Plot Renderer for the data.



You can edit the table after importing data, or manually enter information. To add a row, scroll to the bottom of the table and press <Enter>.

AM Calculator Materials Properties Settings

Once you have added an AM Calculator, the **Configuration** window has these settings tabs where there are many available conditions to set on the **Conditions**, **Materials Properties**, and **Options** tabs and with the specialized **Plot Renderer**.

Materials Properties Tab Settings

This section describes the settings for the **Materials Properties** tab.

AM Calculator Conditions Settings and AM Calculator Options Settings

Use Data From

If there is a Scheil Calculator predecessor to the AM Calculator, you can import the material properties from a **Library** or **Scheil Calculator**. When the AM template is added, the default is to import material properties from Scheil calculations.

When the **with Material Library** template is used, then the AM Calculator > Materials properties are available to import from a **Library** only.

In this case you also can **Save**, **Save as**, **Export to Folder**, **Delete**, and **Rename** the material data both from Scheil and from material library. With **Save** or **Save as**, original data is saved i.e. without any smoothing. With **Export to Folder**, the data is saved with **Smoothing**. the material data both from Scheil and from material library.

Export to folder is intended for using the data in an external simulation software, where using smoothed data is expected to result in fewer numerical issues. **Save** and **Save as** are intended for when the data is to be used in the AM Module. The data will be smoothed according to the smoothing setting before use in the FEM simulation.

Account for Interface Scattering

When **Use data from Scheil Calculator** is selected, you can also select the **Account for interface scattering** checkbox.

The electrical resistivity due to phase interface scattering is evaluated as the scattering constant times sum of the interaction between the volume fraction of all the phases. The default value for the **Phase interface scattering constant** is found to be `4.0e-8` Ωm for aluminum alloys produced with conventional methods. A higher value could be required for the AM process where the rapid solidification results in a very fine microstructure with a large amount of phase interfaces.The contribution to thermal conductivity is assumed to be related to that to electrical resistivity, following the Wiedemann-Franz law.

Either keep the default **Phase interface scattering constant**, which is a constant for evaluating thermal conductivity due to scattering at phase interfaces, or enter another value.

Import

You can import material properties contained in a folder.

Click the **Import from folder and add to libraries** button and navigate to the folder location where the material properties are located.

Smoothing

From the **Smoothing** list, select **Same for all quantities** (where **Little smoothing** is the default) or **Per quantity**. Then either define the smoothing once (**Same for all quantities**) or individually for each quantity. Options are **No smoothing**, **Little smoothing**, **Medium smoothing**, **Large smoothing**, or **Linear**.

Available quantities to define smoothing:

- Heat and heat capacity
- Density
- Thermal conductivity
- Dynamic viscosity
- Surface tension
- Molar volume
- Molar mass of gas

- Driving force for evaporation per mole
- Evaporation enthalpy per mole
- Electric resistivity
- Absorptivity
- Absorptivity vs angle

Plot

From the **Plot** list, choose what quantity to plot:

- Heat
- Apparent heat capacity per kg
- Density
- Thermal conductivity
- Dynamic viscosity
- Surface tension
- Molar volume
- Molar mass of gas
- Driving force for evaporation per mole
- Evaporation enthalpy per mole
- Electric resistivity
- Composition of Gas phase
- Evaporation flux
- Absorptivity (see below for more details)
- Absorptivity vs angle (see below for more details)

Plot: Absorptivity Options

The following absorptivity options depend on what combination of heat source and calculation type is selected on the **Conditions** tab. See AM Calculator Heat Source Settings.

Absorptivity and **Absorptivity vs angle** plot options are available when the conditions below are met:

- When a **Gaussian**, **Core-ring**, **Top-hat**, or **Electron Beam** heat source is selected, plus any one of the **Single Point**, **Batch**, or **Grid** calculation types AND when **Calculated** or **User-defined** is selected.
- When a **Gaussian** heat source is selected, plus a **Heat Source Calibration** calculation type AND when **User-defined** is selected.

Also, for a **Gaussian** heat source, **Heat Source Calibration** calculation type, AND when **Calculated** is selected, then the options are:

- **Absorptivity (wavelength is** *<value from Heat Source settings>* **with prefactor 1.0)**.
- **Absorptivity vs angle (wavelength is** *<value from Heat Source settings>* **with prefactor 1.0)**.

The wavelength *<value from Heat Source settings >* for the **Absorptivity** and **Absorptivity vs angle** is the same as what is entered on the **Conditions** tab. For example, if 1064 nm is entered, it displays on the **Material Properties** tab as **Absorptivity (wavelength is 1064 nm with prefactor 1.0)**.

Show Transition Temperatures

You can also choose to **Show transition temperatures**:

- Solidus, Liquidus, Evaporation
- Solidus
- Liquidus
- Evaporation
- Custom: If selected, also enter a value in the field. The default unit is the same as what is selected globally on the **Tools → Options → Graphical Mode → Default Units** tab.
- None

Evaporation Accommodation Coefficients

The **Evaporation accommodation coefficients** list is hidden by default. Toggle between showing and hiding it, where if you click to **Show evaporation accommodation coefficients** you can to display all the coefficients for the composition and edit these values as needed.

AM Calculator Options Settings

Once you have added an AM Calculator, the **Configuration** window has these settings tabs where there are many available conditions to set on the **Conditions**, **Materials Properties**, and **Options** tabs, as well as with the specialized **Plot Renderer**.

Options Tab Settings

This section describes the settings for the **Options** tab.

AM Calculator Conditions Settings, AM Calculator Heat Source Settings, and AM Calculator Materials Properties Settings

Streamline Upwind Petrov-Galerkin (SUPG)

Select the **Streamline upwind Petrov-Galerkin (SUPG)** checkbox to enable SUPG stabilization scheme for the energy and Navier-Stokes equations.

Damping Factor for the Damped Newton Iteration

Select the **Damping factor for the damped Newton iteration** checkbox to add a damping factor for the damped Newton iteration and enter a value between 0 and 1. The default is 0.7.

It may improve stability but it slows down convergence of the simulation.

Smagorinsky Constant

Enter a **Smagorinsky constant** in the field. This is the value of the constant to use in the fluid flow model. The default is 0.18.

For more information see Fluid Flow in the theory section.

Save Interval for Transient Simulation

Select the interval to save results from transient simulations. If the number of files saved are specified, choose if the step size should increase linearly or exponentially.

From the **Save interval for transient simulation** list choose **Automatic**, **Every Nth time step**, or **Time in seconds**. Then for each also enter as indicated:

- **Automatic**
  - **Max number of files**: The default is`100`**Linear**.
  - Then choose **Linear** or **Exponentially increasing**. Enter another number of files in the field as needed.
- **Every Nth time step**: The default is 1 or enter or use the up and down arrows to choose another number.
- **Time in seconds**: The default is 0.01 or enter another number in the field.

Number of Cores

Select or enter the **Number of cores** available for the simulations. The default value is the total number of physical cores available in the system.

AM Calculator: Working with Probe Data

When you also have licenses either for the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA), for transient simulations you can additionally include probe data from the AM Calculator in the set up of the thermal profile for diffusion and precipitation calculations, respectively.

Workflow to Include Probe Data from Diffusion or Precipitation Simulations

You can use installed examples to visualize how the probes are set up for a Diffusion Calculator (see AM_05: Using AM Calculator Probe Data with the Diffusion Module (DICTRA)) and for the Precipitation Calculator (see AM_12: Using AM Calculator Probe Data with the Precipitation Module (TC-PRISMA)).

1. Set up the probes on the **AM Calculator**. Probes are available for transient calculations only. See AM Calculator Conditions Settings. This must be done before you can use the probe data in the calculations connected to a Diffusion Calculator or Precipitation Calculator.
2. If not already done, add a **Diffusion Calculator** or **Precipitation Calculator** as a successor to the **AM Calculator**.
3. Set up your Diffusion or Precipitation Calculator as needed. Follow the basic settings details for the **Thermal Profile** section as described in Diffusion Calculator Thermal Profile and Precipitation Calculator Thermal Profile.
4. Once the standard settings are completed, and as long as probes are set up, on the **Configuration** window, the section **Probes** is available. Until the AM Calculator is run, the list is empty. After the AM simulation is completed, the data is imported into the table you can choose how to **Condense time-temperature data**. These settings are described below.

Probes

The list of **Probes** is available as long as *Probe Positions* are set up on the AM Calculator and the AM Calculator is performed to generate the data, which is fed into the applicable Calculator (Diffusion or Precipitation). Select the probe you want to plot, for example as a Segregation Profile as shown in example AM_05.

Condense Time-Temperature Data

Use the **Condense time-temperature data** setting to adjust how many time-temperature points are included in the **Thermal Profile** displayed in the **Visualizations** window. For example, for a complex calculation you can choose a **Medium** or **Large** setting to save fewer time steps at this stage of design, which in turn can ensure that a complex diffusion or precipitation calculation is able to finish.

Choose **None**, **Small**, **Medium**, **Large**, or **Custom**.

- **None** (the default) includes all points, i.e. no points are condensed together and all point data are included in the **Thermal Profile** preview. When using the **Custom** setting, this is equivalent to entering a value greater than 1 in the field.
- **Small** condenses a minimum number of points, which means that a *large* number of time steps are used in the calculation and thus lots of time steps are shown.
- **Medium** is when that a medium number of points are condensed together, which means that a *medium* number of time steps are used in the calculation.
- **Large** is when a large number of points are condensed together, which means that there are few, or a *small* number of time steps used in the calculation.
- When **Custom** is selected you can fine-tune the number of points to include. Enter a value between 0 and 1, where 0 maximizes condensing the points (the same as choosing **Large**), 1 minimizes condensing the points (the same as choosing **Small**), and 0.5 is a medium number of points being condensed (the same as choosing **Medium**). If you enter a value greater than 1, it is the same as choosing **None**, i.e. all data points are included. The larger the value, the more points are condenses, until only two points are shown.

About the AM Plot Types

When working with an **AM Calculator** with the **Plot Renderer** as a successor, the visualization is different from the other calculators available in Thermo-Calc. When setting up the **AM Calculator**, there are many options available that impact what plot types are going to be available. Further, when defining the **Plot Renderer**, there are additional ways and axis variables or other setting requirements that enable you to display certain plot types, as well as preview a variety of settings on the **Visualizations** window.

In addition, when a **Plot Renderer** is added as a successor to the **AM Calculator**, the default layout of the **Configuration** window, with respect to the different tabs, relates to how the **AM Calculator** is set up. This is then further related to the tabs located on the **Visualizations** window.

Learn More

See Working with AM Visualizations for information about how these tabs are connected between the windows. Also see Overlaying Plots in the AM Module.

See Plot Types for more information for the Scheil Calculator and Diffusion Calculator, which are also used with the Additive Manufacturing (AM) Module.

* For **Transient**, **Transient with heat source from Steady-state**, and **Evaporation with Steady-state** simulations there are no additional *Calculation Types* selected.

AM Plot Type: 3D Plot

The **3D Plot** is available with all simulation types (*Steady-state*, *Transient*, *Transient with heat source from Steady-state*, and *Evaporation with Steady-state*). It is also available with *Steady-state* calculation types **Heat Source Calibration**, **Batch**, and **Grid**.

The **3D Plot** type has its own tab on both the **Plot Renderer Configuration** window and the **Visualizations** window. This plot type is further visualized using additional **Display** options.

Further, when connecting two AM Calculators to plot combinations of axis variables, separate tabs are added to the **Visualizations** window that have a suffix of the name of the AM Calculator added in brackets, e.g. **3D Plot (AM Calculator 1)**. It is recommended that the AM Calculator is renamed to help you identify which tab belongs to which calculation.

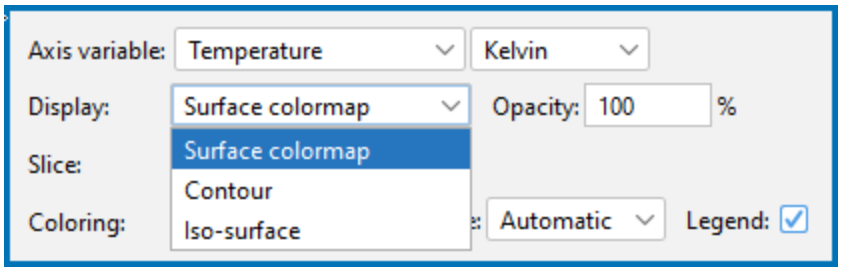
See Overlaying Plots in the AM Module for more details and AM Plot Type: Thermal Gradient vs. Solidification Rate for an example.

By default, CPU rendering of 3D plots is enabled under **Tools > Options**. If there are issues viewing 3D plots in the **Visualizations** window (e.g. a black screen), confirm whether the **Use GPU for 3D plots in Additive Manufacturing Module** checkbox is selected and then try turning it OFF i.e. click to clear the checkbox and return to the default setting.

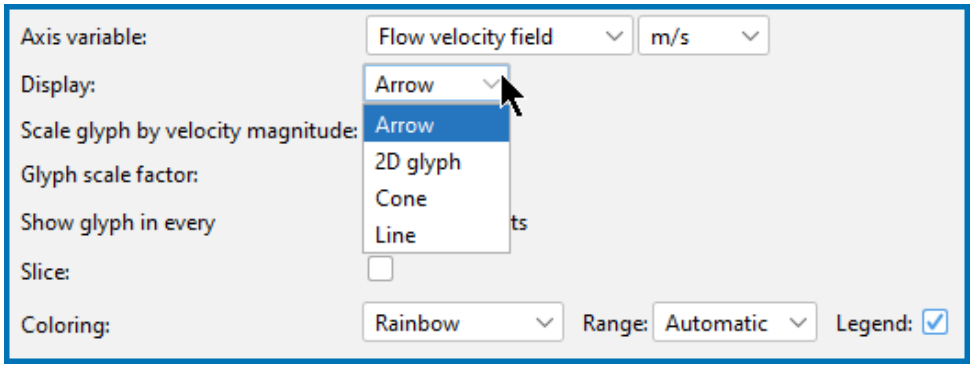
3D Plot Display Options

The **Display** options available are dependent on the *Axis variable* selected. The **Slice** plot, which is a unique type of plot, is also available when either **Surface colormap** or **Contour** is selected.

Surface colormap, Contour, and Iso-surface are available when certain axis variables are selected, for example **Temperature**.



Arrow, 2D Glyph, Cone, or Line are available when **Flow velocity field** is selected as an *Axis variable*. It also requires that the **Fluid flow including Marangoni effect** checkbox is also selected on the **AM Calculator**.



Examples

Plot Types			
Surface Colormap	Slice Plot	Contour	Isosurface
Arrow	2D Glyph	Cone	Line

Surface Colormap

This is an example from AM_01: Transient Simulation of a Single Track.

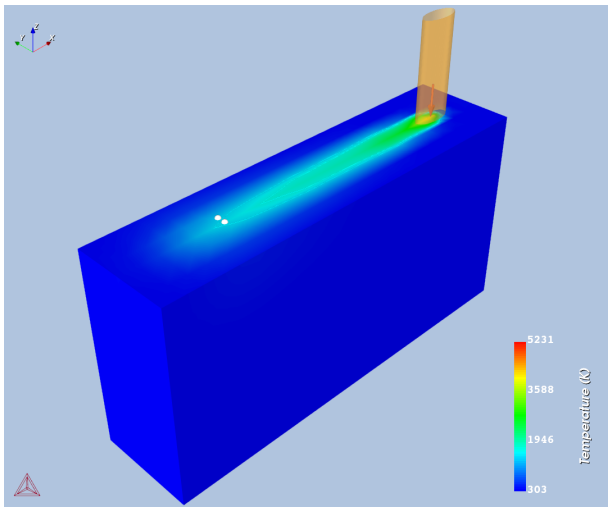


Figure 24: Surface plot of temperature distribution after the single track scan is completed. Probes P1 and P2 can also be seen on the top surface.

Slice Plot

This is an example from AM_01: Transient Simulation of a Single Track.

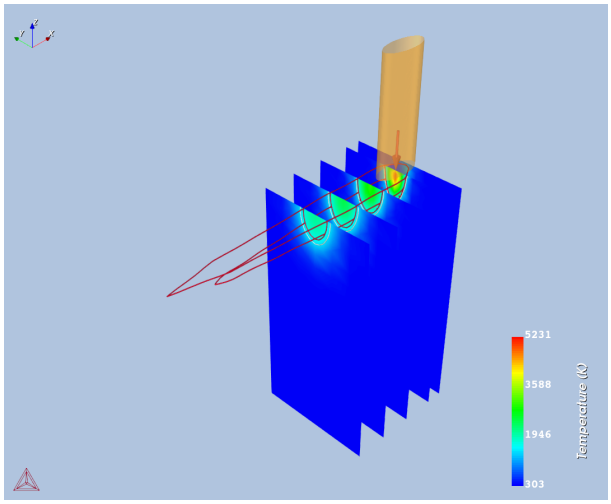

Figure 25: Slices of the computational domain, orthogonal to the scanning direction, showing temperature distribution at different cross-sections. Red tubes show the contour of the melt pool (at liquidus temperature).

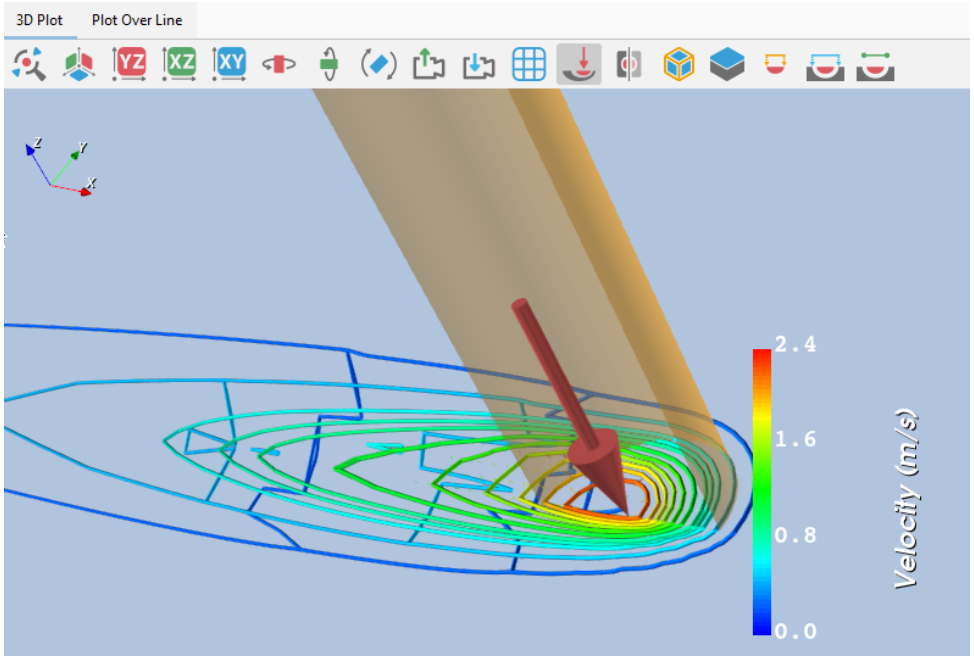
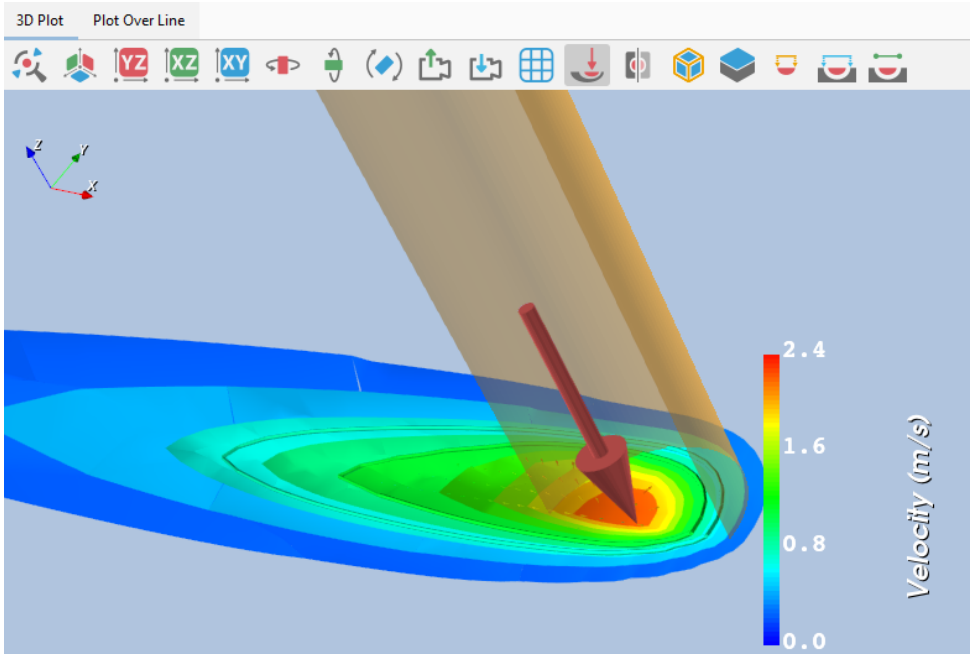
Contour

This is an example using AM_03: Steady-state Simulations to zoom into the **AM Calculator**, which in that example is renamed to **Gaussian HS, with Fluid**. On the **Plot Renderer**, the **Display** setting is changed from the default to **Contour**.



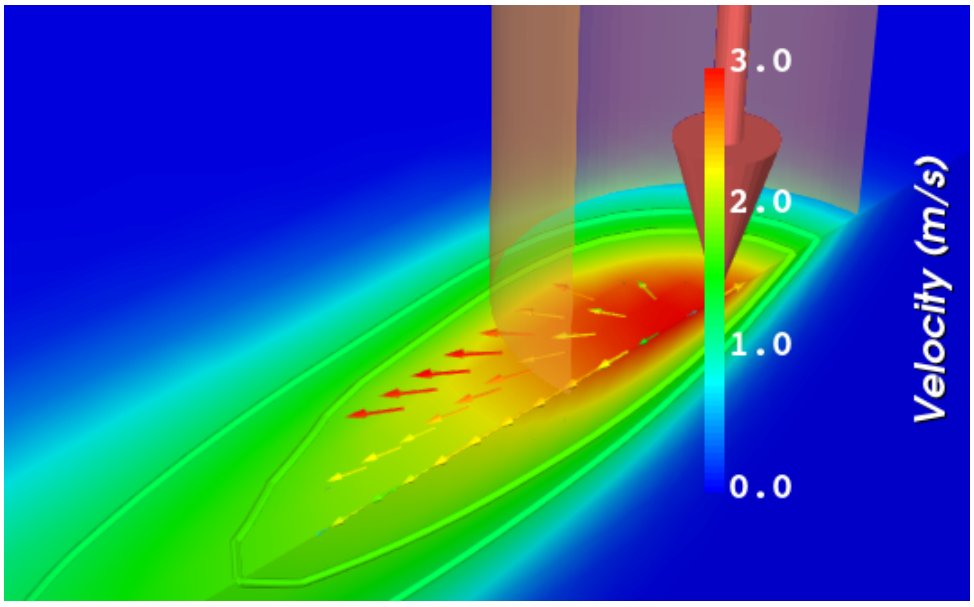
Isosurface

This is an example using AM_03: Steady-state Simulations to zoom into the **AM Calculator**, which in that example is renamed to **Gaussian HS, with Fluid**. On the **Plot Renderer**, the **Display** setting is changed from the default to **Iso-surface**.



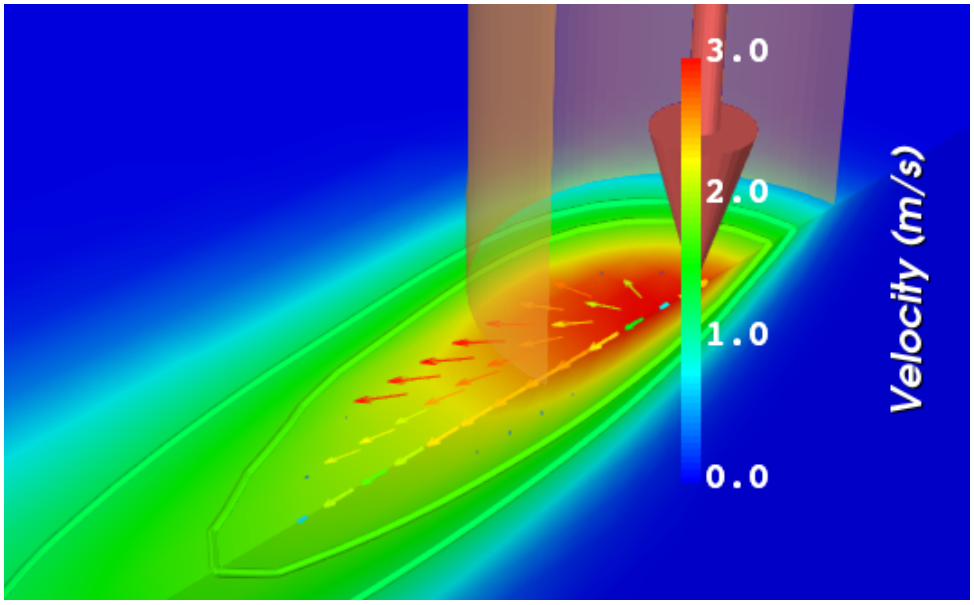
Arrow

This is an example using AM_04: Scheil Transient Steady-state to zoom into one of the AM Calculators, which in this case is renamed to **Steady-state**. On the **Plot Renderer**, and when the *Axis variable* is set to **Flow velocity field**, the **Display** default setting is **Arrow**.



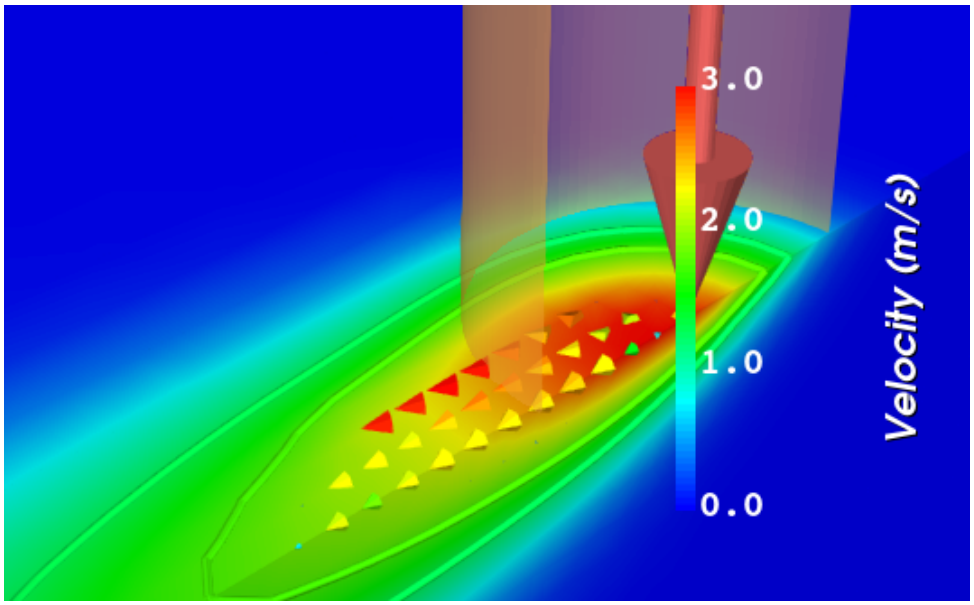
2D Glyph

This is an example using AM_04: Scheil Transient Steady-state to zoom into one of the AM Calculators, which in this case is renamed to **Steady-state**. On the **Plot Renderer**, and when the *Axis variable* is set to **Flow velocity field**, the **Display** setting is changed from the default to **2D Glyph**.



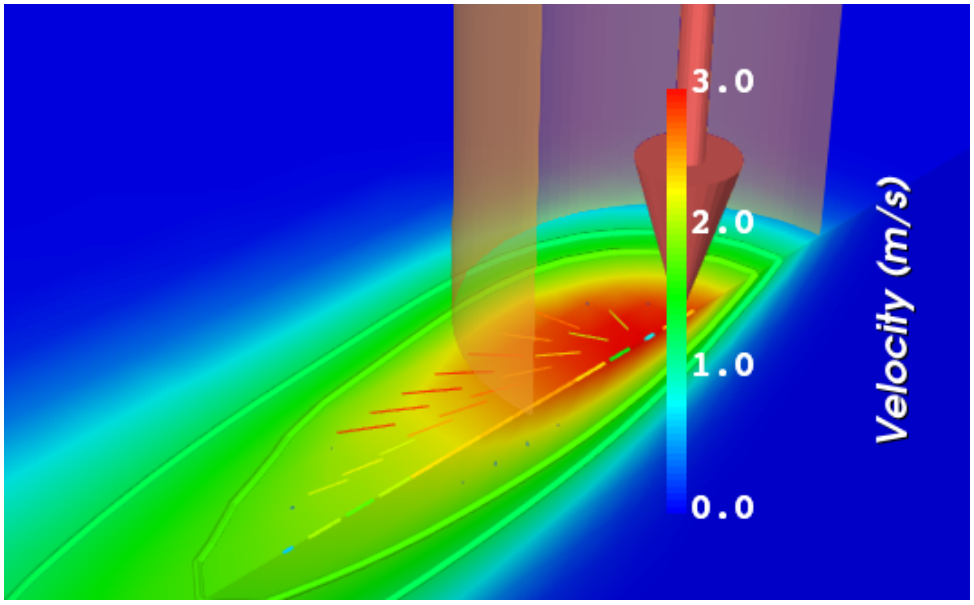
Cone

This is an example using AM_04: Scheil Transient Steady-state to zoom into one of the AM Calculators, which in this case is renamed to **Steady-state**. On the **Plot Renderer**, and when the *Axis variable* is set to **Flow velocity field**, the **Display** setting is changed from the default to **Cone**.



Line

This is an example using AM_04: Scheil Transient Steady-state to zoom into one of the AM Calculators, which in this case is renamed to **Steady-state**. On the **Plot Renderer**, and when the *Axis variable* is set to **Flow velocity field**, the **Display** setting is changed from the default to **Line**.



AM Plot Type: Plot Over Line (2D)

The **Plot Over Line** plot type is available with all simulation types (*Steady-state*, *Transient*, *Transient with heat source from Steady-state*, and *Evaporation with Steady-state*). For Steady-state simulations, it is also available with **Heat Source Calibration**, **Batch**, and **Grid** calculation types.

The **Plot Over Line** type is a 2D plot. On the **Visualizations** window it is available on the **Plot Over Line** tab and on the **Configuration** window on the tab of the same name.

Once the plot is performed, you can also switch between a plot and a **Table View** using the button available on the **Visualizations** window.

The coordinates for the **Plot Over Line Transient with heat source from Steady-state** and its **Steady-state** model are synchronized. This means that if you switch between these computational models, the **Plot Over Line** coordinates show the same result.

Example

This is an example from AM_01: Transient Simulation of a Single Track.

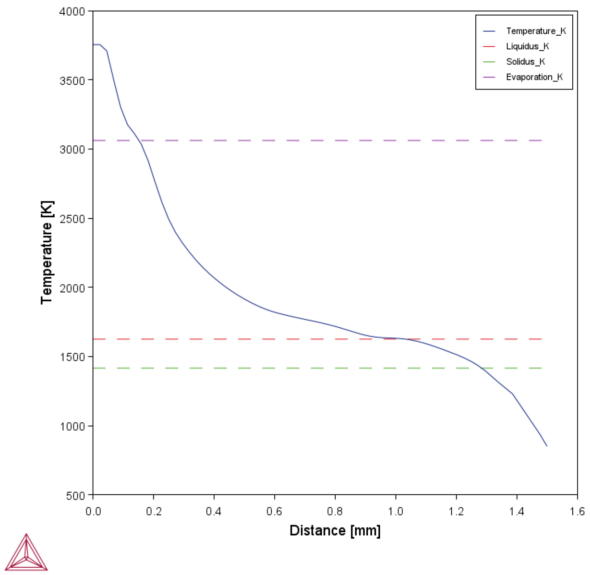


Figure 26: 2D plot over line showing temperature in the tail of the melt pool as a function of distance plotted along the scanning track.

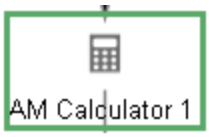
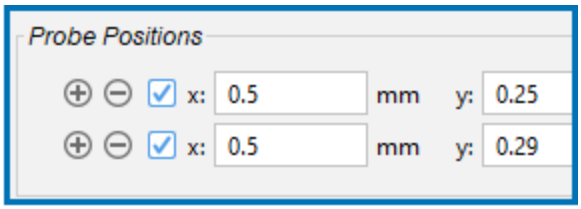
AM Plot Type: Probe (2D)

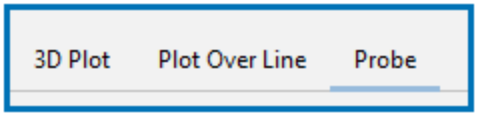
The **Probe** plot type is available with the **Transient** and **Transient with heat source from Steady-state** simulation types.

The **Probe** plot type is a 2D plot. On the **Visualizations** window it is available on the **Probe** tab and on the **Configuration** window on the tab of the same name.

To define a Probe plot requires that *Probe Positions* are selected on the **AM Calculator**. Then when a **Plot Renderer** is added as a successor, a **Probe** tab is available on the **Configuration** window where you can further define the plot.







Once the plot is performed, you can also switch between a plot and a **Table View** using the button available on the **Visualizations** window.

Probe data can also be used with the Diffusion Calculator and Precipitation Calculator when these Calculators are added as successors to the AM Calculator.

Example

The example below is taken from AM_01: Transient Simulation of a Single Track.

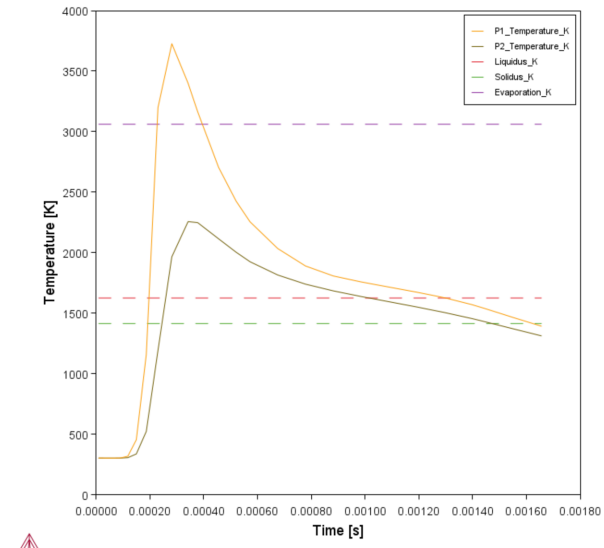


Figure 27: 2D probe plot showing temperature evolution as a function of time at probes P1 and P2.

For use of probe data with the Diffusion Module (DICTRA) see AM_05: Using AM Calculator Probe Data with the Diffusion Module (DICTRA).

For use of probe data with the Precipitation Module (TC-PRISMA) see AM_12: Using AM Calculator Probe Data with the Precipitation Module (TC-PRISMA).

AM Plot Type: Composition History (2D)

The **Composition History** plot type is available with the simulation type *Evaporation with Steady-state*.

The **Composition History** type is a 2D plot. On the **Visualizations** window it is available on the **Composition History** tab and on the **Configuration** window on the tab of the same name.

Once the plot is performed, you can also switch between a plot and a **Table View** using the button available on the **Visualizations** window.

The **Plot quantities** available with this plot type are:

- Track composition change
- Track composition
- Composition of Gas phase
- Last track composition change, where you also can enter *Experimental compositional change* data and errors.

Example

This is an example from AM_16: Composition Change Due to Evaporation.

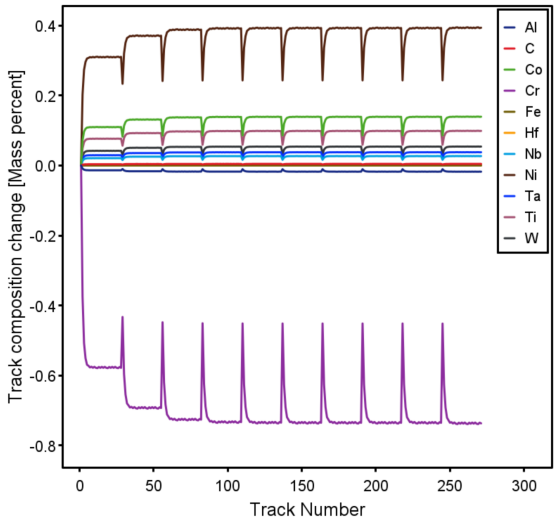

Figure 28: Predicted composition of the alloying elements of IN939 as a function of track number. A total of 10 layers is simulated with 27 tracks on each layer.

AM Plot Type: Heat Source Calibration Parameters

The **Heat Source Calibration Parameters** plot type is available with a **Steady-state** simulation and when **Heat Source Calibration** is selected as the *Calculation Type*.

During the set up, the **Heat Source Calibration Parameters** type also has its own tab called **Heat Source Calibration** on the **Plot Renderer Configuration** window. For more information see Visualizing Heat Source Calibrations.

About Heat Source Calibration

Example

The following is from AM_06a: Calibrating a Heat Source for a 316L Steel.

Also see the companion example, AM_06b: Using the Calibrated Heat Source for a 316L Steel.

A **Heat Source Calibration Parameters** plot shows the calibrated heat source parameters as a function of energy density (P/v) (unit J/mm). From the **Plot Renderer Configuration** window, you can also continue to select which experiments to be used to fit the calibration.

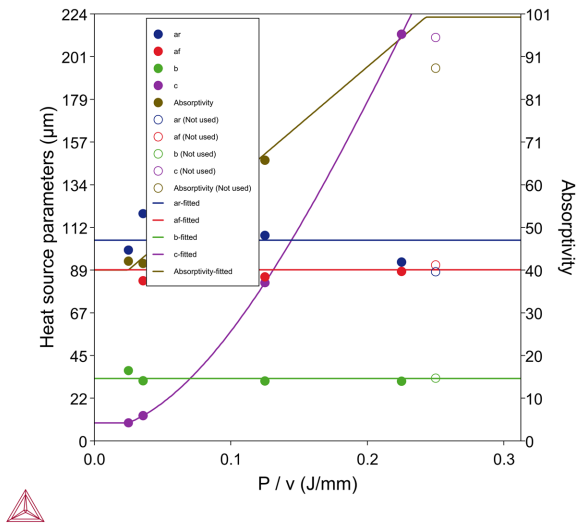

Figure 29: From example AM_06a, the Heat Source Calibration Parameters plot for the double ellipsoidal calibration.

For instance, you can deselect the points that seem to be outliers or where the error bar in experimental data is large.

AM Plot Type: Melt Pool Dimensions

The **Melt Pool Dimensions** plot type is available with a **Steady-state** simulation and when **Heat Source Calibration** is selected as the *Calculation Type*. For more information see Visualizing Heat Source Calibrations.

About Heat Source Calibration

Example

The following is from AM_06a: Calibrating a Heat Source for a 316L Steel.

Also see the companion example, AM_06b: Using the Calibrated Heat Source for a 316L Steel.

A **Melt Pool Dimensions** plot shows melt pool size, both from experiments and simulations, as a function of energy density (P/v). This plot can be used to compare the results from the experiments and optimization simulations.

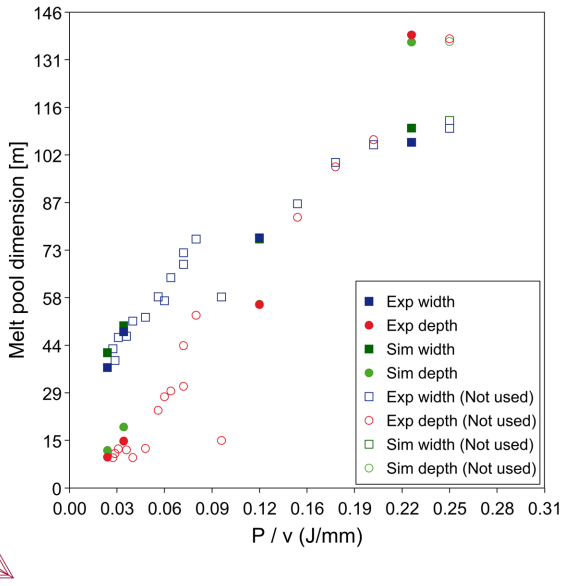

Figure 30: From example AM_06a, the Melt Pool Dimensions plot for the double ellipsoidal calibration.

AM Plot Type: Printability Map

This topic describes the plot type **Printability Map**, which is available with **Batch** or **Grid** calculations for a *Steady-state* simulation. A printability map is also known as a process map.

This plot is available with **Batch** and **Grid** calculations. However, using it with the **Grid** calculation is the preferred method as it provides full coverage of the plot area. Otherwise, if you are doing a **Batch** calculation and only base it on experimental conditions, it often leaves out the most extreme cases so you get areas in the Printability Map that are blank.

Background

Printability maps allow you to plot the likelihood of three possible defects that occur during additive manufacturing: *Keyholing*, *lack of fusion*, and *balling*.

These defects occur based on the speed and power used during the AM process. Printability maps allow you to reduce the risks of these defects by showing the speed and power settings that are optimal, which in turn allows you to calibrate your system to avoid these issues.

- *Keyholing* occurs with low scanning speed and high power.
- *Lack of fusion* occurs with high scanning speed and low power.
- *Balling* occurs if you increase the scanning speed.

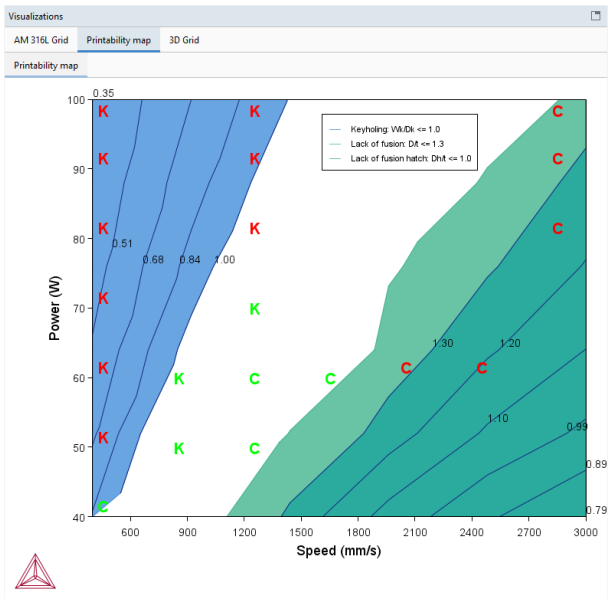

*Figure 31: Printability map for 316L showing regions of keyholing and lack-of-fusion. Experimental information from Hu et. al. [2019Hu] overlaid as coloured labels showing keyhole porosity (**K**), conduction mode with lack-of-fusion porosity (**C**). Green labels showing experiments without defects for conduction mode (**C**) and keyhole mode (**K**).*

The defect regions in the printability maps are defined by functions of the keyhole dimension (Wk, Dk), melt pool dimensions (W, D, L), hatch distance (h), and powder thickness (t) [2019Joh].

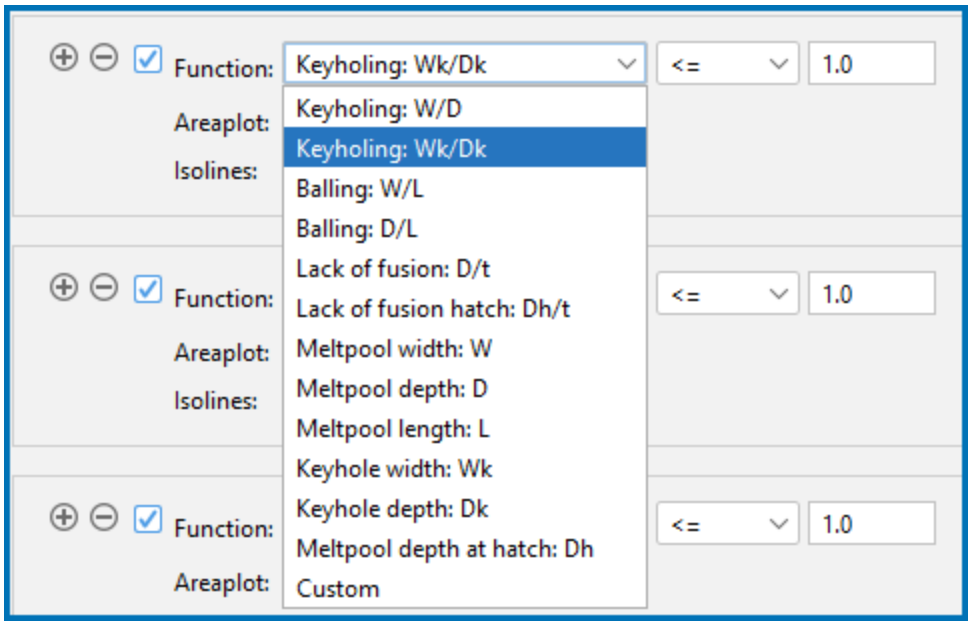

Figure 32: When defining the Printability map on the Plot Renderer for an AM Calculator, you can select from a variety of Functions.

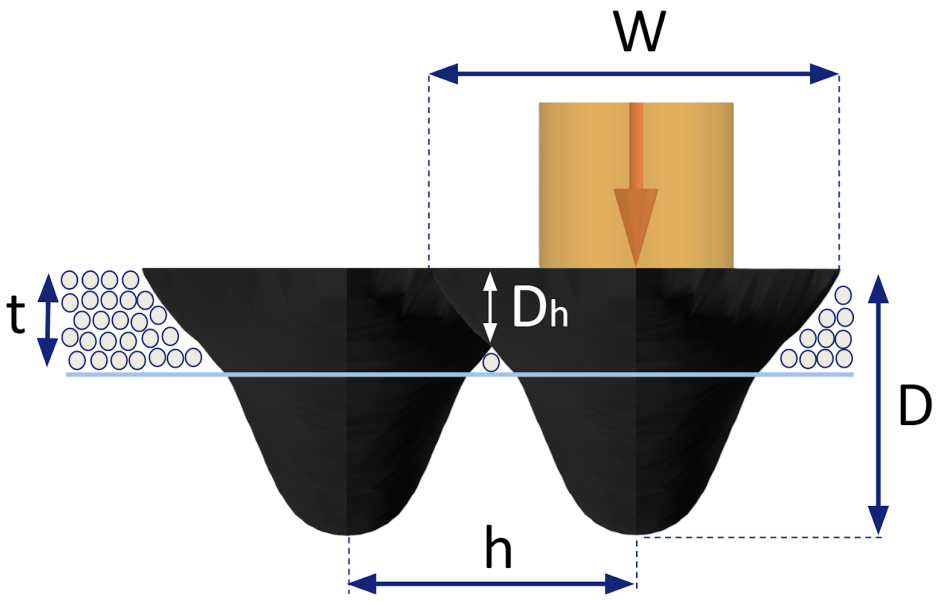

Figure 33: Two single tracks with the melt pool width (W) and depth (D). The hatch distance (h), powder thickness (t), and the melt pool depth at half of the hatch distance (Dh).

Keyholing Porosity

Keyholing is a critical feature in additive manufacturing that occurs at high energy densities (P/v). Keyholing is not only negative, the increased depth of the melt pool can increase productivity. However, deep and narrow keyholes are unstable and can collapse, and lead to keyholing porosity. Keyhole porosity appears close to spherical in shape.

Keyholing porosity can be defined to occur if the width/depth ratio of the keyhole is less than or equal to 1 (i.e. $Wk/Dk \leq 1$). Similarly if a volume heat source is used (that lacks information of the keyhole geometry) the ratio of the melt pool (W/D) can be used instead, where $W/D \leq 1$.

Lack of Fusion

Lack of fusion porosity occurs if the melt pool, due to low energy density (P/v), fails to penetrate the powder thickness. Lack of fusion gives porosity uneven in shape, compared to keyhole porosity that is close to spherical in shape.

Lack of fusion for a single track can be defined to occur if the melt pool depth is smaller than the powder thickness, i.e. $D/t < 1.0$. Additionally the lack of fusion between two tracks, at half of the hatch distance, can be defined to occur if $Dh/t < 1.0$.

Balling

The scan tracks can break up and produce agglomerated particles in spherical shape instead of a single bead. Balling has been defined to occur if ratios W/L [2019Joh] or D/L [2023Kat] are small .

Additional user-defined defect criteria can be defined with the Custom function using any combination of the keyhole dimension (Wk, Dk), melt pool dimensions (W, D, L), hatch distance (h) and powder thickness (t).

Learning Resources

There is a video tutorial about the **Printability Map** on our website and on our YouTube channel. It is also included in the Additive Manufacturing Module YouTube playlist.

These examples highlight the use of the printability map: AM_08a: Grid Calculation for a Ti64 Alloy and AM_09a: Grid Calculation for an SS316L Alloy.

AM Plot Type: Parity Plot

This topic describes the plot type **Parity Plot** which is available with Batch calculations for a Steady-state simulation. This plot type is only to select on the Plot Renderer when the simulation uses the **Batch** *Calculation Type* with an **AM Calculator**.

Parity plots are used when validating the Steady-state Batch calculation against experimentally measured melt pool width and depth. The plot shows the experimental width/depth on the X-axis and the calculated width/depth on the Y-axis. The data should follow the diagonal line for a perfect match between the calculated and experimental values.

Examples

These examples highlight the use of this plot: AM_07: Batch Calculations for an IN718 Alloy, AM_08b: Batch Calculations for a Ti64 Alloy and AM_09b: Batch Calculations for an SS316L Alloy.

The following are from example AM_07.

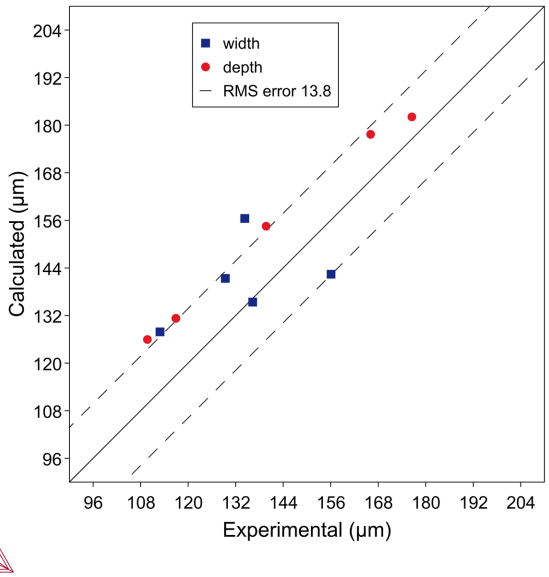

Figure 34: Parity plot comparing experimental versus calculated melt pool width and depth for all the experiments. The experiments are single tracks on bare plate IN718 with varied power and scan speed. The Root Mean Square (RMS) error can also be shown as a dashed line.

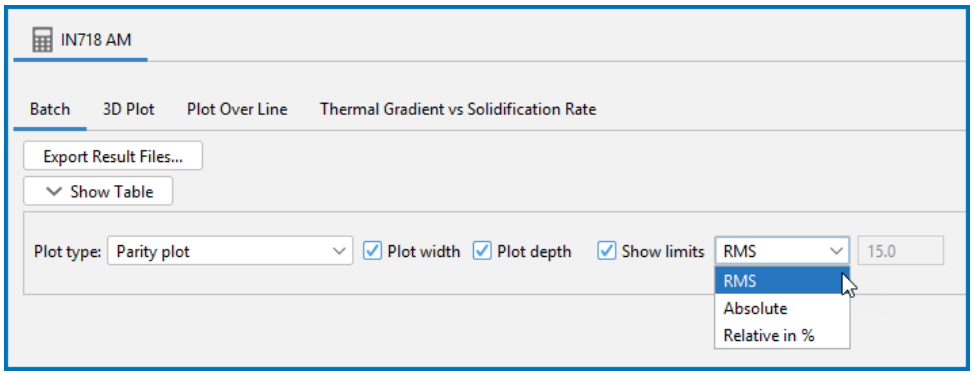

Figure 35: Alternatively, lines for user-defined Absolute or Relative in % error can be shown instead by selecting these options on the Configuration window.

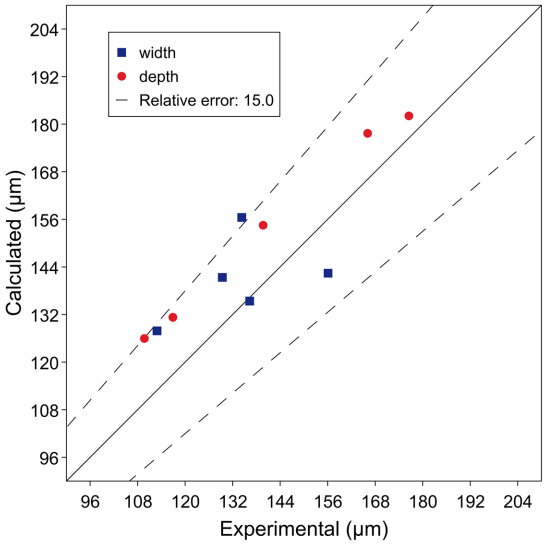

Figure 36: Parity plot comparing experimental versus calculated melt pool width and depth for all the experiments. The experiments are single tracks on bare plate IN718 with varied power and scan speed. In this plot, it is configured to show a Relative in % error of 5 instead of the RMS error.

Keyhole Model with Fluid Flow

This is an example application of using the parity plot when the keyhole model includes fluid flow, which can provide a better prediction of the melt pool size.

About the Keyhole Model

Keyholing can occur with low scanning speed and high power. Including fluid flow in the simulation makes the predictions of the entire melt pool size more accurate, which is especially important at higher energy densities when Marangoni forces are strong.

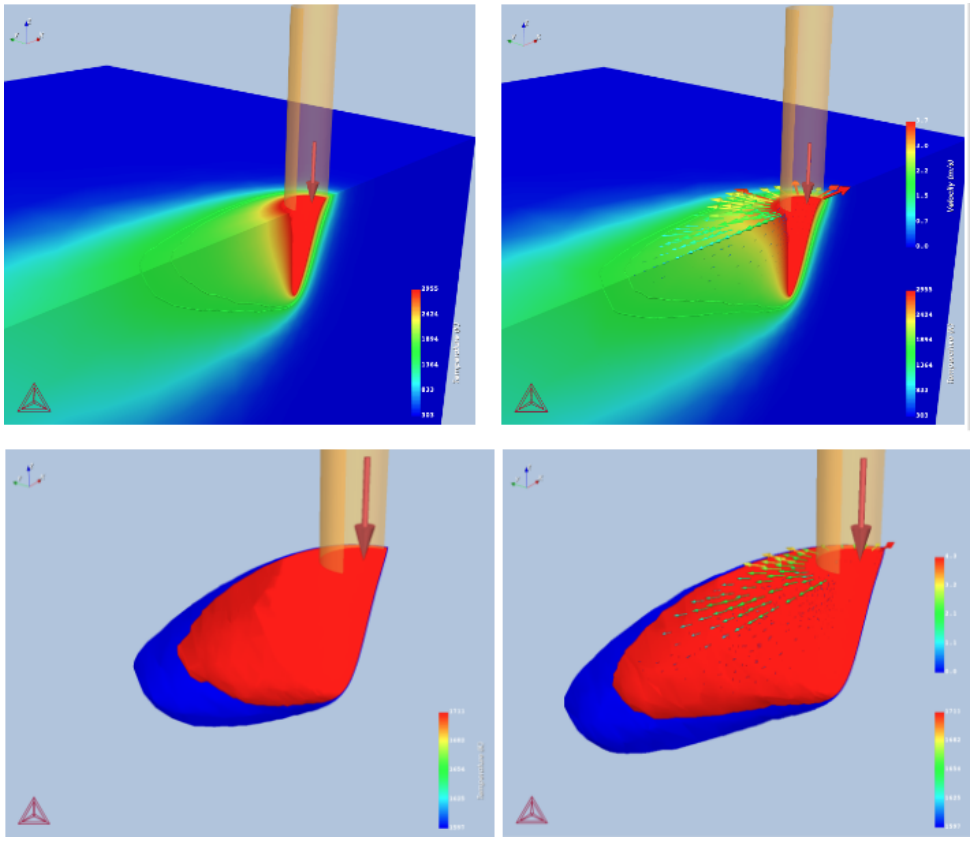

Figure 37: Fluid flow can make the melt pool wider and longer. This example shows the effect when enabling fluid flow for 316L for power 50 W and scan speed 400 mm/s. Left images show without fluid flow and right images with fluid flow enabled. Top row shows the temperature color map. Bottom row shows the isosurfaces for liquidus and solidus, i.e. the size of the melt pool and mushy zone.

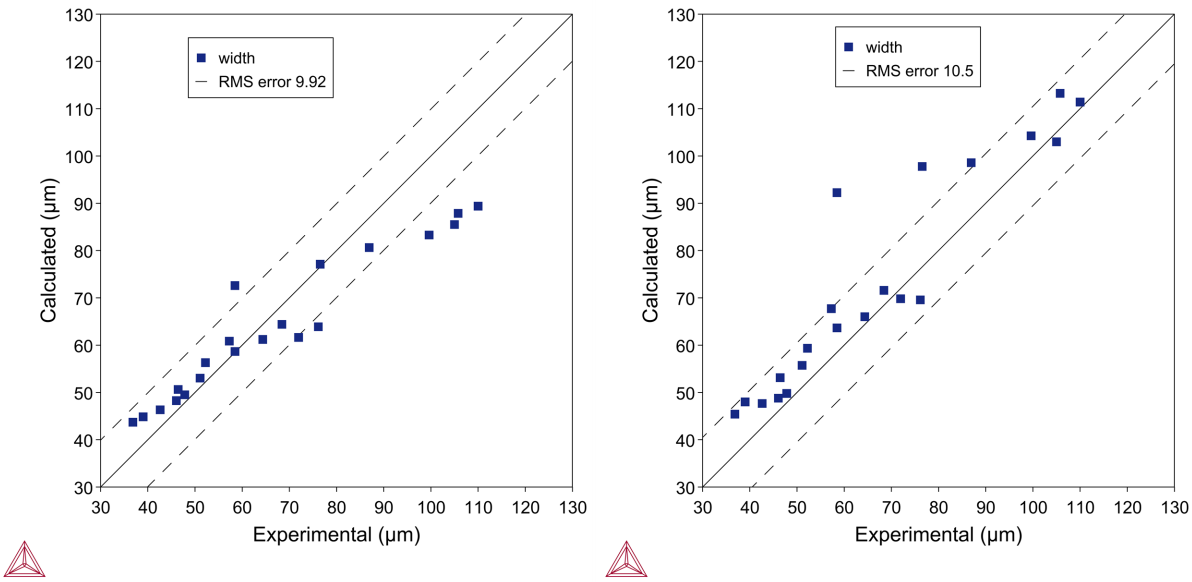

Figure 38: Parity plot for 316L showing how the RMS is reduced for the melt pool width when excluding fluid flow (left) compared to when it is included (right). Experiments from Hu et. al [2019Hu].

[2019Hu] Z. Hu, B. Nagarajan, X. Song, R. Huang, W. Zhai, J. Wei, Formation of SS316L Single Tracks in Micro Selective Laser Melting: Surface, Geometry, and Defects. Adv. Mater. Sci. Eng. 2019, 1–9 (2019).

AM Plot Type: Melt Pool vs Energy Density

This topic describes the plot type **Melt Pool vs Energy Density** which is available with **Batch** or **Grid** calculations for a *Steady-state* simulation.

This plot type is used when validating the Steady state Batch calculation against experimentally measured melt pool width and depth. The plot shows the experimental and simulated melt pool dimensions as a function of the energy density (P/v). The plot type can also be used when experimental melt pool dimension are lacking, e.g. after the Grid calculation, but then naturally only shows the simulated melt pool dimensions as a function of the energy density (P/v).

Examples

These examples highlight the use of this plot: AM_08b: Batch Calculations for a Ti64 Alloy and AM_09b: Batch Calculations for an SS316L Alloy.

This uses example AM_09b.

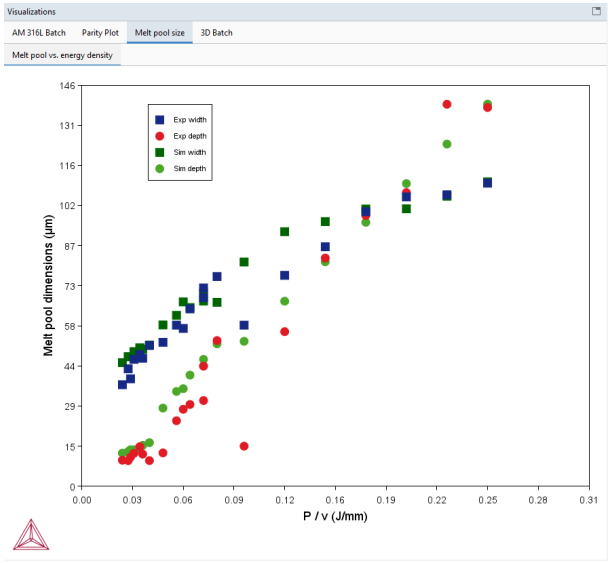

Figure 39: Plot comparing experimental versus calculated melt pool dimensions for all the Batch calculations. The experiments are single tracks with SS316L with varied power and scan speed. The melt pool width and depth are shown on the Y-axis and the energy density (P/v) on the X-axis.

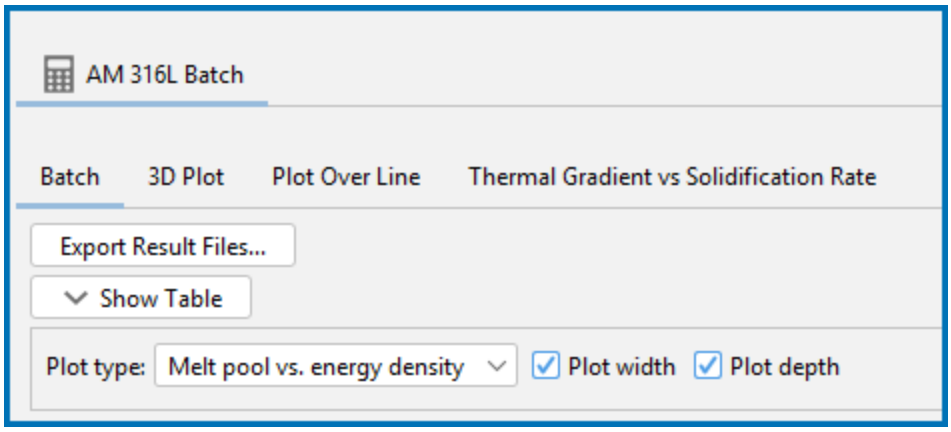

Figure 40: For the plot, you can choose what to include on the plot, to show width and/or depth by selecting the relevant checkboxes on the Configuration window.

AM Plot Type: Thermal Gradient vs. Solidification Rate

This topic describes 2D and 3D versions of plots comparing *thermal gradient* to *solidification rate* along the liquid isotherm. Both the 2D and 3D versions are available with all simulation types (*Steady-state*, *Transient*, *Transient with heat source from Steady-state*, and *Evaporation with Steady-state*).

- The 2D version is accessed on the **Plot Renderer Configuration** window as a tab named **Thermal Gradient vs Solidification Rate**. It is visualized on a tab of the same name on the **Visualizations** window.
- The 3D version is available on the **3D Plot** tab on the **Configuration** (settings) window. It is further visualized on two **3D Plot** tabs on the **Visualizations** window.

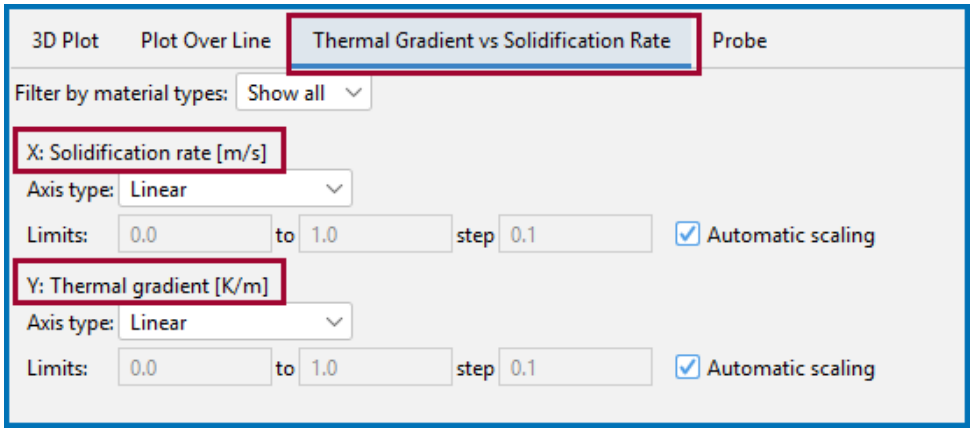
AM_10: CET Transition in an IN718 Alloy includes an example of this plot in both 2D and 3D.

2D Plot

The 2D version of this plot is available on the **Thermal Gradient vs Solidification Rate** tabs on both the **Configuration** (settings) and **Visualizations** window.

You do not need to configure anything on the **AM Calculator** to access the 2D plot.

On the **Thermal Gradient vs Solidification Rate** tab on **Plot Renderer Configuration** window you can adjust the settings for the **Solidification rate** (X-axis) and **Thermal gradient** (Y-axis).



As you adjust settings, watch it dynamically change on the **Visualizations** window. The plot is on the tab of the same name (**Thermal Gradient vs Solidification Rate**). You can switch between the plot and a table format using the **Table View** button.

AM Plots: Table View Options

This uses example AM_10.

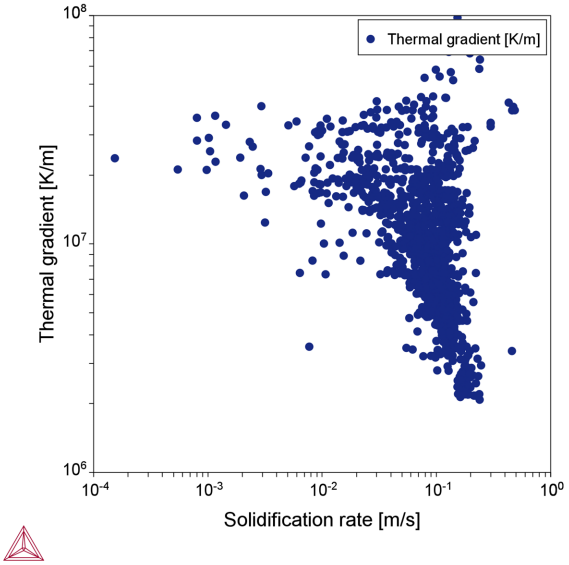


Figure 41: The solidification rate vs thermal gradient is shown on the AM Thermal Gradient & Solidification Rate Plot Renderer.

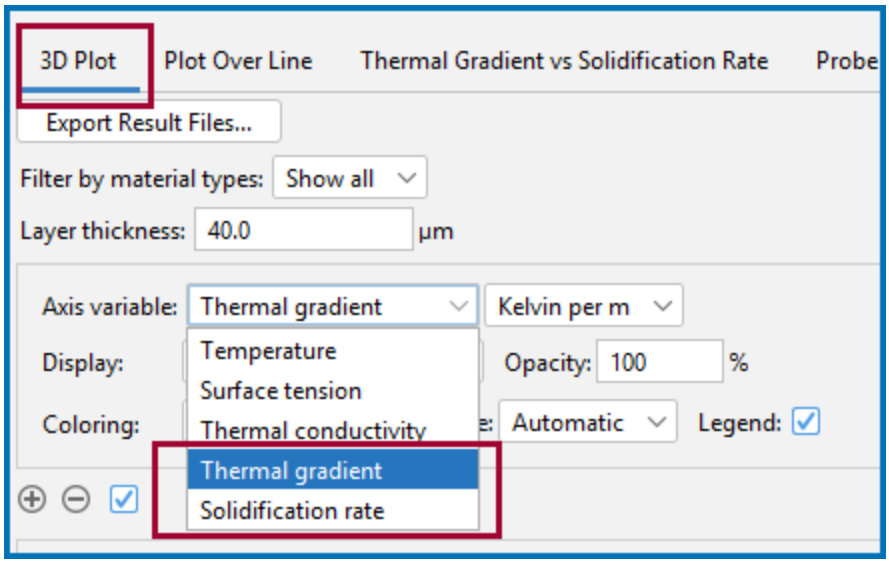
3D Plot

The 3D version of this plot is available on the **3D Plot** tab on the **Configuration** (settings) window. You choose **Solidification rate** and **Thermal gradient** as the **Axis variable**. Use the and buttons as usual to add and remove quantities.



On the **Visualizations** window the comparisons for the different calculation types and variable combinations are plotted on two **3D Plot** tabs.

AM Calculator: Plot Renderer Settings

Once you have added an AM Calculator, you can add the specialized **Plot Renderer**. The following is information about the settings available for a **Plot Renderer** when it is a successor to an **AM Calculator**.

Learn More

The settings listed below are made available based on a variety of combinations, e.g. the type of *simulation* (**Steady-state**, **Transient**, **Transient with heat source from Steady-state**, or **Evaporation with Steady-state**), whether *fluid flow* or the *keyhole* checkboxes are selected, whether *probes* are used, and so on. There are also *Calculation Types* (**Single Point**, **Heat Source Calibration**, **Batch**, and **Grid**), that impact the settings shown, and these options are further included on separate tabs (i.e. **Batch**, **Grid**, **Heat Source Calibration**, **3D Plot**, **Plot Over Line**, **Thermal Gradient vs Solidification Rate**, **Composition History**, etc.), which are further fine-tuned based on the *plot types* or *display types* selected on the **Plot Renderer**.

The software guides you by only providing the relevant settings to define. Due to the number of settings available, these are not in order as to what you see on the **Configuration** window. Where relevant or logical, settings are grouped together and some detail of when or how you would access the setting is included. Scroll or search for the setting or field name as there are many simulation, calculation, display options, and plot type combinations that are available on the relevant tab on the **Plot Renderer Configuration** window.

About the AM Plot Types and Working with AM Visualizations

General

Add a Quantity and Remove a Quantity or Function Buttons

Use the **Add quantity** or **Add function** and **Remove quantity** or **Remove function** buttons to add additional setting groups that include all of the available settings. Click the checkbox next to these buttons to enable or disable any particular settings group.

Show Table or Hide Table

These buttons are available on the **Batch** or **Grid** tabs after running either a **Batch** or **Grid** calculation, respectively.

Use the **Show Table** or **Hide Table** buttons to view the simulation data and using the table you can fine tune the plot. Also see Visualizing Batch Calculations in the AM Module for more information about the columns in the table.

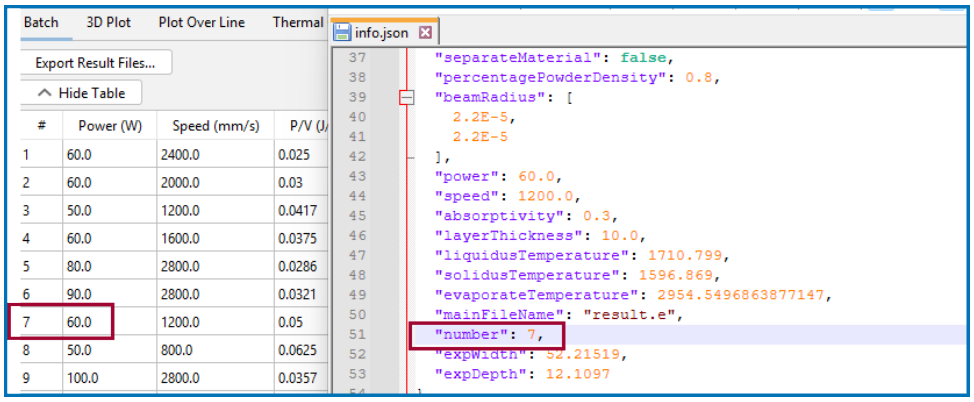
Export Result Files

This option is available on the **Plot Renderer Configuration** window for the following tabs (and the associated plots that are available for each): **3D Plot**, **Grid**, **Batch**, or **Heat Source Calibration**. The button is available after the simulation is run.

Click **Export Result Files** to export the files and visualize the results in external software. The result file(s) in Exodus format (`*.e`) and the json file info `.json` are copied to the folder selected. The json info file contains the settings and results from each data point. You can open the json info file in a text reader (i.e. Notepad) to review it before using the Exodus file in the external software.

When exporting from the **Grid**, **Batch**, and **Heat Source Calibration** tabs, the results are saved in separate subfolders, each containing the `.e` and `.json` files. The Exodus file format is used for finite element analysis.

The folders containing the sets of results files are exported in random order. To match the folder to the original datapoint, open the json file in a text editor. In this file there is a `number` field that matches the row (experiment) number in the table found on the **Plot Renderer Configuration** window for the applicable tab (click **Show Table**). You can use this to match the folder contents back to the datapoint as needed.



In the **Export Result Files** window, in the **Folder Name** field, navigate to the location or enter a file path to where you want to save the files. Create a new folder as needed. Click **Save**. The individual exported files in each folder are named `info.json` and `result.e` and can be used in external software. When there are multiple subfolders (i.e. for Grid, Batch and Heat Source Calibration) the number of folders exported is the same as the number of rows of data selected to be used. If the **Use** checkbox is not selected, the result folder (and files) for that data point is not exported. Click the **Show Table** button to review the rows of data and choose to include or exclude data points from the **Use** column.

Filter by Material Types

This option is available when **Use separate material properties for powder** is selected on the **AM Calculator**.

Select **Filter by material types** to visualize specific material types from the list.

Layer Thickness

Enter a **Layer thickness** in µm. The printed layer thickness is equal to the powder thickness first after multiple layers have been printed. For a single track, or a few layers, the printed layer is often much less than the powder thickness.

Table View

Click the **Table View** button to toggle it ON and OFF between a plot and a table.

AM Plots: Table View Options

Transient-related Simulations

Time

Once a **Transient** simulation plot is calculated, the **Time** step results are listed in a drop-down list. You can choose to look at a specific time point, or click the buttons to the right of the drop-down to navigate the time steps. Hover over the buttons to see the tooltips or see Time Step Navigation Buttons.

Time Step Navigation Buttons

Button	*Action*
⏮	Move to the first time step
◀	Move to the previous time step
▶	Play from the current time step to the last one
▶	Move to the next time step
⏭	Move to the last time step

Rescale Plotting Data Range Over All Time Steps

This is available for **Transient** simulations.

Select the **Rescale plotting data range over all time steps** checkbox to scale min and max values of legends and plots over all time steps.

Axis Variables and Display Options

Axis Variable

Set the state variable you want plotted along the X-axis and the Y-axis. The available variables in the list are based on how your system is set up and options vary.

Choose an **Axis variable** and an applicable unit (indicated in the brackets) from each of the drop-down lists.

- **Solidification rate** (m/s, mm/s, µm/s, or nm/s)
- **Surface tension** (Joule per m^2 or Millijoule per m^2)
- **Temperature** (Kelvin, Celsius, or Fahrenheit)
- **Thermal conductivity** (unitless)
- **Thermal gradient** (Kelvin per m)
- Available when the **Fluid flow including Marangoni effect** checkbox is selected:
  - **Dynamic viscosity** (Pascal-second, milliPascal-second, Poise, or centiPoise)
  - **Flow velocity field** (m/s, mm/s, µm/s, or nm/s)
- Available with **Evaporation with Steady-state** simulations:
  - **Composition**
  - **Composition change**
  - **Evaporation flux**
  - **Lack of fusion porosity**

Display

Based on the **Axis variable** selected, choose the way to **Display** it.

- **Surface colormap**, **Contour**, or **Iso-surface**. For Surface colormap and Contour, you can also click to select the **Slice** checkbox.
- For **Flow velocity field**, choose the object shape to display velocity vectors: **Arrow**, **2D glyph**, **Cone**, or **Line**.

The settings are further described below.

Tubes

Available for display type **Contour**.

The **Tubes** checkbox is selected by default and this displays contour plots as 3D tubes. Click to clear the checkbox and instead display the contours as 2D lines.

Values

Available for display types **Contour** and **Iso-surface**. For Iso-surface you can also specify the opacity of surface plot in %.

Choose the **Values**: **Automatic** (the default), **Custom values**, **Custom range**, **Solidus**, **Liquidus**, or **Solidus and Liquidus**.

- For **Automatic**, enter the **Number of steps**.
- For **Custom values** enter a number in the field.
- For **Custom range** enter the **Min** and **Max** number of lines, then **Number of steps**.
- Select **Solidus** to plot contour/iso-surface at solidus temperature.
- Select **Liquidus** and **Solidus and Liquidus** to plot contour/iso-surface at both solidus and liquidus temperatures.

Some settings are further described in separate sections below.

Number of Steps

Available for **Contour** and **Iso-surface** Display types, and when **Automatic** or **Custom range** Values are selected.

Enter or choose the **Number of steps**.

In some cases for a **Custom range** selection, you need to expand the Configuration window to the right to access this setting.

Opacity

Available for **Surface colormap** and **Iso-surface** (available for all **Values** options).

Enter a value between 0-100 as the percent (%) of **Opacity**.

Slice

This is available for display types **Surface colormap** or **Contour**. Not available for all Axis variables.

Select the **Slice** checkbox to visualize the **Axis variable** on a cross-sectional plane. You can choose the normal of the cross-sectional plane and the distance of the plane from the center of the heat source.

Then choose **X-direction**, **Y-direction**, or **Z-direction**, for the **Distance from center of heat source** and for the **beam radius**.

Coloring and Range

Choose **Rainbow**, **Cool to warm**, **Purple Orange**, **Green Purple**, **Blue Brown**, **Green Red**, **Grayscale**, or **Solid color**.

For all but **Solid color**, choose a **Range**—**Automatic** or **Custom**. Then for **Custom** enter a **Min** and **Max** number.

Legend

Click the **Legend** checkbox to include or click to clear to exclude a legend.

Scale Glyph by Velocity Magnitude

This setting is for a **Flow velocity field Axis variable**. It is available for all **Display** types.

Select the **Scale glyph by velocity magnitude** checkbox to scale the velocity display object (glyph) according to the velocity magnitude. Otherwise the glyphs are scaled uniformly.

Glyph Scale Factor

This setting is for a **Flow velocity field Axis variable**.

Enter a numerical value for the **Glyph scale factor**.

Show Glyph in Every

This setting is for a **Flow velocity field Axis variable**.

For the **Show glyph in every setting**, enter or select the number of grid **points** where velocity glyphs are displayed.

2D Plot Types

You can plot the material properties (2D) so you can specify the quantities and add as many lines as you want directly to the plot in the **Visualizations** window. What you see is **Distance vs Temperature**, first is first layer, second is second layer, and so forth on the 2D plots. You can select the different times from the list at the top at different points and see it on the plot, for example it might be at 26 minutes where you can see it is as the peak of the melt pool max temperature.

Show Transition Temperatures

Available with 2D plot types, such as **Probe** or **Plot Over Line**. It is a dynamic list that updates the plot in the **Visualizations** window after the 2D plot is performed.

Select the different options to better visualize the transition temperature results. From the **Show transition temperatures** list, choose **Solidus, Liquidus, Evaporation**, **Solidus**, **Liquidus**, **Evaporation**, **Custom**, or **None**. For **Custom**, also enter a specific temperature value in the field. Then observe the changes on the plot, where the legend updates and the lines for each option are added or removed based on the selection.

Grid Calculations (Grid, 3D Plot, and Plot Over Line Tabs)

These settings are specific to **Grid** calculations and are on the **Grid** tab. Also see plot related settings: Melt Pool vs Energy Density Plot Type (Batch and Grid Tabs) and Printability Map Plot Type (Batch and Grid Tabs).

Grid Data

This is available on the **3D Plot** and **Plot Over Line** tabs after running a **Grid** *Calculation Type*.

The data in the **Grid data** list shows all the power and scan speed combinations and it is sorted in order of energy density.

Grid Calculation Table

The following is on the **Grid** tab after a **Grid** calculation.

Use the **Show Table** or **Hide Table** buttons to view the simulation data and using the table you can fine tune the plot. The table includes these columns:

- The **Power (W)** and **Speed (mm/s)** columns are the from what was entered under *Grid Definitions*, on the **AM Calculator** i.e. the **Min**, **Max**, and **Number of steps**.
- The **P/v (J/mm)** column is the automatically calculated energy density, defined as the ratio of power and scanning speed.
- The calculated width and depth points, with the prefix **Sim.**, i.e. **Sim.width (µm)** and **Sim.depth (µm)**, to indicate it is the result of the simulation.
- The **Use** column has a checkbox available to include or exclude these points on the plots. When a **Use** checkbox is not selected, the results are also not included if you choose to export the result files. See Export Result Files.

Batch Calculations

These settings are specific to **Batch** calculations. Also see plot related settings: Parity Plot (Batch Tab), Melt Pool vs Energy Density Plot Type (Batch and Grid Tabs), and Printability Map Plot Type (Batch and Grid Tabs).

After the **Batch Experiment Data** set up is completed on the **AM Calculator** and the simulation run, then on the **Plot Renderer** you can start to work with the data you want to plot. Also see Including or Excluding Data Points to understand the interaction between these two tables.

Batch Experiments

Plot Renderer → 3D Plot, **Plot Over Line**, and **Thermal Gradient vs Solidification Rate** tabs after running a **Batch** *Calculation Type*.

The data in the **Batch Experiments** list shows all the power and scan speed combinations and it is sorted in order of energy density.

Batch Calculation Table

Plot Renderer → Batch tab.

You may have already included or excluded data points earlier when previewing the data. Use the **Show Table** or **Hide Table** buttons to view the included or excluded data and continue to fine tune the plot.

On the **Batch** tab the table includes these columns:

- The original experiment data for **Power (W)** and **Speed (mm/s)**, plus the **P/v (J/mm)**.
- The original experiment data for **Width** and **Depth**, now with a prefix **Exp.** e.g. **Exp.width (µm)**, to indicate this is the experimental data.
- The calculated **Width** and **Depth** points, with the prefix **Sim.**, e.g. **Sim.width (µm)**, to indicate it is the result of the simulation.

> Only the experiment data points selected for inclusion when setting up the AM Calculator have data in these two **Sim.** columns.

- The **Use** column has a checkbox available to continue to include or exclude those points on the plots. When a checkbox is not selected, the results are also not included if you choose to export the result files.

> Only points that were originally included in the simulation can be selected or deselected from the **Use** column. If an experiment data point needs to be added, return to the AM Calculator, choose the point (s) to include there, and run the simulation again. Once the simulation is complete, the points are included in this table.

Parity Plot (Batch Tab)

The following settings are available on the **Batch** tab when a **Parity plot** is selected as the plot type.

Plot Width and Plot Depth

Click the **Plot width** and **Plot depth** checkboxes to toggle between displaying these points on the associated tab on the **Visualizations** window for the plot.

Show Limits

Select the **Show limits** checkbox to include additional visual cues on the plot. Choose **RMS**, **Absolute**, or **Relative in %**. For **Absolute** or **Relative in %** enter a number in the field. The plot dynamically updates as you toggle between these options.

Melt Pool vs Energy Density Plot Type (Batch and Grid Tabs)

The following settings are available on the **Batch** or **Grid** tab when a **Melt pool vs energy density** is selected as the plot type.

Plot Width and Plot Depth

Click the **Plot width** and **Plot depth** checkboxes to toggle between displaying these points on the associated tab on the **Visualizations** window for the plot.

Printability Map Plot Type (Batch and Grid Tabs)

The following settings are available on the **Batch** or **Grid** tab when a **Printability map** is selected as the plot type and after running a **Batch** or **Grid** calculation, respectively. The example used in the images is AM_08a.

Show Result Points

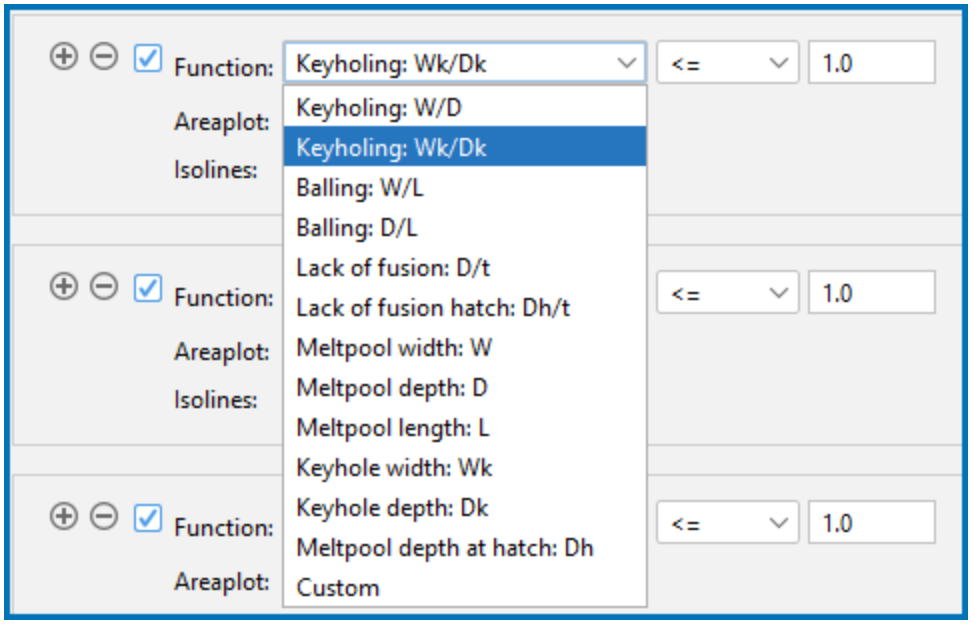
Select or deselect the **Show result points** checkbox to toggle these on and off on the **Visualizations** window. The plot updates dynamically.

Hatch Distance

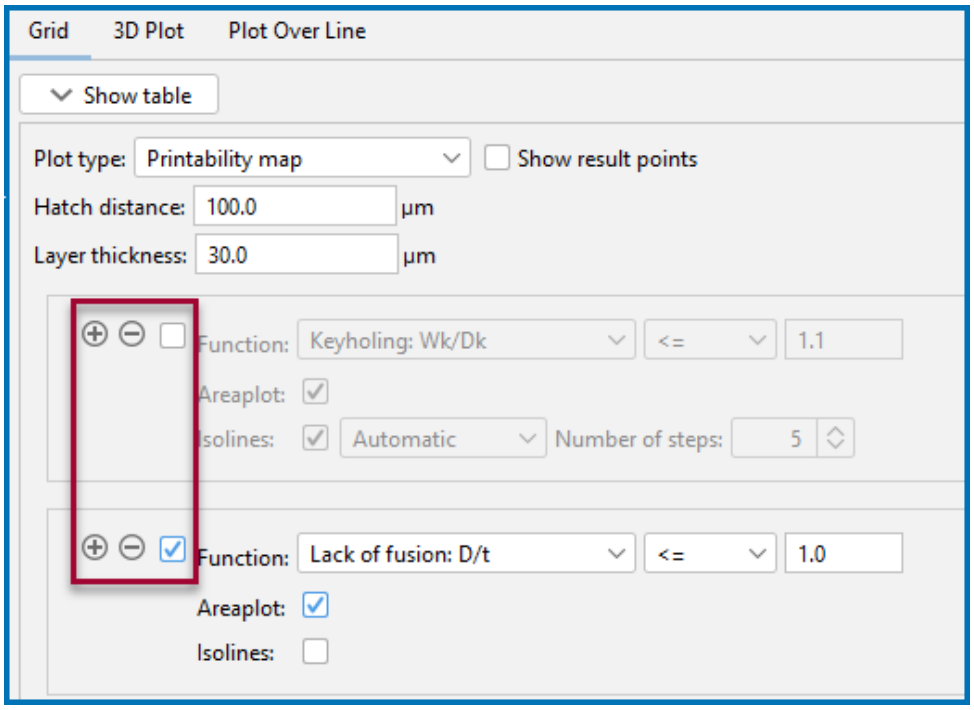
Enter a **Hatch distance** in µm.

Function

Printability maps with varied power and scanning speeds can be simulated showing regions where the defects keyholing porosity, lack of fusion, and balling occur. The defect regions are defined by functions of the keyhole dimension (**Wk**, **Dk**), melt pool dimensions (**W**, **D**, **L**), hatch distance (**h**), and powder thickness (**t**). Use the ⊕ plus and ⊖ minus buttons to add and remove sections to define each **Function**.



Click to toggle the **Function** checkbox to show and hide the selected functions as needed on the **Visualizations** window.



From the list select one of the following for each section added then for each choose **All**, **<=** (less than or equal to), or **>=** (greater than or equal to) and enter a number in the field associated field. On the **Visualizations** window, there are numbered labels to indicate experiments with defects, in **red** , or without defects, in **green**.

- **Keyholing: W/D**
- **Keyholing: Wk/Dk**
- **Balling: W/L**
- **Balling: D/L**
- **Lack of fusion: D/t**
- **Lack of fusion hatch: Dh/t**
- **Meltpool width: W**
- **Meltpool depth: D**
- **Meltpool length: L**
- **Keyhole width: Wk**

- **Keyhole depth: Dk**
- **Meltpool depth at hatch: Dh**
- **Custom**. Then enter a **Name** in the field.

Areaplot

Click the **Areaplot** checkbox to toggle between including the colored sections on the plot.

Isolines

Click the **Isolines** checkbox to include or exclude isolines.

Choose **Automatic**, **Custom**, or **Custom values**.

- For **Automatic**, enter the **Number of steps**.
- For **Custom**, enter the distance between lines i.e. `1.0 1.25 1.5`.
- For **Custom values**, enter a **Min**, **Max**, and **Number of steps**.

Heat Source Calibration Calculations

See AM Calculator Conditions Settings and Visualizing Heat Source Calibrations for more detailed information.

Heat Source Calibration Experiments

Plot Renderer → 3D Plot and **Plot Over Line** tabs after running a **Heat Source Calibration** *Calculation Type*.

The data in the **Heat Source Calibration Experiments** list shows all the power and scan speed combinations and it is sorted in order of energy density.

Heat Source Calibration Table

Plot Renderer → Heat Source Calibration tab.

Click the **Show Table** or **Hide Table** buttons to view or hide the experimental and simulation data. To fine-tune the choice of data points, click the checkbox for the **Use** column for each row (experiment #) to observe the dynamic changes on the **Heat Source Calibration Parameters** and/or **Melt Pool Dimensions** tabs on the **Visualizations** window.

Experiment data and other settings must be configured for this to be available. The data points available in the table are selected on the **AM Calculator** under *Experiment Data* and then you can include or exclude points by selecting or deselecting the relevant checkboxes in the **Use** column.

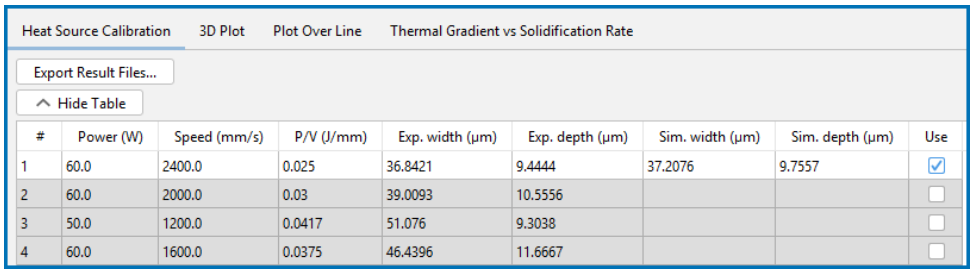
On the **Heat Source Calibration** tab (Plot Renderer) the table includes these columns:

- The original experiment data for **Power (W)** and **Speed (mm/s)**, plus the energy density **P/v (J/mm)**.
- The original experiment data for **Width** and **Depth**, now with a prefix **Exp.** to indicate this is the experimental data, e.g. **Exp. width (µm)**.
- The calculated **Width** and **Depth** points, with the prefix **Sim.** to indicate it is the result of the simulation, , e.g. **Sim. width (µm)**.

Only the experiment data points selected for inclusion when setting up the AM Calculator have data in these two **Sim.** columns.

- The **Use** column has a checkbox available to include or exclude those points on the *Heat Source Calibration Parameters* and *Melt Pool Dimensions* tabs on the **Visualizations** window. Furthermore, if a simulation is not used in a fit, the results from that simulation are not included to generate functions for **Heat Source Calibration** parameters.

Only points that were originally included in the simulation can be selected or deselected from the **Use** column. If an experiment data point needs to be added, return to the AM Calculator, choose the point (s) to include there, and run the simulation again. Once the simulation is complete, the points are included in this table.



#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp. width (µm)	Exp. depth (µm)	Sim. width (µm)	Sim. depth (µm)	Use
1	60.0	2400.0	0.025	36.8421	9.4444	37.2076	9.7557	☑
2	60.0	2000.0	0.03	39.0093	10.5556			☐
3	50.0	1200.0	0.0417	51.076	9.3038			☐
4	60.0	1600.0	0.0375	46.4396	11.6667			☐

Figure 42: From example AM_06a, the Heat Source Calibration tab on the Plot Renderer for a double ellipsoidal heat source calibration for the double ellipsoidal heat source calculation. Here experiment from row #1 is included in the simulation as indicated by the white row and the check mark in the Use column. Rows 2-4 were not included in this simulation and are greyed out. When a checkbox is not selected, the results are also not included if you choose to export the result files.

Heat Source Parameters

Plot Renderer → Heat Source Calibration tab.

These are the parameters you choose on the **Plot Renderer Configuration** window. There is also a **Heat Source Calibration Parameters** tab on the **Visualizations** window that is used in combination with the table to choose data points.

The heat source parameters available to plot for each *Heat Source* type (i.e. *Gaussian*, *Double ellipsoidal*, or *Conical*) selected on the **AM Calculator**:

- *Gaussian*: **Beam radius**. Then based on the **Absorptivity** setting—**Calculated (prefactor calibrated)** or **Constant (calibrated)**—also **Absorptivity prefactor** plus additional options.
- *Double ellipsoidal*: **Absorptivity**, **ar**, **af**, **b**, and **c**
- *Conical*: **Absorptivity**, **re**, **ri**, and **H**.

There is more information about using these parameters in AM Calculator Heat Source Settings.

For all heat source parameters, you can also choose to select:

- A **Constant function** value i.e. the average value from all experiments or a function of energy density, which could also be a **Linear function**, **Cubic function**, or a **Sigmoid function**.

- A **2d cubic function P and v** of *Power* (P) and *Scanning speed* (v).
- For extrapolating outside the range of energy density as given from the experimental data, select a **Constant** value, **Extrapolate linear**, or choose **Extrapolate** for extrapolation using the same function as chosen for interpolation.
- Set the range of energy density to interpolate the heat source parameters by entering the appropriate values in the **Below P/v** and **Above P/v** fields.

There are **R2** values (the coefficient of determination) included that say how well the selected function fits the data. R2 ranges from zero to one, where `1` is a perfect match. E.g. A linear function between two points.

Once all the parameter adjustments are made, you can also retain this information for future reuse (click **Save As** or **Save**). You can also **Rename** or **Delete** these from the list as needed.

The name of the file defaults to using the *Heat Source type* + the *material type*. For example, Double ellipsoidal - 316L, or Gaussian - 316L.

Composition History

This plot type is available with the **Evaporation with Steady-state** simulation type and is found via **Plot Renderer → Composition History** tab.

Choose a plot quantity.

- **Track composition change**
- **Track composition**
- **Composition of Gas phase**: This shows the composition of the Gas phase for each element of the selected alloy as a function of temperature.
- **Last track composition change**

Then for all plot quantities, select **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**. From the last list, select **All** (the default) to include all components, or click to select a specific component from the list.

For **Last track composition change**, also enter **Experimental composition change** data for all the components and include the **Error**.

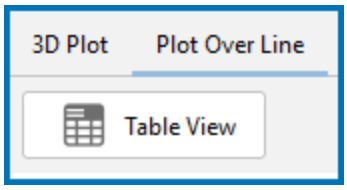
AM Plots: Table View Options

There are ways to view AM plot results as a table on either the **Configuration** or **Visualization** windows for various plots and calculation types.

2D Plots

For 2D plots (**Plot Over Line**, **Probe**, and **Thermal Gradient vs Solidification Rate**), and once the plot is performed, you can switch between a plot and a table by clicking the **Table View** button on the **Visualizations** window.

These plots are available with all calculation types (*Steady-state*, *Transient*, and *Transient with heat source from Steady-state*) simulations.



Batch and Grid Plots

For *Steady-state***Batch** and **Grid** calculations, the available plots **Printability map**, **Meltpool vs energy density**, and **Parity plot**, can also be viewed as a table.

Once the plot is performed, you can toggle to between **Show Table** and **Hide Table** on the **Configuration** window.

Working with AM Visualizations

The AM Calculator visualization using the Plot Renderer is different from the other Calculators available in Thermo-Calc. This topic gives an overview of such differences.

How the Project Nodes are Connected to the Configuration and Visualizations Tabs

The following examples use a mix of adding an AM template and example AM_01 to provide an overview of how the nodes in the **Project** window are connected to the **Configuration** window settings tabs and to the different levels of tabs in the **Visualizations** window. Try this yourself either by adding an AM template or open any of the examples and click around to understand how the geometry, heat source calibration (when applicable), and various plots are connected between all the windows.

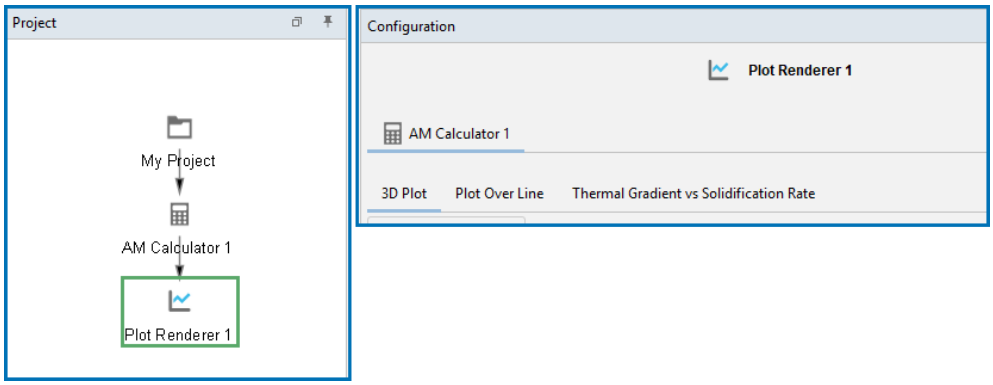
Window Connectivity

- In the **Project** window, the AM Calculator, Diffusion Calculator, and Precipitation Calculator nodes, plus all the associated successor Plot Renderer or Table Renderer nodes, are listed in the **Visualizations** window on the top level tabs using the same name as the node.
- It is recommended you rename the nodes in the Project window to meaningful names that make it easier to navigate the visualizations.
- In the **Visualizations** window, a **Geometry** tab is always associated to the **AM Calculator** node in the Project window. In addition, when a *Heat Source Calibration* calculation is chosen on the **AM Calculator**, there is also a **Heat Source Calibration** secondary level tab associated to this (at the same level as the **Geometry** tab).
- An AM Calculator and all its Plot Renderer successors are listed on the top level tab. The secondary level tab has visualizations related to geometry, heat source calibration, and the available plot types (3D Plot, Plot Over Line, Probe Plot, and the plots associated to heat source calibration).
- The Diffusion Calculator and any Plot Renderer or Table Renderer successors are all listed in the Visualizations window on the top level tab. The secondary level tab has visualizations related to the Composition Profile and Thermal Profile.
- The Precipitation Calculator and any Plot Renderer or Table Renderer successors are all listed in the **Visualizations** window on the top level tab. The secondary level tab has visualizations related to the Thermal Profile.

- The Scheil Calculator is not listed on the top level tab in the **Visualizations** window, but any Plot Renderer or Table Renderer successor for this Calculator is listed on the top level tab.
- Renaming any node in the **Project** window also renames the top level tabs in the Visualizations window.
- The second level tabs on the **Visualizations** window cannot be renamed as these represent the visualization type named by the system e.g. a geometry, plot type (3D Plot, Plot Over Line, Probe Plot, etc.), or a Composition Profile (diffusion simulations) or Thermal Profile (diffusion or precipitation simulations).
- For 2D plots (Plot Over Line 2D Plot, Probe 2D Plot), click the **Table View** button on the applicable tab in the **Visualizations** window to convert the values into a table format.

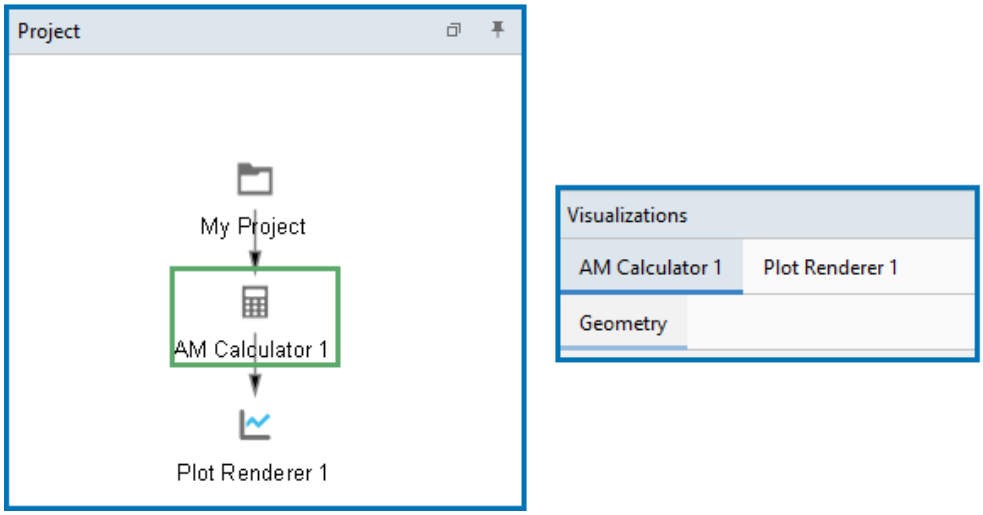
Configuration Window

When a Plot Renderer is added to an AM Calculator in the **Project** window, there are default tabs added to the **Configuration** window where you can further set up the available plot types. In this example, two tabs, **3D Plot** and **Plot Over Line**, are provided for you to set up these plot types.



Visualizations Window

In the **Visualizations** window, the upper tab level is connected to a second level of tabs that represent the available visualizations. A **Geometry** tab is always associated to the **AM Calculator** node. Then for any **Plot Renderer** node, all of the plotting types such as a **3D Plot**, **Plot Over Line**, **Probe**, and **Thermal Gradient vs Solidification Rate** are listed in the secondary tab level.



There is not always something to visualize at the second tab level. Keep an eye on the underlined tabs on both levels, i.e. click the upper level tab and look for the underlined second level tab associated to it and that is what is displayed. Also note that clicking the upper level tabs in the Visualizations window does not change the focus of the node clicked in the Project window, although the opposite is true.

Each node in the **Project** window is represented across the top set of tabs in the **Visualizations** window. Then the associated tab on the **Visualizations** window displays below as a secondary level. For example, in the **Project** window, if you click the AM Calculator node (in AM_01 it is renamed to **Transient, DE HS**), then on the Visualizations window the **Transient, DE HS** tab is highlighted and has a blue underline. On the second tab level, the **Geometry** tab is also underlined to indicate it is associated to the **Transient, DE HS** tab. What is actually displayed in the Visualizations window is based on the second tab.

Then for each Plot Renderer added and defined, the secondary tab level is connected to what is visualized. For example, a Plot Renderer is added to the AM Calculator in the **Project** window. In this case, the node is renamed to **3D plot**. When this node is clicked in the Project window, the **3D plot** tab is highlighted and underlined in the **Visualizations** window.

You can also click each of the top level tabs in the **Visualizations** window at any time to navigate the visualizations, but the node focus in the **Project** window does not change to match.

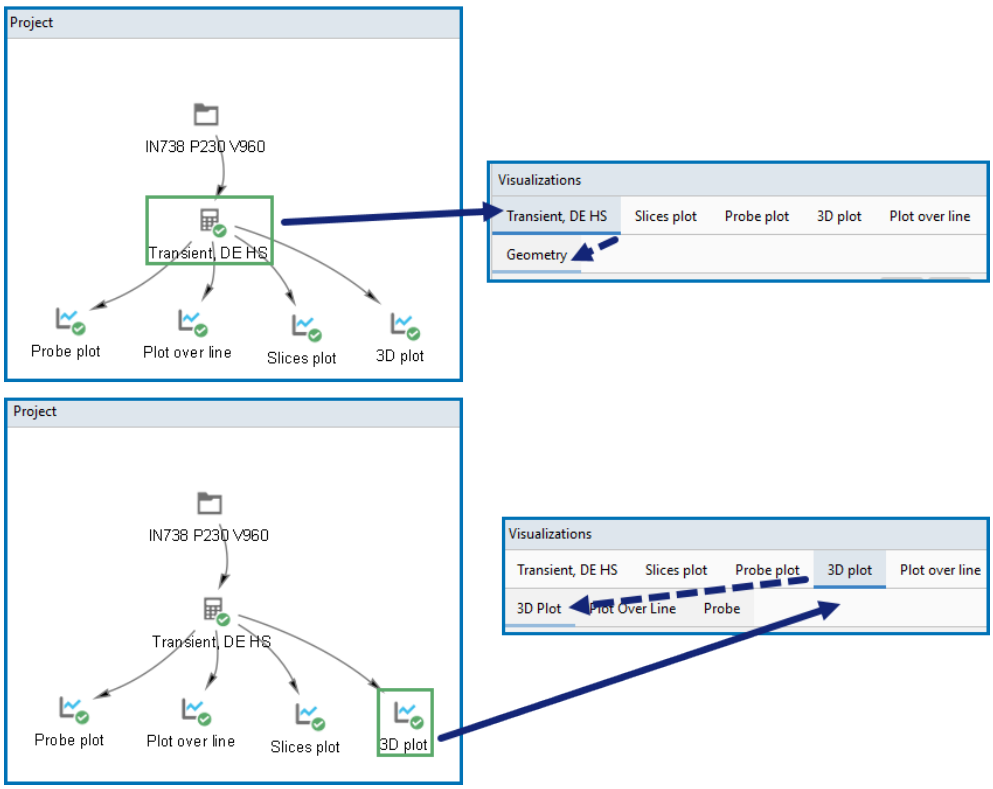


Figure 43: When you click a node in the Project window, the associated tab is highlighted and underlined in the Visualizations window. Then the second level of tabs are further underlined to indicate what is associated to the selected top level tab, and this is what actually displays in the Visualizations window.

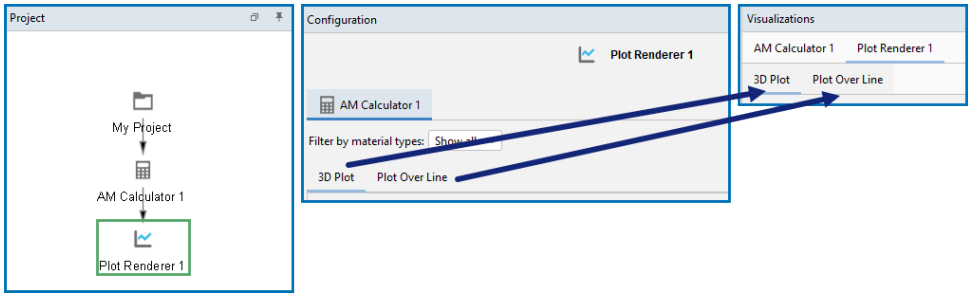


In the **Visualizations** window, the top level tab for Plot Renderer is further connected to the **3D Plot** and **Plot Over Line** tabs. You can determine what you are actually viewing in the Visualizations window based on the upper level highlighted and underlined tab and then further by the second level underlined tab.

Visualizing Heat Source Calibrations

The following is available for a **Steady-state → Heat Source Calibration** *Calculation Type*.

About Heat Source Calibration

During the set up of the **Heat Source Calibration**, experiment data is either entered or imported to the AM Calculator. You can then view the *Heat Source Calibration* on a second level tab in the **Visualizations** window. This is associated to the AM Calculator.

Then once the experiment data is included and the heat source calibration is performed, you can further create plots on the Plot Renderer to examine the *Heat Calibration Parameters* and *Melt Pool Dimensions*.

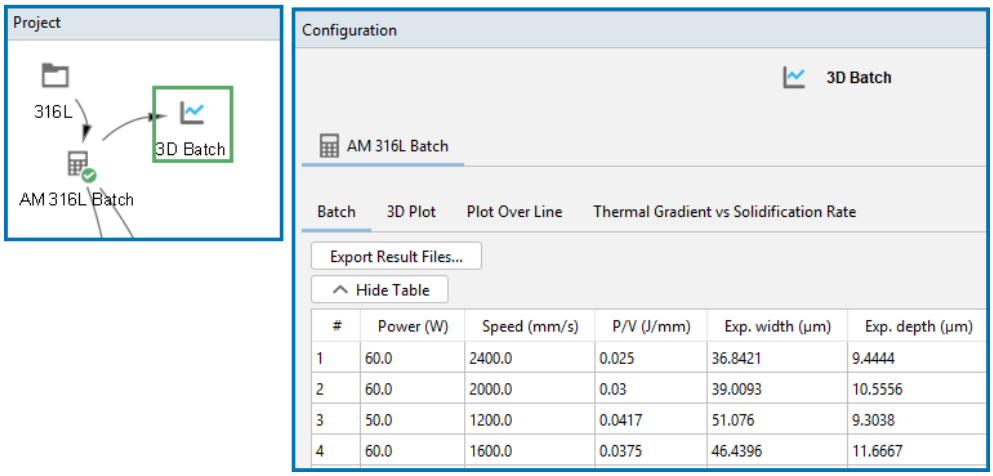
More details about this are described in a separate topic. See Visualizing Heat Source Calibrations.

Visualizing Batch and Grid Calculations

The following is available for a **Steady-state → Batch** or **Grid***Calculation Type*.

Results from **Steady-state** simulations using **Batch** or **Grid** calculations contain multiple steady-state results, one for each power and scan speed. The results can be visualized individually using a **3D Plot** and **Plot Over Line** (described above). The combined result from all steady-state simulations can additionally be visualized from the **Batch** tab (available on the **Plot Renderer Configuration** window after the **Batch** calculation), and similarly from the **Grid** tab after a **Grid** calculation. On these tabs you choose additional plot types **Printability map**, **Parity plot**, and **Melt pool vs energy density**.

A table of the experimental and calculated values can be viewed when you click to toggle between the **Show Table** or **Hide Table** buttons. The table is displayed in the **Plot Renderer Configuration** window for the relevant **Batch** or **Grid** tab.



#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp. width (µm)	Exp. depth (µm)
1	60.0	2400.0	0.025	36.8421	9.4444
2	60.0	2000.0	0.03	39.0093	10.5556
3	50.0	1200.0	0.0417	51.076	9.3038
4	60.0	1600.0	0.0375	46.4396	11.6667

Figure 44: The simulated and experimental melt pool dimension can also be tabulated for all data using the toggle button to Show Table or Hide Table. This is from example AM_09b.

More details about this are described in separate topics. See Visualizing Batch Calculations in the AM Module and for the various plot settings for a Grid, these are included with the general topic, AM Calculator: Plot Renderer Settings.

There is a video tutorial about the **Printability Map** on our website and on our YouTube channel. It is also included in the Additive Manufacturing Module YouTube playlist.

Learn More

See Plot Types for more information for the Scheil Calculator and Diffusion Calculator, which are also used with the Additive Manufacturing (AM) Module.

About the AM Plot Types

AM Visualizations Window Plot Toolbar

The **Visualizations** window by default has tabs included to help you visualize both the set up using the available Calculators (e.g. AM Calculator, Diffusion Calculator, and Precipitation Calculator) and the results that are calculated via a **Plot Renderer** or **Table Renderer**. For 2D plots, you can also view data by clicking the **Table View** button.

Rotate, Zoom, and Pan 3D Plots: AM Calculations and Working with AM Visualizations

AM Plot Toolbar

Button	*Name*	*Action*
	Zoom to heat source position	Click to zoom to the heat source.
	Set view to 3D	Click to reset the view where you zoom out to see the whole geometry.
	Set view direction to YZ, XZ, or XY	Click to orient to a side view in the • YZ-axes direction. • XZ-axes direction. • XY-axes direction.
	Azimuth rotation, Ctrl+ for invert rotation	Click to rotate around the free axis. Press and hold CTRL + click the mouse to control the direction turned.
	Elevation rotation, Ctrl+ for invert rotation	Click to rotate around the free axis. Press and hold CTRL + click the mouse to control the direction turned.

Button	*Name*	*Action*
	Roll rotation, Ctrl+ for invert rotation	Rotate around the free axis Click Ctl+button to control the direction turned.
	Save camera view angle and zoom level	There are two attributes that are saved when the **Save camera view angle and zoom level** button is clicked. The view angle of the camera and the zoom level. Then when you click the **Apply saved camera view and zoom level** , it mirrors the view angle of the camera and the zoom level. This is available for any 3D plot tab on the Visualizations window. Only one camera position can be saved/retained at any time for use.
	Apply saved camera view angle and zoom level	First use the **Save camera view angle and zoom level** to save the desired view. Then click the **Apply saved camera view and zoom level** button to mirror the view angle of the camera and the zoom level. This is available for any 3D plot tab on the Visualizations window. Only one camera position can be saved/retained at any time for use.
	Show grid	Click to turn on and off the mesh grid.
	Show heat source	Click to show and hide the heat source. This button also toggles displaying the **Heat Source Intensity (W/mm^2)** legend on and off in the plot area.
	Mirror geometry	When in steady state you only see half the geometry. Click to show the whole geometry, click again to show half the geometry.
—	Hide layers	Enter a number of layers to hide.
	Show Outer Box	Click to turn on and off the outer box geometry.
	Show line between powder and solid	Click to turn on and off a line and plane around the powder layer thickness.

Button	*Name*	*Action*
	Show Size of the Melt Pool	Click to show or hide the melt pool. This is the same thing as showing the size of the liquidus isosurface plot. When clicked you also see the measurements in the **Event Log** window and shows on the **Visualizations** window.
	Show Size of Melt Pool plus Mushy Zone	Click to show or hide the melt pool and mushy zone. This is the same thing as showing the size of the solidus iso-surface plot. When clicked you also see the measurements in the **Event Log** window and shows on the **Visualizations** window.
	Show Manual Ruler	Click to use the manual ruler to measure the melt flow. • Double click each time to add the start and end points. • To align a ruler on the x-, y-, or z- axis: Hold CTRL when adding or moving the end point. The ruler snaps to the closest point on the same axis. • To move a ruler: Click and hold a point, then drag to reposition. • Right-click a point to delete it.

Menu or Keyboard Options: Geometry and 3D Plots

When working with the AM Calculator (probes) and its associated Plot Renderer (for 3D Plots), there are menu options or tooltip guidelines available to access certain actions for probes, markers, or to save a snapshot image from the **Visualizations** window.

Plot- and Geometry-related Menus to Save Images

When available, right-click in the **Visualizations** window and choose **Save As** from the menu to save the current view in png, gif, or jpg format. This saves an image snapshot of the 3D Plot or Geometry at the zoom level and angle you are currently viewing.

- Geometry: When setting up probes, you can right-click on the Geometry to save the current view.
- 3D Plot: When working with a 3D Plot, you can right-click anywhere on the 3D Plot to save the current view. This option is only available with AM Calculator 3D plots.

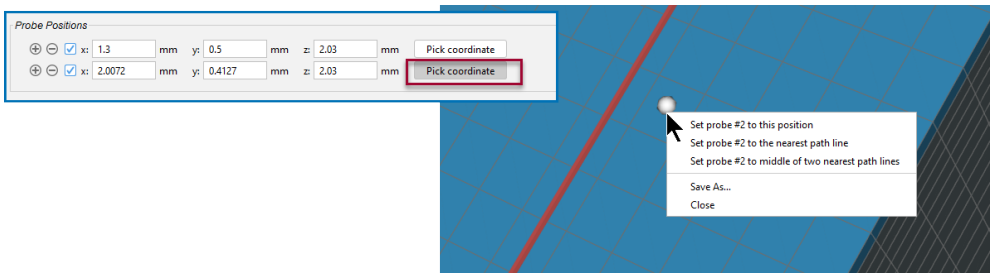
Probe-related Menus and Tooltips

AM Calculator: Working with Probe Data

When you are picking the coordinates for the probe location, there is a menu available when you right-click a point on the Geometry in the Visualizations window. There are also tooltips that can help guide you.

1. On the **Configuration** window for an **AM Calculator**, under *Probe Positions*, click **Pick coordinate**. Hover over the button to view the tooltips with options to:
    a. Double-click on the geometry to pick a coordinate.
    b. Hold the <Ctrl> key and double-click to pick the position at the middle of a layer.
    c. Hold the <Shift> key and double-click to map the picking position with a scanning path.
    d. Hold the <Shift+Alt> keys and double-click to map the picking position to the middle of the scanning path.
2. In the **Visualizations** window on the **Geometry** tab, use one of the methods to add a probe point to the geometry, for example double-click to add a probe.

3. In the **Visualizations** window, right-click to choose an option from the menu associated to the new **Pick coordinate** probe point:
    a. **Set probe to this position**: Sets to the location where the probe is located at the time of selecting.
    b. **Set probe to the nearest path line**: Moves the probe to the path line, which can be where other probes are already set up.
    c. **Set probe to the middle of the two nearest path lines**: This only works if there are two path lines, otherwise the probe does not move.
    d. **Save As...**: Select this to save an image of the current view of the probes (a snapshot at the zoom level chosen). You can save in png, gif, or jpg formats.
    e. **Close** : Closes this menu.

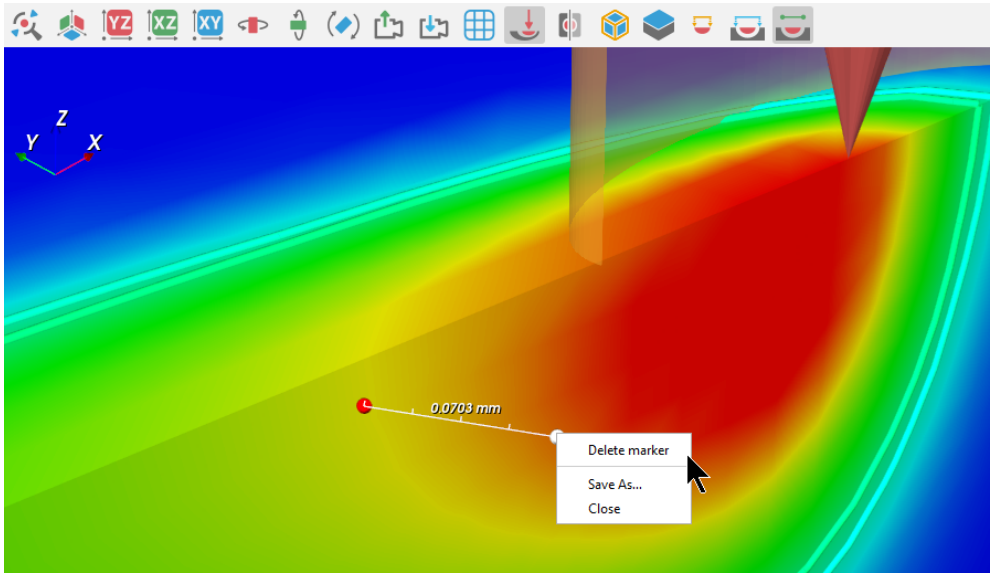


Marker-related Menus and Tooltips for 3D Plots (AM Module Only)

Markers are added to 3D plots in the **Visualizations** window. For example, you are measuring the distance between two points on a heat source.

1. On the **Visualizations** window for an AM Calculator **Plot Renderer** (and after running a **3D Plot**), click the **Show Manual Ruler** button on the toolbar. Hover over the button to view the tooltips with options to:
    a. Double-click each time to add the start and end points.
    b. To align a ruler on the x-, y-, or z-axis: Hold <Ctrl> when adding or moving the end point. The ruler snaps to the closest point on the same axis.
    c. To move a ruler: Click and hold a point, then drag to reposition.
    d. Right-click a point to delete the ruler.
2. Click in the plot area to add markers for the start and end points, for example. Once the marker is on the plot, you can delete it or save an image of the plot at the current view.

- To delete a marker, zoom as close to it as possible and right-click the marker to bring up the menu. Select **Delete marker** from the list. You might have to move the mouse around the area of the marker or zoom further to access the menu options.
- To save an image of the plot at the current view, click anywhere in the plot and select **Save as**. Select this to save an image in png. gif, or jpg format.



Rotate, Zoom, and Pan 3D Plots: AM Calculations

When working with the Additive Manufacturing (AM) Module and the results from an AM Calculator simulation, two general plot types are added to the **Visualizations** window: a *3D plot* and a *Plot over line 2D plot*. The 2D plot has the same functionality as for other calculations but the 3D plot is specific to this Module.

Rotating, Zooming, and Panning the Geometry

In addition to the **Visualizations** window for an AM 3D plot having its own set of buttons (see AM Visualizations Window Plot Toolbar) there are also different ways to work with the 3D plots with respect to rotating, zooming, and panning the geometry around the window.

- In combination with the following actions use these buttons on the toolbar:

  Set View to 3D

  Set View Direction

  .

- **Rotate the geometry** : Left-click and hold the mouse, then move it around the window to rotate in any direction. Hold CTRL + left mouse button to rotate on a specific axis.
- **Zoom in and out**: Scroll the mouse wheel or right-click and move the mouse up and down in the window.
- **Pan the geometry**: Hold Shift + left mouse button then move the mouse up or down, left or right, to move the geometry around the window without zooming.

Go to the Help (press F1 in Thermo-Calc) to view a short video showing the use of these actions.

Overlaying Plots in the AM Module

In general, it is now possible to overlay plots from any Calculator with plots from any other Calculator.

2D plots are overlaid pair-wise which means if you add two or more AM Calculators as a predecessor in one Plot Renderer, similar 2D plots (such as Probe with Probe and Plot Over Line with Plot Over Line, etc.) are grouped and overlaid in one tab on the Visualizations window.

The most important use case is that you can overlay Probe plots from different Transient and Transient with heat source from Steady-state Calculators and Plot Over Line plots from all AM Calculators. Similarly, you can also overlay Meltpool vs energy density and Parity plot from different Batch, Grid, and Heat Source Calibration calculators.

You need to click **Perform** to make plot overlaying work.

It is not possible to overlay two 3D plots. However, when you want to plot two or more variables in a comparable way to overlaying plots in 2D, you use one **Plot Renderer** connected to at least two AM Calculators. Then on the **3D Plot** tab on the **Configuration** (settings) window you choose different quantities from the **Axis variable** list. Use the ⊕ and ⊖ buttons as usual to add and remove quantities. The plots are then viewed on separate **3D Plot** tabs on the **Visualizations** window. After defining the axis variables, click **Perform** to update the plots on the respective **Visualization 3D Plot** tabs. It is also important to rename your AM Calculators in order to better work with these plots.

Visualizing Heat Source Calibrations

This topic describes both the **AM Calculator** and the **Plot Renderer** visualization outcomes related to the heat source calibration calculations for a **Steady-state** simulation.

It is recommended to open and run one of the examples to best understand the wide variety of visualization outcomes.

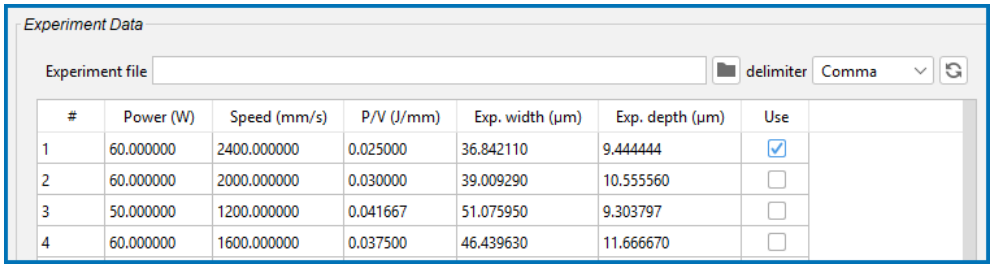
Learn More

AM_06a: Calibrating a Heat Source for a 316L Steel and AM_06b: Using the Calibrated Heat Source for a 316L Steel

To import data for use in batch calculations, it is recommended you review AM Calculator Experiment File Requirements. Also review Working with AM Visualizations, which provides an overview of how most of the windows are connected.

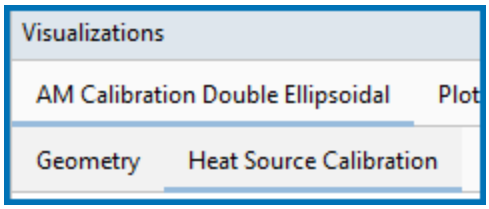
Working with AM Calculator Heat Source Calibration Experiment Data

During the set up of the **Heat Source Calibration**, experiment data is either entered or imported to the **AM Calculator** table where it is visible on its associated **Configuration** window.



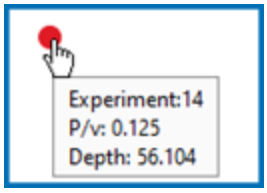
#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp. width (µm)	Exp. depth (µm)	Use
1	60.000000	2400.000000	0.025000	36.842110	9.444444	☑
2	60.000000	2000.000000	0.030000	39.009290	10.555560	☐
3	50.000000	1200.000000	0.041667	51.075950	9.303797	☐
4	60.000000	1600.000000	0.037500	46.439630	11.666670	☐

Click the relevant AM Calculator node in the **Project** window to preview the table data via a **Heat Source Calibration** tab on the **Visualizations** window.



Use the table's **Use** column on the AM Calculator Configuration window to select the relevant checkboxes for which **Width** and **Depth** points to include (i.e. *use*) or exclude (i.e. *not use*).

You can click or hover over any point on the **Heat Source Calibration** preview to display the label, which also includes the corresponding table row (i.e. *Experiment*) number for the point.



On the **Heat Source Calibration** window :

- For this calibration view, **Width** uses blue squares (solid color means used, hollow with same color outline means not used)
- For this calibration view, **Depth** uses red circles (solid color means used, hollow with same color outline means not used)
- The preview shows the energy density (P/v) on the *X*-axis and melt pool dimensions on the *Y*-axis.

Click to select or deselect checkboxes in the table to dynamically watch the selection change on the **Visualizations** window. The points that are selected in this table are used in the simulation results and are later labeled **Exp.Width** and **Exp.Depth** in the Plot Renderer Configuration table (see Figure 47). Then the calculated results are added to new columns labeled **Sim.Width** and **Sim.Depth** in the data table on the Plot Renderer Configuration window (see below).

Sometimes an experiment data point is selected in the table on the AM Calculator but after running the simulation it is not available in the corresponding Plot Renderer table (i.e. it is a greyed out row). This indicates that the calibration could not be calculated for that particular data point.

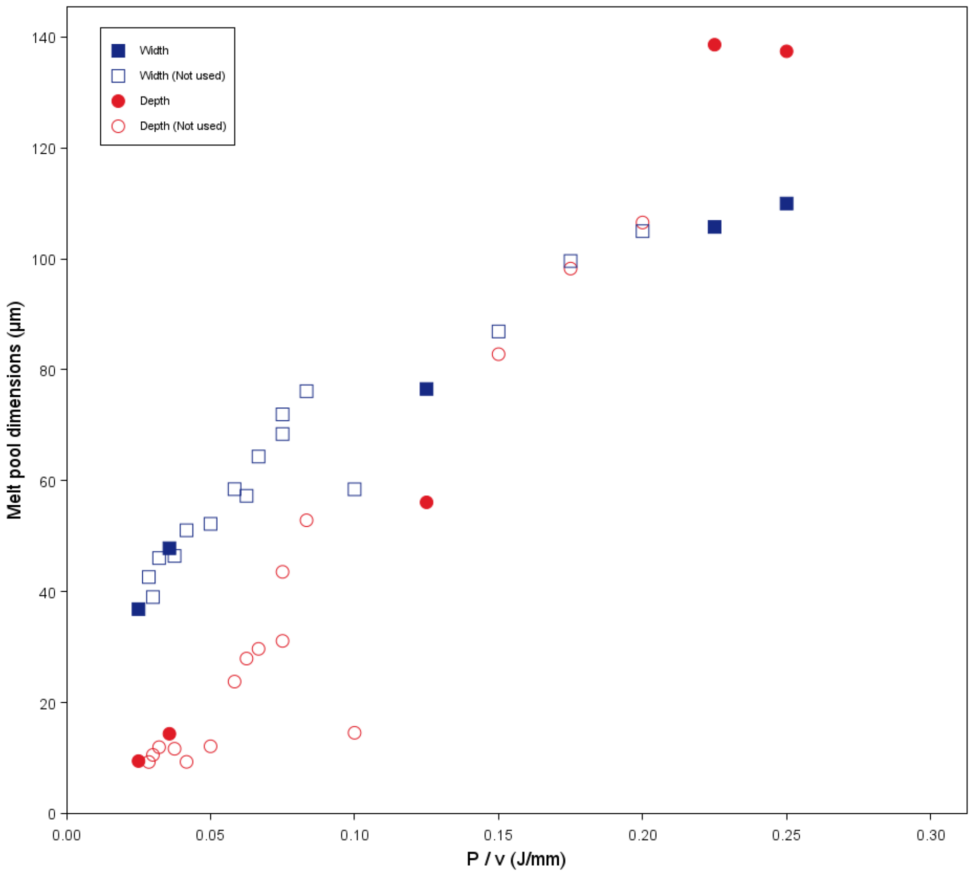


Figure 45: From example AM_06a, this is the heat source calibration preview for the data imported to the AM Calculator node (renamed to AM Calibration Double Ellipsoidal). As per the legend, both "used" (solid color) and "not used" (hollow with outline color) points are included in this preview.

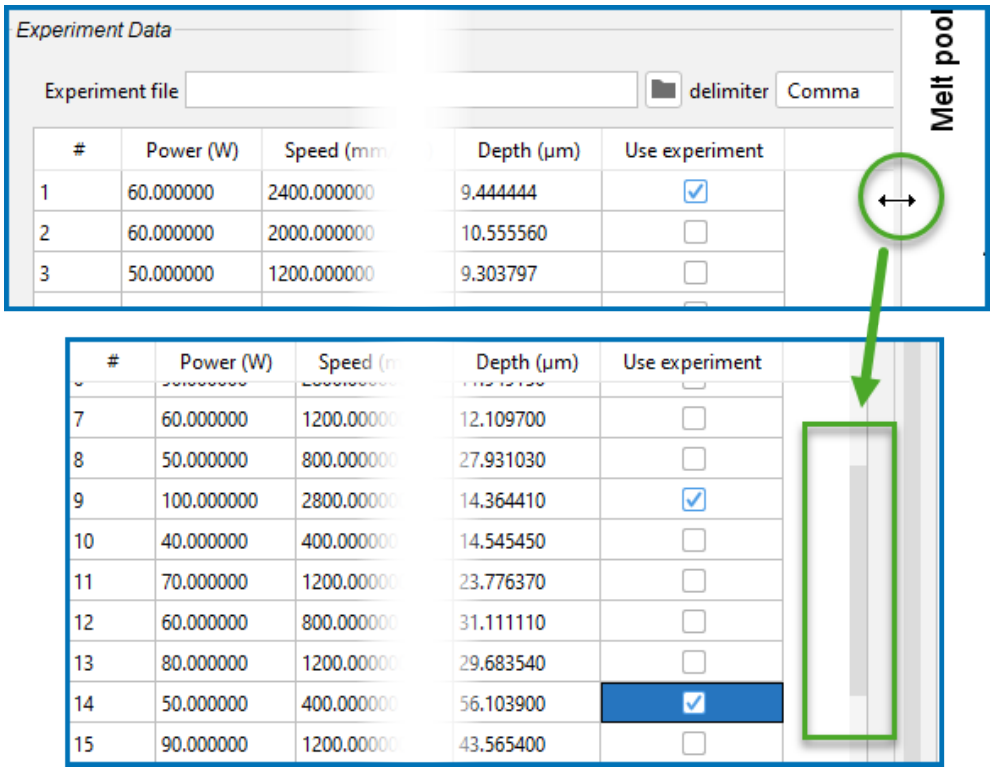
Once a set of data is imported to the table (or entered manually), expand the **Configuration** window to reveal the scroll bars. Then you can scroll up or down, left or right, within the table to select checkboxes for the relevant data points you want to include or exclude. This is applicable to the tables found on the AM Calculator as well as those on the Plot Renderer for the data.



Working with the Plot Renderer for Heat Source Calibrations

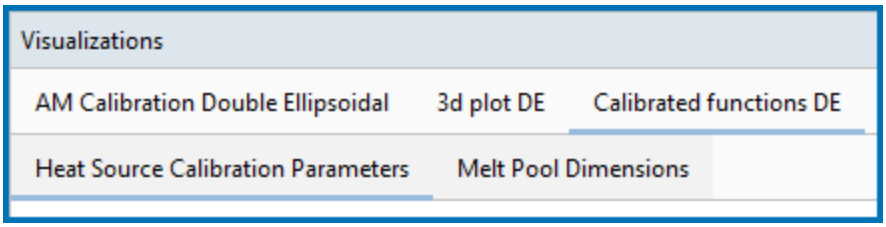
After the calibration is completed on the AM Calculator and the simulation run, then on the **Plot Renderer Configuration** window you can start to use the data.

For additional **Plot Renderer** settings (and other visualization options for plotting) go to AM Calculator: Plot Renderer Settings.

Adding the Heat Source Calibration Plots

1. Add a **Plot Renderer** to the **AM Calculator**.
2. Choose an experiment point from the **Heat Source Calibration** list. The points in this list match the points selected in the **Use** column on the **AM Calculator**.
3. Click **Perform**.

4. Click the **Heat Source Calibration** tab on the **Plot Renderer Configuration** window to (1) view the table of data and (2) view the *Heat Source Calibration Parameters* and *Melt Pool Dimensions* tabs in the **Visualizations** window on the secondary level of tabs. These tabs are where you fine-tune the choice of data points: Click the checkbox for the **Use** column for each row (experiment #) to observe the dynamic changes on the **Heat Source Calibration Parameters** and **Melt Pool Dimensions** tabs on the **Visualizations** window.



Navigating the Heat Source Calibration Table

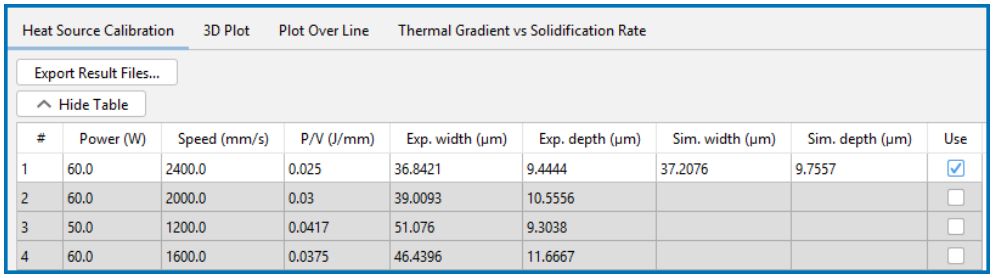
On the **Heat Source Calibration** tab (Plot Renderer) the table includes these columns:

- The original experiment data for **Power (W)** and **Speed (mm/s)**, plus the energy density **P/v (J/mm)**.
- The original experiment data for **Width** and **Depth**, now with a prefix **Exp.** to indicate this is the experimental data, e.g. **Exp. width (µm)**.
- The calculated **Width** and **Depth** points, with the prefix **Sim.** to indicate it is the result of the simulation, , e.g. **Sim. width (µm)**.

> Only the experiment data points selected for inclusion when setting up the AM Calculator have data in these two **Sim.** columns.

- The **Use** column has a checkbox available to include or exclude those points on the *Heat Source Calibration Parameters* and *Melt Pool Dimensions* tabs on the **Visualizations** window. Furthermore, if a simulation is not used in a fit, the results from that simulation are not included to generate functions for **Heat Source Calibration** parameters.

Only points that were originally included in the simulation can be selected or deselected from the **Use** column. If an experiment data point needs to be added, return to the AM Calculator, choose the point (s) to include there, and run the simulation again. Once the simulation is complete, the points are included in this table.



#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp. width (µm)	Exp. depth (µm)	Sim. width (µm)	Sim. depth (µm)	Use
1	60.0	2400.0	0.025	36.8421	9.4444	37.2076	9.7557	☑
2	60.0	2000.0	0.03	39.0093	10.5556			☐
3	50.0	1200.0	0.0417	51.076	9.3038			☐
4	60.0	1600.0	0.0375	46.4396	11.6667			☐

Figure 46: From example AM_06a, the Heat Source Calibration tab on the Plot Renderer for a double ellipsoidal heat source calibration for the double ellipsoidal heat source calculation. Here experiment from row #1 is included in the simulation as indicated by the white row and the check mark in the Use column. Rows 2-4 were not included in this simulation and are greyed out. When a checkbox is not selected, the results are also not included if you choose to export the result files.

Working with the Heat Source Calibration Parameters

Based on the type of heat source selected on the AM Calculator, below the *Heat Source Calibration* table there are additional parameters you can choose to include or exclude from the *Heat Source Calibration Parameters* and *Melt Pool Dimensions* plots.

Once the selection of experiments is made in the **Configuration** window for the **Heat Source Calibration**, you can choose appropriate functions for each heat source parameter including the absorptivity. See Figure 47 for an example of the available parameters for a **Double ellipsoidal** *Heat Source*.

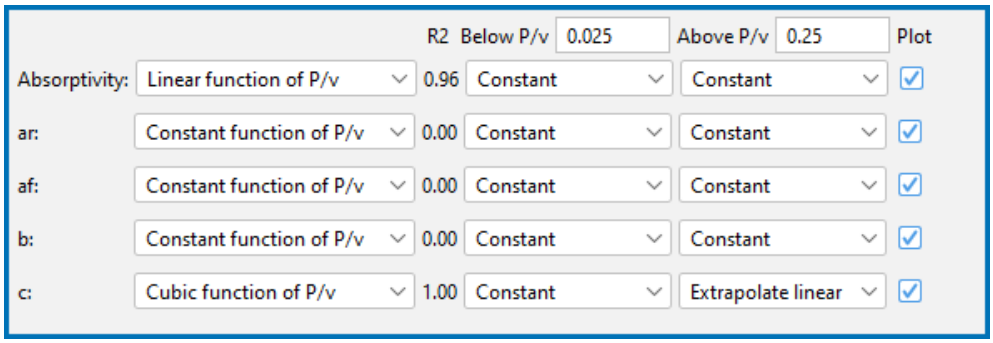


Figure 47: From example AM_06a, these are the available parameters for a double ellipsoidal heat source simulation. The available parameters are based on the heat source chosen on the AM Calculator during set up.

Click to select or deselect the **Plot** checkbox and watch the change on the **Visualizations** window for both the *Heat Source Calibration Parameters* and *Melt Pool Dimensions* plots. There are several options to choose from in this section that each change the plots dynamically.

The heat source parameters available to plot for each *Heat Source* type (i.e. *Gaussian*, *Double ellipsoidal*, or *Conical*) selected on the **AM Calculator**:

- *Gaussian*: **Beam radius**. Then based on the **Absorptivity** setting—**Calculated (prefactor calibrated)** or **Constant (calibrated)**—also **Absorptivity prefactor** plus additional options.
- *Double ellipsoidal*: **Absorptivity**, **ar**, **af**, **b**, and **c**
- *Conical*: **Absorptivity**, **re**, **ri**, and **H**.

There is more information about using these parameters in AM Calculator Heat Source Settings.

For all heat source parameters, you can also choose to select:

- A **Constant function** value i.e. the average value from all experiments or a function of energy density, which could also be a **Linear function**, **Cubic function**, or a **Sigmoid function**.
- A **2d cubic function P and v** of *Power* (P) and *Scanning speed* (v).

- For extrapolating outside the range of energy density as given from the experimental data, select a **Constant** value, **Extrapolate linear**, or choose **Extrapolate** for extrapolation using the same function as chosen for interpolation.
- Set the range of energy density to interpolate the heat source parameters by entering the appropriate values in the **Below P/v** and **Above P/v** fields.

There are **R2** values (the coefficient of determination) included that say how well the selected function fits the data. R2 ranges from zero to one, where `1` is a perfect match. E.g. A linear function between two points.

Once all the parameter adjustments are made, you can also retain this information for future reuse (click **Save As** or **Save**). You can also **Rename** or **Delete** these from the list as needed.

The name of the file defaults to using the *Heat Source type* + the *material type*. For example, Double ellipsoidal - 316L, or Gaussian - 316L.

Visualizations Window

Heat Source Calibration Parameters Plot

A **Heat Source Calibration Parameters** plot shows the calibrated heat source parameters as a function of energy density (P/v) (unit J/mm). From the **Plot Renderer Configuration** window, you can also continue to select which experiments to be used to fit the calibration.

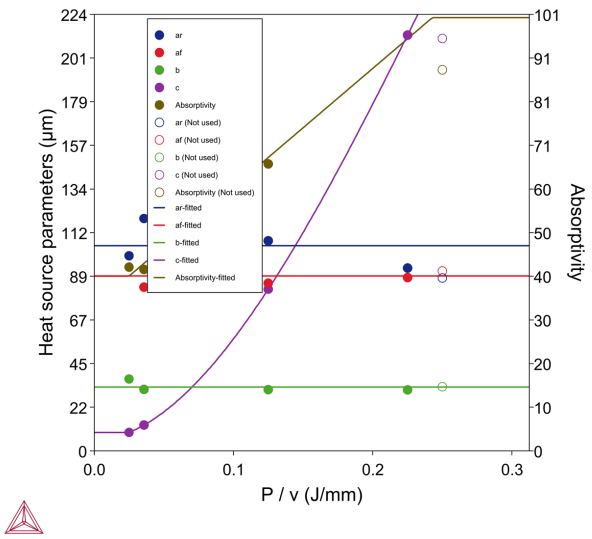

Figure 48: From example AM_06a, the Heat Source Calibration Parameters plot for the double ellipsoidal calibration.

For instance, you can deselect the points that seem to be outliers or where the error bar in experimental data is large.

The selection is done via the checkboxes available in the **Use** column.

Melt Pool Dimensions Plot

A **Melt Pool Dimensions** plot shows melt pool size, both from experiments and simulations, as a function of energy density (P/v). This plot can be used to compare the results from the experiments and optimization simulations.

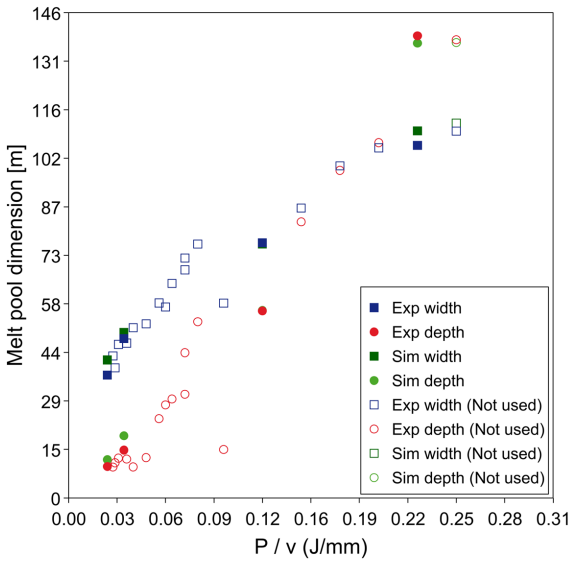

Figure 49: From example AM_06a, the Melt Pool Dimensions plot for the double ellipsoidal calibration.

3D Plot and Plot Over Line

Use a **3D Plot** to visualize all the experiments for which the calibration is performed. To show the 3D plot for a certain experiment, select the corresponding experiment from the **Heat Source Calibration Experiments** menu. The configuration in the **3D Plot** works in the same way as for a single point steady-state calculation.

For **Plot Over Line**, plot the data along a line for the selected experiment. To show the plot over line for a specific experiment, select the corresponding experiment from the **Heat Source Calibration Experiments** menu. The configuration in the **Plot Over Line** works in the same way as for a single point steady-state calculation.

About the AM Plot Types

Visualizing Batch Calculations in the AM Module

This topic describes the **AM Calculator** visualizations related to the **Batch** calculations for a **Steady-state** simulation. There are further settings and visualization possibilities s that are available when you are working on the **Plot Renderer**.

It is recommended to open and run one of the examples to best understand the wide variety of visualization outcomes.

Learn More

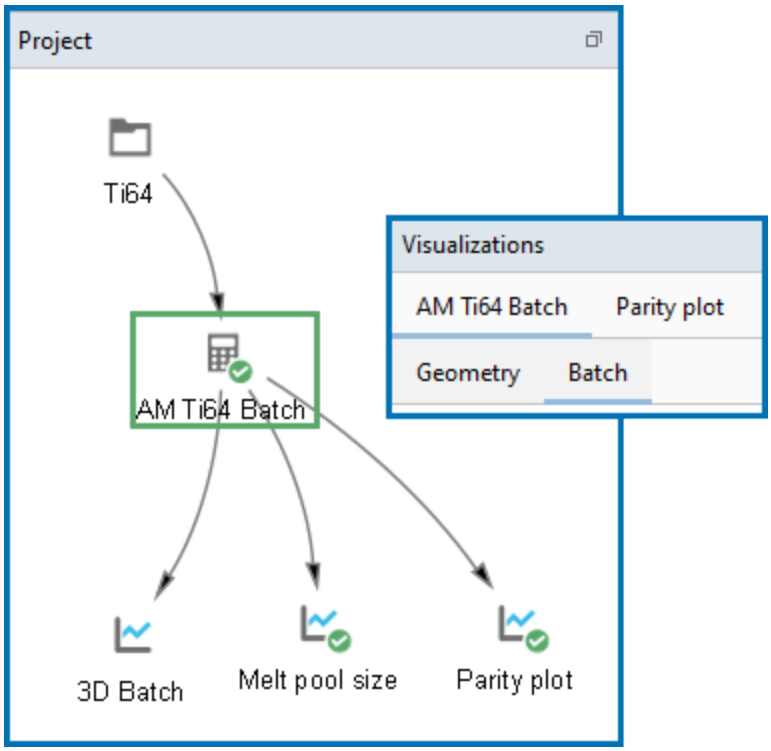
AM_07: Batch Calculations for an IN718 Alloy, AM_08b: Batch Calculations for a Ti64 Alloy, and AM_09b: Batch Calculations for an SS316L Alloy.

To import data for use in batch calculations, it is recommended you review AM Calculator Experiment File Requirements. Also review Working with AM Visualizations, which provides an overview of how most of the windows are connected.

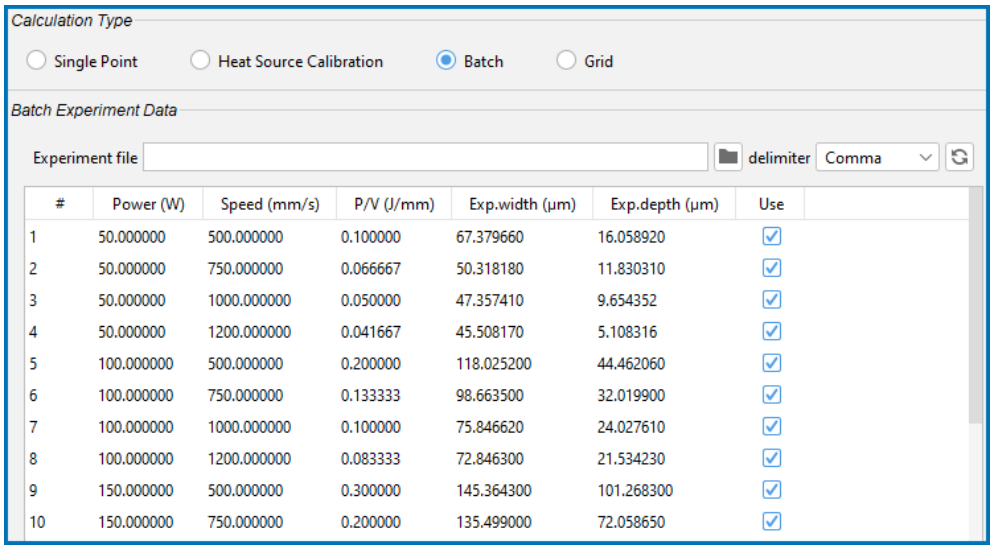
Working with AM Calculator Batch Experiment Data

From example AM_08b, where the general behavior related to importing data to the table is the same as other places in Thermo-Calc.

In the **Project** window, click the relevant **AM Calculator** node (in this example renamed to **AM Ti64 Batch**) to work on the **Configuration** window and preview the table data via a **Batch** tab on the **Visualizations** window.



During the set up of a calculation, the *Batch Experiment Data* is imported into the **AM Calculator Configuration** window, where you can review the data and choose to include or exclude data points by selecting and deselecting the checkboxes as needed in the **Use** column (see Figure 50). At the same time, you can observe the change as this is updated in the **Visualizations** window (see Figure 51). Data can also be entered directly into the table.



#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp.width (µm)	Exp.depth (µm)	Use
1	50.000000	500.000000	0.100000	67.379660	16.058920	☑
2	50.000000	750.000000	0.066667	50.318180	11.830310	☑
3	50.000000	1000.000000	0.050000	47.357410	9.654352	☑
4	50.000000	1200.000000	0.041667	45.508170	5.108316	☑

Figure 50: The experimental data used for the Batch calculation for the single track experiments of Ti64 is imported to the AM Calculator table where you can review the data points and include or exclude as needed using the checkboxes.

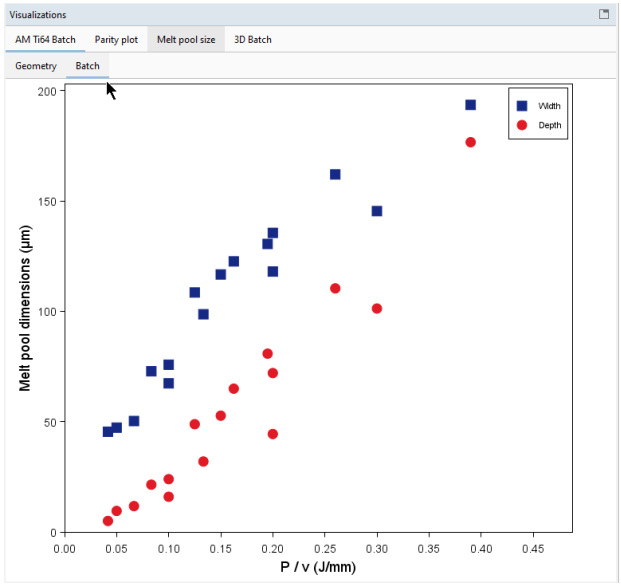

Figure 51: The visualization of the experimental melt pool dimensions are shown as a function of the energy density P/v. You can adjust the selected points in the Batch Experiment Data table and watch the updates dynamically in this window.

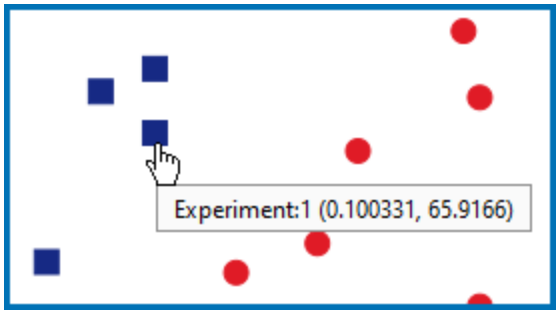
Including or Excluding Data Points

The following discusses visualization options available on the **Configuration** windows for both the **AM Calculator** and **Plot Renderer**.

You can click or hover over any point on the **Batch** preview to display the label, which also includes the corresponding table row (i.e. *Experiment*) number for the point.



Use the table's **Use** column on the **AM Calculator Configuration** window to select the relevant checkboxes for which **Width** and **Depth** points to include (i.e. *use*) or exclude (i.e. *not use*).

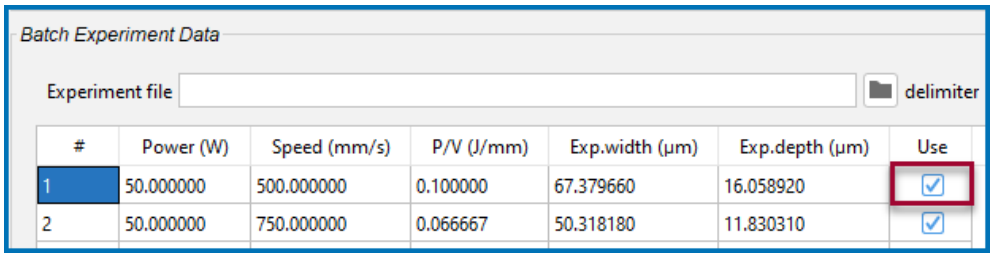


Figure 52: From example AM_08b, on the AM Calculator, the checkbox for row (experiment) #1 can be deselected to exclude the data point in the calculations.

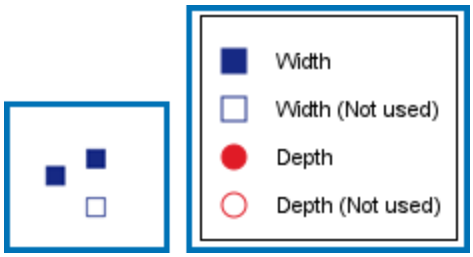
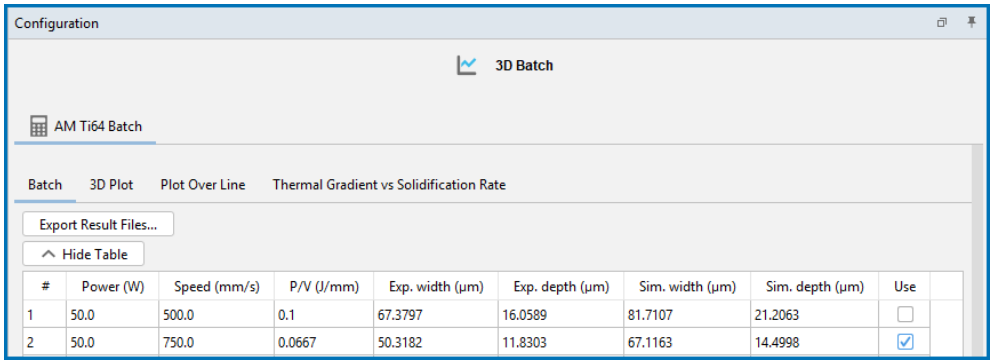
On the **Batch** tab on the **Visualizations** window, the preview shows the **P/v** on the *X*-axis and **Melt pool dimensions** on the *Y*-axis:

- **Width** uses blue squares (solid color means used, hollow with same color outline means not used)
- **Depth** uses red circles (solid color means used, hollow with same color outline means not used)

When you toggle the **Use** checkbox selection, the preview dynamically updates in the **Visualizations** window to indicate which data points are used (filled) or not used (hollow), both on the preview and in the legend.



The points that are selected in the *Batch Experiment Data* table are used in the simulation results and are later labeled **Exp.Width** and **Exp.Depth** in the **Plot Renderer Configuration** table (see Figure 53). Then the calculated results are added to new columns labeled **Sim.Width** and **Sim.Depth**.



#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp. width (µm)	Exp. depth (µm)	Sim. width (µm)	Sim. depth (µm)	Use
1	50.0	500.0	0.1	67.3797	16.0589	81.7107	21.2063	☐
2	50.0	750.0	0.0667	50.3182	11.8303	67.1163	14.4998	☑

Figure 53: From example AM_08b, this is the Batch tab on the Plot Renderer Configuration window where row (experiment) #1 data point is excluded from the results after selecting it on the AM Calculator. When a checkbox is not selected here, the results are also not included if you choose to export the result files. The details about Plot Renderer settings are in the topic AM Calculator: Plot Renderer Settings.

Working with the Batch Table on the Plot Renderer

After the **Batch Experiment Data** set up is completed on the **AM Calculator** and the simulation run, then on the **Plot Renderer Configuration** window you can start to work with the data you want to plot. Also see Including or Excluding Data Points to understand the interaction between these two tables.

For additional **Plot Renderer** settings (and other visualization options for plotting) go to Batch Calculations.

Navigating the Batch Table

You may have already included or excluded data points earlier when previewing the data. Use the **Show Table** or **Hide Table** buttons to view the included or excluded data and continue to fine tune the plot.

On the **Batch** tab the table includes these columns:

- The original experiment data for **Power (W)** and **Speed (mm/s)**, plus the **P/v (J/mm)**.
- The original experiment data for **Width** and **Depth**, now with a prefix **Exp.** e.g. **Exp.width (µm)**, to indicate this is the experimental data.
- The calculated **Width** and **Depth** points, with the prefix **Sim.**, e.g. **Sim.width (µm)**, to indicate it is the result of the simulation.

Only the experiment data points selected for inclusion when setting up the AM Calculator have data in these two **Sim.** columns.

- The **Use** column has a checkbox available to continue to include or exclude those points on the plots. When a checkbox is not selected, the results are also not included if you choose to export the result files.

Only points that were originally included in the simulation can be selected or deselected from the **Use** column. If an experiment data point needs to be added, return to the AM Calculator, choose the point (s) to include there, and run the simulation again. Once the simulation is complete, the points are included in this table.

Additive Manufacturing (AM) Module Examples Collection

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. Without a license you are in *Demo Mode* where you can, for example, open and view example set ups, run some examples, add templates and nodes to the Project window, adjust some Configuration settings, and preview some functionality on the Visualizations window.

Learn more about the Additive Manufacturing (AM) Module on our website including the details about database compatibility or to watch a webinar. You can also use the Getting Started Guide to learn about the key features available or visit our YouTube channel.

The first time you open an Additive Manufacturing (AM) Module example after a new Windows installation of Thermo-Calc, it copies various files that can take some time to download. Then the example itself can take further time to open where it seems that the program is frozen. After the first instance, the other examples should not take as long to load.

AM_01: Transient Simulation of a Single Track

The following example is part of a series showing some of the features of the Additive Manufacturing (AM) Module and the **AM Calculator**. In this example, a single track simulation is performed using the **Transient** model of the AM Calculator.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_01_Transient_DE_No_Marangoni.tcu`

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. Without a license you are in *Demo Mode* where you can, for example, open and view example set ups, run some examples, add templates and nodes to the Project window, adjust some Configuration settings, and preview some functionality on the Visualizations window.

Some examples (AM_01, AM_02, AM_03, and AM_06b) are available to all users. These examples can be run without an additional Additive Manufacturing license when you are in DEMO (demonstration) mode. However, the AM Module is not available with the Educational version of Thermo-Calc. Search the help for Available Options with the Additive Manufacturing (AM) Module. See Available Options for details.

Material Properties

These properties are the same for both AM_01 and AM_02 [2021Gra].

- Inconel 738LC: Ni-15.8 Cr-8.6 Co-2.7 W-3.3 Ti-3.6 Al-1.8 Ta-1.8 Mo-0.04 Fe-0.8 Nb-0.002 Mn-0.1 C Mass percent.
- Database: TCNI12
- The material property was pre-calculated, and stored as a built-in material library of the Additive Manufacturing (AM) Module.

Model Configuration

The transient model solves for the heat equation in the entire 3D domain, including the melt pool, and is therefore, computationally expensive to solve. The fluid flow inside the melt pool due to the Marangoni effect is not included in this example. The double ellipsoidal, or the so-called Goldak heat source model, is used to predict melt pool size and temperature distribution during single track scanning. The parameters for the double ellipsoidal heat source are computed using optimization in a steady-state case for the given process parameters (power and scanning speed) and the melt pool size reported in the paper by Grange et al. [2021Gra]. The resulting parameters are shown in Figure 1.

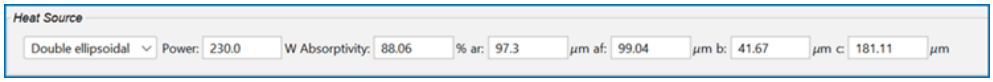

Figure 1: Optimized heat source parameters entered on the AM Calculator for the experiment given in Grange et al. [2021Gra] with power = 230 W and scanning speed = 960 mm/s.

The geometry for a transient simulation, as given in the paper by Grange et al. [2021Gra], is shown in Figure 2. The base plate is 2 mm in length, 0.5 mm in width, and with a thickness of 0.95 mm. A layer of powder with a thickness of 55 µm is deposited on the solid substrate. The powder layer, however, has the same material properties as the solid substrate. The laser beam with a power of 230 W develops linear scanning with constant velocity 960 mm/s. The trajectory evolves from initial position (x, y) = (0.25, 0.25) mm to final position (1.75, 0.25) mm on the top surface.

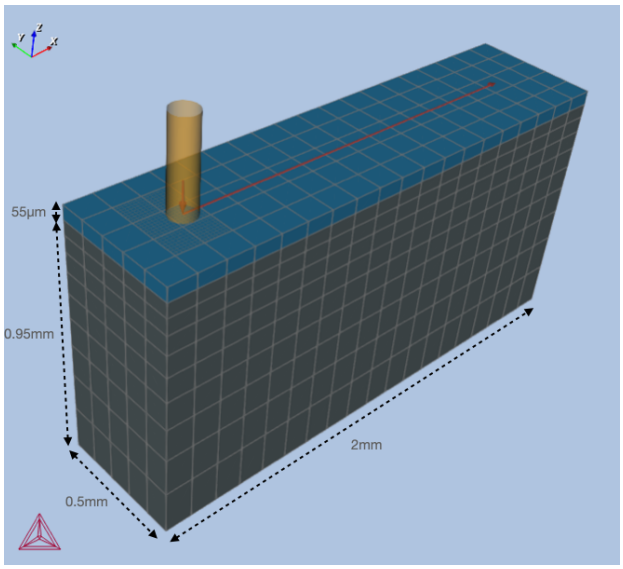

Figure 2: The geometry used for the Additive Manufacturing (AM) Module examples AM_01 and AM_02.

Two probes monitor the temporal evolution of temperature at positions shown in Figure 3. The results can be presented by tabulated data or as 2D graph plots.

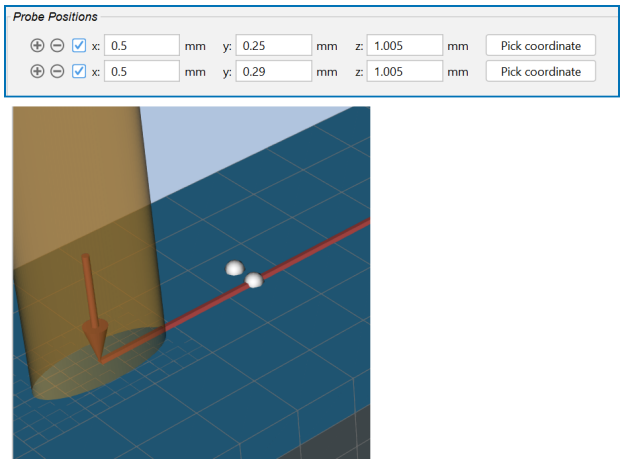

Figure 3: Probe positions for Probes P1 and P2, where P1 is placed exactly on the scanning track while P2 is placed at a distance of 0.04 mm from the track, as shown in a close up of the probes on the Visualizations window.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

> When you run (Perform) this example, it takes at least 30 minutes for the calculations to complete.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation(s).

- **Geometry**: View the geometry and adjust parameters visually by changing inputs on the Configuration window. Add probes needed.
- Melt pool and other dynamically changing features can also be visualized and changed.
- **Plot** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, click a **Plot Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

In the surface plot it shows the temperature distribution after the scanning process is completed. It is noted that the melt pool shape reaches a steady-state when the laser beam approaches the end of the scanning track. The melt pool dimensions at the end of scanning track is given in the table.

Melt Pool Dimension	*Size (mm)*
Width	0.125
Depth	0.144
Length	1.12

If you are in the project file, click the **Probe plot** node in the Project window and the **3D Plot** tab in the Visualizations window.

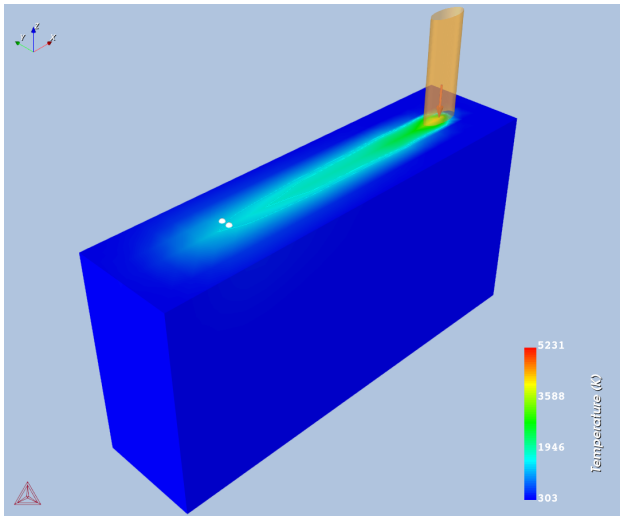

Figure 4: Surface plot of temperature distribution after the single track scan is completed. Probes P1 and P2 can also be seen on the top surface.

It is also possible to plot quantities at different cross-sections inside the domain by selecting the **Slice** checkbox on the **Plot Renderer Configuration** window under the **3D Plot** tab. The next figure shows the temperature slices plotted at cross-sections orthogonal to the scanning direction.

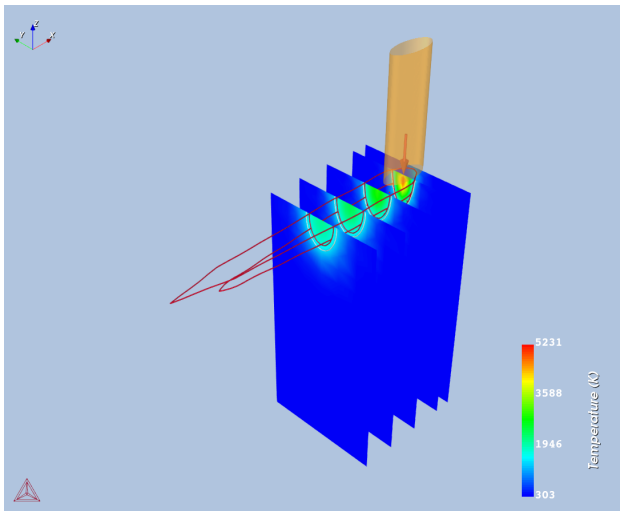

Figure 5: Slices of the computational domain, orthogonal to the scanning direction, showing temperature distribution at different cross-sections. Red tubes show the contour of the melt pool (at liquidus temperature).

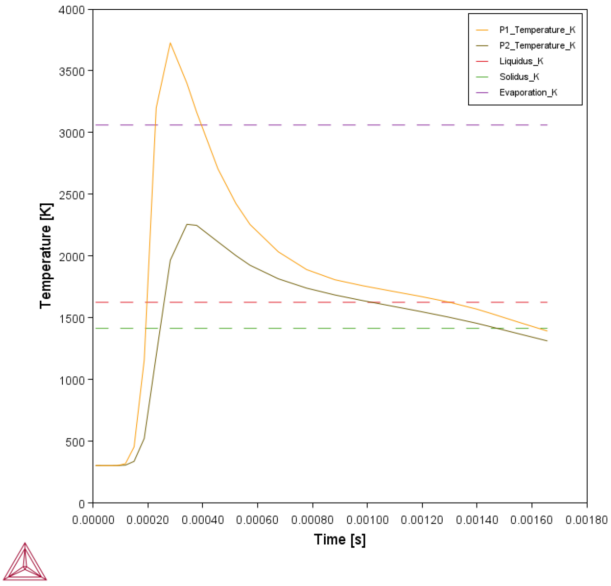

Figure 6: 2D probe plot showing temperature evolution as a function of time at probes P1 and P2.

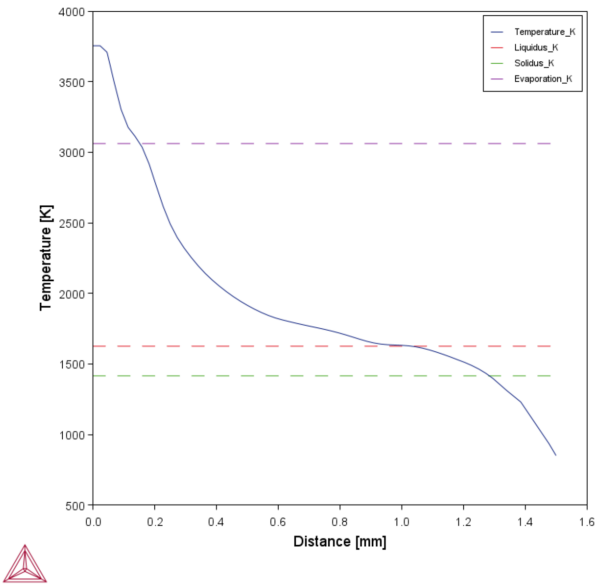

Figure 7: 2D plot over line showing temperature in the tail of the melt pool as a function of distance plotted along the scanning track.

AM_02: Transient and Steady-state Simulations of a Single Track

The following example is part of a series showing some of the features of the Additive Manufacturing (AM) Module and the **AM Calculator**. This example builds on the work done by Grange et al. [2021Gra] and is similar to example AM_01. The difference however is that in this example a single track simulation is performed using **Transient with heat source from Steady-state** model instead of the **Transient** model.

The **Transient with heat source from Steady-state** model exploits the assumption that the melt pool size and temperature distribution reaches a steady-state almost instantly and thus first solves for a **Steady-state** case with the given process parameters. The result from the **Steady-state** in the form of temperature distribution in the melt pool is then mapped as a heat source in the transient simulation. This novel approach is much faster and efficient than the approach used in example AM_01 where the heat equation is solved in the entire 3D domain.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_02_TransientSS_DE.tcu`

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. Without a license you are in *Demo Mode* where you can, for example, open and view example set ups, run some examples, add templates and nodes to the Project window, adjust some Configuration settings, and preview some functionality on the Visualizations window.

Some examples (AM_01, AM_02, AM_03, and AM_06b) are available to all users. These examples can be run without an additional Additive Manufacturing license when you are in DEMO (demonstration) mode. However, the AM Module is not available with the Educational version of Thermo-Calc. Search the help for Available Options with the Additive Manufacturing (AM) Module. See Available Options for details.

Material Properties

These properties are the same for both AM_01 and AM_02 [2021Gra].

- Inconel 738LC: Ni-15.8 Cr-8.6 Co-2.7 W-3.3 Ti-3.6 Al-1.8 Ta-1.8 Mo-0.04 Fe-0.8 Nb-0.002 Mn-0.1 C Mass percent.

- **Geometry**: View the geometry and adjust parameters visually by changing inputs on the Configuration window.
- Melt pool and other dynamically changing features can also be visualized and changed.
- **Plot** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, click a **Plot Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

With the example open and after it is run, the following is a summary of what is visible on the **Visualizations**window.

The figure below shows the surface plot of temperature distribution after the single track scanning is completed. The temperature profile is qualitatively similar to the one in example AM_01, however the maximum temperature is slightly lower in example AM_02. This could be due to selection of a coarse mesh in both examples which sometimes could affect the maximum temperature.

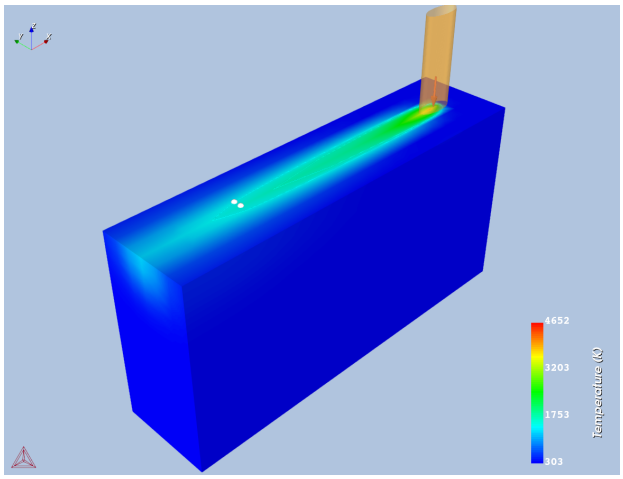

Figure 11: Surface plot of temperature distribution after the single track scan is completed. Probes P1 and P2 can also be seen on the top surface.

The melt pool dimensions for AM_02 are given in the following table, which are very similar to the melt pool dimensions obtained in example AM_01.

Melt Pool Dimension	*Size (mm)*
Width	0.127
Depth	0.129
Length	1.12

A qualitative comparison between AM_01 and AM_02 can also be made by looking at probe plots. The probe plot for AM_02 is given in Figure 12.

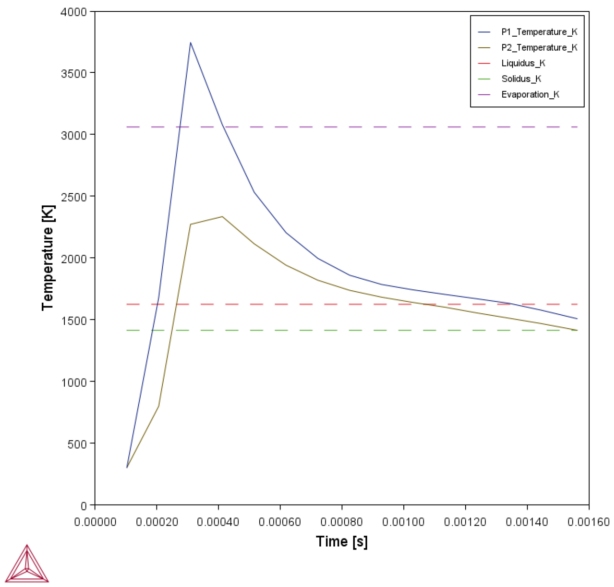

Figure 12: 2D probe plot showing temperature evolution as a function of time at probes P1 and P2.

Despite the fact that maximum temperature is higher in AM_01, the temperature profile in the tail of the melt pool and close to the melt pool is very similar. This can also be concluded by comparing plot over lines for the two examples, where the plot over line for AM_02 is given in Figure 13.

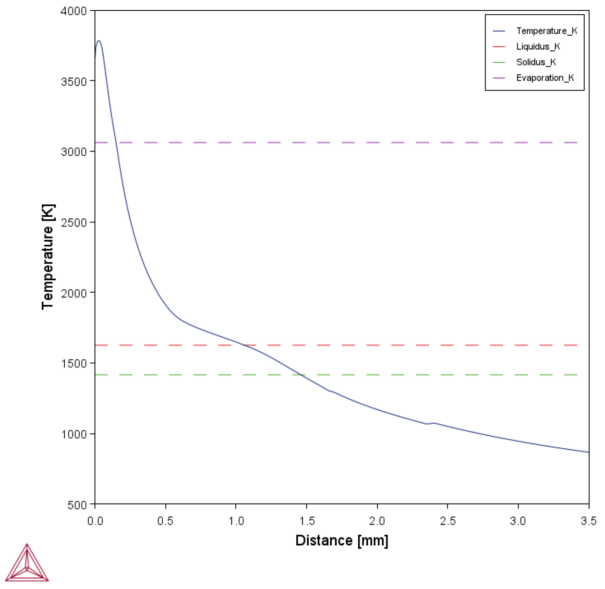

Figure 13: 2D plot over line showing temperature in the tail of the melt pool as a function of distance plotted along the scanning track.

AM_03: Steady-state Simulations

The following example is part of a series showing some of the features of the Additive Manufacturing (AM) Module and the **AM Calculator**.

In this example steady-state simulations are performed for IN625 with different conditions i.e.

i. without fluid flow in the melt pool,
ii. with fluid flow in the melt pool due to Marangoni effect, and
iii. using separate material properties for powder and fluid flow in the melt pool due to Marangoni effect.

and then the results are compared to demonstrate the effects of fluid flow and separate material properties for the powder on the temperature distribution as well as on the shape of the melt pool.

For the first two simulations, the same material properties are used for both powder and solid substrate.

In steady-state simulations it is assumed that the heat source (laser beam) moves with a uniform speed relative to the base plate. In this case, the model is solved by modifying governing equations to a reference frame attached to a moving heat source. Furthermore, in steady-state mode you can make use of symmetry along the width of the geometry and solve for only half of the domain.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_03_Steady.tcu`

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. Without a license you are in *Demo Mode* where you can, for example, open and view example set ups, run some examples, add templates and nodes to the Project window, adjust some Configuration settings, and preview some functionality on the Visualizations window.

Some examples (AM_01, AM_02, AM_03, and AM_06b) are available to all users. These examples can be run without an additional Additive Manufacturing license when you are in DEMO (demonstration) mode. However, the AM Module is not available with the Educational version of Thermo-Calc. Search the help for Available Options with the Additive Manufacturing (AM) Module. See Available Options for details.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation(s).

- **Geometry**: View the geometry and adjust parameters visually by changing inputs on the Configuration window.
- Melt pool and other dynamically changing features can also be visualized and changed.
- **Plot** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, click a **Plot Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

Results Discussion

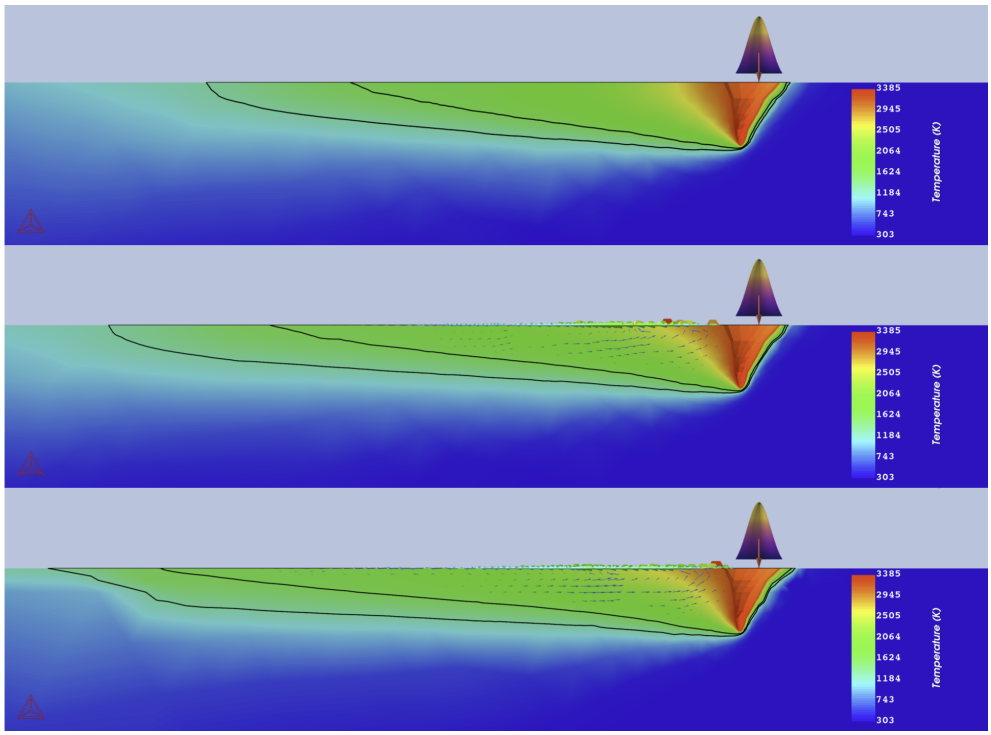

Figure 14: A comparison of the melt pool depth for different simulation conditions; (top) without fluid flow, (middle) with fluid flow in the melt pool and (bottom) with both fluid flow and different material properties for the powder layer. Isocontours show the boundaries of (inner) melt pool and (outer) mushy zone.

The table shows a comparison of the melt pool dimensions for different simulation conditions.

Simulation Set Up	*Melt Pool Dimensions (mm)*		
	Width	*Depth*	*Length*
Without fluid flow	0.115	0.111	0.736
With fluid flow	0.147	0.111	0.869
Separate powder material properties	0.194	0.111	1.064

Figure 14 shows the effect of fluid flow on temperature distribution and size of the melt pool for the given process parameters. A quantitative comparison is also given in the table. It can be seen that with the addition of fluid flow due to gradient in surface tension (Marangoni effect), the melt pool tends to increase its dimensions in all three directions. This is because the negative gradient in surface tension with respect to the temperature creates an outward flow on the surface of the melt pool which consequently increases the width and length of the melt pool, as shown in Figure 15.

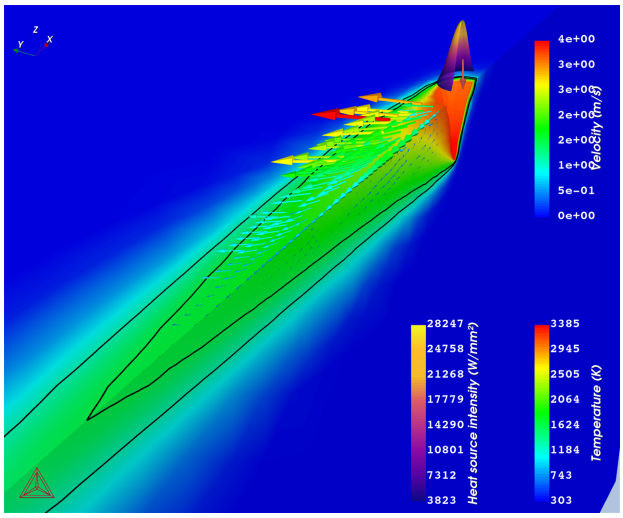

Figure 15: Vectors showing flow field in the melt pool due to gradient in surface tension. The colors of the vectors represent the magnitude of the velocity. Surface colormap shows the temperature distribution.

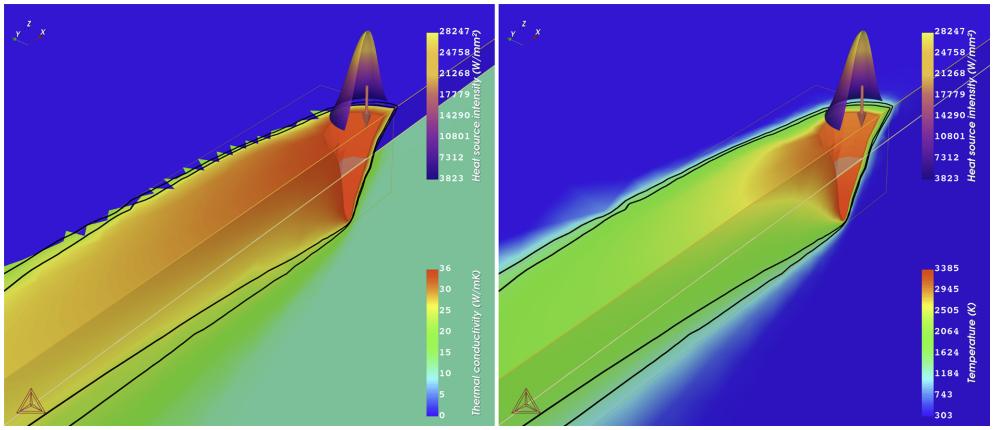

Figure 16: Surface colormap of temperature dependent thermal conductivity showing different values in powder and liquid/solid and (right) the corresponding temperature distribution.

Using separate material properties for powder has a significant effect on both the temperature distribution and the size of the melt pool. This is because a lower thermal diffusivity in the powder makes the temperature to diffuse more towards the length of the

melt pool hence causing a significant increase in the length of the melt pool (shown in Figure 16) as compared to the first two cases. There is also an obvious increase in the width of the melt pool while the depth of the melt pool is almost the same as with the fluid flow. Furthermore, the maximum temperature is also highest in the case with separate material properties.

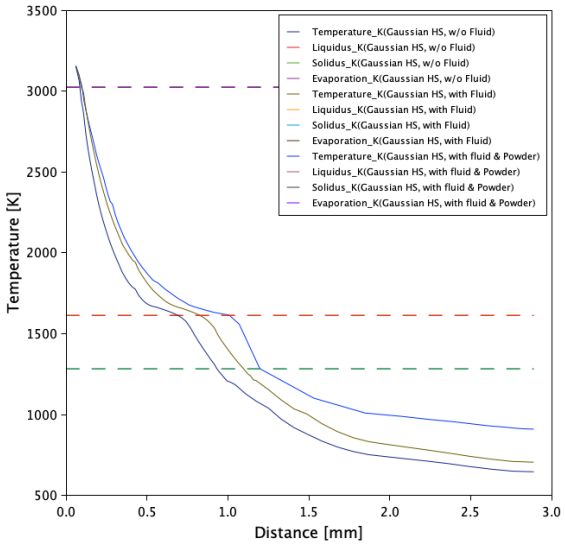

Figure 17: Temperature distribution along the top surface of the melt pool from the heat source position toward the tail. The plot compares three conditions: no fluid flow (solid blue line), fluid flow only (dashed green line), and combined powder and fluid flow (dash-dotted red line).

AM_04: Scheil Transient Steady-state

In this example, three different simulations are performed: Steady-state, Transient Single track, and Transient Multilayer. Both Transient Single track and Transient Multilayer use **Transient with heat source from Steady-state** model to compute time-dependent temperature distribution in the given geometry. The primary difference between this example and the previous examples (AM_01 to AM_03) is that, in this case, the material properties data is retrieved from the Scheil Calculator whereas in the previous examples the material properties are taken from the preinstalled material library. Furthermore, this example simulates scanning of two layers of powder where the second layer is spread on the top of the first layer when scanning of the first layer is completed.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_04_Scheil_TransientSS.tcu`

Material chosen for this example is Ti-6Al-4V. To run this example requires both version TCTI5.0 and newer of the TCS Ti/TiAl-based Alloys Database (TCTI) in addition to a license for the Additive Manufacturing (AM) Module. Some portions of this example are also covered in the Getting Started Guide on our website.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes at least 30 minutes for the calculations to complete.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation(s).

- **Geometry**: View the geometry and adjust parameters visually by changing inputs on the Configuration window.
- Melt pool and other dynamically changing features can also be visualized and changed.
- **Plot** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, click a **Plot Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

Steady-state

The Steady-state calculator of this example computes temperature distribution in a steady state for the power of 100 W and scanning speed of 600 mm/s. The beam radius in this example is taken as 100 µm. For the geometry, the steady-state model only needs the height of the solid substrate as the input, which is taken as 2.0 mm. The solid substrate is covered with a powder layer of thickness 55 µm. This example also takes into account the effect of fluid flow due to Marangoni forces inside the melt pool.

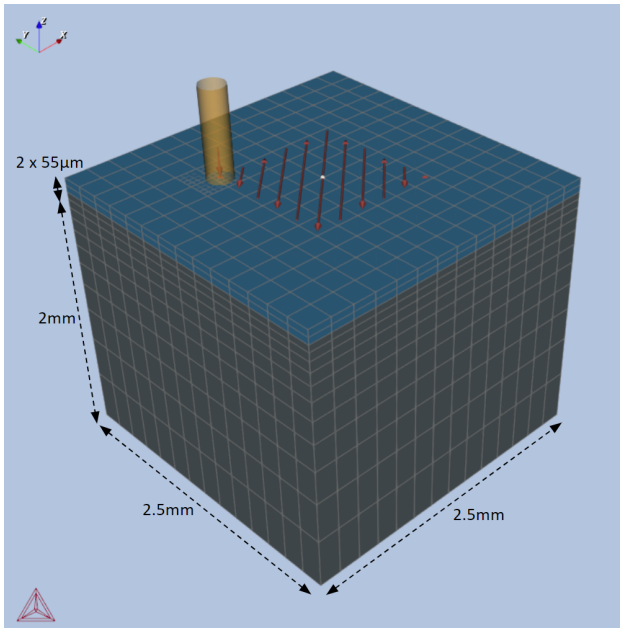

Figure 18: Geometry definition for Transient Multilayer. The scanning strategy shows the scanning pattern on the top most layer.

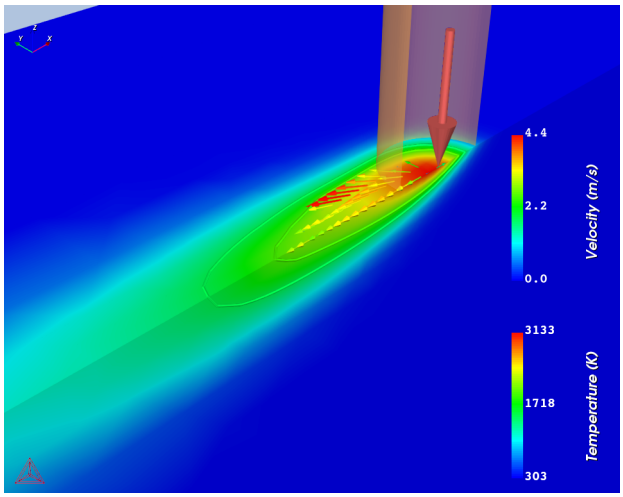

Figure 19: Temperature distribution around the melt pool and mushy zone for the Steady-state case. Velocity vectors representing the fluid flow inside the melt pool can also be seen.

Transient Single Track

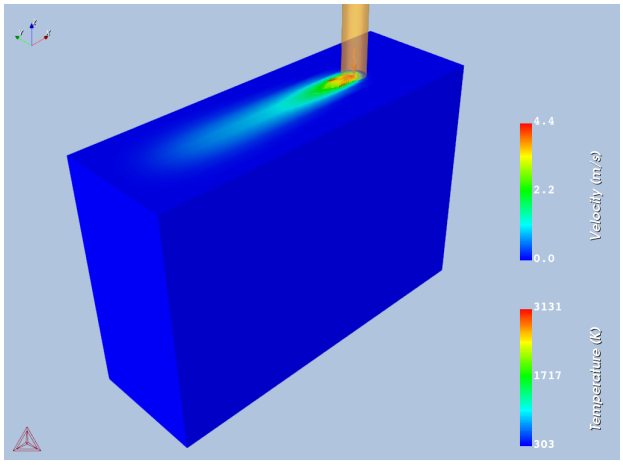

Figure 20: 3D Surface colormap showing temperature distribution at the end of single track transient simulation. The velocity vectors around the heat source show the direction of fluid flow in the melt pool.

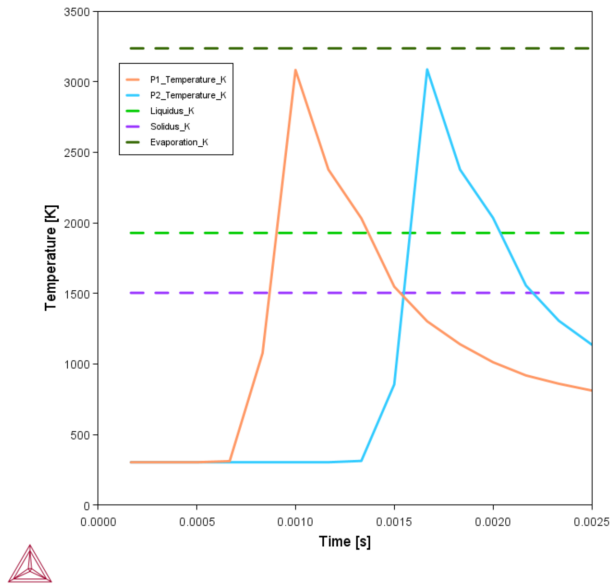

Figure 21: 2D Plot showing temperature as a function of time from Probe 1 (orange) and Probe 2 (blue) after the single track scan is completed.

Transient Multilayer

AM_05: Using AM Calculator Probe Data with the Diffusion Module (DICTRA)

The microstructure of a hot-work tool steel additively manufactured using laser powder-bed fusion (L-PBF) is studied in detail by microstructure characterization and computational thermodynamics and kinetics by C.-Y. Chou et al. [2021Cho].

This example demonstrates the application of adding probes to an AM Calculator and then using this data via the Thermal Profile that is set up on a connected Diffusion Calculator. The example also uses a Scheil Calculator to collect some materials data that is then further used with the AM Calculator prior to using the probe data generated by the AM Calculator.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_05_AM_Probe_to_Diffusion.tcu`

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. This example also requires a license for the Diffusion Module (DICTRA), plus additional database licenses for the TCS Steel and Fe-alloys Database (TCFE) (TCFE13 and newer), and the TCS Steels/Fe-Alloys Mobility Database (MOBFE) (MOBFE8 and newer).

Background

According to the thermodynamics of this steel, δ-ferrite is the solid phase stable at the highest temperature and would be the first solid phase to form during solidification from a thermodynamic point of view, see Figure 27.

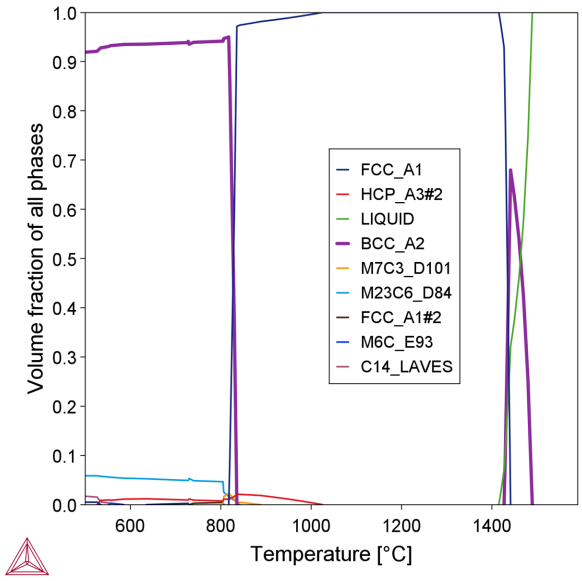

Figure 27: Equilibrium property diagram calculated in Thermo-Calc of the tool steel showing δ-ferrite would be the first solid phase to form during solidification according to equilibrium.

However, the high solidification and cooling rates during the L-PBF process lead to suppression of δ-ferrite and instead solidification of an austenite phase directly containing a cellular substructure where the alloying elements have segregated to the inter-cellular regions.

The microsegregation can be predicted by reducing the complex solidification behavior to a diffusion problem in one dimension enabling comparisons with the measured segregation profiles quantified at a nanometer scale.

Configuration and Calculation Set Up

For all calculations, the simplified composition Fe-0.35C-4.93Cr-0.45Mn-2.24Mo-0.25Si-0.54V (mass%) was used with δ-ferrite suspended on the System Definer.

The **Additive Manufacturing** template was used to first add the **System Definer**, **Scheil Calculator**, **AM Calculator**, and **Plot Renderer** to the **Project** window tree. Additionally, a **Diffusion Calculator** was added as a successor to the AM Calculator in order to automatically import the time-temperature profile from the AM simulation into the diffusion simulation. See Figure 28 (or refer to the example if you have it open) to see the layout.

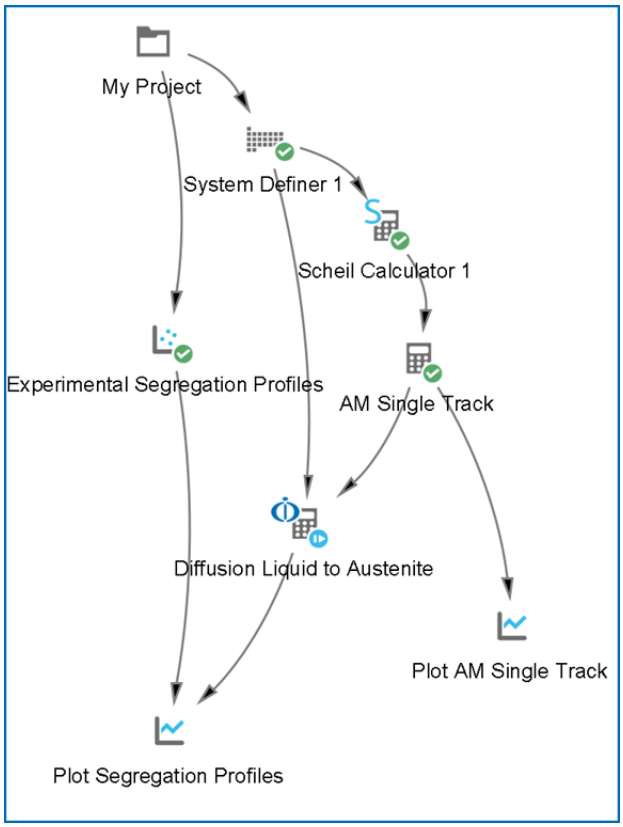

Figure 28: Project tree of the example containing activities from the default Additive Manufacturing template with additional Diffusion Calculator and Experimental File Reader nodes added, where the segregation profiles datasets are pulled from the Experimental File Reader.

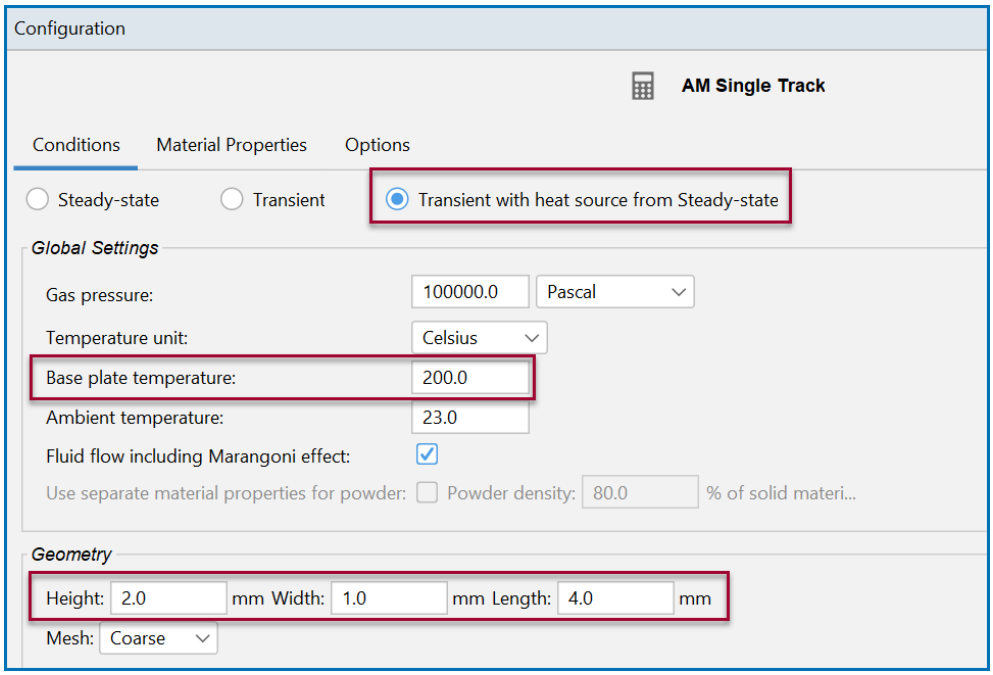
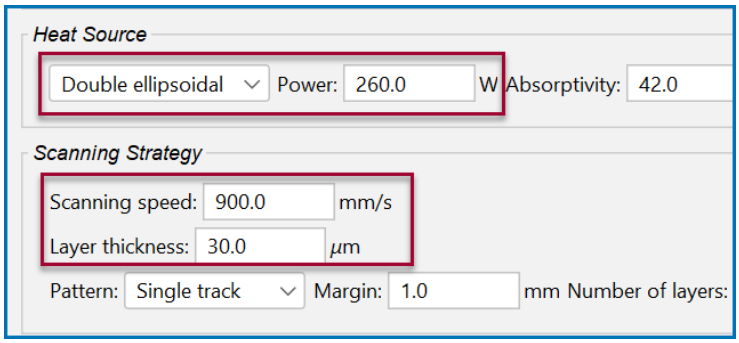
On the **AM CalculatorConfiguration** window, the calculation type **Transient with heat source from Steady-state** is selected with a single track scan pattern and a **Geometry** of 2 mm x 1 mm x 4 mm (height x width x length). The **Base plate temperature** is set to 200 °C.

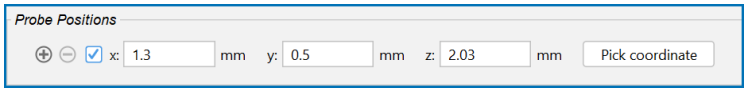


Additional settings are then made on the **Configuration** window as follows.

The **Double ellipsoidal** volume heat source was previously assessed as a function of linear energy density for a similar material and directly applied to the experimental conditions of a volumetric energy density of 80 J/mm^3. The laser **Power** is entered at 260 W, **Scanning speed** at 900 mm/s, and powder **Layer thickness** 30 µm. Below is a snapshot of the settings.



A probe was then added in the center of the scan track at a distance of 1.3 mm from the edge. The **Probe Positions** can either be entered directly on the Configuration window or click the **Pick coordinate** button and then click on the geometry in the **Visualizations** window to directly choose the probe point (or points if there is more than one probe added).



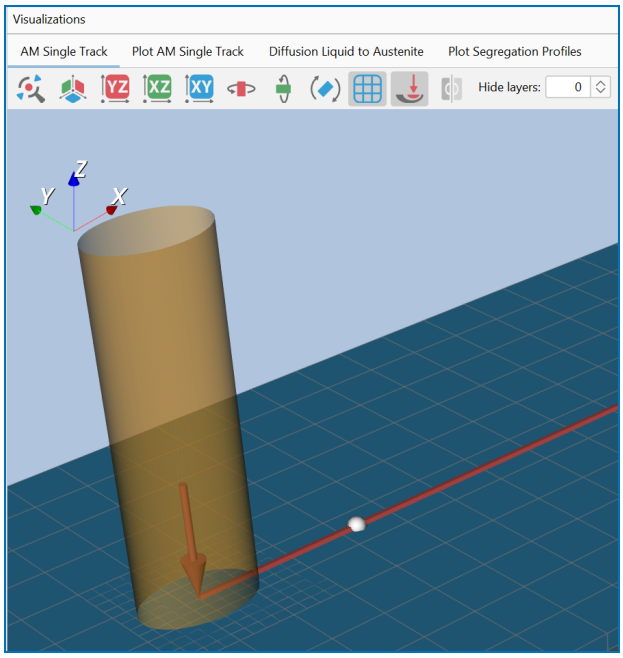


Figure 29: Close up of the probe point added to the geometry for the single track AM simulation.

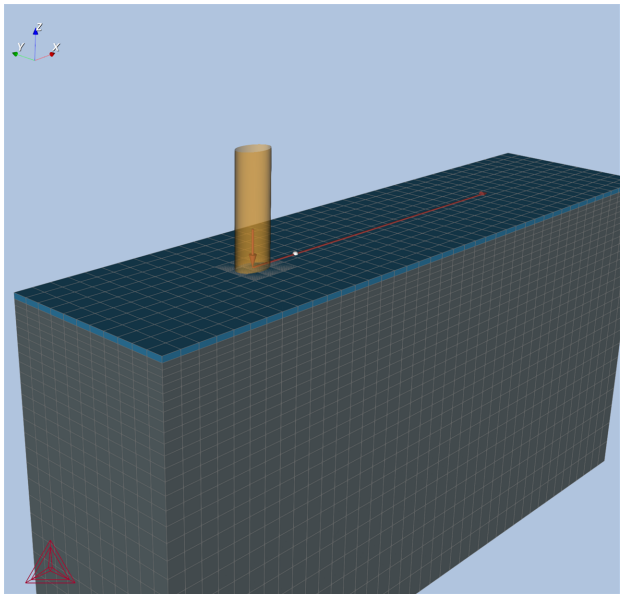

Figure 30: The full geometry set up for the single track AM simulation with a probe point added to the middle of the scan. Open the example to better see the set up and to try working within the window.

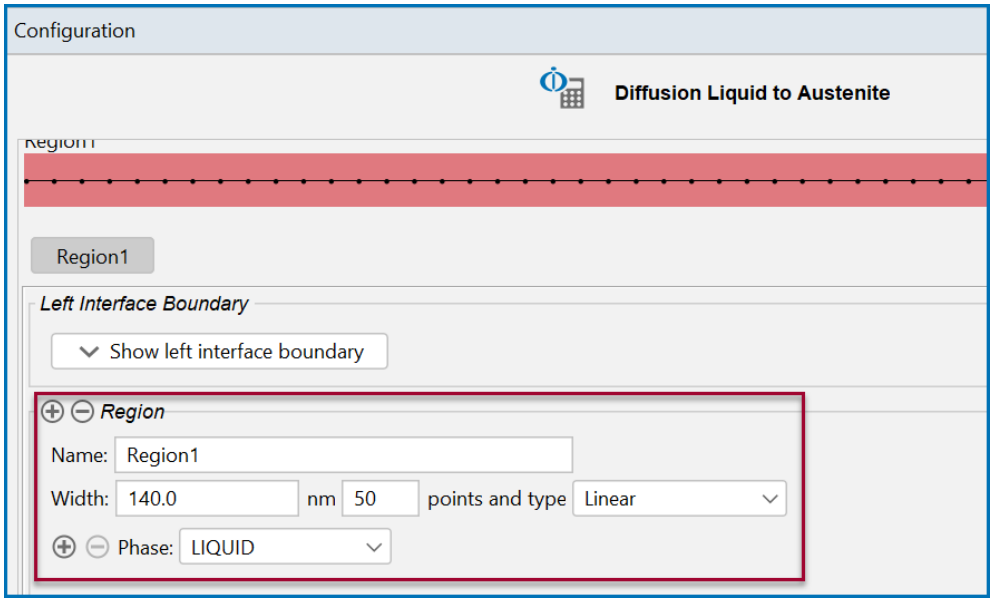
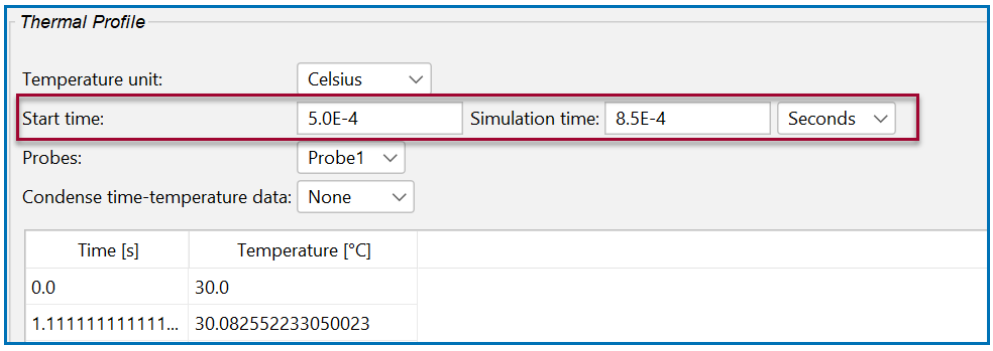
Diffusion Calculations

For the Diffusion Module (DICTRA) solidification calculations using the **Diffusion Calculator**, only the liquid to austenite (FCC) transformation was simulated. On the **Diffusion CalculatorConfiguration** window, a **Region** of 140 nm with liquid and FCC allowed to form at the right boundary is set.



In the *Thermal Profile* section, the time temperature from the probe was selected between a **Start time** of 5.0E-4 and **Simulation time** of 8.5.0E-4 s in order to only simulate the solidification, which can be viewed on the **Visualizations** window as in Figure 31. Note that the probes need to be added and then run in the AM Calculator to make this data available in for this part of the calculation.



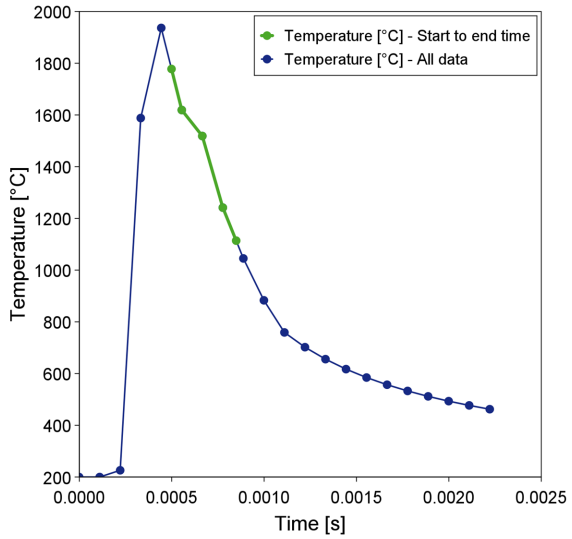


Figure 31: Time temperature profile of the probe in the AM simulation. The green curve show the part of the profile used during the diffusion simulation with the Diffusion Calculator.

The calculated segregation profiles are finally compared with the STEM-EDS line scans as shown in Figure 32.

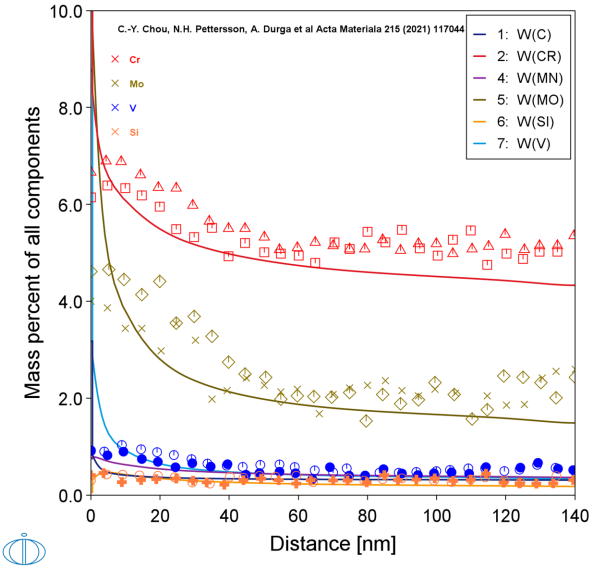

Figure 32: The simulated segregation profile with overlaid experimental STEM-EDS line scans from C.-Y. Chou et al. [2021Cho].

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

> When you run (Perform) this example, it can take over three hours to complete the calculations.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation(s). This example highlights some of these capabilities:

- **Probes**: Probes are added to the AM Calculator during the set up either by entering coordinates or directly adding these to the geometry. See Figure 29 and Figure 30 for example.
- **Thermal Profile**: The Diffusion Calculator Thermal Profile settings automatically include the probe data and you can visualize to help you continue the simulation. See Figure 31.
- **Plot** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, click a **Plot Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window. See Figure 32.

AM_06a: Calibrating a Heat Source for a 316L Steel

This example demonstrates the calibration of the heat source using the Gaussian as well as Double ellipsoidal heat sources. In this example, experimental data is taken from Hu. et al. [2019Hu] where the authors performed single-track experiments using the selective laser melting (SLM) process on 316L stainless steel for varying processing conditions. The power ranges from 50 W to 100 W while the scanning speed varies from 400 mm/s to 2800 mm/s. The data imported from [2019Hu], consisting of 21 experimental points, is saved in the project file.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_06a_Calibrate_Heat_Sources_316L.tcu`

An Additive Manufacturing Module license is needed to run AM_06a.

Some examples (AM_01, AM_02, AM_03, and AM_06b) are available to all users. These examples can be run without an additional Additive Manufacturing license when you are in DEMO (demonstration) mode. However, the AM Module is not available with the Educational version of Thermo-Calc. Search the help for Available Options with the Additive Manufacturing (AM) Module. See Available Options for details.

Material Properties

- SS316L: Fe-17.0Cr-12.0Ni-2.5Mo-0.03C Mass percent
- Database: TCFE13
- The material properties are precalculated, and stored as a built-in material library with the Additive Manufacturing (AM) Module.

AM Calculator Configuration Settings

The AM_06a example contains two AM Calculators, which are renamed to **AM Calibration Gaussian** and **AM Calibration Double Ellipsoidal**.

- **AM Calibration Gaussian** uses a **Gaussian***Heat Source* with the **keyhole model**.
- **AM Calibration Double Ellipsoidal** uses a **Double ellipsoidal***Heat Source*.
- The heat source parameters for both heat sources are calibrated for the given experimental data.
- For both AM Calculators, the **Base plate temperature** and the **Ambient temperature** use a value of 353 K and the **Layer thickness** is 10 µm. The rest of the Configuration settings keep the original defaults.

For **AM Calibration Gaussian**, all of the 21 experimental points that are imported to the *Experiment Data* table are selected to be used in the calibration. This is because, for the Gaussian heat source with the keyhole model, one wants to obtain a single constant value for beam radius as well as absorptivity to correctly predict the melt pool size for a range of power and scanning speed. It is also in order to obtain the best possible value it is good to include as many experiments as you can to calibrate the heat source parameters.

For this AM Calculator, other settings include:

- **Constant (calibrated)**, which means the absorptivity is not a function of temperature or angle, and a constant value is calibrated for each experiment.
- The **Beam radius** is set to **Calibrated**, which means that both beam radius and absorptivity are calibrated.
- **Calibrate for** is set to **Width and depth**, which means that the experimental values for both width and depth are used for calibration.

For **AM Calibration Double Ellipsoidal**, only five (5) experiment points are selected to perform the calibration. Two experiments are selected from the lower energy density, two from the higher energy density, and then one experiment is selected in the middle region of the two extremes.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results

before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it can take about an hour to complete the calculations.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation(s).

See Visualizing Heat Source Calibrations for an extended overview of what is available and how to navigate the many options for visualizing the heat source calibration data.

Calibrated Functions

For **AM Calibration Gaussian**, a comparison of the melt pool dimensions from the experiments and calibration simulation is shown in Figure 33.

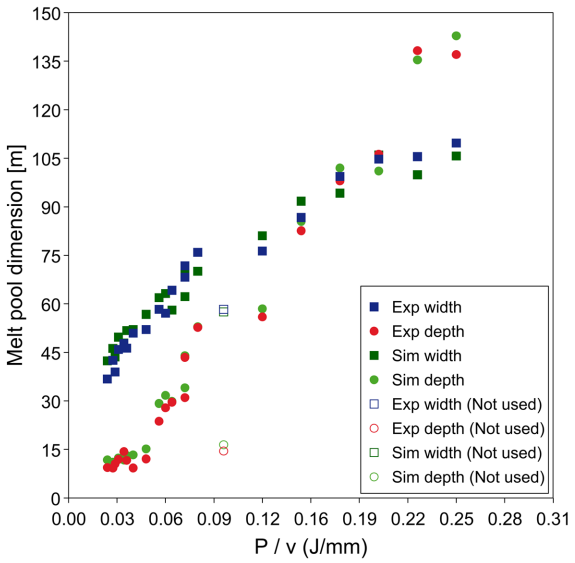

Figure 33: A comparison of melt pool dimension for Gaussian heat source calibration. The "Not used" points shown in the legend are because a checkbox is not selected in the 'Use' column for row 10 on the Plot Renderer Configuration window.

The resulting calibrated heat source parameters for **AM Calibration Gaussian**, are shown in Figure 34.

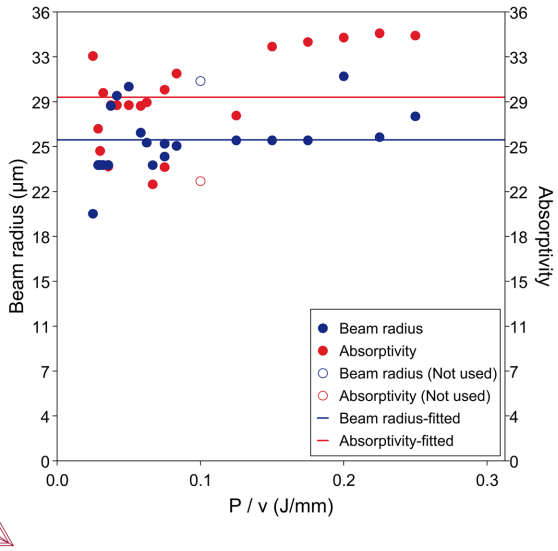

Figure 34: Calibrated heat source parameters for Gaussian heat source calibration.

In order to obtain the expressions for **Absorptivity** and **Beam radius**, one of the experiments (*Experiment # 10*) is not included. This is because *Experiment # 10* is an outlier and you can see that the values for *Exp width* and *Exp depth* (hollow square) then the *Sim width* and *Sim depth* (hollow circle) are excluded in Figure 33.

For both **Absorptivity** and **Beam radius** the **Constant function of P/v** is chosen to be saved as a calibrated heat source. Absorptivity of the material at the printing conditions is usually unknown in these experiments which is why it is regarded as a fitting parameter. Beam radius, on the other hand, is most often known, but does not match the definition of beam radius in the Gaussian heat source model used in the simulation, which is why a different value is obtained as compared to the one used in the experiment.

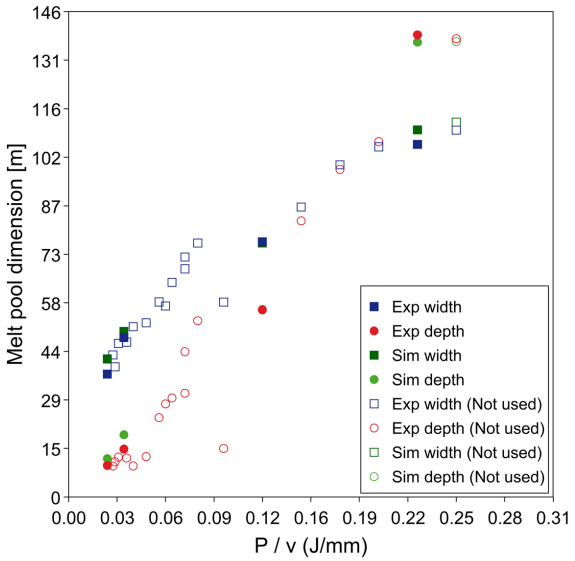

Figure 35: A comparison of melt pool dimension for double ellipsoidal heat source calibration.

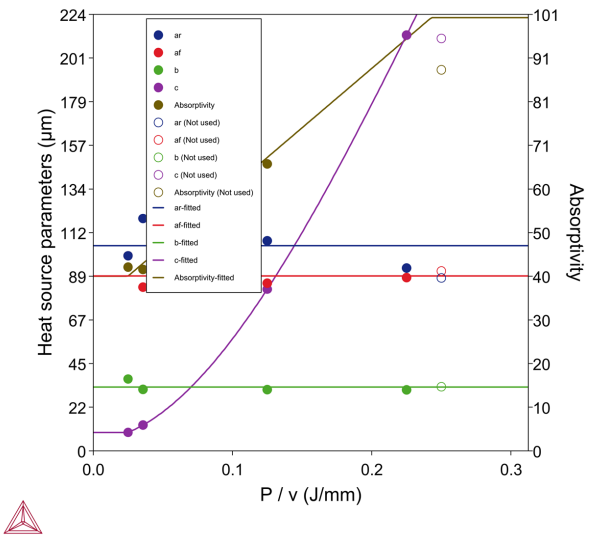

Figure 36: Calibrated heat source parameters for double ellipsoidal heat source calibration.

While selecting the functions for heat source parameters for double ellipsoidal, it was seen that **ar**, **af**, and **b** remained almost unchanged for all the experiments. Therefore the **Constant function of P/v for ar, af, and b** is used. For **Absorptivity**, a **Linear function of P/v** gave the best R2 value while for **c** a **Cubic function of P/v** gave the best R2 value. One of the experiments (experiment # 21) was excluded (i.e. the checkbox is deselected) to get a suitable curve for all functions.

AM_06b: Using the Calibrated Heat Source for a 316L Steel

This example demonstrates the use of the two calibrated heat sources that are saved in the example AM_06a. One heat source is of the Gaussian type while the other heat source is Double ellipsoidal. For both heat sources, expressions are saved as a function of energy density (P/v) for all heat source parameters as well as the absorptivity. The example consists of four AM Calculators, two of which use a Gaussian heat source while the other two use a Double ellipsoidal heat source, and where the processing conditions for all four AM Calculators are taken from Hu et al [2019Hu].

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_06b_Use_Calibrated_Heat_Sources_316L.tcu`

Other than an Additive Manufacturing (AM) Module license, this example does not require an additional license to run it, although its companion example, AM_06a, does.

Material Properties

- SS316L: Fe-17.0Cr-12.0Ni-2.5Mo-0.03C Mass percent
- Database: TCFE13
- The material properties are precalculated, and stored as a built-in material library with the Additive Manufacturing (AM) Module.

Configuration and Calculation Set Up

There are four AM Calculators where all the calculators use the **Steady-state** simulation type and the **Single point***Calculation Type*. The purpose of this example is to use the saved heat sources from AM_06a and then validate the results by comparing the melt pool size from the simulations with the experimental melt pool dimensions as given in Hu et. al [2019Hu].

The saved heat sources are selected from the *Heat Source* list on the AM Calculator, where a subsection called **Users heat sources** includes all previously saved heat sources. In the example, two calculators use the **Gaussian - 316L - beam d 15um** user-defined heat source, and two use the **Double ellipsoidal - 316L - beam d 15um** user-defined heat source. The **Base plate temperature** and **Ambient temperature** is set to 353 K, while the **Layer thickness** is set to 10 µm.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation(s).

For this example, it is best to open and run this simulation to be able to view all the different plots and outputs to various tabs on both the various Configuration windows as well as the Visualizations window.

See Visualizing Heat Source Calibrations for an extended overview of what is available and how to navigate the many options for visualizing the heat source calibration data.

Gaussian Heat Source and Keyhole Model

The different processing conditions are selected to simulate both the conduction mode as well as the keyhole mode. For **Gaussian - 316L - beam d 15 um** heat source, with P = 100 W and scanning speed = 2800 mm/s, the dominant mode of heat transfer is conduction, which is why a shallow melt pool is obtained. The results from the simulations are fairly close to the ones from the experiments, as can be seen in *Table 1*.

With P = 80 W and scanning speed = 400 mm/s, a keyhole mode is observed in the experiments. This is also predicted from the simulations as can be seen in Figure 37.

A comparison of the melt pool depth from the simulations and the experiments for the latter case shows that the calibrated Gaussian heat source with the keyhole model predicts the melt pool depth with reasonable accuracy. However, it underpredicts the melt pool width. This is because fluid flow due to Marangoni forces is not included in these simulations, which probably causes the melt pool to widen in the experiments.

Calculator Name	*Power [W]*	*Scanning Speed [mm/s]*	*Melt Pool Width*		*Melt Pool Depth*	
			Simulation [µm]	*Experiment [µm]*	*Simulation [µm]*	*Experiment [µm]*
AM use calibrated Gaussian P100 u2800	100	2800	53.30	47.82	12.93	14.36
AM use calibrated Gaussian P80 u400	80	400	93.25	105	102.71	106.57

Table 1: A comparison of the melt pool dimensions from the simulations and experiments using the calibrated Gaussian heat source.

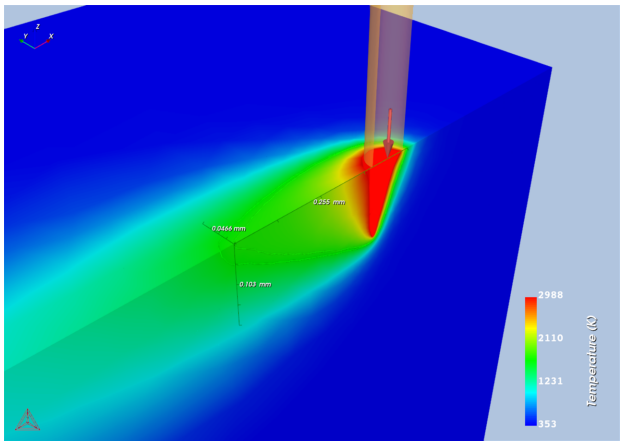

Figure 37: Steady-state temperature distribution around the melt pool for SS316L with P = 80 W and scanning speed = 400 mm/s using the calibrated Gaussian heat source with the keyhole model. A keyhole can also be seen formed just below the location of the heat source.

Double Ellipsoidal Heat Source

For the **Double ellipsoidal - 316L - beam d 15 um** heat source, two different processing conditions are selected to simulate both the conduction mode as well as the keyhole mode. For both processing conditions, the prediction of the melt pool size from the simulations is in fairly good agreement with the results from the experiments as can be seen in *Table 2*.

The temperature distribution using the calibrated double ellipsoidal heat source with P = 80 W and scanning speed = 400 mm/s is shown in Figure 38.

Calculator Name	*Power [W]*	*Scanning Speed [mm/s]*	*Melt Pool Width*		*Melt Pool Depth*	
			Simulation [µm]	*Experiment [µm]*	*Simulation [µm]*	*Experiment [µm]*
AM use calibrated DE P80 u1200	100	1200	65.07	64.34	31.63	29.68
AM use calibrated DE P80 u400	80	400	103.65	105	112.29	106.57

Table 2: A comparison of the melt pool dimensions from the simulations and experiments using the calibrated double ellipsoidal heat source.

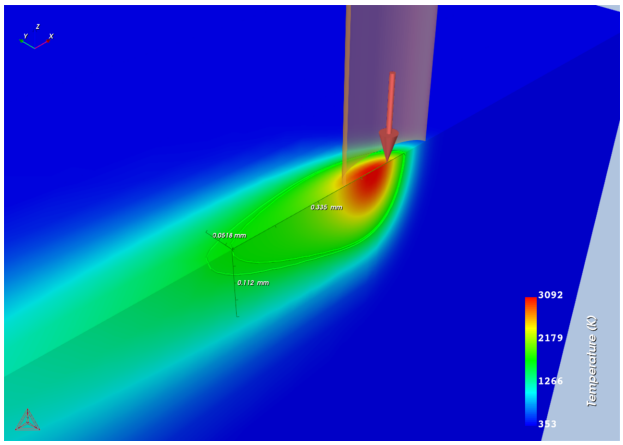

Figure 38: Steady-state temperature distribution around the melt pool for SS316L with P = 80 W and scanning speed = 400 mm/s using the calibrated double ellipsoidal heat source.

AM_07: Batch Calculations for an IN718 Alloy

This example shows the use of the **AM Calculator** with a **Steady-state** mode and **Batch** *Calculation Type* where it compares calculated and measured melt pool dimensions. The experimental data are from the 2022 NIST AM-Bench Test Series [2022NIST] where single track experiments were performed on a IN718 bare plate at different power and scan speeds.

The use of different **Plot types** in this example include a **Parity plot**, **3D plot** showing the keyhole, and **Printability map**.

This example is part of a set using a **Steady-state** simulation with a **Gaussian** heat source, plus the **Keyhole model** including **Fluid flow**. These examples collectively show the use of **Batch** and **Grid** calculation types plus various plot types such as **Printability maps**, **Parity plots**, and **Melt pool vs energy density**. The examples are numbered AM_07 to AM_09b.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_07_Batch_IN718.tcu`

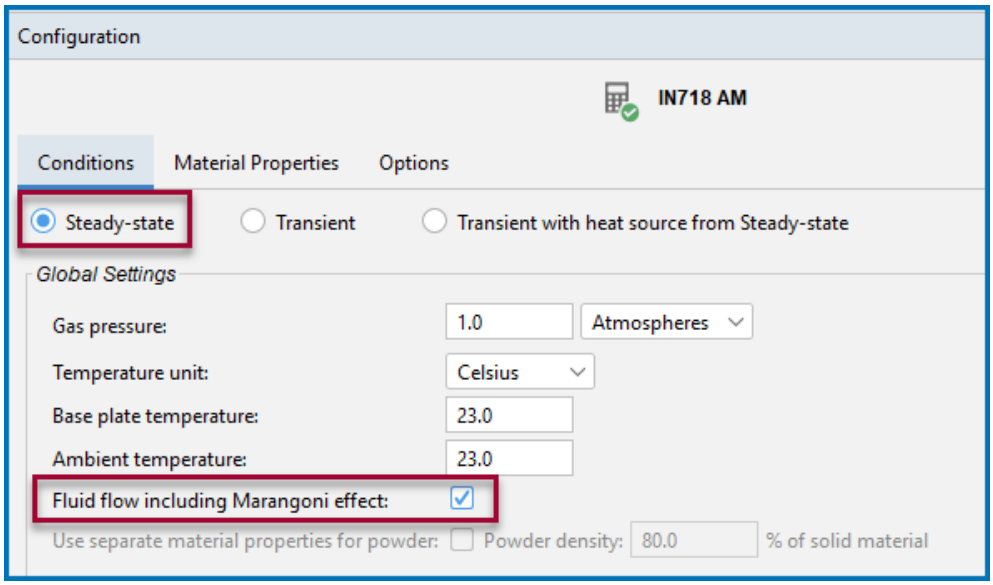
This example requires an Additive Manufacturing (AM) Module license.

Some examples (AM_01, AM_02, AM_03, and AM_06b) are available to all users. These examples can be run without an additional Additive Manufacturing license when you are in DEMO (demonstration) mode. However, the AM Module is not available with the Educational version of Thermo-Calc. Search the help for Available Options with the Additive Manufacturing (AM) Module. See Available Options for details.

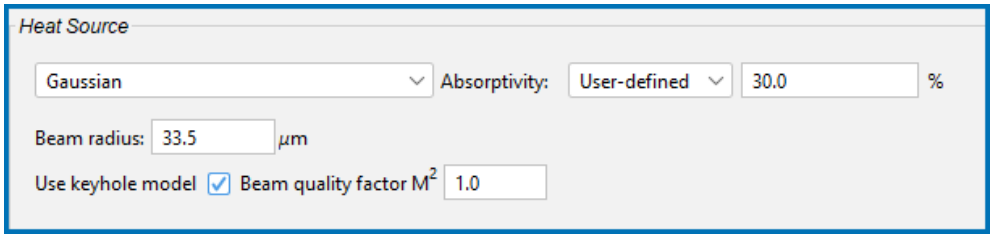
Configuration and Calculation Set Up

Below highlights the main settings for this example.

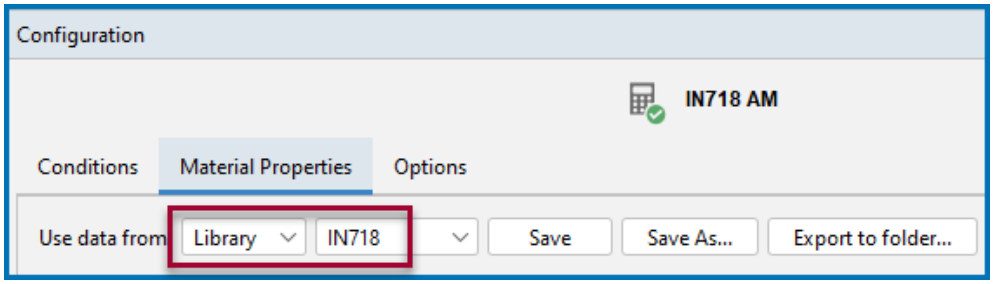
The **Steady-state** simulation is selected and the **Fluid flow including Marangoni effect** checkbox is selected.



The *Heat Source* is set to **Gaussian** and uses the **Keyhole model**. The printers in the experiments had a beam diameter of `67` µm so the Gaussian **Beam radius** is set to `33.5` µm. The **Absorptivity** is set to `30.0` %.

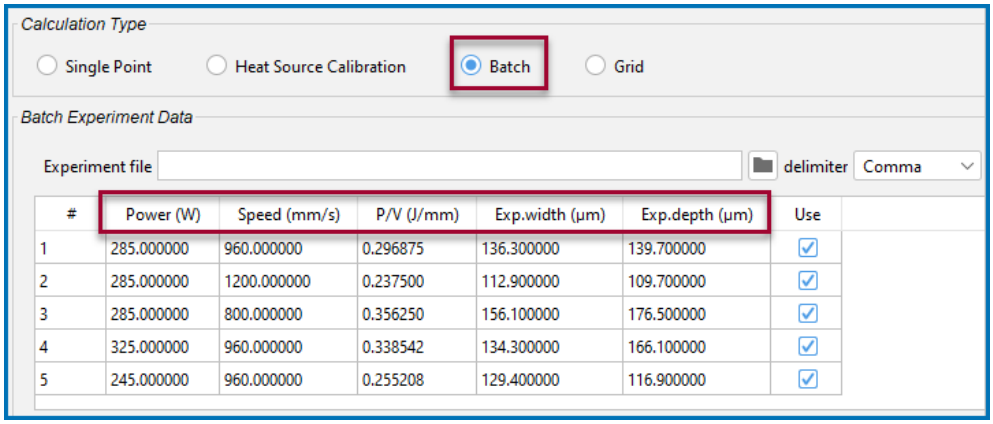


The **IN718** material is selected from the **Material Properties** library. The material properties are precalculated and stored as a built-in material **Library**.



The **Batch***Calculation Type* is used to set up all the conditions from the multiple experiments in a single calculation. The experimental *Power* and scan *Speed* as well as the measured melt pool *Width* and *Depth* were collected in a CSV file and read into the software. This data is then saved in the project file.

In the *Batch Experiment Data* table you can see that the power ranges between `245` W to `285` W and the scan speed ranges between `800` mm/s to `1200` mm/s.



#	Power (W)	Speed (mm/s)	P/V (J/mm)	Exp.width (µm)	Exp.depth (µm)	Use
1	285.000000	960.000000	0.296875	136.300000	139.700000	☑
2	285.000000	1200.000000	0.237500	112.900000	109.700000	☑
3	285.000000	800.000000	0.356250	156.100000	176.500000	☑
4	325.000000	960.000000	0.338542	134.300000	166.100000	☑
5	245.000000	960.000000	0.255208	129.400000	116.900000	☑

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes at least 30 minutes for the calculations to complete.

There is a wide variety of information shown both in the **Visualizations** and **Plot Renderer Configuration** windows that can be viewed during configuration and after performing the calculation(s). Not all views, such as the **Geometry** or previews, nor all additional output (i.e. plots) are shown in this section and it is recommended that you open and run the example to review all available options and results.

Parity Plot

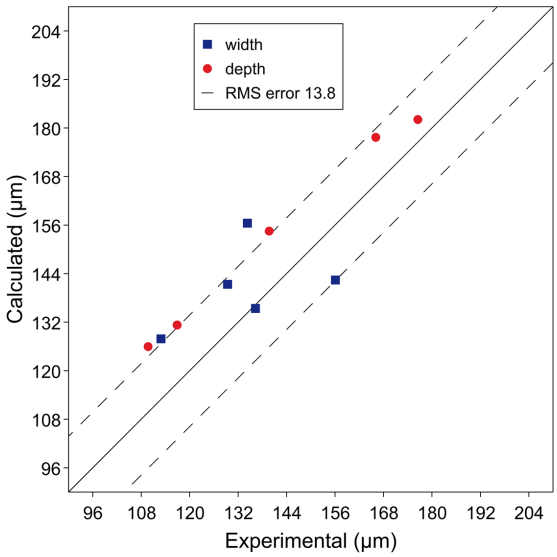


Figure 39: Parity plot comparing experimental versus calculated melt pool width and depth for all the experiments. The experiments are single tracks on bare plate IN718 with varied power and scan speed. The Root Mean Square (RMS) error can also be shown as a dashed line.

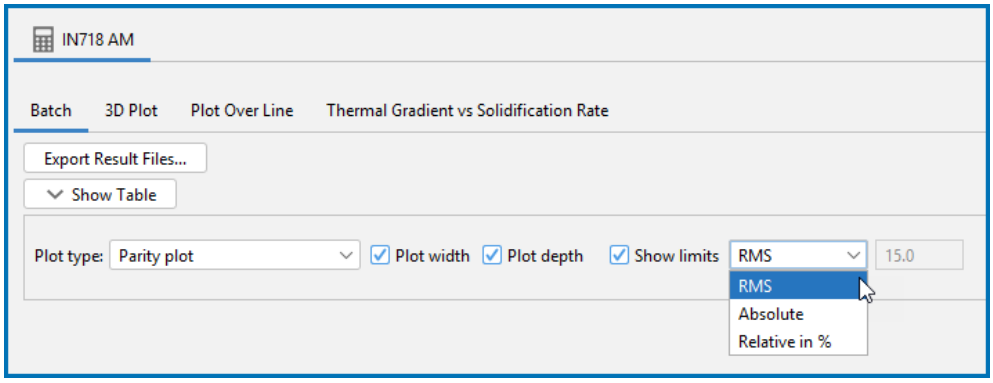

Figure 40: Alternatively, lines for user-defined Absolute or Relative in % error can be shown instead by selecting these options on the Configuration window.

3D Plot with Surface Colormap

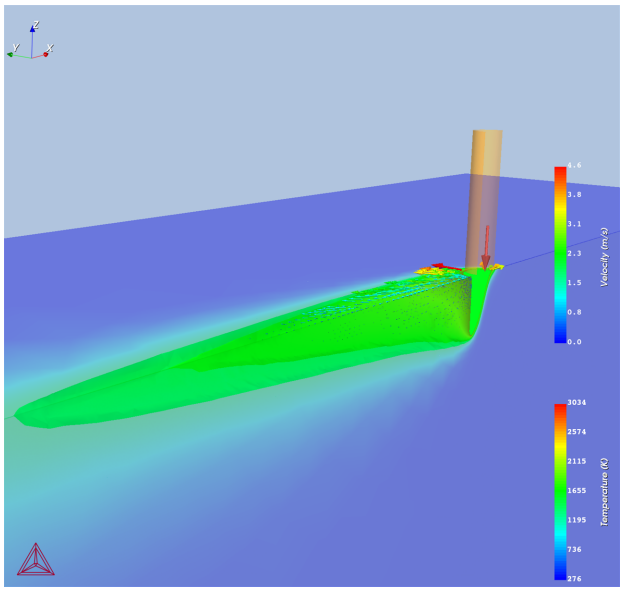

Figure 41: 3D plot showing a keyhole for the second simulation that uses power 285 W and scan speed 1200 mm/s.

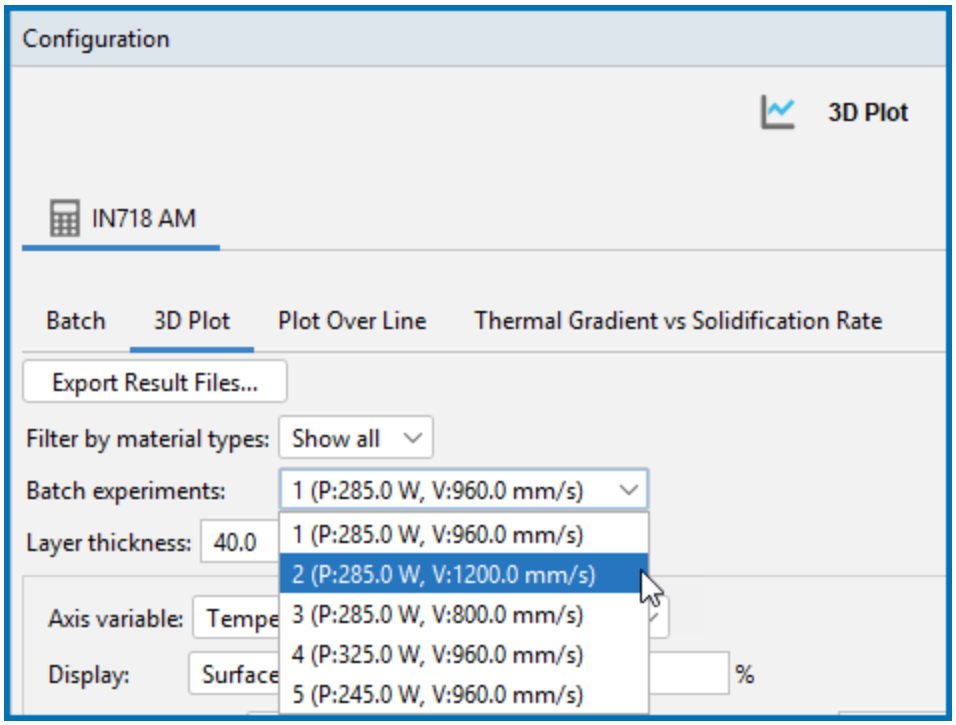

Figure 42: Selecting the Batch experiment number to display in the Visualizations window for the 3D plot shown in Figure 41.

AM_08a: Grid Calculation for a Ti64 Alloy

This example shows the use of the **AM Calculator** with a **Steady-state** mode and **Grid** *Calculation Type* where it compares the calculated and measured printability map. Printability maps are also known as *process maps*. The experiments are from Dilip *et. al* [2017Dil] where they performed single track experiments with the alloy Ti64 at different power and scan speeds. They also printed cubes and performed measurements of the porosity amounts for each experimental condition.

The use of different **Plot types** in this example include a **Printability map** and a **3D plot** with surface colormap.

This example is part of a set using a **Steady-state** simulation with a **Gaussian** heat source, plus the **Keyhole model** including **Fluid flow**. These examples collectively show the use of **Batch** and **Grid** calculation types plus various plot types such as **Printability maps**, **Parity plots**, and **Melt pool vs energy density**. The examples are numbered AM_07 to AM_09b.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_08a_Printability_Map_Ti64.tcu`

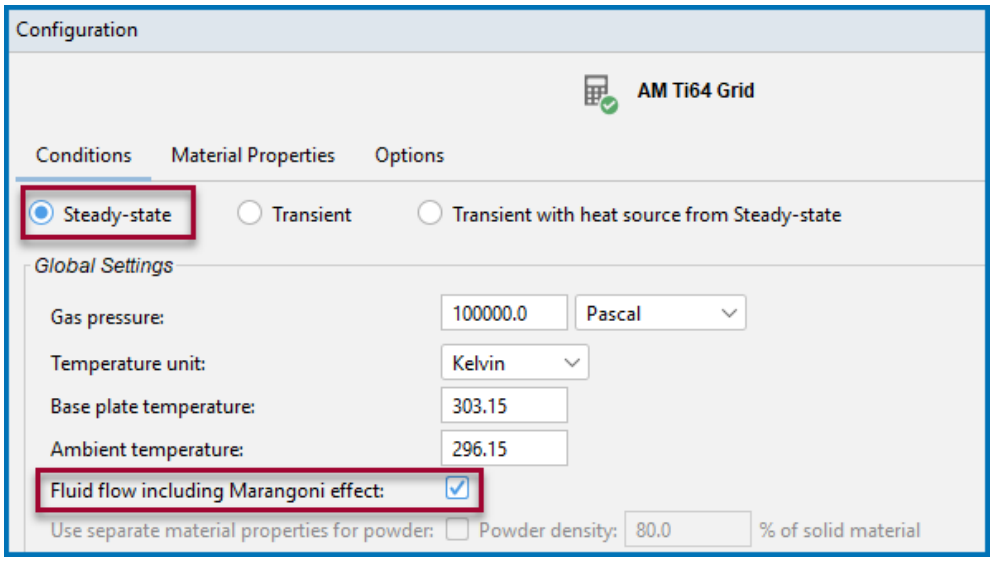
This example requires an Additive Manufacturing (AM) Module license.

Configuration and Calculation Set Up

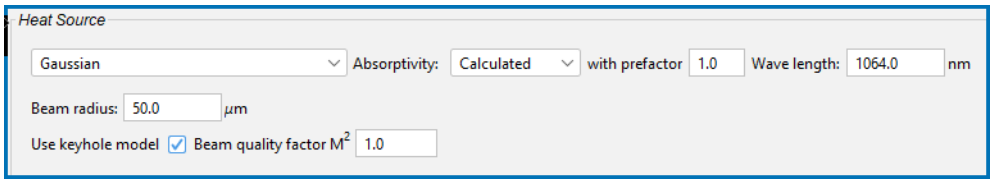
Below highlights some of the settings for this example to compare with experimental data of Ti64.

This example builds on the previous one (AM_07) and it is recommended to review this and to open the example file to locate and follow along for the settings described here and found on the **Configuration** window.

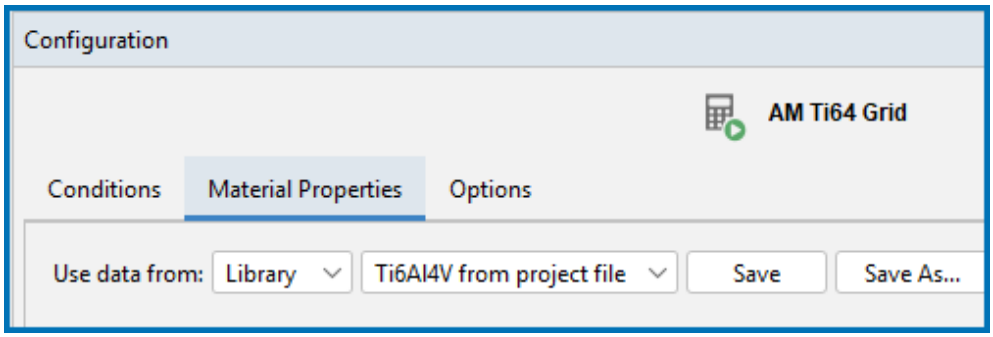
The **Steady-state** calculation includes **Fluid flow**.



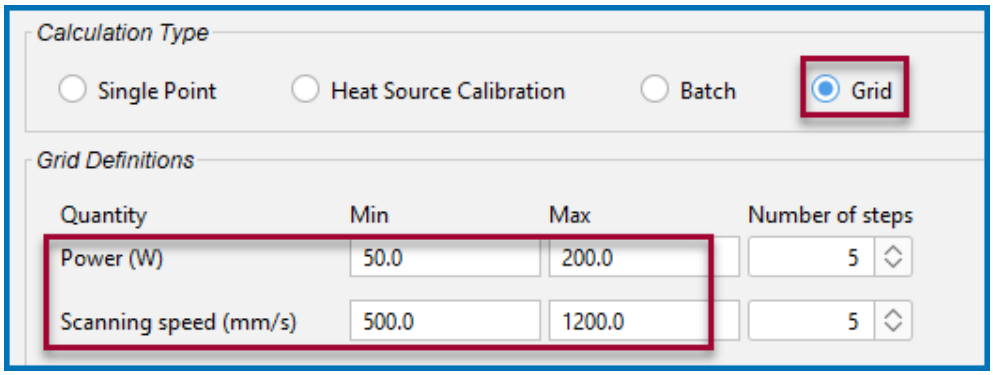
The *Heat Source* is set to **Gaussian** and uses the **Keyhole model**. The printers in the experiments had a beam diameter of `100` µm so the Gaussian **Beam radius** is set to `50` µm. The **Absorptivity** is set to **Calculated**.



The **Ti6Al4V from project file** material is selected from the **Material Properties** library. The material properties are precalculated and stored as a built-in material **Library**.



The **Grid***Calculation Type* is used to cover all the conditions from the experiments in a single calculation. The **Power** ranges between `50–200` W and the **Scanning speed** ranges between `500–1200` mm/s.



Visualizations

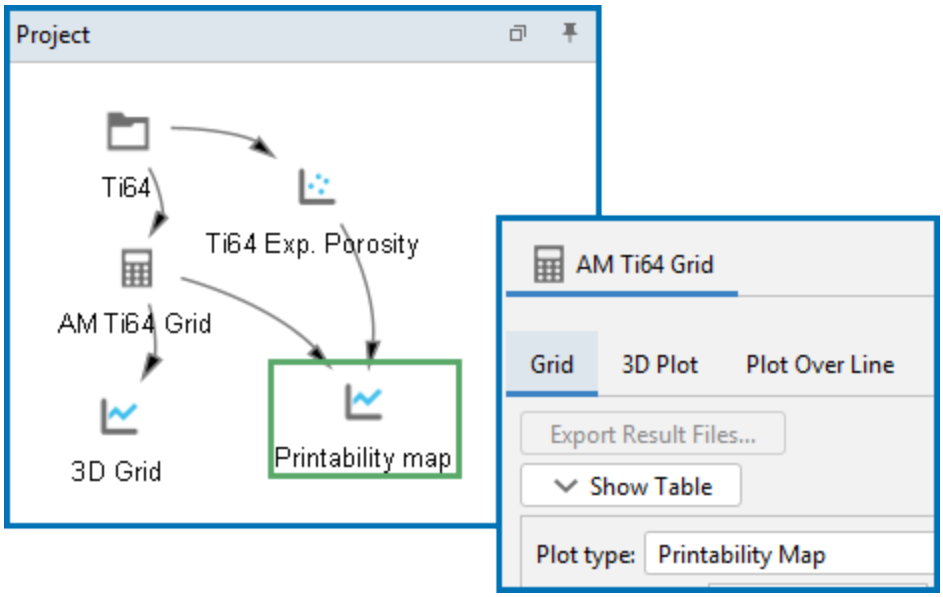
Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it can take around two hours to complete the calculations.

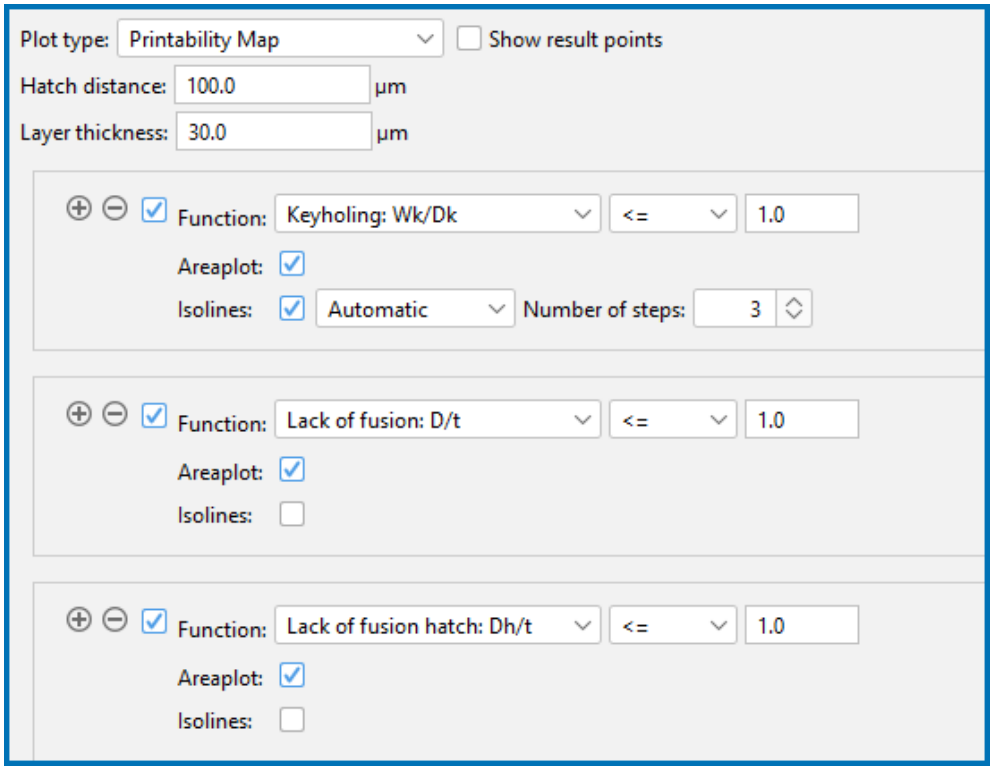
There is a wide variety of information shown both in the **Visualizations** and **Plot Renderer Configuration** windows that can be viewed during configuration and after performing the calculation(s). Not all views, such as the **Geometry** or previews, nor all additional output (i.e. plots) are shown in this section and it is recommended that you open and run the example to review all available options and results.

Plot Renderer Configuration Window

The combined results from the **Grid** calculation can be viewed under the matching **Grid** tab on the Plot Renderer **Configuration** window where it is set to use the **Printability map** plot type. In this example, the **Plot Renderer** node is renamed to **Printability map** in the **Project** window.



The experimental value of `30` µm powder thickness (**Layer thickness**) and `100` µm for the **Hatch distance** seems to be too big to produce dense builds according to this lack of fusion criteria. Full density can then in principle only be achieved by melting the regions between tracks by shifting the layers printed on top so the full depth of the melt pool covers unmelted regions.



Printability Map and 3D Plot

There is a video tutorial about the **Printability Map** on our website and on our YouTube channel. It is also included in the Additive Manufacturing Module YouTube playlist.

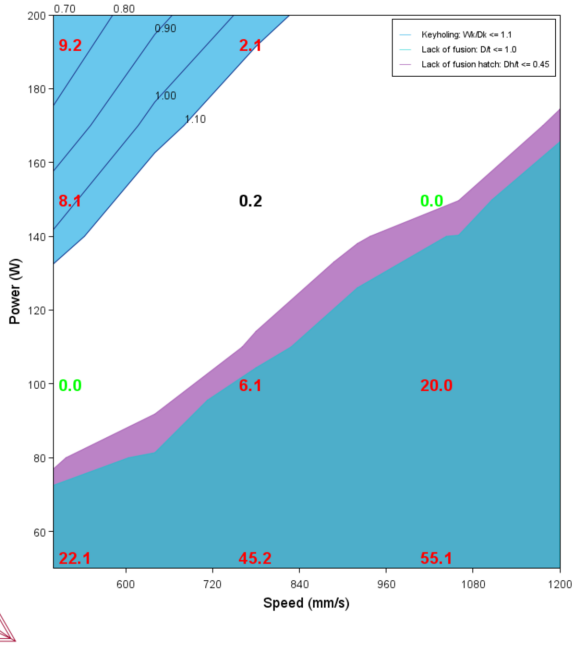


Figure 43: The calculated printability map for Ti64 showing the regions for keyholing porosity (upper left) and lack of fusion porosity to the lower right. The labels show the measured amount of porosity. Labels in red show regions with severe amounts of porosity and labels in black/green show regions with little or no defects.

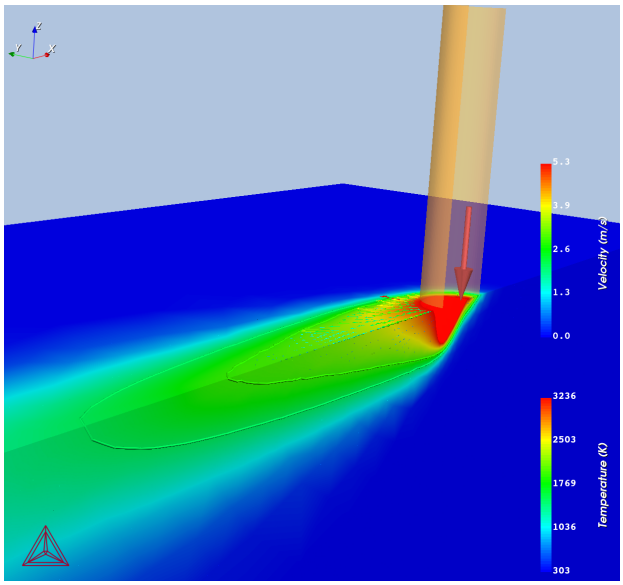

Figure 44: 3D plot showing a keyhole for the simulation that uses power 200 W and scan speed 1200 mm/s.

- File name: `AM_09a_Printability_Map_316L.tcu`

This example requires an Additive Manufacturing (AM) Module license.

Configuration and Calculation Set Up

Below highlights some of the settings for this example. This example builds on the previous ones (AM_07, AM_08a, and AM_08b) and it is recommended to review these and to open the example file to locate and follow along for the settings described here and found on the **Configuration** window.

The **Steady-state** calculation is configured with the **Gaussian***Heat Source* with the **Keyhole model** and includes **Fluid flow**.

The Gaussian **Beam radius** is set to 22 µm. The **Absorptivity** is set to 30 % and in the *Scanning Strategy* section, the powder **Layer thickness** is set to 10 µm.

The **SS316L** material is selected from the **Material Properties** library. The material properties are precalculated and stored as a built-in material **Library**.

The **Grid***Calculation Type* is used to cover all the conditions from the experiments in a single calculation. The **Power** ranges between 40–100 W and the **Scanning speed** ranges between 400–3000 mm/s.

Visualizations

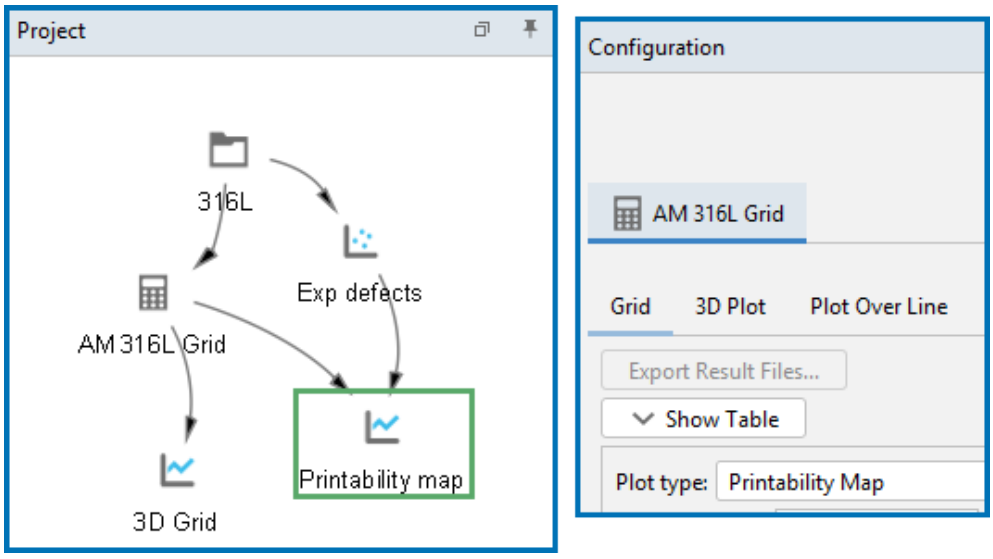
Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it can take around two hours to complete the calculations.

There is a wide variety of information shown both in the **Visualizations** and **Plot Renderer Configuration** windows that can be viewed during configuration and after performing the calculation(s). Not all views, such as the **Geometry** or previews, nor all additional output (i.e. plots) are shown in this section and it is recommended that you open and run the example to review all available options and results.

Plot Renderer Configuration Window

The combined results from the **Grid** calculation can be viewed under the matching **Grid** tab on the Plot Renderer **Configuration** window where it is configured to use the **Printability map** plot type. In this example, the **Plot Renderer** node is renamed to **Printability map** in the **Project** window.



Next each **Function** is defined and limits were adjusted to match the experimental regions of keyholing and lack of fusion porosity.

- The keyholing limit (**Keyholing: Wk/Dk**) is kept at default `1.0`.
- The **Lack of fusion: D/t** is increased from default of `1.0` to `1.3`.
- The experiments were only single-track and the lack of fusion at half of the hatch distance (**Lack of fusion hatch: Dh/t**) is kept at default `1.0` and only included together with the **Hatch distance** of `35` µm for demonstration purposes.

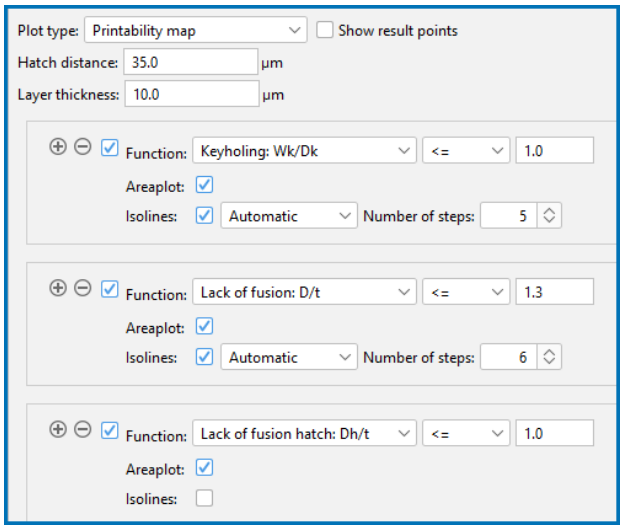


Figure 50: The settings for the printability map with the Function limits defined for keyholing, lack of fusion, and lack of fusion at half of the hatch distance (as described in the text).

Printability Map and 3D Plot

There is a video tutorial about the **Printability Map** on our website and on our YouTube channel. It is also included in the Additive Manufacturing Module YouTube playlist.

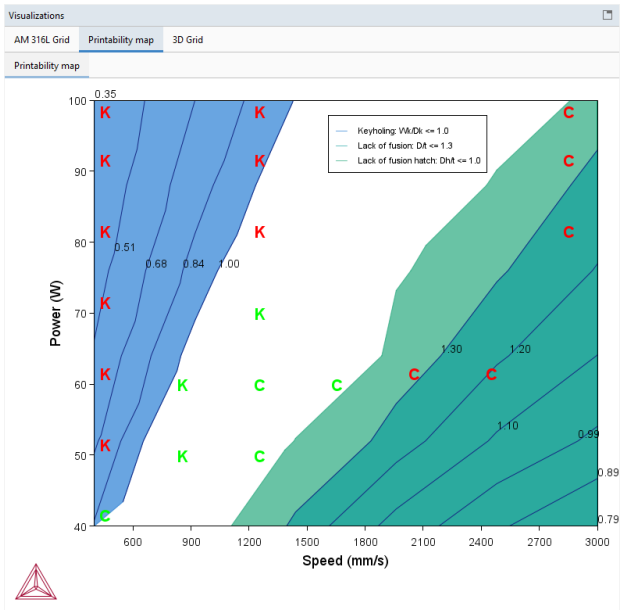

*Figure 51: Printability map for 316L showing regions of keyholing and lack-of-fusion. Experimental information from Hu et. al. [2019Hu] overlaid as coloured labels showing keyhole porosity (**K**), conduction mode with lack-of-fusion porosity (**C**). Green labels showing experiments without defects for conduction mode (**C**) and keyhole mode (**K**).*

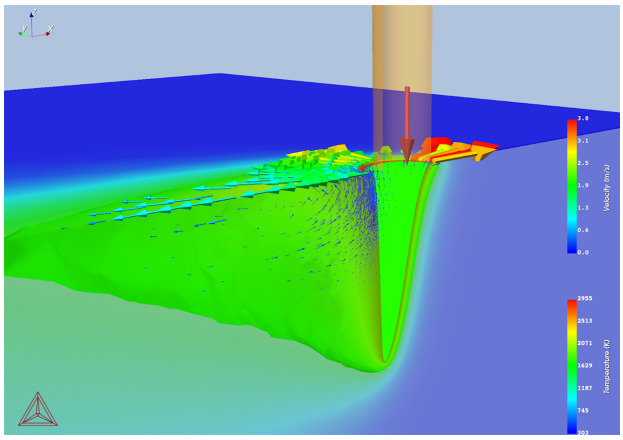

Figure 52: 3D plot showing a keyhole for the simulation that uses power 100 W and scan speed 400 mm/s.

AM_10: CET Transition in an IN718 Alloy

The example uses a **Scheil Calculator**, **AM Calculator**, and the **Property Model Calculator** with the **Columnar to Equiaxed Transition** Property Model to compare calculated CET curves for an IN718 alloy (from example PM_G_17) with the solidification conditions of the melt pool in the AM simulation.

Background

A Scheil with solute trapping calculation is done first on the **Scheil Calculator** to generate thermophysical properties data to the **AM Calculator**. A steady-state AM simulation is done to predict the solidification conditions in the melt pool, the solidification rates, and thermal gradients.

Then using the **Property Model Calculator** with the **Columnar to Equiaxed Transition (CET)** model, the calculated CET curves for an IN718 alloy are fed into the **AM + CET** node (the renamed Plot Renderer), where together the data from the AM and Property Model calculations are combined and overlaid on one plot.

The literature data from Polonsky et al. [2020Pol] are not purely experimental data, but rather combined with experimental equiaxed evidence and model calculations with numerical values of thermal gradients, growth velocity as well as tip undercooling. Polonsky et al. estimated tip undercooling based on a Scheil calculation, which smeared out the composition inhomogeneity at the dendrite front, hence underestimating the undercooling. Since both tip undercooling and nucleation site density promotes the formation of equiaxed crystals, an increase in undercooling in this example calculation leads to a decrease in nucleation site density compared to the results in [2020Pol] if one were fitting the same set of data.

- Folder: **Additive Manufacturing**
- File name: `AM_10_Columnar_to_Equiaxed_Transition_IN718.tcu`

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. This example also requires additional database licenses for the TCS Ni-based Superalloys Database (TCNI) (TCNI12 and newer), and the TCS Ni-alloys Mobility Database (MOBNI) (MOBNI6 and newer).

Configuration and Calculation Set Up

On the **Scheil Calculator** (renamed to *Scheil with solute trapping*) , the **Scheil with solute trapping** is used with these specific settings:

- Trans-interface diffusivity: **Same for all elements**
- Prefactor: `5.0E-9`
- Maximum velocity for infinite driving force: `2000` m/s
- Model: **Aziz**
- Interface driving force: **Driving energy**

For the **AM Calculator** (renamed to *AM Steady-state*), the **Steady-state** calculation is configured as a **Gaussian** *Heat Source* with the **Keyhole model** and includes **Fluid flow**. It also uses a **Single Point** calculation with the **Calculated Absorptivity**.

On the **Property Model Calculator** (renamed to *Columnar to Equiaxed Transition*) a **One Axis** calculation for the **FCC_L12** primary phase is done using the CET parameters entered on the **Configuration** window.

The settings on the Property Model Calculator include:

- Interfacial energy: `0.5` J/m^2.
- Number of nucleation sites: `4.0E11`/m^3
- Nucleation undercooling : `4.0` K
- Equiaxed exponent: `3.13`
- Solve for: **Thermal gradient**
- Equiaxed fractions: `0.01 0.49 0.99`
- Solidification rate: `log10(v)`

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a wide variety of information shown both in the **Visualizations** and **Plot Renderer Configuration** windows that can be viewed during configuration and after performing the calculation(s). Not all views, such as the **Geometry** or previews, nor all additional output (i.e. plots) are shown in this section and it is recommended that you open and run the example to review all available options and results.

The thermal gradients and solidification rate can be visualized in 2D or 3D. Figure 59 shows the thermal gradient along the melt pool boundary in a 3D plot. Only the data corresponding to solidification conditions are shown. The thermal gradients corresponding to melting conditions are filtered out and only the tail part of the meltpool are shown.

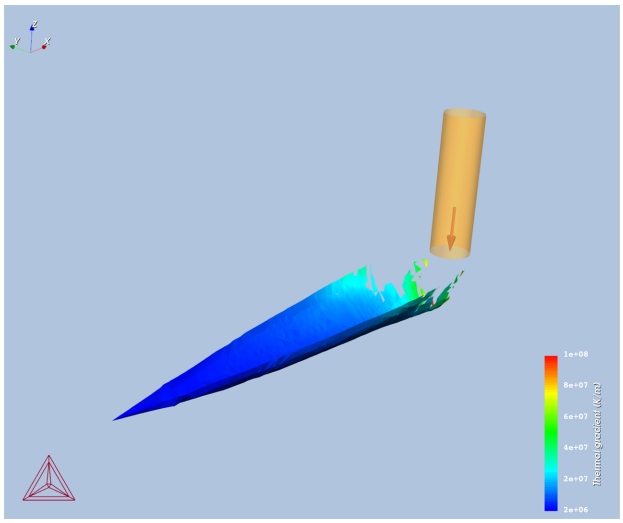

Figure 59: The 3D Plot for the 3D Thermal Gradient Plot Renderer.

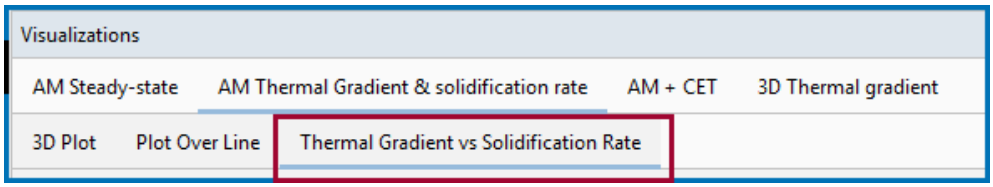
Both the thermal gradients and solidification rates from the melt pool can be visualized at the same time in a 2D scatter plot when the Plot Renderer tab **Thermal Gradient vs Solidification Rate** is selected.



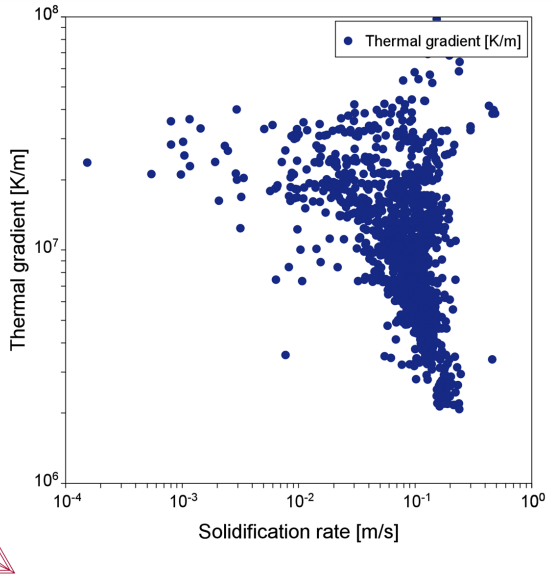


Figure 60: The solidification rate vs thermal gradient is shown on the AM Thermal Gradient & Solidification Rate Plot Renderer.

Figure 61 is an example of a plot where the results from both the AM simulation and the CET model for the IN718 thermal gradient vs solidification rate are overlaid on the same plot. The blue, red, and green lines show the increasing equiaxed fraction from the CET Property Model and the points show the solidification conditions at the melt pool calculated with the Additive Manufacturing (AM) Module. When the results are overlaid like this, you can see that nearly all the points (those below the purple line) exist in a fully columnar region.

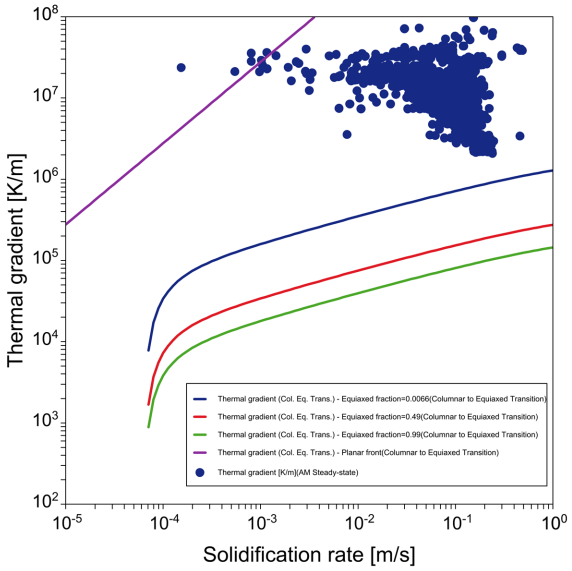

Figure 61: The solidification rate vs the thermal gradient overlaying both plots from the AM Calculator and Property Model Calculator (via the AM + CET Plot Renderer).

AM_11: Comparing Single Tracks Printed on Casted and LPBF Substrates

Bogdonova et al. [2024Bog] performed single track experiments with the alloy Al10SiMg. The study compared the printing of single tracks on two types of substrates—one fabricated with traditional casting and the other with laser powder bed fusion (LPBF).

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: `AM_11_Batch_Al10SiMg.tcu`

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. This example also requires an additional database license for the TCS Al-based Alloys Database (TCAL) (TCAL9 and newer).

Background

It is well known that the thermal conductivity of the alloy Al10SiMg is drastically reduced in the as-printed condition when fabricated by LPBF compared to conventionally manufactured counterparts [2022Gha].

Thermal conductivity in Thermo-Calc is modeled as a temperature- and composition-dependent property per phase, and the conductivity of the alloy is taken as an average over the stable phases. The composition of the primary phase can change greatly depending on the fabrication method where the LPBF method results in rapid solidification and solute trapping of solute alloy elements.

Thermal conductivity can generally be reduced by different scattering phenomena (pores, defects, phase interfaces) within the microstructure and can therefore be lower than the calculated conductivity averaged over the phases.

The electrical resistivity due to phase interface scattering is evaluated as the scattering constant times sum of the interaction between the volume fraction of all the phases. The default value for the phase interface scattering constant is found to be 4.0e-8 Ωm for aluminum alloys. The contribution to thermal conductivity is assumed to be related to that of electrical resistivity, following the Wiedemann-Franz law.

The rapid solidification during LPBF generally results in a much finer microstructure compared to traditional casting. LPBF fabricated Al10SiMg solidifies with a cellular primary FCC structure and a eutectic structure between the cells [2021Lef]. An increased interface scattering constant more than 4.0E-8 can be argued given the much finer structure that has a large number of phase interfaces.

In this example the effect on material properties and melt pool dimensions is compared when printing single tracks on the two types of substrates. The material properties for the traditionally cast alloy is calculated using regular Scheil and the default interface scattering constant of `4.0E-8`. The material properties for the LBPF fabricated alloy is calculated using Scheil with solute trapping and the effect of increasing the interface scattering is shown.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a wide variety of information shown both in the **Visualizations** and **Plot Renderer Configuration** windows that can be viewed during configuration and after performing the calculation(s). Not all views, such as the **Geometry** or previews, nor all additional output (i.e. plots) are shown in this section and it is recommended that you open and run the example to review all available options and results.

When you run (Perform) this example, it can take around two hours to complete the calculations.

Material Properties for the As-cast Substrate Material

The TCS Al-based Alloys Database (TCAL) is selected on the **System Definer** (renamed to *Scheil As-cast*). The as-cast Al10SiMg alloy has the composition of Al-10.8Si-0.3Mg-0.1Cu-0.1Fe.

The **Scheil Calculator** (renamed to *Scheil As-cast*) is configured with default settings for AM with an evaluation of thermophysical properties from 5000 K down to room temperature. The **Calculation type** is set to **Classic Scheil**.

Material Properties for the LPBF Printed Substrate Material

The TCS Al-based Alloys Database (TCAL) is selected in the **System Definer** (renamed to *Scheil printed*). The LPBF Al10SiMg alloy has almost the same composition (Al-10.8Si-0.3Mg-0.1Cu-0.2Fe) with only a small difference in Fe content.

The **Scheil Calculator** (renamed to *Scheil Solute-Trapping*) is configured with the default settings for AM with an evaluation of thermophysical properties from 5000 K down to room temperature. The **Calculation type** is set to **Scheil with solute trapping**.

Comparing Material Properties Between the Substrates

Two plots overlay results from the two Scheil Calculators in Figure 62. The Plot Renderer, renamed to *Si in primary FCC*, shows the Si content in the primary FCC phase. The classic Scheil calculation gives less than 1.5 at% Si. The solute trapping simulation results in twice the Si content with about 3 at% Si in the primary FCC phase. Atom probe experiments for a LPBF printed Al10SiMg alloy measured 3.08 at% Si in the FCC cell structure for the as-printed condition [2021Lef].

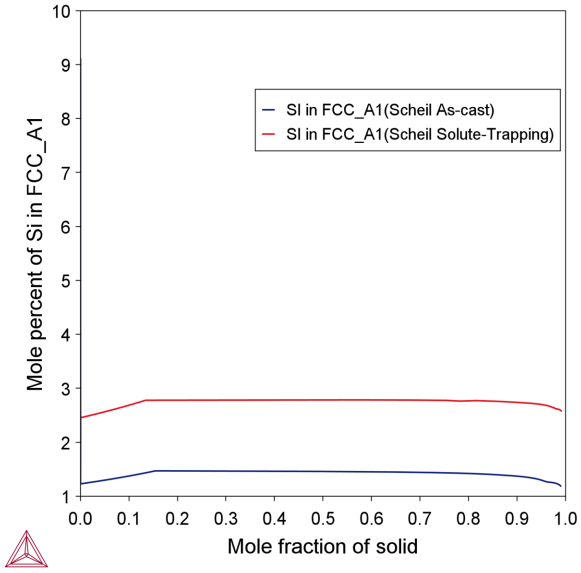

Figure 62: Silicon content in the primary FCC phase comparing regular (classic) Scheil with Scheil and solute trapping. The solute trapping almost doubles the Si content in the primary FCC phase.

Figure 63 is another overlaid plot that takes the results from two Scheil Calculator predecessors to show how the thermal conductivity varies with temperature. The conductivity for the as-cast substrate (blue line), that uses classic Scheil and the default setting for the phase interface scattering constant (`C = 4.0E-8`), naturally gives the highest thermal conductivity. The red line shows the reduction in conductivity due to solute trapping and the increased Si content in the primary phase. The green line shows further reduction in thermal conductivity due to the increased interface scattering when the scattering constant was increased (`C = 1.0E-7`).

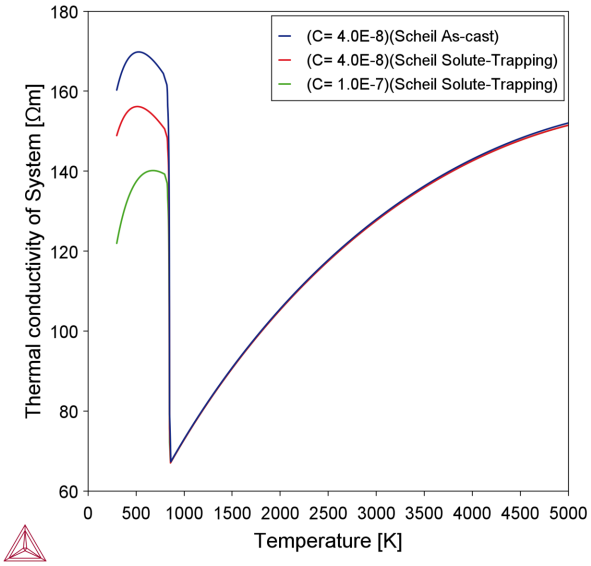

Figure 63: Thermal conductivity for as-cast substrate and printed substrate. Blue line shows conductivity for as-cast structure using the default setting for the interface scattering constant (C = 4.0E-8). The red line shows the reduced conductivity due to the solute trapping. Finally, the green line shows further reduction in thermal conductivity due to increased interface scattering where C = 1.0E-7.

Batch AM Steady-State Simulations

Two AM Calculators are next set up. These are renamed to *As-cast Batch* and *AM Batch*. These AM batch steady-state simulations are configured with similar settings, except for the interface scattering and the measured experimental melt pool dimensions that are different for the as-cast and LPBF fabricated substrates. The interface scattering settings are found on the **Material Properties** tab for both AM Calculators:

- The as-cast substrate uses the default interface scattering (`C = 4.0E-8`).
- The LPBF as-printed substrate uses the increased value for interface scattering (`C = 1.0E-7`).

The shared settings in the AM Calculator configuration (on the **Conditions** tab) are:

- Uses **Fluid flow including Marongoni effect** and the **keyhole model**.
- **Absorptivity** is selected as **Calculated** and the **with prefactor** is set to `1.8` times the calculated value in order to match the experimental melt pool dimensions.

> The need to use a large prefactor is probably related to surface oxides and that the calculated absorptivity is for an oxide free liquid surface. The stable oxide Al_2O_3 often forms at the surfaces of Al-alloys where it remains in solid form to above 2000 °C and evaporates well above 3000 °C.

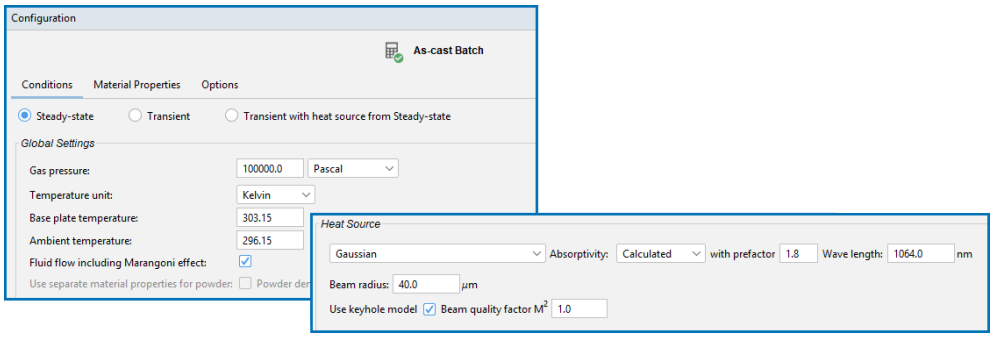

Figure 64: The settings window for an AM steady-state simulation for the As-cast Batch calculator. Fluid flow and Gaussian heat source with keyhole model are enabled, plus it uses a calculated absorptivity with a prefactor set to 1.8.

> To reduce total calculation time, for each AM Calculator only 5 of the 12 experiments are selected on the Plot Renderer (click **Show Table** to see the details). However, the example still takes about two hours to perform.

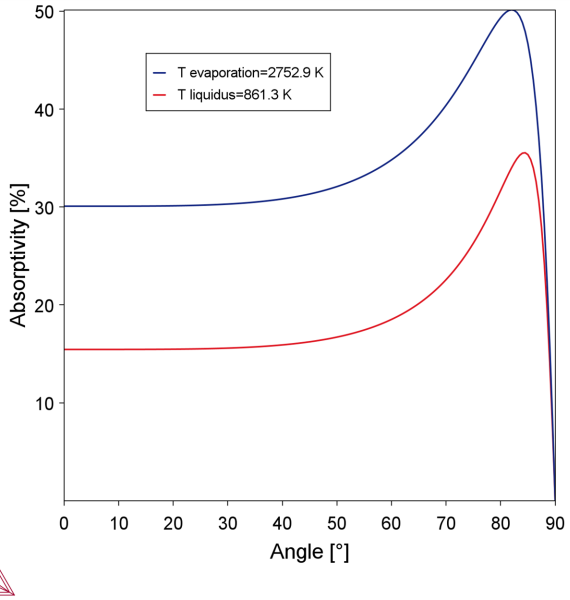

Figure 65: The temperature- and incident angle-dependent absorptivity. Red curve shows the absorptivity as a function of incident angle at the liquidus temperature, the blue curve shows the corresponding absorptivity at the evaporation temperature.

Turbulent Flow - Large Eddy Simulations

Al-alloys have in general lower viscosity compared to other metallic alloys (e.g. Ti-, Fe- or Ni-based alloys). The low viscosity in combination with high fluid flow rates can result in turbulent flows. This happens in this example for the simulations at the higher energy densities. The turbulent flow model implemented in the AM simulation is based on *Large Eddy Simulations* (LES) where the large-scale motions are represented directly and smaller-scale motions are modeled. A larger Smagorinsky constant filters more small-scale motions to be modeled. The example increases the Smagorinsky constant to `0.5`. The simulations with the highest energy densities will otherwise fail to converge with the default value of `0.18`.

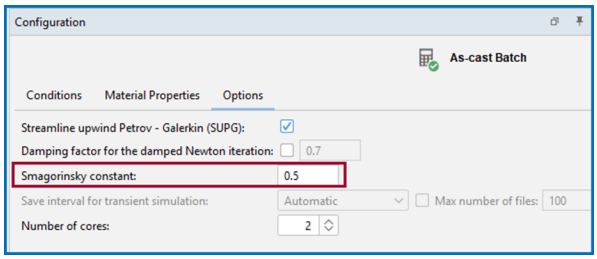

Figure 66: On the Options tab for the AM Steady-State simulation (As-cast Batch) with an increased Smagorinsky constant to handle the high turbulent flows.

The following parity plot examples compare the experimental versus calculated melt pool dimensions. In general a good trend can be seen for both the simulations with the as-cast and LPBF fabricated substrates. The experimental melt pools are in general deeper than the simulated with an increasing error with increasing depth of the melt pool.

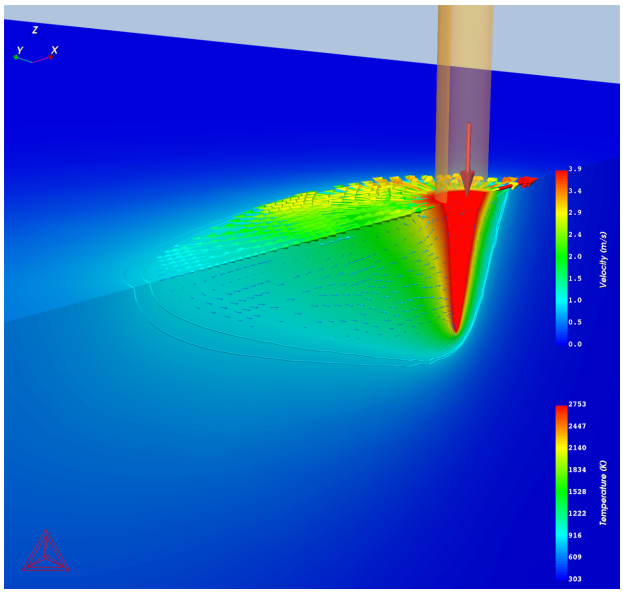

Figure 67: 3D plot of melt pool for as-cast substrate where P = 325 W and scanning speed = 600 mm/s.

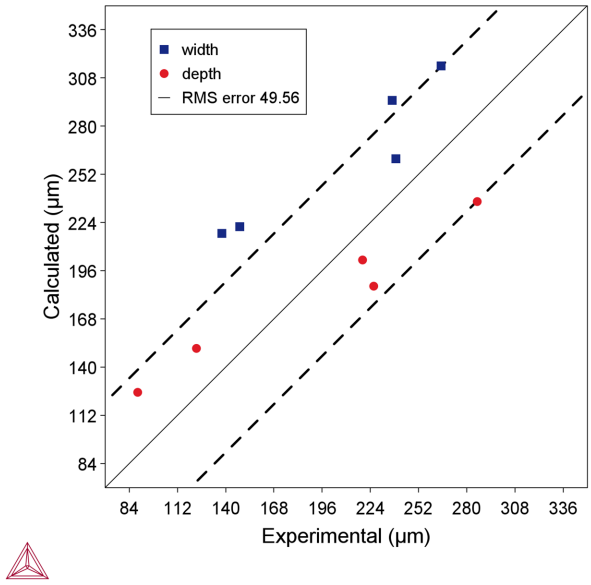

Figure 68: Parity plot for as-cast substrate when 5/12 experiments are calculated.

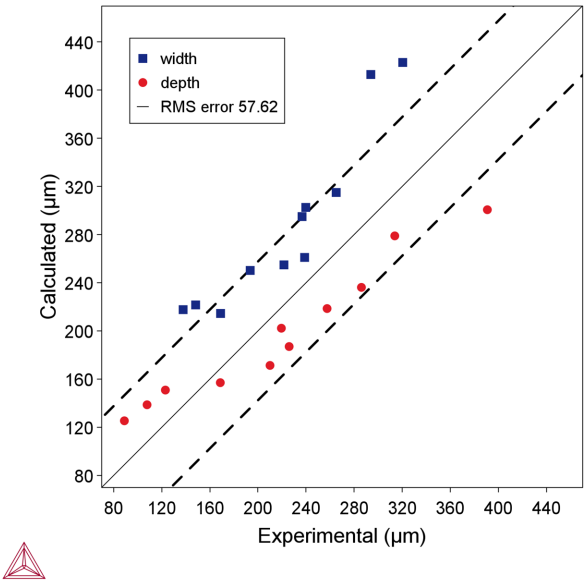

Figure 69: Parity plot for as-cast substrate when all 12 experiments are calculated.

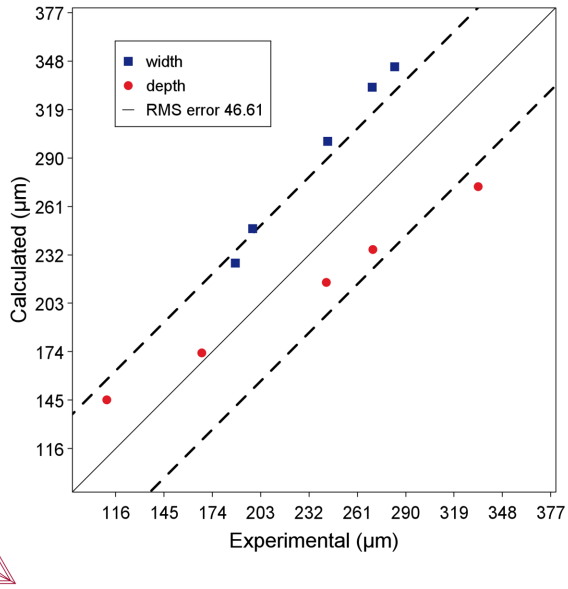

Figure 70: Parity plot for LPBF printed substrate when 5/12 experiments are calculated.

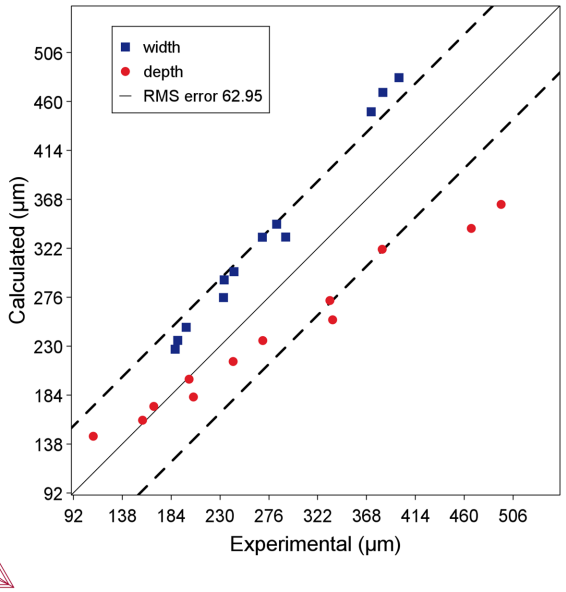

Figure 71: Parity plot for LPBF printed substrate when all 12 experiments are calculated.

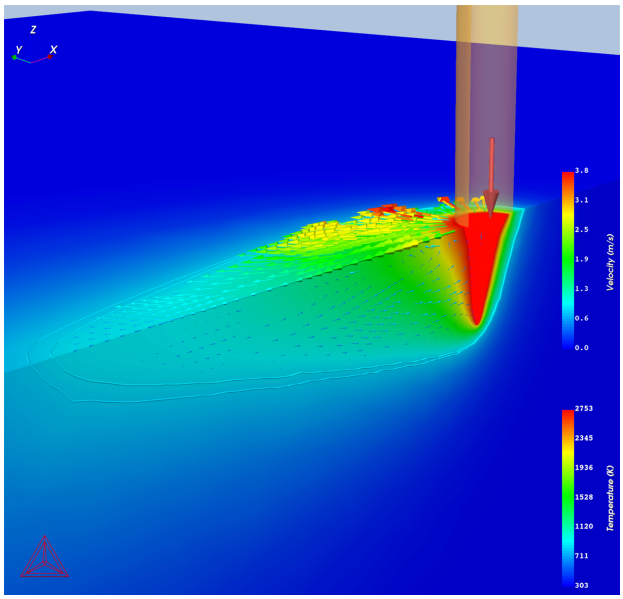

Figure 72: 3D plot of melt pool for LPBF printed substrate where P = 325 W and scanning speed = 1200 mm/s.

AM_12: Using AM Calculator Probe Data with the Precipitation Module (TC-PRISMA)

This example demonstrates the coupling of the **AM Calculator** with the **Precipitation Calculator** via probe data from an AM simulation. Both a thermodynamic and mobility database is needed for the precipitation calculation, so the AM Material Library cannot be used. Instead, a **Scheil Calculator** is used to calculate the material properties used in the AM simulation.

The example simulates the incipient melting and re-precipitation of gamma prime in CMSX-4 during Selective Electron Beam Melting (SEBM) during a single pass of the beam. The SEBM process is simulated using an Electron Beam heat source. A transient with heat source from Steady-state simulation of a single track is simulated, with a cooling time of 150 s. The bed and ambient temperature is elevated to 950 °C. The process parameters are taken from Ramsperger et al. [2016aRam].

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: *AM_12_AM_Probe_to_Precipitation.tcu*

A separate license is required to perform calculations with the Additive Manufacturing (AM) Module. This example also requires a license for the Precipitation Module (TC-PRISMA), plus additional database licenses for the TCS Ni-based Superalloys Database (TCNI) (TCNI13 and newer is recommended for best results), and the TCS Ni-alloys Mobility Database (MOBNI) (MOBNI6 and newer).

Background

Ramsperger and Körner [2016bRam] demonstrated that it is possible to print single crystal CMSX-4 components using SLBM with an elevated bed temperature. The main challenge encountered is fracture during printing. The formation of gamma prime may incur a drop in ductility that contributes to fracture. Understanding the precipitation kinetics of gamma prime during 3D printing is important with regards to identifying optimum process parameters, and determining how best to heat treat the final component.

Wahlmann et al. [2019Wah] studied gamma prime kinetics in emulated SLBM thermal conditions, indirectly measuring the size of the gamma prime using X-ray diffraction during repeated nucleation and dissolution thermal cycles imitating the thermal history of an SLBM build. Figure 73 shows the calibration of the Precipitation Calculator to capture the measured kinetics.

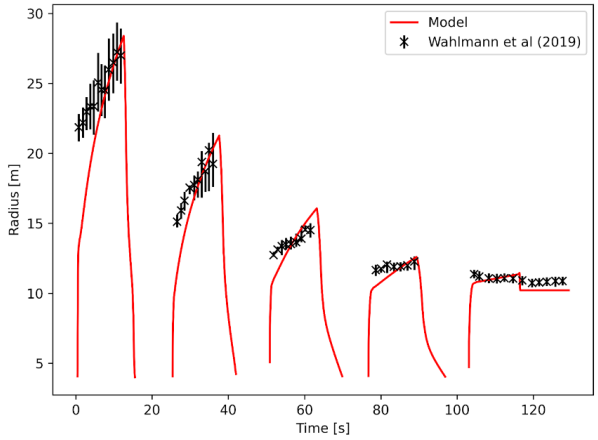

Figure 73: A comparison of the indirectly measured gamma prime size evolution during thermal heat treatment emulated an SLBM process with predictions from the Precipitation Calculator using the Thermo-Calc Ni-based superalloys databases (TCNI12 and MOBNI6) [2019Wah].

This AM Calculator to Precipitation Calculator example uses the calibrated parameters for gamma prime kinetics shown in Figure 73. The Precipitation Calculator includes the possibility for incipient melting of the gamma prime, which is predicted to occur during the first pass of the electron beam. Incipient melting describes the phenomena where solid-state precipitates are heated rapidly to a high temperature beyond their solvus temperature. The precipitates reach a temperature where they melt before the parent matrix phase. The Precipitation Calculator removes the gamma prime dispersion upon melting.

Configuration and Calculation Set Up

The **Additive Manufacturing** template was used to first add the **System Definer**, **Scheil Calculator**, **AM Calculator**, and **Plot Renderer** to the **Project** window tree. Additionally, a **Precipitation Calculator** was added as a successor to the AM Calculator in order to automatically import the time-temperature profile from the AM simulation into the precipitation simulation.

Open the example to see the **Project** tree layout and review the settings for each activity. It is useful to click around in the interface to understand where the settings are located and configured. This section highlights the relevant settings for this example.

System Definer

On the **System Definer**, the nickel-based superalloy CSMX-4 composition was approximated by Ni-9.8Co-6.4Ta-6.5Cr-6.4W-5.7Al-2.8Re-0.97Ti-0.62Mo-0.086Hf, (mass%). The thermodynamic (TCNI) and mobility (MOBNI) nickel-based superalloy databases were selected, with the phase **DIS_FCC_A1** included.

You can include or exclude phases from the **Phases and Phase Constitution** tab on the System Definer.

AM Calculator

On the **AM Calculator Configuration** window, the calculation type **Transient with heat source from Steady-state** is selected with a single track scan pattern and **Geometry** of 5 mm x 5 mm x 5 mm (height x width x length). The **Base plate temperature** and **Ambient temperature** is set to 950 °C with a gas pressure of 1 Pa.

Additional settings are then made on the **Configuration** window as follows.

- In the *Heat Source* section, **Electron Beam** is selected with a **Power** of `1110` W, a **Calculated Absorptivity**, an **Acceleration voltage** of 60 kV, and a **Beam radius** of 250 µm. The **keyhole model** checkbox is selected.
- In the *Scanning Strategy* section, the **Scanning speed** is `2000` mm/s and the **Layer thickness** is `50` µm. A **Cooling time** of `150` s is included.
- In the *Top Boundary Conditions* section, the **Evaporation** checkbox is selected to include this in the model.
- In the *Probe Positions* section, a single probe is added to the center of the top surface of the component, below the powder layer. See the **Geometry** tab as shown in Figure 74.

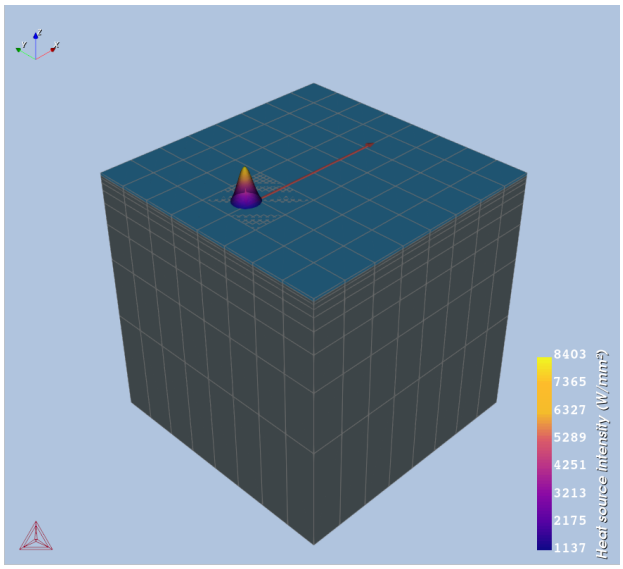

Figure 74: The full geometry set up for the single track AM simulation with a probe point added to the middle of the scan. Open the example to better see the set up and try working in the Visualizations window.

Precipitation Calculator

The following highlights the relevant settings to make on the **Configuration** window for this example.

On the **Options** tab:

- Both the **Preprocess equilibrium data** and **Include incipient melting** checkboxes are selected.

On the **Conditions** tab, under *Matrix Phase*:

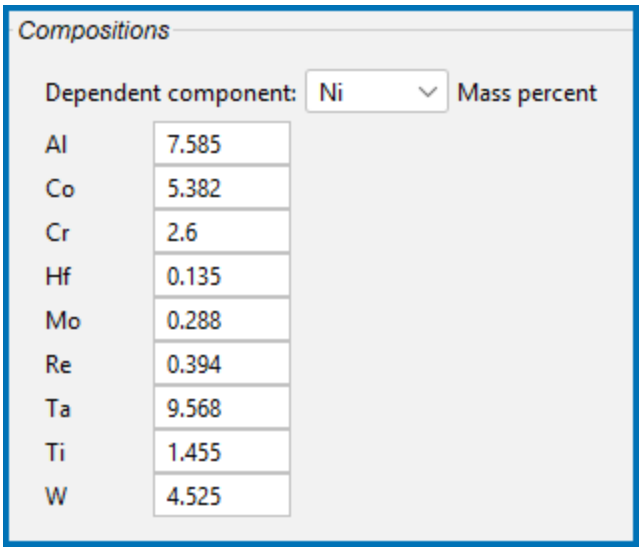
- **DIS_FCC_A1** is selected.

  Also see "Selecting the Disordered Phase as a Matrix Phase" in the *Precipitation Module User Guide*, or search for this in the help.

- Click **Show Details**, then for **Mobility adjustment > Prefactor**, keep **Same for all elements** and enter `6.0` for the **Prefactor**.

On the **Conditions** tab, under *Precipitate Phase*:

- **FCC_L12#2** is selected.
- **Nucleation sites** = **Bulk**
- **Interfacial energy** = `0.035` J/m^2
- Click **Show Details**, then:
  - **Phase energy addition** = `-55.0` J/mol
  - Select the **Preexisting size distribution** checkbox.
  - Click **Edit Particle Size Distribution**, and note the *Compositions* entered.



In the **Preexisting Particle Size Distribution** window you can also adjust other settings. In this case, the size distribution is approximated by a Weibull distribution function with a mean radius of 200 nm, an Alpha of 2.0, and a fraction offset of 0.5 Search for "Particle Size Distribution (PSD)" in the *Precipitation Module User Guide*, or in the help.

On the **Conditions** tab, under *Calculation Type*:

- **Temperature unit** = **Kelvin**
- **Start time** = `0.0`
- **Simulation time** = `150.01`**Seconds**
- **Probes**: **Probe1**
- **Condense time-temperature data** = **None**

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation(s).

Figure 75 and Figure 76 show the predicted evolution of the precipitate dispersion including the change in mean radius and volume fraction, respectively. The second Y axis in both figures shows the temperature. The initial gamma prime size distribution describes the gamma prime that has formed during the production of the AM powder. It is too large to dissolve during the rapid heating as the electron beam heats the component, and melts before the matrix. The gamma prime re-precipitates upon resolidification and cooling below the gamma prime solvus, and coarsens whilst held at elevated temperature. The incipient melting of the initial size distribution is clearly evident.

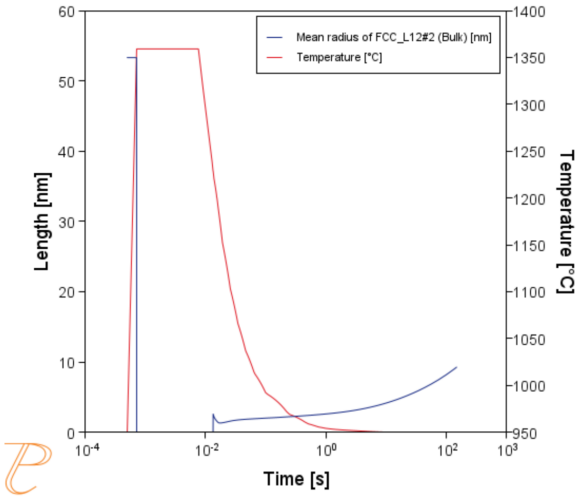


Figure 75: The mean radius and temperature as a function of temperature, with the mean radius on the left axis, and the temperature on the right axis.

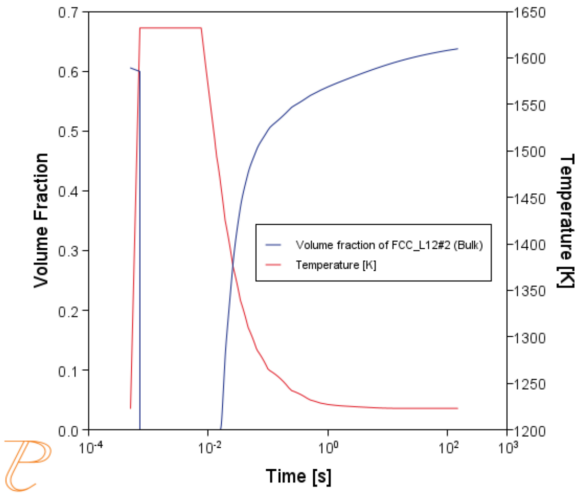

Figure 76: The volume fraction and temperature as a function of temperature, with the volume fraction on the left axis, and the temperature on the right axis.

The gamma prime distribution just prior to incipient melting is observed at 0.004 s. It has not dissolved significantly during the rapid heating as the electron beam passes. At 1 s the material has solidified and cooled to a temperature where gamma prime has nucleated and grown. The size distribution at the end of the simulation is shown at 150.1 s. Figure 77 shows the size distributions at these times during the single track AM simulation.

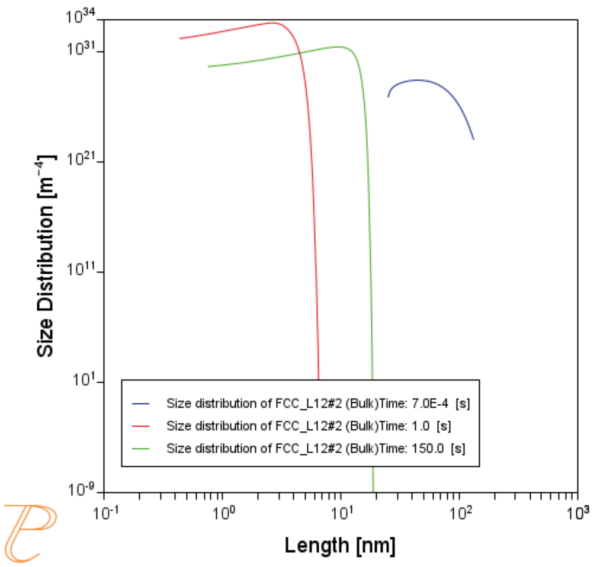

Figure 77: The size distributions of gamma prime at key points during the simulation.

AM_13: Using the Core-ring Beam Shape

This **Steady-state** example demonstrates the use of **Core-ring** *Heat Source* model available in the AM Module with **Batch** calculations.

The heat source parameters for the **Core-ring** heat source, as well as the processing parameters (power and speed), are taken from Holla et al. [2024Hol]. The example also compares the predicted melt pool dimensions with the experimental data from this paper.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: *AM_13_CoreRing_BeamShape.tcu*

This example requires an Additive Manufacturing (AM) Module license.

Background

In a core-ring heat source, the energy is distributed between the central core and the surrounding ring, allowing for more precise control of heat input and a more uniform temperature distribution, reducing the risk of unstable keyhole formation [2023Bi]. Furthermore, a wider melt pool with the **Core-ring** beam shape as compared to a Gaussian profile allows enlargement of the hatch distances and together with the possibility of using higher scanning speeds, results in faster printing process and increased productivity [2021Grü].

The inclusion of a **Core-ring** heat source model in the AM Module, together with the keyhole model, allows you to predict the temperature evolution and melt pool shape along with the transition from conduction mode to keyhole mode for a **Core-ring** heat source. The experimental data taken from the literature [2024Hol] demonstrates the use of a **Core-ring** heat source for single track experiments on stainless steel 316L bare plates. A wide range of process parameters (power = 200 W – 900 W and scanning speed = 200 mm/s – 800 mm/s) also shows different cases for both conduction as well as the keyhole mode, which are correctly predicted in this example by the simulation results.

Material Properties

- SS316L: Fe-17.0Cr-12.0Ni-2.5Mo-0.03C Mass percent
- Database: TCFE13 and with interface scattering = 1e-07.
- The material properties are precalculated, and stored as a built-in material library with the Additive Manufacturing (AM) Module.

AM Calculator Configuration Settings

This example contains one AM Calculator, which is renamed to **Core-ring_20/80**. On the **Configuration** window, **Conditions** tab, this **Steady-state** calculation is configured with the **Core-ring***Heat Source* with the **Keyhole model** and includes **Fluid flow**.

The **Custom Mode** is used in order to set all the heat source parameters as given in Table 2 of [2024Hol]. Individual settings are entered to match:

- **Beam radius-Core**: 47.6 µm
- **Beam radius-Ring**: 25.29 µm
- **Ring radius**: 68.4 µm

The **Amount of power in the ring** is set to **80%**, which is equivalent to 20/80 beam shape in [2024Hol].

The **Absorptivity** is set to **Calculated** with a **prefactor** of `1.2`. It uses the **keyhole model** where the **Beam quality factor M**^{2} is kept as `1.0`.

The **Batch***Calculation Type* is used to set up all the conditions from the experiments in a single calculation. In the *Batch Experiment Data* section, the experimental **Power** and scan **Speed** as well as the measured melt pool Width (**Exp width**) and Depth (**Exp. depth**) were collected in a CSV file and imported into the software. This data is then saved in the project file.

In the *Batch Experiment Data* table, the **Power** ranges between 200 W to 900 W, and the scan **Speed** ranges between 200 mm/s to 800 mm/s.

AM Calculator Conditions Settings and AM Calculator Heat Source Settings

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

For more information also see Working with AM Visualizations.

Parity Plot

This specific **Parity** plot is shown by clicking the **Parity Plot** node in the **Project** window. Then you can see on the **Visualizations** window it is in the tab of the same name. The settings are located on the **Configuration** window on the **Batch** tab.

The plot compares experimental and calculated melt pool width and depth for all experiments. The experiments are single tracks on bare plate SS316L with varied power and scan speed using a **Core-ring** heat source.

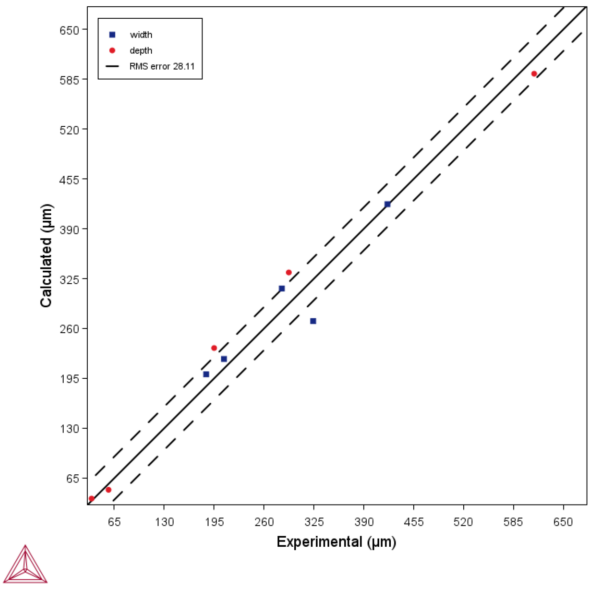

Figure 78: Parity plot comparing experimental and calculated melt pool width and depth for all the experiments when using a Core-ring heat source. The Root Mean Square (RMS) error can also be seen as a dashed line.

3D Plots

The specific **3D Plot** that is highlighted in this section is shown by clicking the **3D Plot** node in the **Project** window. Then on the **Visualizations** window on the tab of the same name, you can use various toolbar buttons to navigate and experiment with the views, for example:

Zoom to Heat Source position

In Figure 79, and using a combination of the **Plot Renderer Configuration** window settings on the **3D Plot** tab and the **Visualizations** window, different zoom levels and adjusting the **Glyph scale factor** setting helps to clearly show the melt pool and velocity vectors.

Further, the plot on the left is displayed by choosing the applicable **Batch experiments** results from the list (P=200 W, V=500 mm/s) and this set of experiments undergoes melting in conduction mode. Then the plot on the right is displayed by choosing the applicable **Batch experiments** results (P=600 W, V=200 mm/s) and that one forms a keyhole.

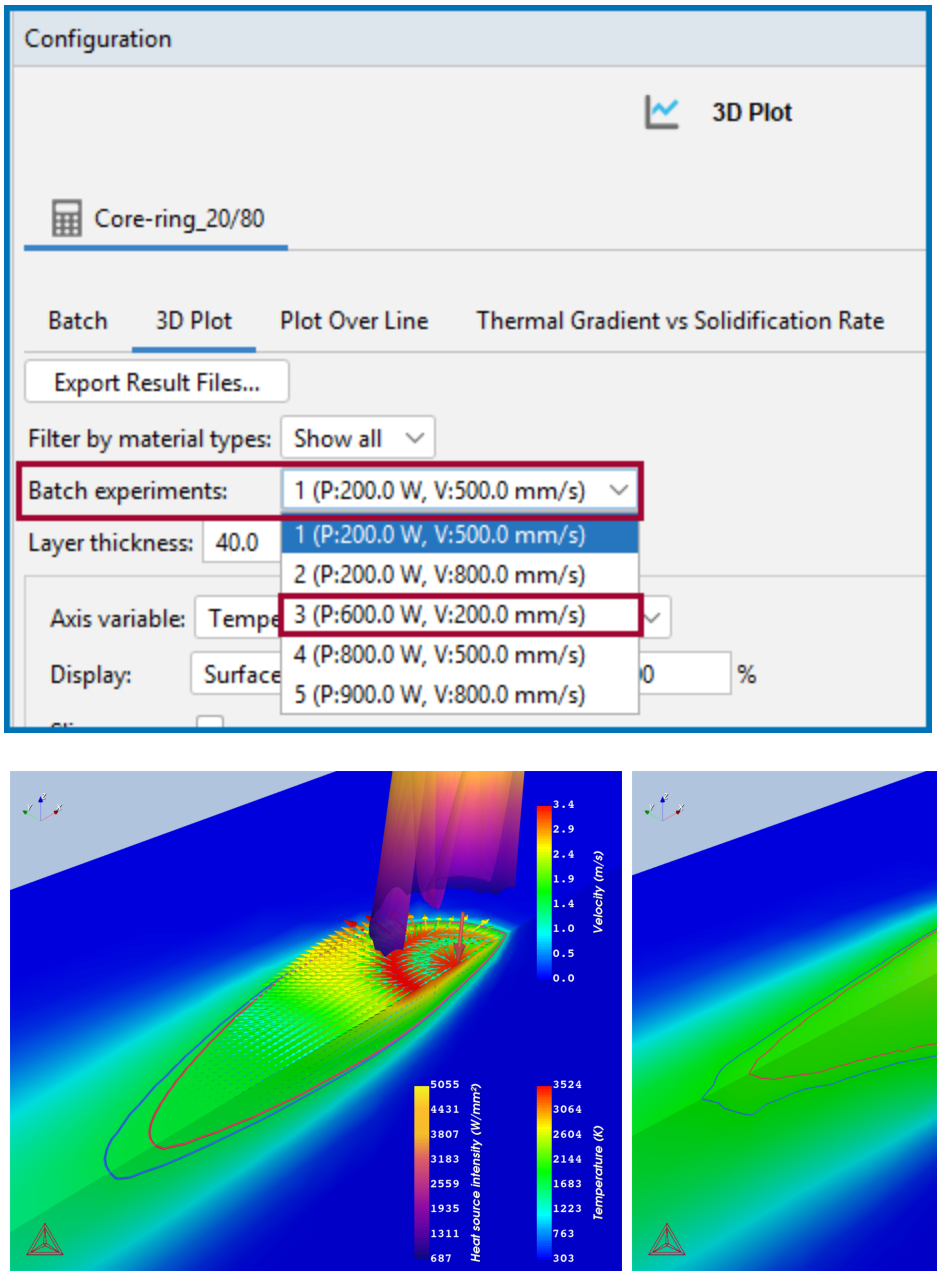

Figure 79: A comparison of the melt pools for two different processing conditions: Red and blue isocontours show liquidus and solidus temperatures, respectively. See the text for details.

In Figure 80 you can click the **Set View** button plus **Mirror Geometry** button to obtain this top view of a **Surface colormap**.

In general, you can play around with the **3D Plot Configuration** window settings. For example, for the right-hand side figure, you can view the **Flow velocity field** with different **Display** types such as an **Arrow** (shown).

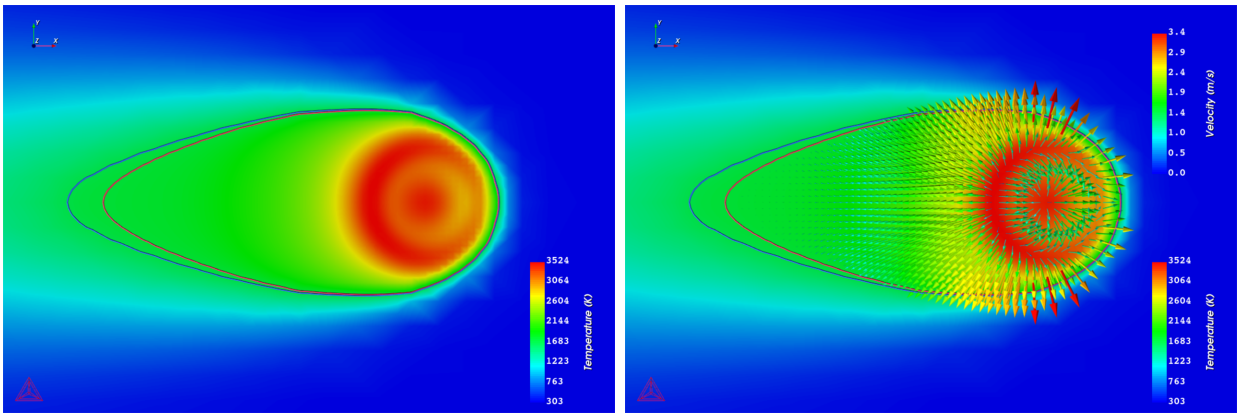

Figure 80: Top view (XY) of the surface colormap showing (left) temperature distribution due to the 20/80 Core-ring beam shape, and (right) velocity field caused by the distinctive temperature profile, resulting in widening of the melt pool. P=200 W, V=500 mm/s. Red and blue isocontours show liquidus and solidus temperatures, respectively.

In Figure 81, this cross-section compares the melt pool shape and size for **Batch experiment 1** (P=200 W, V=500 mm/s) to the experimental results as shown in Figure 9 in the paper by [2024Hol].

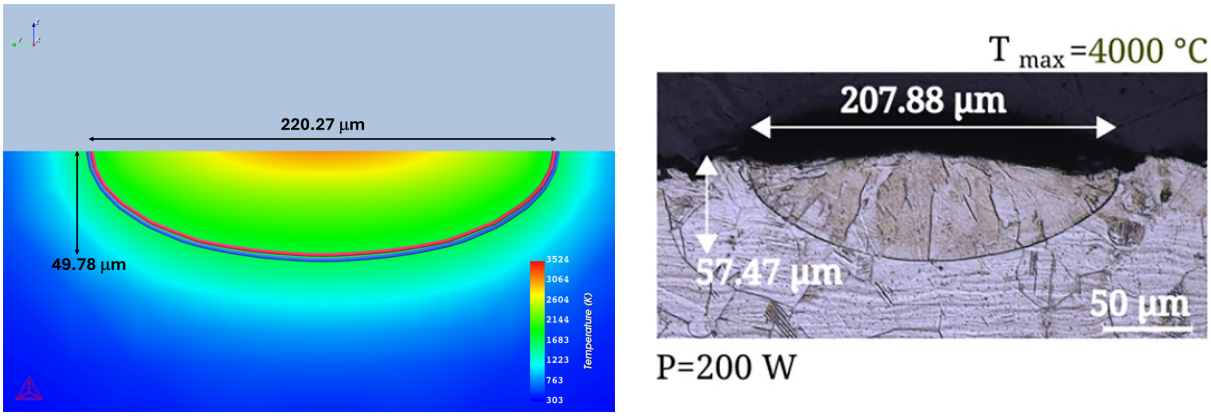

Figure 81: A cross-section comparing melt pool shape and size for P=200 W, V=500 mm/s from (left) simulation and (right) experiments [2024Hol-Fig9]. Red and blue isocontours in the simulation result show liquidus and solidus temperatures, respectively.

In Figure 82, the formation of the meltpool is shown on the left and compared to a cross-section that is taken from **Batch experiment 3** (P=600 W, V=200 mm/s) to show the formation

of a keyhole and the maximum melt pool size, where you can also see the widening of the melt pool due to fluid flow. Compare this to Figure 83, which are the experimental results as shown in Figure 9 in the paper by [2024Hol].

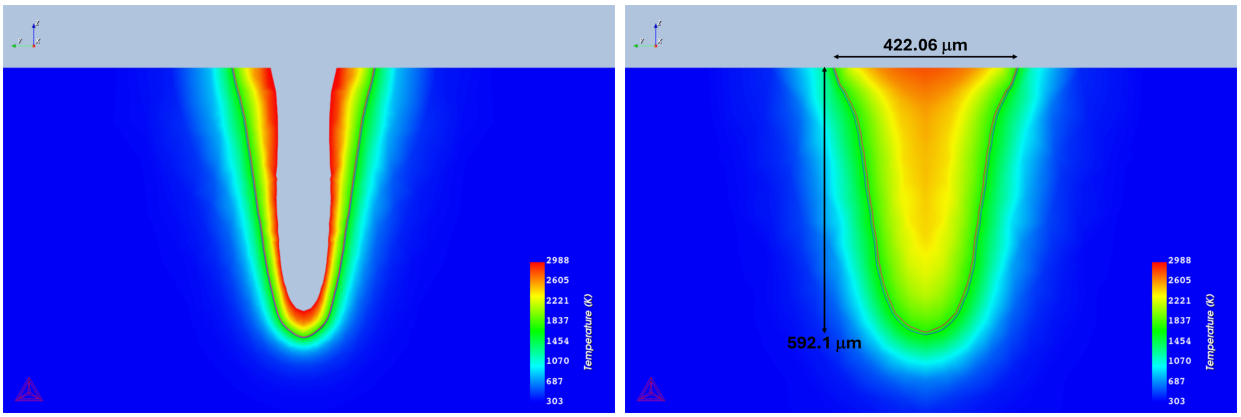

Figure 82: Cross-sections at different locations along the scanning direction showing (left) formation of keyhole and (right) maximum melt pool dimensions for P=600 W, V=200 mm/s. See the text for more.

Figure 83: Cross-section showing the experimental melt track for the same processing conditions shown in Figure 82. From [2024Hol-Fig9].

About the Heat Source Models

Learn more about the Additive Manufacturing (AM) Module on our website including the details about database compatibility or to watch a webinar. You can also use the Getting Started Guide to learn about the key features available or visit our YouTube channel.

For TC-Python users, there is an example using **Core-ring**: `pyex_AM_09_CoreRing_BeamShape.py`. There is a companion example in Graphical Mode using **Top-hat**: AM_14: Using the Top-hat Beam Shape.

AM_14: Using the Top-hat Beam Shape

This **Steady-state** example demonstrates the use of **Top-hat** *Heat Source* model in the AM Module with **Batch** calculations.

The processing parameters (power and speed) and other processing conditions such as the layer thickness are taken from Sow et al. [2020Sow]. The example also compares the predicted melt pool dimensions with the experimental data.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: *AM_14_TopHat_BeamShape.tcu*

This example requires an Additive Manufacturing (AM) Module license.

Background

The primary benefit of the Top-hat heat source beam shape, in comparison to the Gaussian beam shape, is uniform energy distribution across the beam spot, leading to even heating of the material surface. With lower peak intensity as compared to the Gaussian beam, a Top-hat beam also allows the use of larger beam size that not only increases productivity but also reduces vapor-induced instabilities [2020Sow]. The inclusion of Top-hat heat source model in the AM Module, together with the keyhole model, allows you to predict the temperature evolution and melt pool shape along with the transition from conduction mode to keyhole mode for a Top-hat heat source. The example uses experimental data taken from the literature [2020Sow] and demonstrates the use of Top-hat heat source with a rather large beam size for single track experiments on an IN625 alloy.

Material Properties

- IN625: Ni-21.5Cr-5.0Fe-0.5Si-0.5Mn-9.0Mo-0.4Ti-1.0Co-1.8Nb-1.8Ta-0.4Al Mass percent
- Database: TCNI12 and with solute trapping and interface scattering = 1e-07.
- The material properties are precalculated, and stored as a built-in material library with the Additive Manufacturing (AM) Module.

AM Calculator Configuration Settings

This example contains one AM Calculator, which is renamed to **Top-hat**. On the **Configuration** window, **Conditions** tab, this **Steady-state** calculation is configured with the **Top-hat***Heat Source* with the **Keyhole model**.

Fluid flow is not used in this example (the **Fluid flow including Marangoni effect** checkbox is not selected). Although fluid flow plays a crucial role in determining the shape and size of the melt pool, in this case it was found that it overestimates the melt pool width for most cases when fluid flow is included.

In the *Geometry* section, the **Height** of the base plate is set to `3.0` mm and in the *Scanning Strategy* section the **Layer thickness** is changed to 50.0 µm.

In the *Heat Source* section, the **Beam radius** is set to `450` µm.

In the [2020Sow] paper, it is mentioned that the beam diameter for the top-hat distribution is 500 µm. However, in Figure 2 of this paper, where intensity is plotted against the distance for the top-hat beam, the actual diameter looks much larger than that. In order to match the intensity distribution, the beam radius is therefore set to 450 µm.

Also in the *Heat Source* section, the **Absorptivity** is set to **Calculated** with a **prefactor** of `1.0` and in the keyhole model, **Beam quality factor M^2** is kept as `1.0`.

The **Batch***Calculation Type* is used to set up all the conditions from the experiments in a single calculation. In the *Batch Experiment Data* section, the experimental **Power** and scan **Speed** as well as the measured melt pool Width (**Exp width**) and Depth (**Exp. depth**) were collected in a CSV file and imported into the software. This data is then saved in the project file.

Data with the error bars is also read and stored in the project file, that is later used to plot error bars together with the experimental values of melt pool width and depth.

In the *Batch Experiment Data* table, the **Power** is always 1000 W and the scan **Speed** ranges between 25 mm/s to 500 mm/s.

AM Calculator Conditions Settings and AM Calculator Heat Source Settings

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

For more information also see Working with AM Visualizations.

Parity Plot

This specific **Parity** plot is shown by clicking the **Parity Plot** node in the **Project** window. Then you can see on the **Visualizations** window it is in the tab of the same name. The settings are located on the **Configuration** window on the **Batch** tab.

The plot compares experimental and calculated melt pool width and depth. It can be seen that the calculated melt pool width shows a fairly good agreement with the measured values. A mixed trend is however, seen for the melt pool depth. For lower energy densities, the calculated and measured melt pool depth matches quite well, however it starts to deviate once the melting appears to happen in the keyhole mode in the experiments, while it is still in the conduction mode in the calculations. For the last three points, where the calculations also predict a keyhole mode, the melt pool depth matches quite well with the measured value, except for the very last point where it is somehow overpredicted. The difference in depth could be attributed to the uncertainty in the actual beam size of the top-hat beam.

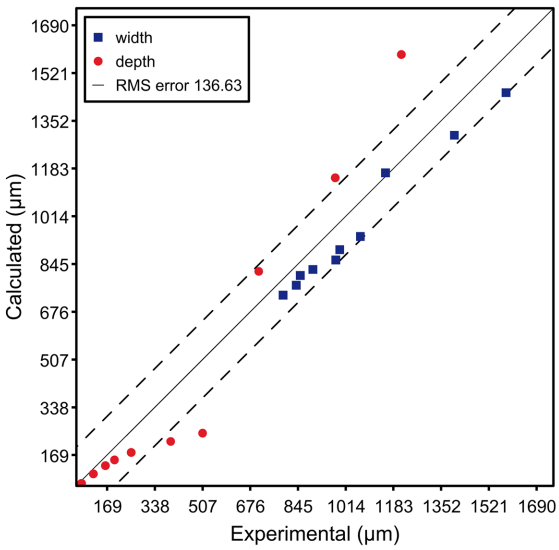

Figure 84: Parity plot comparing experimental and calculated melt pool width and depth for all the experiments. The experiments are single tracks on IN625 with constant power and varied scan speed using the Top-hat heat source. The Root Mean Square (RMS) error can also be seen as a dashed line.

Melt Pool Dimensions

This **Melt Pool vs Energy Density** plot is shown by clicking the **Melt Pool Dimensions** node in the **Project** window. Then you can see on the **Visualizations** window it is in the tab of the same name. The settings are located on the **Configuration** window on the **Batch** tab.

The plot shows a comparison of the experimental and calculated melt pool width and depth, where the error bars are also plotted with the measured data. Rather large error bars, especially for the higher energy density cases, show that the overall trend for the calculated values of melt pool width and depth is in good agreement with the measured values. Some improvements are however needed for the low energy density cases where a huge deviation is found between the calculated and measured values.

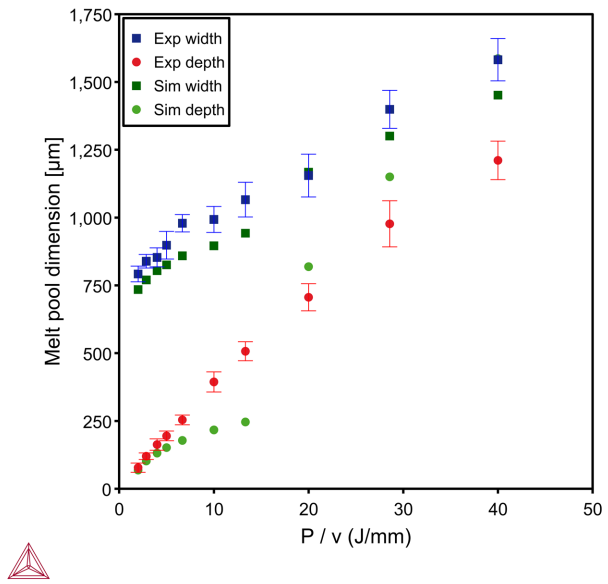

Figure 85: A comparison of the experimental and calculated melt pool width and depth for all the experiments. The error bars on the experimental data are also shown.

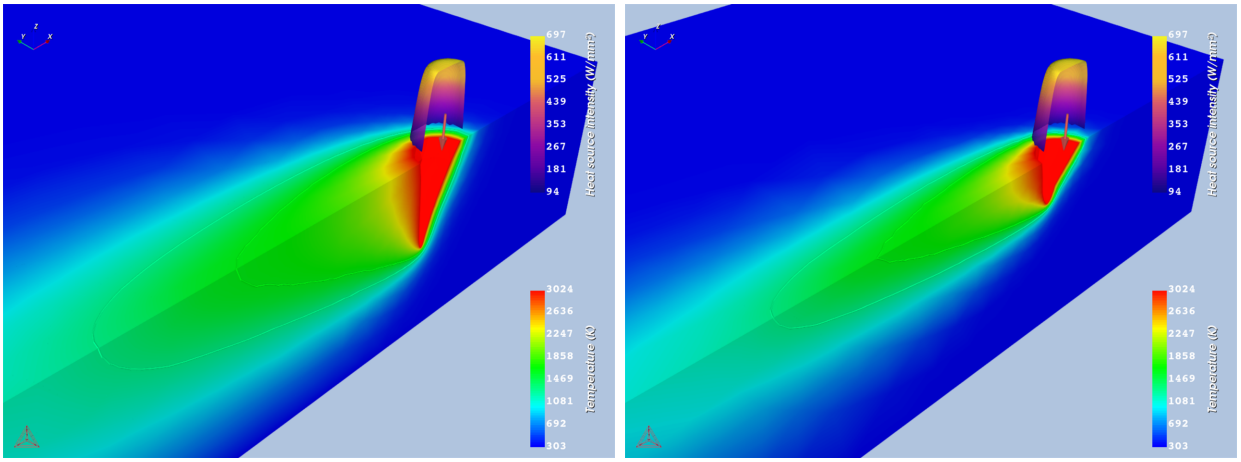
3D Plots



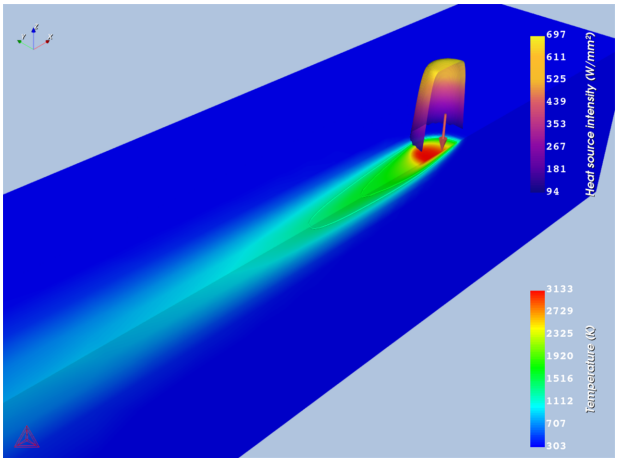


Figure 86: A comparison of the temperature distribution for three different processing conditions: (top-left) P=1000 W, V=25 mm/s, (top-right) P=1000 W, V=50 mm/s, both of which form keyhole during melting and (bottom-left) P=1000 W, V=250 mm/s that undergoes melting in conduction mode.

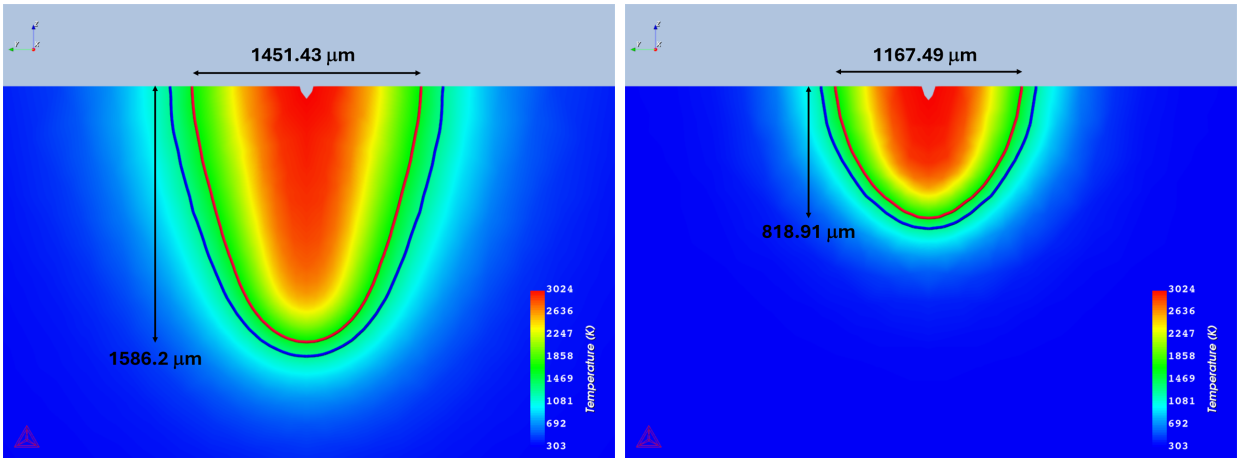
For the comparisons in Figure 87, all cross-sections are taken where the melt pools attain maximum width and depth. Red and blue isocontours show liquidus and solidus temperatures, respectively.



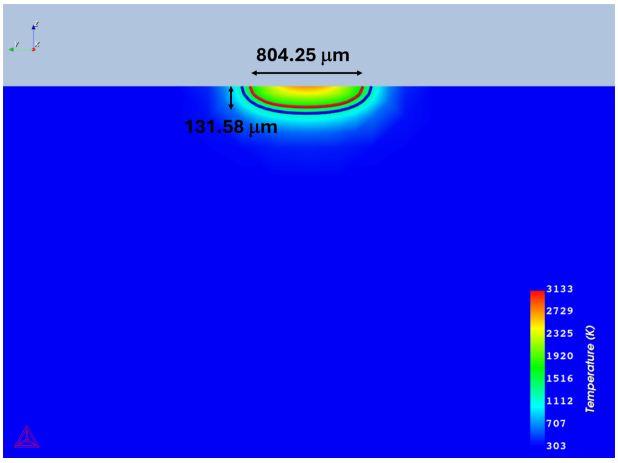


Figure 87: Cross-sections comparing melt pool shape and size for (top-left) P=1000 W, V=25 mm/s, (top-right) P=1000 W, V=50 mm/s and (bottom-left) P=1000 W, V=250 mm/s.

AM_15: Electron Beam Melting in an IN718 Alloy

This steady-state example demonstrates the use of **Electron Beam** *Heat Source* for **Batch** calculations.

The experimental data as well as the process conditions are taken from [2019Din]. The steady-state calculations represent single bead experiments where electron beam was used to scan an IN718 base plate at 1025 °C. The example also compares the predicted melt pool dimensions with the experimental data from this paper.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: *AM_15_Electron_Beam_Melting_IN718.tcu*

This example requires an Additive Manufacturing (AM) Module license.

Background

In an Electron Beam melting (EBM) process, a high energy electron beam is used to selectively melt the powder layer inside a vacuum chamber. In the Additive Manufacturing (AM) Module, the energy distribution from the electron beam is approximated using a Gaussian profile. In the paper [2019Din], authors performed a series of single bead experiments on the IN718 base plate (Case B in the paper) using an A2X EBM system (Arcam AB). The process was performed under a controlled vacuum.

Material Properties

- IN718: Ni-0.05C-0.14Mn-0.08Si-18.27Cr-0.57Al-2.9Mo-5.15Nb-0.01Ta-1.04Ti-0.79Co-19.18Fe-0.04Cu Mass percent
- Database: TCNI12 and with interface scattering = 1e-07. The material properties are precalculated, and stored as a built-in material library with the Additive Manufacturing (AM) Module.

AM Calculator Configuration Settings

This example contains one AM Calculator, which is renamed to **Electron Beam Melting**. On the **Configuration** window, **Conditions** tab, this **Steady-state** calculation is configured with the **Electron Beam** Heat Source with the **Keyhole model** and includes **Fluid flow**.

The **Gas pressure** is set to 0.2 Pascal. The **Base plate temperature** as well as the **Ambient temperature** are set to 1025 °C. The **Height** of the base plate is set to 3.0 mm.

The **Absorptivity** of the Electron Beam heat source is set to be **Calculated** with a **prefactor** of 1.0. The **Acceleration voltage** of the beam, as mentioned in the paper, is set 60.0 kV.

The **Beam radius** of the electron beam is not mentioned in the experimental setup of the paper. We have set the Beam radius to 125.0 µm, which is also the minimum beam radius of the A2X EBM system. The **Convective heat transfer coefficient** is set to 0.0 W/m^2 to eliminate any heat loss due to convection in the vacuum chamber.

Experimental data for the **Batch** calculation is taken from Case B in the paper (single bead experiments on a bare metal plate). Data for low scanning speed i.e. < 300 mm/s is not included in the example.

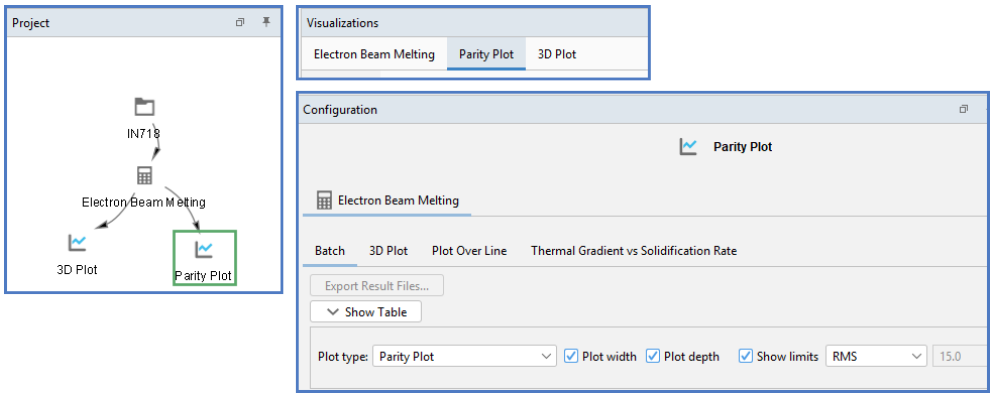
Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

For more information also see Working with AM Visualizations.

Parity Plot

This specific Parity plot is shown by clicking the **Parity Plot** node in the **Project** window. Then you can see on the **Visualizations** window it is in the tab of the same name. The settings are located on the **Configuration** window on the **Batch** tab.



The plot compares experimental and calculated melt pool width and depth for all experiments. The experiments are single bead experiments on bare plate IN718 with varied power and scan speed using an **Electron Beam** heat source.

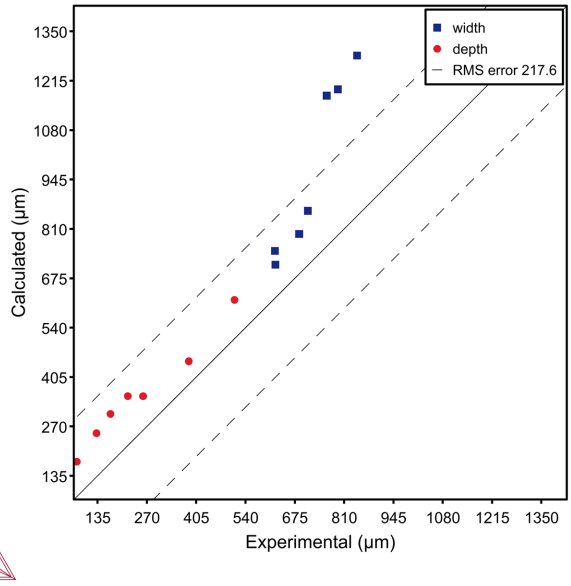


Figure 88: Parity plot comparing experimental and calculated melt pool width and depth for all the experiments when using an Electron Beam heat source. The Root Mean Square (RMS) error can also be seen as a dashed line.

3D Plots

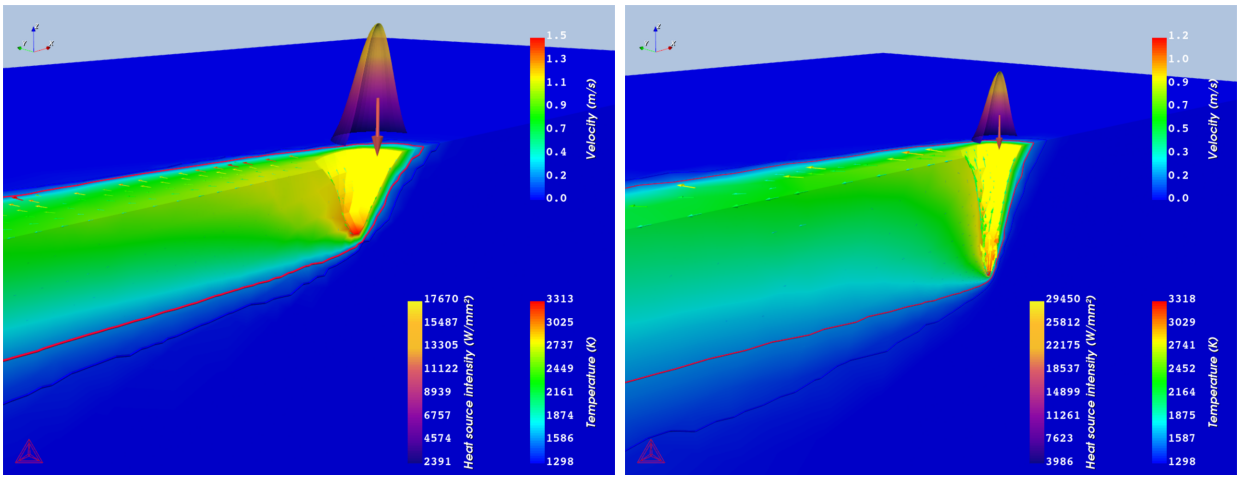

Figure 89: A comparison of the keyhole profile for two different processing conditions (left) P=600 W, v=1000 mm/s, and (right) P=1000 W, v=300 mm/s.

AM_16: Composition Change Due to Evaporation

This example demonstrates the application of the **Evaporation with Steady-state** simulation type within the AM Module, to predict the change in alloy composition caused by selective evaporation during multi-track and multi-layer scanning. The example also presents several key plot quantities associated with the *Evaporation with Steady-state* simulation including last track composition change, composition change as a function of track number, and final composition of the alloy.

The experimental data as well as the process conditions are taken from [2024Muk]. The **Evaporation with Steady-state** simulation first runs a steady-state model for the given process parameters, followed by the evaporation model for the desired scanning strategy. The steady-state calculation represents a single-track experiment on a nickel-based superalloy, IN939, with a power of 200 W and a scan speed of 1800 mm/s. The example also compares the predicted composition of the last track with the experimental data from this paper.

Project File and License Information

- Folder: **Additive Manufacturing**
- File name: *AM_16_Composition_Change_Evaporation.tcu*

This example requires an Additive Manufacturing (AM) Module license.

Background

One of the significant challenges in the Laser Powder Bed Fusion (LPBF) process is the selective evaporation of alloying elements. The intense laser energy creates extremely high peak temperatures in the melt pool, causing elements with lower boiling points to vaporize preferentially. This leads to a shift in the chemical composition of the final part compared to the original powder. This compositional change can degrade key mechanical properties, reduce corrosion resistance, and alter phase formation. It may also increase porosity due to vapor recoil and keyhole instability. It is, therefore, important to predict the change in composition of the alloy to achieve the final material properties and microstructure, or perhaps to optimize the process parameters in order to reduce the evaporation of the volatile elements.

Material Properties

On the **Configuration** window, **Material Properties** tab, these are the details of the built-in *Library Information*:

- IN939: Ni-22.1Cr-18.8Co-1.96W-0.01Hf-0.06Fe-1.76Al-3.8Ti-0.97Nb-1.37Ta-0.16C Mass percent
- Database: TCNI13 with solute trapping and interface scattering = 1e-07. The material properties are precalculated, and stored as a built-in material library with the Additive Manufacturing (AM) Module.

On this tab, also click **Show evaporation accommodation coefficients** to display a list of the evaporation accommodation coefficients for the alloying elements in IN939. Systematic deviations in evaporation rates associated with specific elements can be accounted for by introducing elemental accommodation coefficients, α_i as fitting parameters. In this example, the coefficients for all elements are set to 1, except for Cr, which is set to 0.65; this is also the default value for Cr. The effect of varying the accommodation coefficients can be examined by selecting the plot quantities **Composition of Gas Phase** or **Evaporation Flux**.

AM Calculator Configuration Settings

This example contains one AM Calculator, which is renamed to **AM Evaporation Calculator**. On the **Configuration** window, **Conditions** tab, the **Evaporation with Steady-state** simulation type calculation is selected. Fluid flow is included in the example while separate material properties for the powder are ignored. Specific settings are listed below.

- The power of the Gaussian heat source is set to 200 W, with a beam radius of 40 mm.
- The scanning speed is configured to be 1800 mm/s and the layer thickness is set to 30 mm.
- The scanning pattern is kept as bidirectional, which is also the default scanning pattern for the evaporation model.
- The hatch spacing is set to 0.05 mm, in order to match the scanning strategy from [2024Muk].
- A total of 10 layers is used in this example to ensure that the composition reaches a steady-state and can be considered representative of the average composition in a larger printed part.
- The chosen scanning strategy produces 27 tracks on each layer, resulting in a total number of 270 tracks across 10 layers.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

For more information also see Working with AM Visualizations.

Composition and Composition Change

All Plot Renderer nodes are renamed to match the tabs and plots shown in the **Visualizations** window.

In the **Project** window, click the **Composition change** node to view the plot for all alloying elements (Figure 90). Click **Composition** to view the composition plot for all elements (Figure 91). For both, you can see that on the **Visualizations** window these are on the respective **3D Plot** tab.

The *Axis variables* **Composition change**, **Composition**, **Lack of fusion porosity**, and **Evaporation flux** are available only for the **Evaporation with Steady-state** model. The composition as well as the composition change can be plotted in **Mass percent**, **Mass fraction**, **Mole percent**, and **Mole fraction**. Both composition and composition change can be plotted for either **All** elements, in which case you can also have a shared legend by selecting the **Shared for all elements** checkbox, or for individual elements by selecting the element from the drop-down menu.

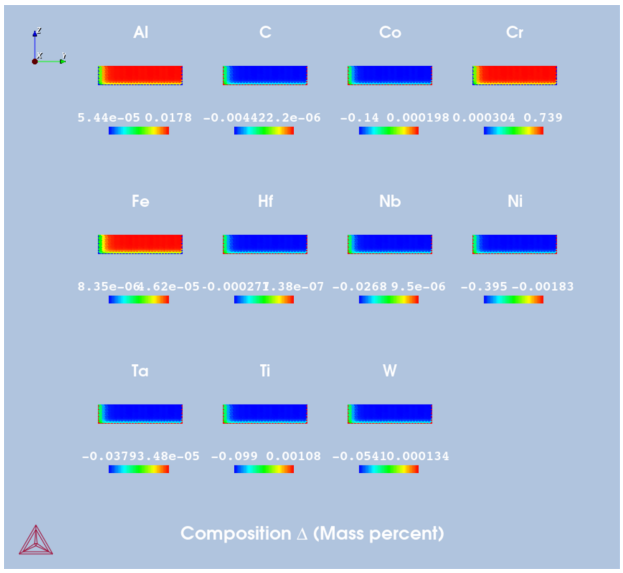

Figure 90: Composition change of the alloying elements of IN939 after 10 layers with 27 tracks on each layer, using a power of 200 W and a scan speed of 1.8 m/s.

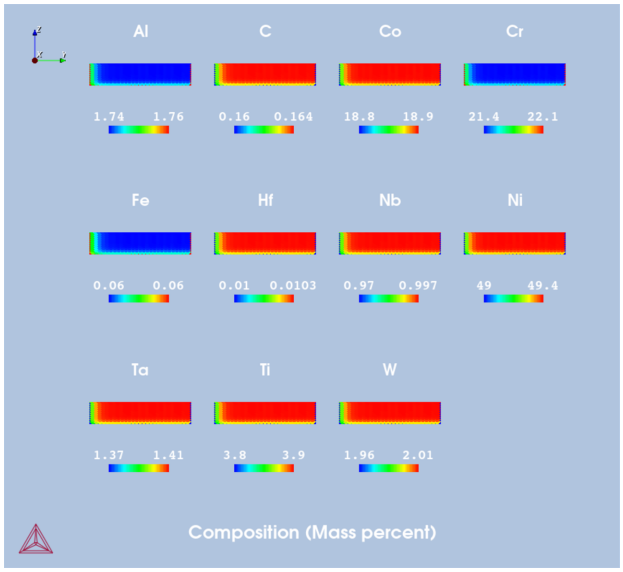

Figure 91: Composition of the alloying elements of IN939 after 10 layers with 27 tracks on each layer, using a power of 200 W and a scan speed of 1.8 m/s.

Last Track Composition Change

Figure 92 shows the composition change of the last track in mass percent, compared with the experimental values. The simulations are performed using the identical process parameters (laser power, scan speed, beam radius, and layer thickness) as those applied in the experiments [2024Muk]. It can be seen that for IN939 and the given process parameters, the Thermo-Calc model predicts that Cr is the most susceptible element, which is also corroborated by the experimental results. Furthermore, the numerical prediction of the alloy composition exhibited excellent agreement with the experimental data, with the simulated values for most of the alloying elements residing well within the associated error bars.

In the **Project** window, click the **Last track composition change** node to view the plot in Figure 92. Then you can see in the **Visualizations** window it is on the **Composition History** tab. You can also view composition change of individual elements (instead of the **All** already selected) by choosing the respective element from the drop-down menu found on the **Configuration** window.

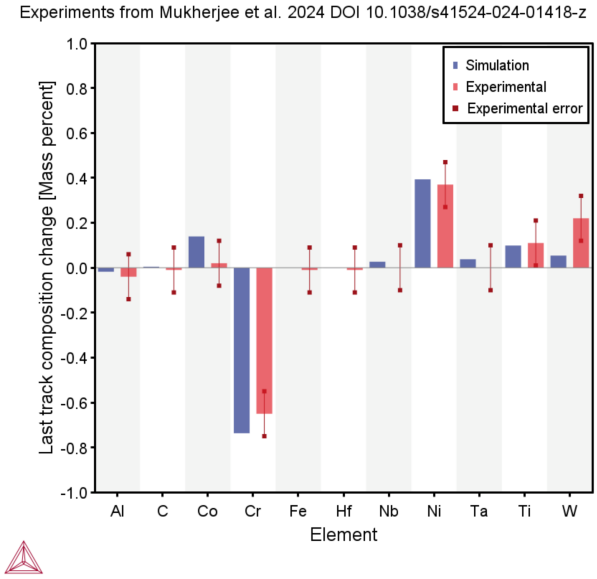

Figure 92: Predicted composition change of the alloying elements (blue) of IN939 in the last track (number 270) compared to the experimental values (red) taken from [2024Muk].

Track Composition Change

The change in composition of all alloying elements of IN939 as a function of track number (Figure 93) can be shown as the other plots by clicking the **Track composition change** node in the **Project** window. The most significant change in the composition occurs in the first track where only the powder is melted. Subsequent tracks (tracks 2–27) within the same layer partially overlap previously processed material, leading to a gradual evolution of composition. A pronounced change is then observed at the transition to the next layer (track 28). By the final track (track 270), the composition has reached a steady-state and can be considered representative of the average composition in a larger printed part.

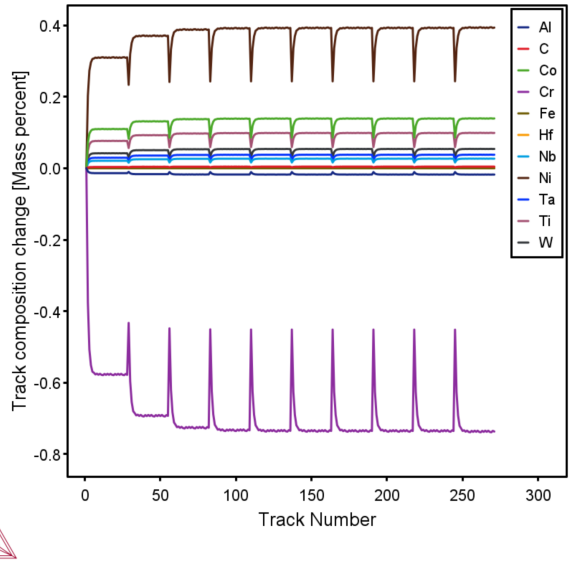

Figure 93: Predicted composition of the alloying elements of IN939 as a function of track number. A total of 10 layers is simulated with 27 tracks on each layer.

About the Diffusion Module (DICTRA)

The Diffusion Module (DICTRA) is an Add-on Module to Thermo-Calc. It is used for simulation of diffusion controlled transformations in multicomponent systems. The simulation calculations are both time- and space-dependent. The Diffusion Module (DICTRA) is available in both Graphical Mode (as the *Diffusion Calculator*) and Console Mode (as the *DICTRA module*).

The Diffusion Module (DICTRA), which is often just referred to as DICTRA, is ideally suited to solve diffusion simulations that include a moving boundary (*Stefan problems*). The multicomponent diffusion equations in the various regions of a material are solved under the assumption that thermodynamic equilibrium holds locally at all phase interfaces. Simulations are one-dimensional and three different geometries can be performed: planar, cylindrical, and spherical.

Examples of cases that have been simulated using the Diffusion Module (DICTRA) include:

- Microsegregation during solidification
- Homogenization of alloys
- Growth/dissolution of carbides, nitrides and intermetallic phases
- Coarsening of precipitate phases
- Interdiffusion in compounds, e.g. coating systems
- Austenite to ferrite transformations in steel

In order to perform a simulation in the Diffusion Module, both a thermodynamic database and a kinetic database is needed. The thermodynamic database is a normal Thermo-Calc database, whereas the kinetic database contains information about the atomic mobility of individual elements in various phases.

Using the Diffusion Module (DICTRA) you can solve a variety of problems, some of which are described in Types of Diffusion Simulations.

About Working with the Diffusion Module in Graphical Mode

This technical content includes an overview of the Diffusion Module (DICTRA) and describes in generic terms how you can define a system, set up and perform simulations, and then visualize the results. There is also a section to help you troubleshoot your simulation.

Which Mode Should I Use?

The Diffusion Module (DICTRA) is available in both Graphical Mode and Console Mode.

Before you start using these topics, it is recommended that you review the Thermo-Calc specific content. Also see Graphical Mode vs Console Mode to give you an overview of the differences. Understanding the capabilities of each mode will help you during the design of a simulation. Although Console Mode has a couple more advanced features, it is highly recommended to use Graphical Mode. Also see Key Differences Between Modes in the Diffusion Module.

The two modes can be run simultaneously, but there is no communication between them. What you do in Graphical Mode does not affect the state of the Console Mode session and vice versa. This can be important to remember if you create a simulation in one mode and then decide to switch to the other mode.

Learning Resources

How you proceed depends on your experience with the software as well as your level of expertise with diffusion simulations. In addition to this guide the following supplemental documentation and training resources can help you learn how to use the Diffusion Module (DICTRA).

Documentation Resources

You can search or browse all the documentation available either from within Thermo-Calc (press F1 or go to **Help → Online Help**) or browse the PDFs included with your installation by going to **Help → Manuals Folder**).

Read more about the Diffusion Module (DICTRA) on our website. There is also a Getting Started with the Diffusion Module (DICTRA) page available. If you are in Thermo-Calc, press F1 to search the help to learn about the available settings included with the Add-on Module.

The Role of Diffusion in Materials: A Tutorial is available for download on our website. It is intended for engineers interested in using the Diffusion Module (DICTRA), as well as students learning about the role of diffusion in materials. It is designed to be useful at many levels, from undergraduate studies to someone with a PhD and experience in a related field.

Training and Video Tutorials

Some of the Graphical Mode examples have video tutorials. Watching those videos may help you with your simulation in Console Mode. You may also decide to enroll in a training course or use the self-paced Learning Hub.

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

An Important Note About Terminology

DICTRA is an acronym for *DIffusion-Controlled TRAnsformations*. The software of the same name has been included in the suite of Thermo-Calc products for many years. When you are working on Console Mode the terminology reflects this historical connection as do all the literature that cites the use of DICTRA.

With the introduction of the Graphical Mode version of DICTRA, and to better describe what the Add-on Module does, the product name is now the *Diffusion Module (DICTRA)*. However, this means some of the terminology between the modes cannot be consistent even though the theory and concept behind the software is fundamentally the same. For example, in Graphical Mode the term "DICTRA" is not used when describing the Diffusion Calculator node.

In Console Mode there is also some terminology to be aware of as there are two submodules within the program:

- The DICTRA_MONITOR: To run simulations of diffusion controlled transformations, and
- DIC_PARROT: To assess experimental data and uses this data to optimize mobilities module.

In the documentation for Console Mode, *DICTRA* and *DICTRA module* are used interchangeably to refer to the DICTRA_MONITOR module.

Graphical Mode vs Console Mode

There are two interfaces available in Thermo-Calc: *Graphical Mode* with a graphical user interface (GUI) and *Console Mode*, which uses a command line interface. Thermo-Calc and the Diffusion Module (DICTRA) are available in both modes, and all other Add-on Modules are only available in Graphical Mode.

If you are a new user, Graphical Mode is a good way to learn how to work with Thermo-Calc. Depending on what you want to simulate, in some advanced use cases Console Mode can have additional functionality but until you are comfortable with the concepts, it is recommended you start in Graphical Mode.

General Terminology

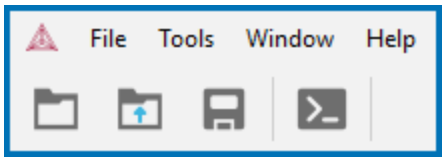
In Graphical Mode calculations are set up, carried out, and visualized as part of a *project*. The steps in the project are performed with *activities*. There are templates and Quick Start Assistants available to guide you through the process of defining the project. See Getting Started Links, Templates, and the Property Navigator.

In Console Mode you work with *modules*, which are managed using commands typed at a prompt. Some modules, called *response-driven modules*, ask you a series of questions that typically take you through the process of defining your system, setting calculation conditions, performing calculations and plotting the results.

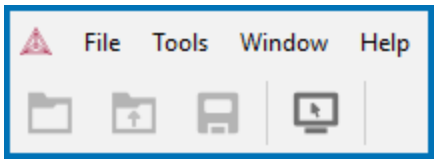
Switching Between Modes

The first time you open Thermo-Calc, it defaults to Graphical Mode. For any future instance it defaults to the last mode used.

Along the top of the GUI is the Graphical Mode Toolbar where you switch between modes.



In Console Mode, except for the **Switch to Graphical Mode** button, the toolbar is not used.



See Menu, Toolbar, and Keyboard Shortcuts for information about the **Tools**, **Window**, and **Help** menus, which are available in both modes.

File Extensions

The file extensions are different based on the mode you are in. In Console Mode the extensions are also based on whether you are working with Thermo-Calc or the Diffusion Module (DICTRA).

In Graphical Mode, the Thermo-Calc project files have the extension *.`tcu`. This includes the examples for the Add-on Modules.

In Console Mode, Thermo-Calc macro files have a *.`TCM` extension and the Diffusion Module (DICTRA) file extension is *.`DCM`. In addition to macro files in Console Mode the are also *Log* files and *Workspace* files, which also differ.

Modes Run Simultaneously

The two modes can be run simultaneously, but there is no communication between them. What you do in Graphical Mode does not affect the state of the Console Mode session and vice versa. One exception is the plot settings.

Global Settings: Graphical and Console Mode Plotting

Data Optimization and Thermodynamic / Kinetic Assessments

Although many calculations can be done in either mode, data optimization (i.e. PARROT) and thermodynamic or kinetic assessments (i.e. custom database development) are only available in Console Mode or using an SDK such as TC-Python.

Key Differences Between Modes in the Diffusion Module

Below are some of the main differences between the available features or simulation types in Graphical Mode (GM) and Console Mode (CM). There are also other differences not listed in the table such as slight differences between terminology and the file formats, for example.

For the Graphical Mode version of the Diffusion Module, additional functionality is scheduled for future versions of Thermo-Calc.

Graphical Mode vs Console Mode Features

Feature Differences	*GM*	*CM*	*Comment*
Plots	x	x	
Planar, cylindrical and spherical geometries	x	x	
Homogenization	x	x	
Homogenization functions	x	x	The varieties with excluded phases are only available in Console Mode.
Tables	x	x	
Setting boundary conditions	x	x	For Graphical Mode, the Mixed activity and Zero Flux and Composition boundary conditions are available. Additional boundary conditions are planned.
Importing Scheil segregation profiles	x	x	
Importing composition profiles from file	x		
Data optimization (PARROT)		x	

Graphical Mode vs Console Mode Simulation Types

Simulation Type Differences	*GM*	*CM*
Isothermal and Non-Isothermal simulations	x	x
Growth of intermediate phases in compounds	x	x
Growth or dissolution of precipitates	x	x
Microsegregation during solidification	x	x
Austenite to ferrite transformations	x	x
Interdiffusion in compounds	x	x
Coarsening		x
Carburizing, and Nitriding and nitrocarburization	x	x
Paraequilibrium		x
Thermomigration		x
Grain boundary models		x
Pearlite models		x
Interpolation scheme		x
Cell calculations		x

About the Homogenization Functions

The geometrical interpretation of the Hashin-Shtrikman bounds are concentric spherical shells of each phase. For the general lower Hashin-Shtrikman bound the outermost shell consists of the phase with the most sluggish kinetics and vice versa for the general upper bound. The geometrical interpretation of the Hashin-Shtrikman bounds suggest further varieties of the bounds, viz. *Hashin-Shtrikman bound with prescribed matrix phase* and *Hashin-Shtrikman bound with majority phase as matrix phase*, where the outermost shell consist of a prescribed phase or the phase with highest local volume fraction, respectively.

The geometrical interpretation of the Wiener bounds are continuous layers of each phase either parallel with (upper bound) or orthogonal to (lower bound) the direction of diffusion.

The labyrinth factor functions (described below) are available in Console Mode and when using TC-Python.

The labyrinth factor functions implies that all diffusion takes place in a single continuous matrix phase. The impeding effect on diffusion by phases dispersed in the matrix phase is taken into account by multiplying the flux with either the volume fraction (*Labyrinth factor f with prescribed matrix phase*), or the volume fraction squared (*Labyrinth factor f**2 with prescribed matrix phase*), of the matrix phase.

The varieties with excluded phases (described below) are available in Console Mode and when using TC-Python.

The varieties with excluded phases are useful in several respects. First, if a phase is modeled as having zero solubility for a component, the mobility of that component in that phase is undefined, which causes a (non-terminal) error. Setting a phase as excluded causes the mobility of all components in that phase to be set to zero. Second, often there are some major matrix solid solution phases and some minor precipitate phases. If the mobilities in the minor precipitate phases are zero the lower Hashin-Shtrikman bound is useless as it produces a kinetic coefficient of zero. However, using *General lower Hashin-Shtrikman bound with excluded phase(s)* the excluded phases are not considered when evaluating what phase has the most sluggish kinetics.

Diffusion Module (DICTRA) Licenses

You can start (and install) the Thermo-Calc software without a valid license but you cannot do any calculations. To show information about the available and installed licenses, from the main menu select **Help → Show License Info**.

Network License Restrictions

The Diffusion Module (DICTRA) requires a separate license. If you are using a network client installation of Thermo-Calc, then you may not be able to use the Diffusion Module (DICTRA) even if you have access to a license server with a valid network license file. This is because other clients who are part of your network installation may have checked out all instances of the network license allowed to run simultaneously.

Graphical Mode and Entering Demo Mode

In Graphical Mode only, and for users with a network license, you must exit Thermo-Calc to release the license for use. The license is checked out as soon as you add a Diffusion Calculator and remains unavailable to others until you exit the program.

With a network license, and if as per above you temporarily do not have access to a license, you are automatically put into *Demo Mode*. Then the Diffusion Calculator is available with three elements. See Diffusion Module Available Graphical Mode Features for more information.

Console Mode

In Console Mode, a license is checked out when you enter the DICTRA module and it is checked back in when you leave the module. You do not need to exit the program.

If you are working in Console Mode and try to enter DIC_PARROT after having been in the PARROT module earlier in the session, a message displays: `DICTRA PARROT disabled after using PARROT`. To enter DIC_PARROT relaunch Thermo-Calc and enter these commands starting in the SYS module: GOTO_MODULE DIC_PAR.

See License Activation and Installation Types for more information about network licenses.

Types of Diffusion Simulations

The Diffusion Module (DICTRA) is used to simulate diffusion-controlled transformations in multicomponent alloys. A short summary of the types of simulations it can handle are listed below and whether it is available in Graphical (GM) or Console (CM) Mode.

The three main simulation types that are available for both modes are briefly compared in this section.

Graphical Mode vs Console Mode Simulation Types

Simulation Type	*Examples*	*Graphical Mode*	*Console Mode*
One-phase simulations	Homogenization of alloys	x	x
	Carburizing and decarburizing of e.g. steel in austenitic state		x
Moving boundary simulations	Growth or dissolution of precipitates	x	x
	Microsegregation during solidification	x	x
	Austenite to ferrite transformations	x	x
	Growth of intermediate phases in compounds	x	x
	Coarsening of precipitates		x

Cooperative growth	Growth of pearlite in alloyed steels		x

Simulation Type	*Examples*	*Graphical Mode*	*Console Mode*
Deviation from local equilibrium	Calculations under paraequilibrium conditions		x

Learn More

For Graphical Mode, see the Quick Start Guide: Graphical Mode Diffusion Module (DICTRA) for examples of single phase, moving boundary phase, and multiphase simulations.

For Console Mode, also see Models in the Diffusion Module and the Quick Start Guide: Console Mode Diffusion Module (DICTRA).

Diffusion in a Single-Phase System

The simplest simulation is one where certain elements in one phase diffuse over time in that single phase. To simulate this, you create one region and enter one phase into that region. You can set up the system under various conditions by defining profiles for how temperature and pressure change over time.

This type of simulation is available for both Graphical and Console Mode.

In Console Mode you can also simulate how the boundary conditions of the region change over time.

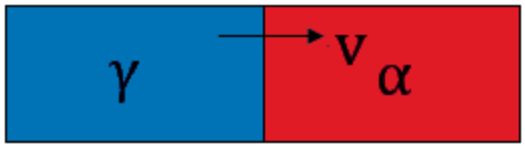
Simulate diffusion in a single-phase system.

Moving Boundary Muftiphase System

With two regions in a single cell you can simulate how diffusion causes phase transformations. For example, you can simulate how an individual particle grows or dissolves as a function of time. The result is a simulation of how the boundary between the regions migrate over time. As in the case of a one-phase simulation, you can set up the system under various conditions by defining profiles for how temperature changes over time.

This type of simulation is available for both Graphical and Console Mode.

In Console Mode you can also set up the system to see how the boundary conditions of the region change over time.



Simulate a moving boundary multiphase system.

Normally, simulations are performed under the assumption that thermodynamic equilibrium holds locally at all phase interfaces.

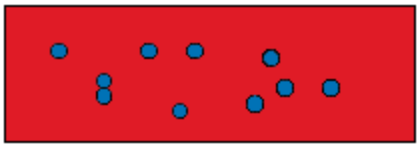
In Console Mode it is also possible to simulate a moving phase boundary problem while assuming that para-equilibrium conditions apply at the phase boundary.

Diffusion in Disperse Systems

You can perform simulations where one or more dispersed phases are present in a matrix phase. For example, you can simulate how carburization causes precipitation of carbides in an austenitic matrix phase.

In both Graphical Mode and Console Mode, problems involving diffusion in disperse systems are handled with the homogenization model.

In Console Mode and if you are using the disperse model instead of the recommended homogenization model, the dispersed phases act as point sinks or sources of solute atoms in the simulation and the fraction and composition is calculated from the average composition in each node, assuming that equilibrium holds locally in each volume element.



Simulate diffusion in a disperse system.

The homogenization model allows you to take into account diffusion in all phases for which you have kinetic data; the homogenization model treats all phases in the same way regardless of which phase is entered as type matrix and which phases are entered as type spheroid.

In Graphical Mode, the *Homogenization* model is automatically selected as the default solver when multiple phases are selected in a region.

In Console Mode, there are two ways in which you can simulate diffusion in a system that contains a dispersed phase, but it is strongly recommended that you use the *homogenization model*. See About the Homogenization Model.

Simulate diffusion with the homogenization model.

Diffusivity Theory

In order to perform simulations using the Diffusion Module (DICTRA), both thermodynamic and kinetic descriptions are needed. Moreover, the results and the accuracy of the simulations critically depend on the quality of these descriptions. So far there is much less kinetic data which has been systematically assessed in the same way as thermodynamic data.

In the theoretical treatment of diffusive reactions one usually works with diffusion coefficients which are evaluated from experimental measurements. In a multicomponent system a large number of diffusion coefficients have to be evaluated, and moreover, they are generally functions of alloy composition and are interrelated. A database would thus be very complex. A superior alternative is to store atomic mobilities in the database, rather than diffusion coefficients. The number of parameters which need to be stored in a multicomponent system are then substantially reduced and the parameters are independent. The diffusion coefficients, which are used in the simulations, can then be obtained as a product of a thermodynamic and a kinetic factor.

The thermodynamic factor is essentially the second derivatives of the molar Gibbs energy with respect to the concentrations, and is known if the system has been assessed thermodynamically. The kinetic factor contains the atomic mobilities, which are stored in the kinetic database. The purpose of this topic is to describe how concentration, temperature and pressure dependence of the atomic mobility can be modeled, as well as to describe relations between the different diffusion coefficients and the atomic mobility.

Modeling of the Atomic Mobility

From absolute-reaction rate theory arguments the mobility coefficient for an element $\mathbf{B}$, $\mathbf{M_B}$ may be divided into a frequency factor M_B^0 and an activation enthalpy, $\mathbf{Q_B}$, i.e.

[*Eq. 1*] $$M_B = M_B^0 \exp\left(-\frac{Q_B}{RT}\right)\frac{1}{RT}{}^{mg}\Gamma$$

${}^{mg}\Gamma$ is a factor taking into account the effect of the ferromagnetic transition [Jönsson, 1994a]. ${}^{mg}\Gamma$ is a function of the alloy composition. It has been suggested by Jönsson, 1994b that one should expand the logarithm of the frequency factor, $\ln M_B^0$, rather than the value itself, thus the mobility, $\mathbf{M_B}$, is expressed as:

[*Eq. 2*] $$M_B = \exp\left(\frac{RT\ln M_B^0}{RT}\right)\exp\left(-\frac{Q_B}{RT}\right)\frac{1}{RT}{}^{mg}\Gamma$$

Both $\mathrm{RT\ln}M_B^0$ and $\mathrm{Q_B}$ generally depend upon the composition, temperature, and pressure. In the spirit of the CALPHAD approach [Ågren, 1996], the composition dependency of these two factors, is represented with a linear combination of the values at each endpoint of the composition space, and a Redlich-Kister expansion, viz.

[*Eq. 3*] $$\Phi_B = \sum_i x_i \Phi_B^i + \sum_i \sum_{J>i} x_i x_j \left[\sum_{r=0}^{m} {}^r\Phi_B^{i,j} (x_i - x_j)^r \right]$$

where Φ_B represents $\mathrm{RT\ln M_B}$ or $\mathrm{-Q_B}$. Φ_B^i is the value of Φ_B for pure *i* and thus represents one of the endpoint values in the composition space. ${}^r\Phi_B^{i,j}$ are binary interaction parameters. The commas separate different species interacting with each other. $\mathrm{x_i}$ and $\mathrm{x_j}$ are mole fractions of elements *i* and *j* respectively. Each individual Φ parameter, i.e. Φ_B^i and ${}^r\Phi_B^{i,j}$ is stored in the database and may be expressed as a polynomial in temperature and pressure, if necessary. The Φ_B^i and ${}^r\Phi_B^{i,j}$ are referred to in the database as MF and MQ parameters, e.g.

$$\mathrm{MF(BCC_A2\&CR,NI:VA;0) = R*T*LN(+8.50E\text{-}05)}$$

is used to represent the frequency factor to the mobility of Cr in pure Ni, i.e. $\mathrm{RT\ln}M_{Cr}^{Ni0}$, whereas:

$$\mathrm{MQ(BCC_A2\&CR,NI:VA;0) = \text{-}2.18E{+}05}$$

represents $-Q_{Cr}^{Ni}$. The magnetic effect is represented by Jönsson's model [1994a].

[*Eq. 4*] $$^{mg}\Gamma = \exp(6\alpha\xi)\exp\left(\frac{-\alpha\xi Q_B}{RT}\right)$$

where ξ represents the state of the magnetic order ($0 < \xi < 1$) at the temperature under consideration and α is treated as a constant, approximately equal to 0.3 in bcc alloys. For fcc alloys the ferromagnetic effect on diffusion is usually neglectable, i.e. $\alpha \approx 0$. When there is magnetic ordering it is thus necessary to make the division into MF and MQ because $^{mg}\Gamma$ depends on $\mathrm{Q_B}$, i.e. MQ. The full expression then becomes:

$$RT\ln[RTM_B] = RT\ln M_B^0 - Q_B + RT\ln{}^{mg}\Gamma = \sum MF + \sum MQ + RT\ln{}^{mg}\Gamma$$

Both MF and MQ may be arbitrary polynomials in temperature and if there is no magnetic effect, i.e. $\mathrm{RT}ln^{mg}\Gamma = 0$, it is sufficient to enter either one of them. For example, the mobility of Cr in pure Ni may as well be stored as:

$$\mathrm{MF(FCC_A1\&CR,\ NI:VA;0) = 0}$$

and

$$\mathrm{MQ(FCC_A1\&CR,NI:VA;0)} = -Q_{Cr}^{Ni} + \mathrm{RT}\ln M_{Cr}^{Ni0}$$

In order to build a database it is necessary to find values on MF and MQ (or when no magnetic effect is considered MQ alone). In many cases such data can be found in the literature. The tracer diffusivity D_B^* is directly related to the mobility M_B by means of the Einstein relation

[*Eq. 5*] $$D_B^* = RTM_B$$

and when there is no magnetic effect on the mobility, e.g. ${}^{mg}\Gamma = 1$, then from Equation 2 and Equation 5 it is found that:

[*Eq. 6*] $$\mathrm{MQ} = RT\ln M_B^0 - Q_B = RT\ln D_B^*$$

In a more complex database the model parameters are determined from an optimization procedure, where all experimental information is taken into account, see for example Jönsson, 1995 and Engström and Ågren, 1996.

Relationship Between Diffusion Coefficients and Atomic Mobilities

Phenomenological Coefficients

For crystalline phases the vacancy-exchange mechanism of diffusion is predominant, i.e. diffusion occurs by atoms jumping into neighboring vacant lattice sites. From the absolute reaction rate theory, and by assuming that the vacancy concentration is governed by thermodynamic equilibrium, the diffusional flux of a component *k* in the lattice fixed frame of reference can be expressed as [Andersson and Ågren, 1992]:

[*Eq. 7*] $$\tilde{J}_k = -c_k y_{Va}\Omega_{kVa}\frac{\partial \mu_k}{\partial z}$$

Here $\mathrm{c_k}$ is the amount of *k* per unit volume, $\mathrm{y_{Va}}$ is the fraction of vacant lattice sites on the sublattice where *k* is dissolved, Ω_{kVa} is a kinetic parameter which gives the rate of exchange if there is a vacancy adjacent to a *k*-atom,

and μ_k is the chemical potential of component *k*. The mobility $\mathrm{M_k}$ is here defined as:

[*Eq. 8*] $\mathrm{M_k} = \mathrm{y_{Va}}\Omega_{\mathrm{kVa}}$ when *k* is substitutional

[*Eq. 9*] $\mathrm{M_k} = \Omega_{\mathrm{kVa}}$ when *k* is interstitial

From Equation 7, Equation 8 and Equation 9 it is possible to identify the so called phenomenological parameters that relate the flux of *k* to all the driving forces, i.e. $\mathbf{L_{kk} = c_k M_k}$ when *k* is substitutional, $\mathbf{L_{kk} = c_k y_{Va} M_k}$ when *k* is interstitial, and $\mathbf{L_{ki} = 0}$ when $\mathbf{k \neq i}$. The fluxes in the lattice-fixed frame of reference may now be expressed as:

[*Eq. 10*] $$\tilde{J}_k = -\sum_{i=1}^{n} L_{ki} \frac{\partial \mu_i}{\partial z} = -L_{kk} \frac{\partial \mu_k}{\partial z}$$

Transformation to the volume-fixed frame of reference, or the number-fixed frame of reference with respect to the substitutional elements, which may be regarded as the same, if as assumed in the Diffusion Module (DICTRA), the partial molar volumes are independent of concentration, and the partial molar volumes of the interstitials are neglected, yields

[*Eq. 11*] $$J_k = -\sum_{i=1}^{n} L'_{ki} \frac{\partial \mu_i}{\partial z}$$

where

[*Eq. 12*] $$L'_{ki} = \sum_{j=1}^{n} (\delta_{jk} - c_k V_j) L_{ji}$$

where δ_{jk} is the Kronecker delta, i.e.,=1 when j=k and 0 otherwise. $\mathbf{V_j}$ is the partial molar volume of element *j*.

Interdiffusion Coefficients

Generally, it is much more convenient to express the fluxes as functions of concentration gradients, rather than gradients in chemical potential. This is accomplished by rewriting Equation 11 using the chain rule of derivation, i.e.

[*Eq. 13*] $$J_k = -\sum_{i=1}^{n} L'_{ki} \sum_{j=1}^{n} \frac{\partial \mu_i}{\partial c_j} \frac{\partial c_j}{\partial z}$$

or equally if the unreduced diffusivities, D_{kj} are introduced,

[*Eq. 14*] $$J_k = -\sum_{j=1}^{n} D_{kj} \frac{\partial c_j}{\partial z}$$

The D_{kj} matrix introduced in Equation 14 may be identified by comparing with Equation 13,

[*Eq. 15*] $$D_{kj} = \sum_{i=1}^{n} L'_{ki} \frac{\partial \mu_i}{\partial c_j}$$

The $\frac{\partial \mu_i}{\partial c_j}$ are purely thermodynamic quantities, sometimes they are referred to as thermodynamic factors. It is now evident that the diffusivities may be looked upon as consisting of two separate parts, one purely thermodynamic and one kinetic.

There is a relation between the n concentration gradients in Equation 14 and for practical calculations one usually chooses to eliminate one of them. The reduced diffusivities in a volume-fixed frame of reference, where it is assumed that all the substitutional species have the same partial molar volumes, and furthermore, only the substitutional species contribute to the volume, i.e. the Diffusion Module (DICTRA) frame of reference, is expressed as,

[*Eq. 16*] $D^n_{kj} = D_{kj} - D_{kn}$ when *j* is substitutional

[*Eq. 17*] $D^n_{kj} = D_{kj}$ when *j* is interstitial

where *n* is taken as the dependent species. Using these diffusivities Equation 14 now becomes,

[*Eq. 18*] $$J_k = -\sum_{j=1}^{n-1} D^n_{kj} \frac{\partial c_j}{\partial z}$$

Equation 18 contains the so-called interdiffusion coefficients, sometimes referred to as chemical diffusivities. These diffusivities may be evaluated experimentally from e.g. diffusion couple experiments.

Intrinsic Diffusion Coefficients

The individual or intrinsic diffusion coefficients, that are defined in the lattice-fixed frame of reference by:

[*Eq. 19*] $$\tilde{J}_k = -\sum_{j=1}^{n-1} {}^i D^n_{kj} \frac{\partial c_j}{\partial z}$$

can also be evaluated from diffusion couple experiments, if in addition to concentration profiles the Kirkendall velocity can be estimated from the movement of inert markers. As the interdiffusion coefficients, the intrinsic diffusion coefficients can also be calculated from the mobilities. However, this time by applying the chain rule of derivation on Equation 10 and remembering that $\mathbf{L_{ki} = 0}$ when $\mathbf{k \neq i}$, i.e.

[*Eq. 20*] $$\tilde{J}_k = -\sum_{j=1}^{n} L_{kk} \frac{\partial \mu_k}{\partial c_j} \frac{\partial c_j}{\partial z}$$

The intrinsic diffusion coefficients may be identified in Equation 20 as:

[*Eq. 21*] $${}^i D_{kj} = L_{kk} \frac{\partial \mu_k}{\partial c_j}$$

Also here there is a relation between the *n* concentration gradients. If one of the concentrations are chosen as dependent, and if the same approximation as previously used for the partial molar volumes of the different elements is applied, then the intrinsic diffusion coefficients defined in Equation 19 are finally found.

[*Eq. 22*] $^{i}D^{n}_{kj} = {}^{i}D_{kj} - {}^{i}D_{kn}$ when *j* is substitutional

[*Eq. 23*] $^{i}D^{n}_{kj} = {}^{i}D_{kj}$ When *j* is interstitial

Self-diffusion Coefficient

The self-diffusion coefficient of A is the diffusivity of A in the limit of pure A. Studies of self-diffusion usually utilize radioactive tracer atoms A* of the same element.

Impurity Diffusion Coefficient

When the diffusion of a solute B in a solvent A is studied at an extremely small concentration of B, which e.g. radio tracers permit, then the impurity diffusion coefficient of B in A is observed.

Diffusion Module Available Graphical Mode Features

The Diffusion Module is an Add-on Module to the core Thermo-Calc software.

A separate license is required to perform calculations for more than three elements. Without it you are able to use the module in *Demo Mode*. This is not available in Console Mode.

Diffusion Templates

Under **Non-Equilibrium Calculations**, the **Homogenization** and **Diffusion** templates are available to all Thermo-Calc users when in Graphical Mode.

If you are using the Diffusion Module in Demo Mode, see Demonstration (Demo) Mode for what is available to you. Even if you have a license, you may find yourself in Demo Mode if you have a network license and all the licenses are checked out. See Diffusion Module (DICTRA) Licenses for more information.

Using the Templates

After opening Thermo-Calc in Graphical Mode, in the templates section under **Non-Equilibrium Calculations** click:

- **Homogenization** to add a *System Definer*, *Scheil Calculator*, *Diffusion Calculator*, and two *Plot Renderer* nodes to the **Project** tree.
- **Diffusion** to add a *System Definer*, *Diffusion Calculator*, and *Plot Renderer* to the **Project** tree.

Creating a Project from a Template

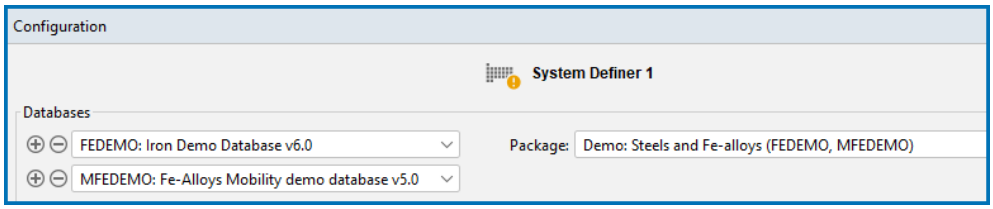
Diffusion Calculator

A Diffusion Calculator allows you to set the conditions for your calculation that define the geometry, regions, phases, grids, composition profiles, and the thermal profile, plus additional options. Many of the settings are automatically set as you define your system. Details about this activity are described in Diffusion Calculator.

Demo Database Packages for the Examples Collection

Both a thermodynamic and mobility database are required to run the Diffusion Module simulation. If you have a Diffusion Module (DICTRA) license you can run all the examples because the demonstration database packages are included with your installation.

Select the database packages from the **System Definer Configuration** window to run a simulation.



Demonstration (Demo) Mode

The Diffusion Module and some examples are available to all Thermo-Calc users but only for simulations with three elements. If you do not have a license then you are in *Demo Mode* when using the Diffusion Calculator, or either of the templates.

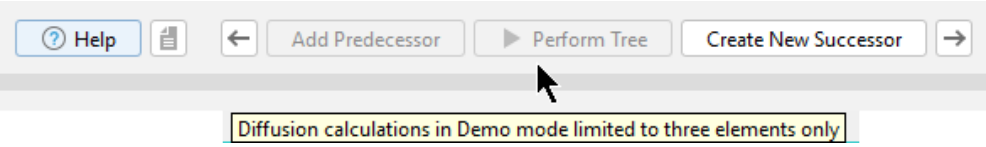
Diffusion Templates

If you are in DEMO mode then this is indicated by the addition of **DEMO** text under the button.

Diffusion Calculator

If you are experimenting with the Diffusion Calculator in Demo Mode then you may have access to a variety of databases based on your license. However, you can only define three elements for a demo simulation.

If you define more than three elements on the System Definer, when you go to the Diffusion Calculator, the **Perform** button is unavailable and the tooltip explains why.



Even if you have more than three elements, the Plot Renderer **Perform** button is still available. However, if you click the button and try to run the simulation the **Event Log** displays an error message.

Additive Manufacturing (AM) Module

There is connectivity between the Diffusion Module (DICTRA) or the Precipitation Module (TC-PRISMA) and the Additive Manufacturing (AM) Module when you have full licenses available for all relevant Add-on Modules and databases.

You can add a Diffusion Calculator or Precipitation Calculator as a successor to the AM Calculator and then when probes are included with the AM Calculator this data can be further used with the thermal profile.

Details are in the AM Module documentation. See AM Calculator: Working with Probe Data.

Basic Terminology in Graphical Mode

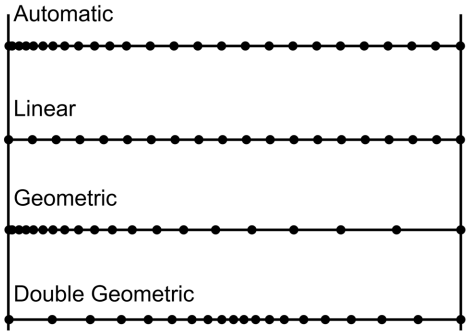
These terms are specific to working in Graphical Mode. The overall simulation in Console Mode is comparable but there are some differences in terminology and functionality.

Region

In Graphical Mode, a system consists of one *cell* with one or multiple *regions* in which the diffusion problem is to be solved.

Grid Types

These grid types are used in diffusion simulations: automatic, linear, geometric, and double geometric. When you are setting up the simulation, in either Console Mode or Graphical Mode, a region must have a grid defined.



Phases

Each region must contain at least one *phase*. The so-called *homogenization model* is used if multiple phases are added inside a region, then the average properties of the local phase mixture is used. Phase(s) can also be added to interphases of region(s) and then only participate in the simulation if the driving force for precipitation of the phase exceeds a predefined value. A new region is then created where the name of the region is set to the name of the phase but with `R_` added as a prefix.

Composition

These types of composition variables are used in the configuration of the Diffusion Calculator: *mass (weight) fraction*, *mass (weight) percent*, *mole fraction*, or *mole percent*.

The *u-fractions* are used in the diffusion equations. The u-fraction of a component *k* is defined as

$$\mu_k = \frac{x_k}{\sum_{j \in S} x_j}$$

The summation is only performed over the substitutional elements. The choice of the volume fixed frame of reference in the calculations make it convenient to use a composition variable which is related to the volume. The definition of the u-fraction is based upon the assumption that a species may or may not contribute to the volume of a phase. An interstitial element is assumed to not contribute to the volume. Substitutional elements are assumed to contribute equally to volume. Weight fraction, mole fraction or u-fraction can be used when plotting the results from a simulation.

Geometry and Coordinates

The Diffusion Module (DICTRA) can only handle diffusion problems where compositions vary along one spatial coordinate. The geometry of your system can be *planar*, *cylindrical*, or *spherical*.

The *planar* geometry corresponds to an infinitely wide plate of a certain thickness. If the system has a planar geometry then the lower boundary (the zero coordinate) is at the left side of the system. The upper boundary (the coordinate with the highest value) is at the right side of the system.

Boundary Conditions

Boundary conditions are conditions that define how matter behaves at the boundaries of your system. By default, matter is not allowed to cross the system boundaries.

You can change the setting for both the lower boundary (left side/centre) and the upper boundary (right side/surface) of the system.

Setting up a Diffusion Simulation in Graphical Mode.

Graphical Mode Diffusion Calculator Examples

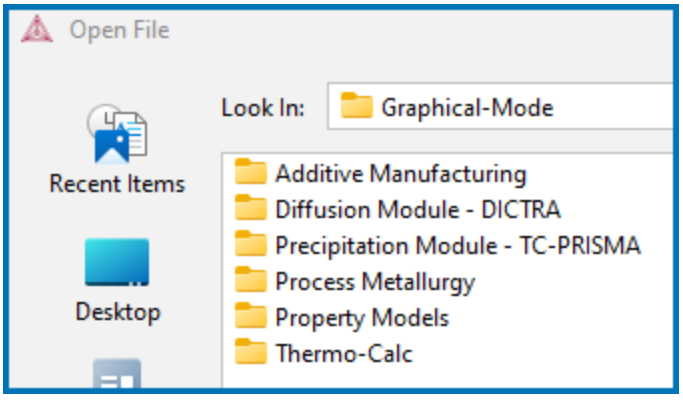
About the Examples

Opening the Diffusion Calculator Examples

Graphical Mode examples are available for Thermo-Calc and the Add-on Modules. There are also examples for the Property Models, including the material specific model libraries (i.e. Steel, Nickel, etc.). These are in the format of project files (*.tcu).

To open an example project file:

1. Open Thermo-Calc.
2. Confirm you are in Graphical Mode. If not, click the **Switch to Graphical Mode** button.
3. There are these ways to open the folders and files:
   - From the main menu select **File → Examples Files**
   - From the main menu select **Help → Examples Files**.
   - Click the **My Project** node and on the **Configuration** window, click the **Example Calculation** button.
4. The examples are divided into folders. Navigate to the folder and project file you want and double-click to open.



5. The Graphical Mode examples are stored without calculated results so you will want to run the example calculation and generate a plot or table. To do this, click the first node in the tree at the top of the **Project** window. Then right-click and select **Perform Now**.

Some examples require additional licenses in order for the calculation to run.

Setting up a Diffusion Simulation in Graphical Mode

When you are using the Graphical Mode version of the Diffusion Module (DICTRA), the steps to set up a simulation are a combination of adding *Activity* nodes (the System Definer, Diffusion Calculator, and Plot Renderer) and then defining the applicable settings for each of these nodes in a Configuration window.

The following is a general overview of the steps to set up the simulation.

1. Use the **Diffusion** template to add the System Definer, Diffusion Calculator, and Plot Renderer activity nodes.
2. On the **System Definer**, you select the thermodynamic and kinetic databases, add elements and phases, and generally define the system.
3. On the **Diffusion Calculator**, you set the geometry (by default the geometry is planar), add region(s) and enter grid(s) and phase(s) in the region(s). You then enter composition (s) of phase(s).
4. On the **Plot Renderer** or **Table Renderer**, you choose how to visualize your diagrams, and then run the simulation, i.e. you **Perform** the sequence of nodes you have defined in the tree to produce the output simulation.

Define the Diffusion Calculator

This topic lists the basic steps to define a **Diffusion Calculator**.

Working with diffusion simulations is an advanced topic. It is recommended you review the Diffusion Module (DICTRA) documentation and videos available or search for a specific topic.

1. Add a **Diffusion Calculator** node to the **System Definer**. If you used the **Diffusion** template (on the **My Projects Configuration** window under **Non-Equilibrium**), click the node to display the **Configuration** settings window.

2. In the Diffusion Calculator **Configuration** window, enter the settings described in Conditions Tab Settings and Options Tab Settings.

   The **Composition Profiles** and **Thermal Profile** are both set up on the **Configuration** window for a Diffusion Calculator. These are previewed in the **Visualizations** window.

3. Once you have finished defining the Diffusion Calculator, you also choose settings on the Plot Renderer. Some additional settings are specific to the Diffusion Calculator Plot Renderer.

Learn More

When you also have licenses either for the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA), for transient simulations you can additionally include probe data from the AM Calculator in the set up of the thermal profile for diffusion and precipitation calculations, respectively.

Diffusion Module Available Graphical Mode Features

Diffusion Module (DICTRA) Graphical Mode Examples Collection

Diffusion Calculator

A **Diffusion Calculator** allows you to set the conditions for, and perform, a diffusion calculation. You can add the calculator to the System Definer directly (right-click and select it from the **Create New Successor** menu).

There are also templates available under **Non-Equilibrium** that you can use to quickly set up a simulation. See Getting Started Links, Templates, and the Property Navigator.

Once you have added a Diffusion Calculator, the **Configuration** window has **Conditions** and **Options** settings tabs where there are many available conditions to set and then continue the settings with the specialized **Plot Renderer**.

- **Conditions**: Set the conditions for your calculation that define the geometry, regions, phases, grids, composition profiles, and thermal profile.

  The **Composition Profiles** and **Thermal Profile** are both set up on the **Configuration** window for a Diffusion Calculator. These are previewed in the **Visualizations** window.

- **Options**: Modify the simulation conditions such as the choosing the default solver (automatic or homogenization) and the time integration method. Also define the time step controls and if you choose homogenization as the solver, define further settings such as the interpolation scheme and whether to use global minimization or not.
- **Plot Renderer**: There are also unique settings available for this calculator once you add a Diffusion Calculator Plot Renderer.

Learn More

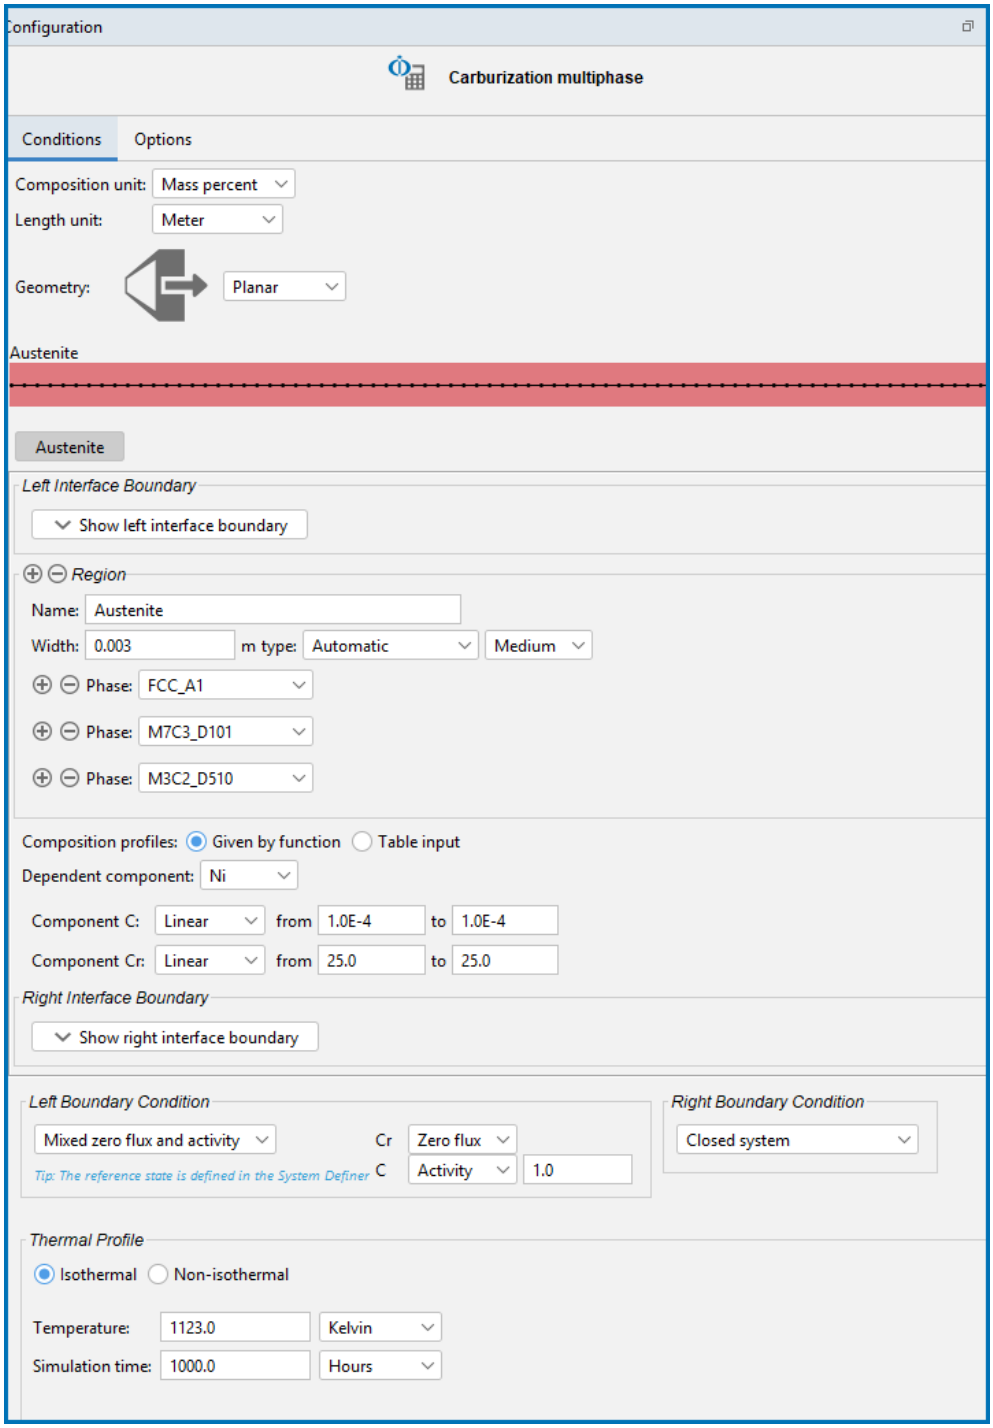
The Diffusion Calculator is available with three elements if you do not have the additional Diffusion Module (DICTRA) license. With the Add-on Module you can use all available elements as per the licensed database selected. See Diffusion Module Available Graphical Mode Features for details about this and other options available with additional licenses.

Working with these simulations is an advanced topic. It is recommended you review the documentation and videos available or search for a specific topic.

Define the Diffusion Calculator

Conditions Tab Settings

The following **Configuration** window is shown using project example file D_07: Multiphase Carburization of an Alloy.



These are the settings available from the **Conditions** tab. To edit the global defaults for some settings, go to the **Options** window (different from the tab). See Global Settings: Diffusion Calculator.

General

Composition Unit

Choose a **Composition unit** from the list: **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**.

Length Unit

Choose a **Length unit** from the list: **Meter**, **Millimeter**, **Micrometer**, **Nanometer**, or **Ångström**.

Geometry

Choose a **Geometry**: **Planar**, **Spherical**, or **Cylindrical**. For **Cylindrical**, also enter a value for the **First interface position**.

With a cylindrical or spherical geometry, the system's zero coordinate (left boundary) is at the center of the cylinder or sphere. The highest coordinate (right boundary) is defined by the cylinder or sphere radius.

Geometry	*Graphic*
Planar	
Spherical	
Cylindrical	

Mobility Adjustment

Click the **Show Mobility Adjustment** button to access these settings.

Phase

Click the add ⊕ button to **Add a phase** or the minus ⊖ button to **Remove a phase**. Then choose a phase from the list.

Mobility Adjustment, Prefactor, and Activation Energy

The **Mobility adjustment** parameters modify the atomic mobility data from a database.

Choose **Same for all elements**, which applies the adjustment to all elements, or **Per element** to adjust to each individual element. Then for the following settings, enter one set of values for **Same for all elements**, or individually for **Per element**.

- **Prefactor** (unitless) is a parameter that multiplies to the mobility data from a database. This value scales the mobility by a constant amount.

  For the Precipitation Calculator, this can be useful, for example, when the material has a higher than normal vacancy concentration at the start of the precipitation simulation. (e.g. from a prior solutionizing and quenching treatment).

- The **Activation energy** (J/mol) is a value that adds to the activation energy of mobility data from a database. This value scales the mobility by a temperature-dependent amount. Similar usage as the **Mobility adjustment >Prefactor** setting.

Learn More

Options Tab Settings, Region Settings, Boundary Conditions, Composition Profiles, and Diffusion Calculator Thermal Profile.

The **Composition Profiles** and **Thermal Profile** are both set up on the **Configuration** window for a Diffusion Calculator. These are previewed in the **Visualizations** window.

The Diffusion Module (DICTRA) in Console Mode has commands to perform some of the settings also available on the Diffusion Calculator. Where possible the name of the command is indicated and includes a link to the topic.

Region Settings

This topic lists the region settings for the **Diffusion Calculator**.

There should be one unique phase in each region.

Settings

Left and Right Interface Boundary

Toggle between hiding and showing the **Left interface boundary** or **Right interface boundary**.

Click the **Add quantity** or **Remove quantity** buttons as required to add a **Phase** and then enter a value for the **Driving force** as required. The default driving force is `1.0E-5`.

Name

Enter a **Name** for the region in the field. For example, enter `Austenite`. This name is automatically updated on the tab and above the grid points graphic.

Width

Enter a numerical value in the **Width** field. The unit is the one selected for the **Length unit**.

Type (of Grid)

Select a type of grid:

Automatic is not available when the **Composition profiles: Table input** is selected. See Composition Profiles.

- **Automatic** for an automatic grid point distribution. An appropriate grid is generated at the start of the simulation where the grid points are automatically distributed according to the entered composition profile and boundary conditions.
- **Linear** for an equally spaced grid.
- **Geometric** for a grid that yields a varying density of grid points in the region.
- **Double geometric** to have a high number of grid points in the middle or at both ends of a region.

Automatic Grid Type Settings

For an **Automatic** grid type, also choose a grid accuracy level: **Coarse**, **Medium**, **Fine**, or **Custom**.

The values for the Grid Accuracy settings for each option differ when calculated by Thermo-Calc based on whether it is the Classic or Homogenization model.

- If you are using a Classic model: Fine 75/1.25, Medium 50/1.2, Coarse 25/1.15 (Number of points/Max geometric factor)
- If you are using the Homogenization model: Fine 100/1.03, Medium 80/1.02, Coarse 60/1.01 (Number of points/Max geometric factor)

For **Custom**, also enter values for:

- **max number of points**: the maximum number of equidistant points in a region.
- **max geometric factor**: Value in the geometrical factor in the series determining the distribution of the grid points. A geometrical factor larger than one yields a higher density of grid points at the lower end of the region and a factor is smaller than one yields a higher density of grid points at the upper end of the region.

Points (Linear, Geometric, and Double Geometric Grids)

For **Linear**, **Geometric**, or **Double geometric** grids, enter a numerical value in the **points** field. The default is 50.

Ratio (Geometric Grid)

For a **Geometric** grid, choose or enter a number for the **Ratio** to determine the distribution. A geometrical factor larger than one yields a higher density of grid points at the lower end of the region and a factor smaller than one yields a higher density of grid points at the upper end of the region.

Lower Ratio and Upper Ratio (Double Geometric Grid)

For a **Double geometric** grid, specify two geometrical factors. Enter a **Lower ratio** for the distribution in the lower (left) part of a region, and an **Upper ratio** for the distribution in the upper (right) part of a region.

Phase

Choose a **Phase** from the list. The available options are defined in the System Definer. At least one phase that dissolves all system elements must be selected.

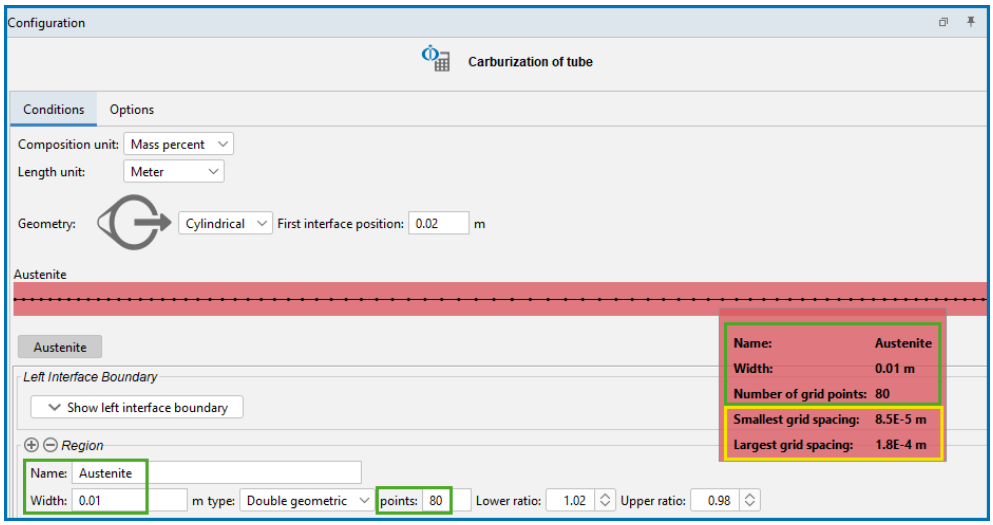
Click the **Add phase** or **Remove phase** buttons as required.

TIP: View a Summary of the Region Grid Point Settings

When working with the **Diffusion Calculator** in Graphical Mode, you can hover over the grid points on the **Configuration** window to view additional tooltip details about the region.

The settings information includes the **Name** of the region (in the example it is renamed to **Austenite**), the **Width** of the region, and the number of grid **points**.

For all types of grids, useful calculated information is included about the **Smallest grid spacing** and **Largest grid spacing** points. The information is available to prevent you from setting a combination with too many grid points and a high geometric factor that could lead to unusable grid point spacings.



An example of a Diffusion Calculator Configuration window. The Region settings (in the green boxes) are taken directly from the settings. The Smallest and Largest grid spacing details (in the yellow box) are taken from the grid point placement information calculation. This is using example D_06.

Learn More

Composition Profiles and Diffusion Calculator Thermal Profile

The **Composition Profiles** and **Thermal Profile** are both set up on the **Configuration** window for a Diffusion Calculator. These are previewed in the **Visualizations** window.

Boundary Conditions

Boundary conditions are conditions that define how matter behaves at the boundaries of your system. By default, matter is not allowed to cross the system boundaries.

You can change the setting for both the lower boundary (left side/centre) and the upper boundary (right side/surface) of the system.

Examples D_06: Diffusion Through a Tube Wall and D_07: Multiphase Carburization of an Alloy use boundary conditions.

Settings

The boundary condition settings are done on the **Diffusion Calculator**. The following describes the options available for the *Left boundary* and *Right boundary* conditions.

Closed System

By default it is a **Closed system**. Choose **Mixed zero flux and activity** or **Composition** if the system is not closed. Corresponds to a fix flux value, which is set to zero at all times. This is the default boundary condition.

Composition

Allows you to set a fix composition at the boundary.

In Console Mode this is similar to the command STATE_VARIABLE_VALUE, but in Graphical Mode this condition is limited to setting a fixed composition.

Mixed Zero Flux and Activity

The flux of selected components is either set to zero or a prescribed activity value.

For **Mixed zero flux and activity**, and for each independent element selected in the **Composition profile**, choose either **Zero flux** or **Activity** from the lists and enter a value in the field when **Activity** is selected. The reference state for the components are taken from the System Definer **Components** tab.

In the field for **Activity**, enter a formula that the software evaluates during the calculation.

The formula can be:

- A function of the variable TIME
- A constant

The formula must be written with these rules:

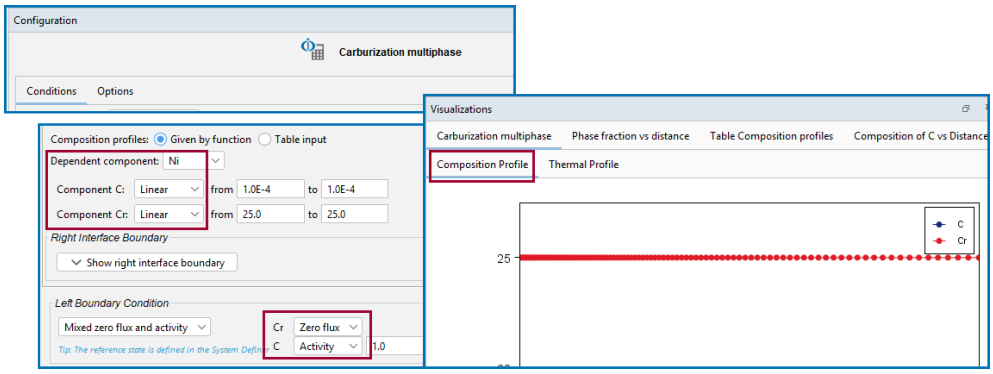
- A number must begin with a number (not a dot)
- A number must have a dot or an exponent (E)

The operators + , - , * , / , ** (exponentiation) can be used and with any level of parenthesis.

As shown, the following operators must be followed by `()` i.e. open and closed parentheses:

- SQRT(X) is the square root
- EXP(X) is the exponential
- LOG(X) is the natural logarithm
- LOG10(X) is the base 10 logarithm
- SIN(X), COS(X), TAN(X), ASIN(X), ACOS(X), ATAN(X)
- SINH(X), COSH(X), TANH(X), ASINH(X), ACOSH(X), ATANH(X)
- SIGN(X)
- ERF(X) is the error function

This is from example *D_07: Diffusion Carburization Multiphase*.



Options Tab Settings

The following settings are available on the **Options** tab for a Diffusion Calculator.

- Simulation Conditions
- Timestep Control
- Classic and Homogenization Model Settings

Global Options

You can change these settings locally for a specific Calculator or globally for some defaults in the **Options** *window* (a different location than the tab).

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Graphical Mode** tab and the **Diffusion** node in the tree.

Learn More

Global Settings: Diffusion Calculator.

Simulation Conditions, Timestep Control, Classic and Homogenization Model Settings, and About the Homogenization Functions

Simulation Conditions

The following settings are available on the **Options** tab for a Diffusion Calculator.

Options Tab Settings

Default Solver

Choose the *Default solver*: **Automatic** or **Homogenization**. Select **Homogenization** to define the *Homogenization Model Specific* sections.

Classic and Homogenization Model Settings

The homogenization solver (called the homogenization model in Console Mode) is useful when you want to simulate long-range diffusion through a multiphase mixture, under the assumption that local equilibrium holds at each node point.

Time Integration Method

Automatic , **Trapezoidal**, or **Euler backwards**.

The default is **Automatic** where the default degree of implicity corresponds to trapezoidal (0.5) for classic and Euler Backward (1.0) for the homogenization model. If large fluctuations occur in the profiles it may be necessary to use the more stable but less accurate *Euler backwards*.

Save Results on File

Yes, **No**, or **Every nth.**. Select **Every nth** to enter a value in the field.

This setting determines if the results are to be saved on file during the course of the simulation. Select:

- **Yes** to always save on file.
- **No** to never save on file.
- **Every nth.** to save every n^{th} time to file. Then enter an integer value ranging from 0 to 99.

Use Forced Starting Values in Equilibrium Calculations

The default, **Automatic**, allows the software program to automatically use forced starting values to perform the equilibrium calculations. When a phase with an ordering contribution is entered into the simulation, for example the gamma-prime/FCC_l12 phase in Ni-base superalloys, forced starting values are automatically turned on. Or choose **Yes** or **No**.

Default Driving Force for Phases Allowed to Form at Interfaces

Enter a value in the field. The required driving force (evaluated as `DGM (ph)`) to be used for determining whether an inactive phase is stable. DGM is the variable for the driving force that is already divided by RT, and it is dimensionless. The default is `1E-5`.

Suffixes

Timestep Control

The following settings are available on the **Options** tab for a Diffusion Calculator.

Options Tab Settings

Max Relative Error

Enter a value in the field. The default is `0.05`.

Max Absolute Error

Enter a value in the field. The default is `1.0E-5`.

Timestep

Enter values in the fields.

> This value is always in seconds.

- **Initial**: What is used as the initial time step. The default is `1.0E-7`.
- **Smallest allowed**: The smallest time step allowed during the simulation. This is required when using the automatic procedure to determine the time step. The default is `1.0E-7`.
- **Max % of simulation time**: The default is `10`.

Factor Specifying the Maximum Increase in the Time Step Taken from One Time Step to Another

For example, if 2 is entered the maximum time step is twice as long as the previous time step taken. Enter a value in the field. The default is 2.

The Timestep is to be Controlled by the Phase Interface Displacement During the Simulation

The default is **Automatic**. When a liquid phase is entered in a simulation this option is automatically turned on. Optionally choose **Yes** or **No** to set whether the time step is to be controlled by the phase interface displacement during the simulation.

Classic and Homogenization Model Settings

The following settings are available on the **Options** tab for a Diffusion Calculator.

Classic Model Specific

Activity or Potential

Use the [**activity** or **potential**] of a component in order to find the correct tieline at the phase interface.

Determines whether the program should use the potential or the activity of a component in order to find the correct tie-line at the phase interface. The potential or the activity is varied by the program and is set in order to reduce the degrees of freedom at the local equilibrium.

Flux Balance Equation Accuracy

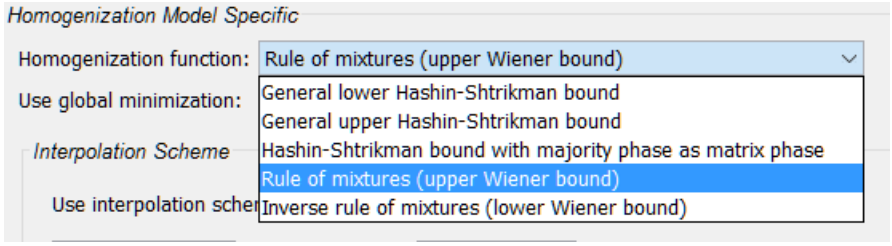
Required accuracy during the solution of the flux balance equations. The default is `1.0E-16`.

Homogenization Model Specific

This section is available when **Homogenization** is selected (or automatically selected) as the **Default solver**. These settings are available on the **Options** tab.

Homogenization Function

Several functions are available. The default is **Rule of mixtures (upper Wiener bound)**. See About the Homogenization Functions.



Use Global Minimization

Select the checkbox for global minimization used in equilibrium calculations. In general, using global minimization significantly increases the simulation time, but there is also a significantly reduced risk for non-converged equilibrium calculations.

Interpolation Scheme

When the homogenization model is used, simulations are run using an implicit finite volume method to increase numerical stability. Because of this, and other factors, homogenization model simulations generally run slower than other comparable simulations. You can reduce simulation time with the **Use Interpolation scheme** checkbox. The checkbox is selected by default.

Discretization

[**Logarithmic** or **Linear**] discretization with *[number of]* steps in each dimension.

- For the linear discretization the scheme is not used at node points where the content of one or more solutes fall below a certain critical value. For such cases, where composition span many orders of magnitude, the logarithmic discretization can be tried.
- Enter the number of steps in composition space. In the limit where an infinite number of steps are used, exactly the same solution is obtained as without the interpolation scheme. However, excellent results can be obtained with a reasonable discretization. The default is `10000` steps.

Memory to Use

This is the fraction of free physical memory to be used by the interpolation scheme.

Select **Megabyte** or **Fraction of free** and then enter a value in the field.

Diffusion Calculator Plot Renderer

The following is information about the settings available in both Simplified and Advanced Mode for a Plot Renderer when it is a successor to a **Diffusion Calculator**.

When you select **Advanced Mode** as the *Plot type*, this expands the variable options available from both the *X*- and *Y-Axes* lists. Otherwise the axis variables default to the most logical combination.

Simple Mode

When you open the Diffusion Calculator Plot Renderer, it defaults to **Simple Mode**. Use the **Advanced Mode** to have more flexibility.

Use **Simple Mode** to define the most common axis variables. The software automatically sets the correct **Plot condition** and **Independent variable**.

X-axis Variable

Select the variable for the *X*-axis: **Distance** or **Time**.

- For **Distance** also choose a unit (**Meter**, **Millimeter**, **Micrometer**, **Nanometer**, or **Ångström**) and what **Region** to include. The list contains the regions defined on the Diffusion Calculator or you can choose **All regions**.
- For **Time** choose a unit (**Seconds**, **Minutes**, **Hours**, or **Days**).

Y-axis Variable

Select the variable to plot on the *Y*-axis. The available options are based on choices such as whether **Distance** or **Time** is chosen for the *X*-axis, whether isothermal or non-isothermal is selected, whether there is a homogenization solver, or if there is one or more regions.

Distance Along the X-axis

If **Distance** is plotted along the *X*-axis, then by default the **Composition** is plotted along the *Y*-axis.

- From the list in the middle, choose the component to plot, or select **All**.
- From the next list, choose the unit to be **Mass percent**, **Mole percent**, **Mass fraction**, **Mole fraction**, or **u-fraction**.

Time Along the X-axis (One Region)

If **Time** is plotted along the *X*-axis, then choose the *Y*-axis variable to plot plus the additional settings:

- **Total phase fraction**: **By volume** or **By mass**. Then select a phase from the list.
- **Total fraction of component**: **By mole** or **By mass**. Then select a component from the list.
- **Total fraction of component in phase**: **By mole** or **By mass**. Then select a component and a phase from the lists.

Distance Along the X-axis (Homogenization)

If **Distance** is plotted along the *X*-axis and a homogenization solver is being used, then choose **Composition** or **Phase fraction** to plot on the *Y*-axis. Then select the applicable settings.

- Choose the component to plot, or select **All** and the unit **Mass percent**, **Mole percent**, **Mass fraction**, **Mole fraction**, or **u-fraction**.
- Choose **By mole** or **By mass** then select a component from the list.

Time Along the X-axis (Two or More Regions)

If **Time** is plotted along the *X*-axis, then choose the *Y*-axis variable to plot plus the additional settings:

- **Total phase fraction**: **By volume** or **By mass**. Then select a phase from the list.
- **Total fraction of component**: **By mole** or **By mass**. Then select a component from the list.
- **Total fraction of component in phase**: **By mole** or **By mass**. Then select a component and a phase from the lists.
- **Composition at interface**: **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**. Then choose a **Region** and whether it is **Upper** or **Lower** and a component.
- **Position of interface**: Choose a unit (**m**, **µm**, or **nm**) and the interface.
- **Velocity of interface**: Choose a unit (**m**, **µm**, or **nm**) and the interface.

- **Width of region**: Choose a unit (**m**, **µm**, or **nm**) and the interface.
- For a **Non-isothermal** profile, **Temperature** is available. Choose a unit **Kelvin**, **Celsius**, or **Fahrenheit**.

Axis Type

Click **Show more**. Select the type of axis scale: **Linear**, **Logarithmic**, **Logarithmic 10**, or **Inverse**.

Limits

Click **Show more**. Specify the range along the axis to show in the plot. In the fields, enter the minimum and maximum values of the axis variable. You can also determine the **step** size between the tick marks along each axis.

Select the **Automatic scaling** checkbox to allow the program to set the limits.

Add and Remove Axes

Use the **Add an axis** and **Remove this axis** buttons to add additional *X*- and/or *Y*-axes to a plot or to merge plots (to overlay one plot with another in the same diagram).

Advanced Mode

Use **Advanced Mode** to select any combination of axis variables, and then access further settings such as the **Plot condition**, **Region**, and **Independent variable**. Examples of advanced plot options are activity of a component at an interface, diffusivities, and diffusion paths. Also user-defined functions can be used as plot variables where Console Mode syntax is used to define functions. In some cases, sensible default values are selected, but they can be changed according to your needs.

Distance along X-Axis - Advanced Time Setting

An alternative **Time** setting is available in **Advanced Mode**.

When the *X*-axis variable is **Distance**, for the Y-axis choose a **Time** unit (**Seconds**, **Minutes**, **Hours**, or **Days**). Enter a numerical value.

Plot Condition and Independent Variable

- If any plot axis variable of the type **Integral** is selected, then the plot condition is set to **Integral** and the independent variable is set to **Time**.
- If a plot axis variable is set to **Time** then the plot condition is set to **Time** and the Independent variable is also set to **Time**.
- If a plot axis variable is set to **Distance** then the plot condition is set to **Distance** or **Interface** and the Independent variable is set to **Distance**.

Plot Condition	*Independent Variable Settings Based on the Plot Condition*
Time: Choose a unit (**Seconds**, **Minutes**, **Hours**, or **Days**). Enter a numerical value.	The default is **Distance**: Choose a **Global** or **Local** distance. A **Global** distance is counted from the rightmost interface of the system. A **Local** distance is counted from the lower interface of the Region selected. You can also choose **Time**, which requires no further settings.
Distance: Choose a specific **Region** from the list or use the default **All regions**.	The default is **Time** and there are no further settings. You can also choose a **Global** or **LocalDistance**. A **Global** distance is counted from the rightmost interface of the system. A **Local** distance is counted from the lower interface of the Region selected.
Interface: From the lists choose a **Region** and whether it is the **Upper** or **Lower** region.	The default is **Distance**: Choose a **Global** or **Local** distance. A **Global** distance is counted from the rightmost interface of the system. A **Local** distance is counted from the lower interface of the Region selected. You can also choose **Time**, which requires no further settings.
Integral	The default is **Time** and there are no further settings. You can also choose a **Global** or **LocalDistance**. A **Global** distance is counted from the rightmost interface of the system. A **Local** distance is counted from the lower interface of the Region selected.

Conditions Tab Settings and Plot Renderer: Configuration Settings

Plot Type: Simple Mode and Advanced Mode

See Quantities Groups Available for Plots and Tables for a general list of quantities. However, for the Diffusion Calculator Plot Renderer Advanced Mode and Simple Mode plot types, there are no defined groups to choose from.

Plot Type: Simple Mode and Advanced Mode

The Plot Renderer is a dynamic activity node with options such as being able to choose from a variety of *Plot types* based on the Calculator and Calculation Type selected.

Simple Mode and **Advanced Mode** as a *Plot type* are only available for the Diffusion Module (DICTRA) in Graphical Mode. Unlike many other Calculators, the Diffusion Calculator does not require the selection of a *Calculation Type* before a Plot Type is available on the Diffusion Calculator Plot Renderer.

Simple Mode

Use **Simple Mode** to define the most common axis variables. The software automatically sets the correct **Plot condition** and **Independent variable**.

For one example using **Simple Mode**, see D_04: Fe-C Moving Boundary - Austenite to Ferrite.

Advanced Mode

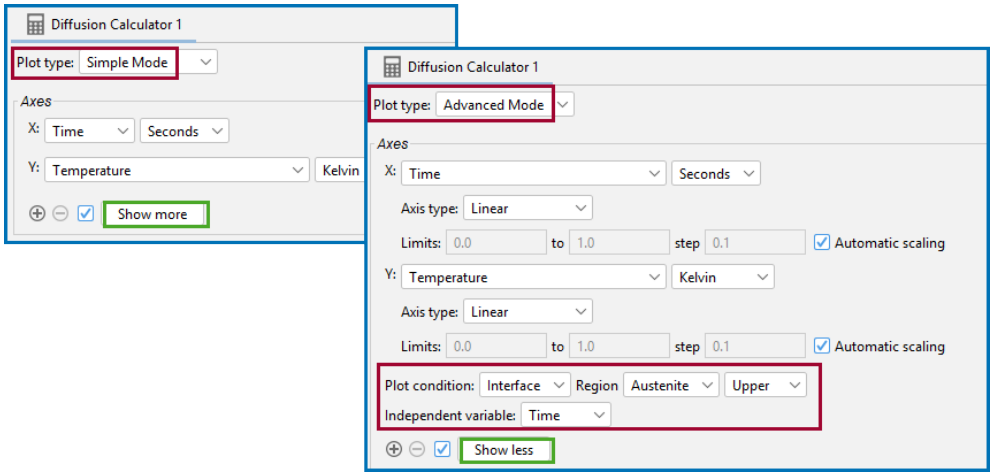
Use **Advanced Mode** to select any combination of axis variables, and then access further settings such as the **Plot condition**, **Region**, and **Independent variable**. Examples of advanced plot options are activity of a component at an interface, diffusivities, and diffusion paths. Also user-defined functions can be used as plot variables where Console Mode syntax is used to define functions. In some cases, sensible default values are selected, but they can be changed according to your needs.

For one example using **Advanced Mode**, see D_10: Iron (Fe) Homogenization in Scheil.

Switching Between Modes

You can try yourself to switch between **Simple Mode** and **Advanced Mode** and then change the settings to how you want it using example D_04: Fe-C Moving Boundary - Austenite to Ferrite.

In the **Plot Renderer** settings window, click **Show more** and **Show less** to toggle between viewing all or some of the available settings.



Comparing Simple Mode (left) to Advanced Mode (right) on a Plot Renderer as a successor to a Diffusion Calculator. For Advanced Mode, there are additional settings made available based on the combination of axis variables.

Learn More

Calculation Types in Graphical Mode

See Plot Types detailing availability *By Calculator*, *By Plot Type*, or *By Calculation Type*.

Composition Profiles

The **Composition Profiles** are set up on the **Configuration** window for a . These are viewed in the **Visualizations** window.

For most calculations, you can include data as follows.

- *Given by function* (linear, step, or function). See Composition Profiles: Given by Function. The grid types available to select are **Automatic**, **Linear**, **Geometric**, or **Double geometric**.
- *Table input* that can be either directly entered or imported. See Composition Profiles: Table Input (i.e. Data File Import). The grid types available to select are **Linear**, **Geometric**, or **Double geometric**.
- *Solidification data*. For a **Diffusion Calculator** that is a successor to the **Scheil Calculator**, you can perform a Scheil solidification calculation followed by kinetic homogenization simulation of segregated composition profile. In this case, there are different options on the **Configuration** window for this section. The profile then uses information from the Scheil Calculator. See Composition Profiles: Scheil Segregation Profiles.

When using the **Table input** setting, you can directly enter data in the table or you can import a **Data file**. If you import a data file, even though it is a simple set of data, first prepare it based on the Guidelines for Importing Data Files to Composition Profiles.

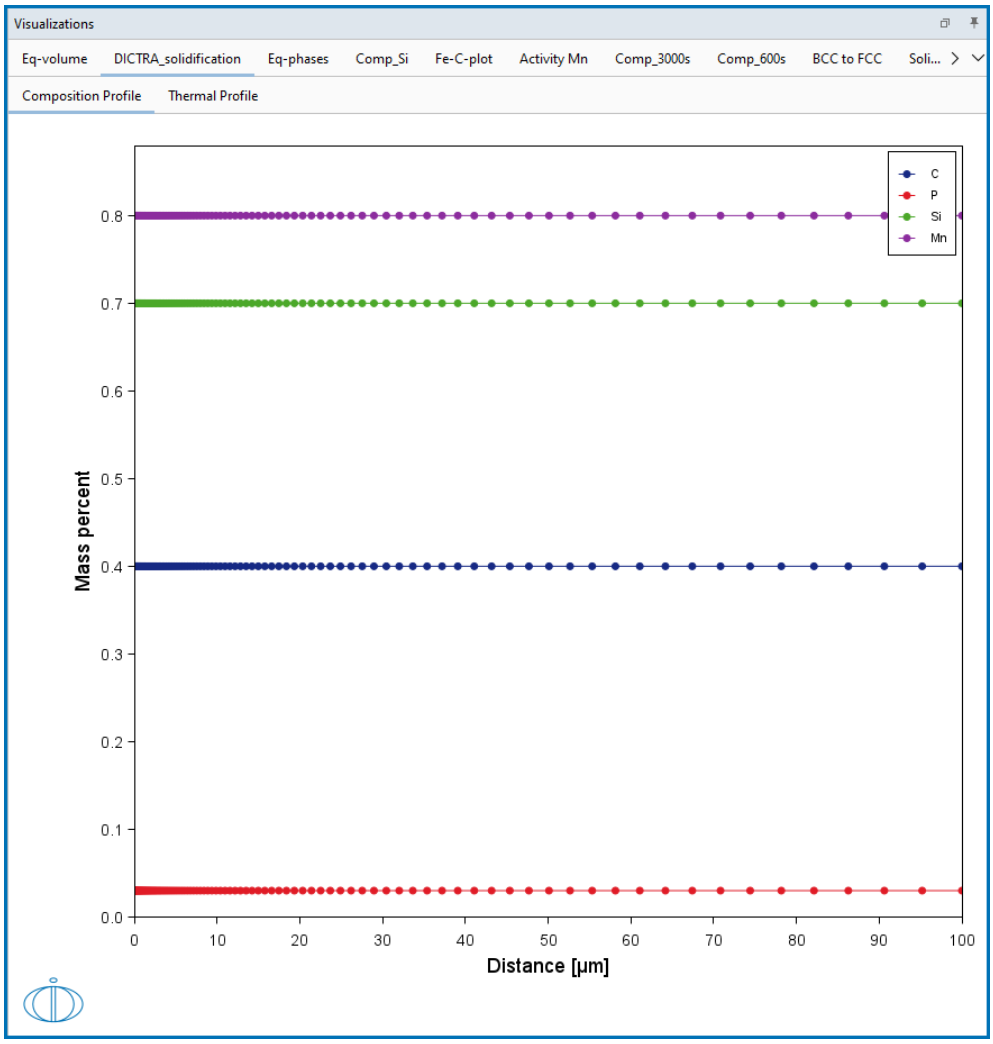


Figure 1: This composition profile is from example D_08 Microsegregation During Solidification. Other examples using this feature are D_04_Diffusion_Fe-C_Moving_Boundary_Austenite_to_Ferrite and D_09 Ni_Post_Weld_Heat_Treatment_From_File, which are all included with your installation.

Composition Profiles: Given by Function

1. On the Diffusion Calculator **Configuration** window, first enter the required settings described in Conditions Tab Settings including the Region Settings and Boundary Conditions.
2. Click to select the **Composition profiles** → **Given by function** option.
3. Select a **Dependent component** for which the composition does not need to be given. The available options depend on the phase description.

4. For each **Component** choose one of these options:
   - **Linear**: Enter numerical values in the **from** and **to** fields.
   - **Step**: Enter numerical values in the **from**, **to**, and **step at** fields. The unit is the same as the **Length unit** selected at the top of the Configuration window.
   - **Function**: Enter a composition function in the field using SI units. The syntax to use for writing functions is a Python syntax (a programming language). Any valid Python expression that is a function of the distance variable *x* will work.

     You can use the standard Jython math library but you must prefix these functions with the text "math" For example: `10 + math.sin (x*2)`. The Jython math library is available here: https://www.jython.org/.

   - The error function `erf(X)` is also available in the Jython math library and can be called with `math.erf(x)`.
   - Another useful function is the Heaviside step-function `hs(X)`. For example, `3+2hs(x-1e-4)` provides a concentration of 3 at the left side and 5 at the right side with a sharp step in the concentration profile at 1e-4m=100 mm.
5. The **Composition Profile** is previewed in the **Visualizations** window as in Figure 1. Make adjustments to the settings as needed and watch it dynamically change in the window.
6. After completing this section, also continue with Boundary Conditions and the Diffusion Calculator Thermal Profile.

Composition Profiles: Table Input (i.e. Data File Import)

1. On the Diffusion Calculator **Configuration** window, first enter the required settings described in Conditions Tab Settings including the Region Settings and Boundary Conditions.
2. Click to select the **Composition profiles** → **Table input** option.
3. Select a **Dependent component** for which the composition does not need to be given (i.e. it is excluded from the table). The available options depend on the phase description. The **Composition unit** and **Length unit** are taken from the settings already entered.

4. To enter data directly into the table:
    a. Click in each cell under the applicable columns, e.g. **Distance** and then each individual component such as **Fe**, **Al**, etc.
    b. Directly enter the values in the table. Press `<Enter>` to add rows and use the scroll bars to navigate the table.
5. To import a data file:
    a. It is important to first prepare the data file as in Guidelines for Importing Data Files to Composition Profiles.
    b. When the data file is ready, to the right of the **Data file** field, click the file button to load the file.
    c. Navigate to a data file such as an MS Excel spreadsheet (with ***.xls** or ***.xlsx** extensions) or a ***.csv** file. You can also use other programs (e.g. Google Sheets) to enter data and export to a CSV format that can be read by the software. Click **Open** to import the data to the **Configuration** window table.
    d. If there are issues with the above import, experiment with choosing the delimiter type that corresponds to the data in the file: **Comma** (,), **Colon** (:), **Equals sign** (=), **Semicolon** (;), or **Tab**—that matches the delimiter in the data file. Click the **Reload** button. The data is imported to the **Configuration** window table.
6. The **Composition Profile** is previewed in the **Visualizations** window as in Figure 1. Make adjustments to the settings as needed and watch it dynamically change in the window.
7. After completing this section, also continue with Boundary Conditions and the Diffusion Calculator Thermal Profile.

Composition Profiles: Scheil Segregation Profiles

This section is specific to when the **Homogenization** template is used, or generally when a **Diffusion Calculator** is a successor to the **Scheil Calculator**.

When this is the case, the *Composition profiles* take information from the Scheil calculation, and then you can choose to **Average over all solidified phases** (the default), where **All solidified phases** is further selected by default or you can define by **Custom phases**.

Alternatively, choose **Primary dendrite phase**, where it is assumed that other phases formed during solidification will not dissolve during homogenization. The **Primary dendrite phase** can only be BCC, FCC, or HCP.

Also when **Primary dendrite phase** is selected, the Scheil segregation profiles for fast diffusers are not available. The alloy composition for fast diffusers that is defined on the Configuration Window Settings next to the **Fast diffusers** checkbox is used instead.

The segregated composition profile can be assumed to be equal to a concentration profile for regular Scheil assumptions. i.e. the segregated composition profile as a function of solidified material can be directly mapped to a concentration profile given the secondary arm spacing. This direct relation between segregated and concentration profiles is no longer valid when fast diffusers are used. Then the fast diffusers equilibrate at all temperatures during the Scheil solidification and the concentration profiles for fast diffusers therefore change at every temperature. The average segregated profile for all elements (also fast diffusers) as a function of solidified material represent the composition profile at the final temperature at the end of solidification.

To learn about the **Homogenization** template, see Getting Started Links, Templates, and the Property Navigator.

Example D_10: Iron (Fe) Homogenization in Scheil uses the **Homogenization** template to demonstrate the use of the Scheil data with a diffusion calculation.

Guidelines for Importing Data Files to Composition Profiles

The **Composition Profiles** settings are done on the **Configuration** window for a . The profile is then previewed in the **Visualizations** window.

You can import data from a file. There are specific guidelines needed to correctly prepare the data in the file to ensure it imports without errors.

Region Settings, Boundary Conditions, Composition Profiles, and Diffusion Calculator Thermal Profile.

Data File Requirements

The following are instructions about setting up the data file when **Table input** is selected for the Composition Profiles.

The data in the spreadsheet or csv file can include the distance and the compositions, plus the parameters defining the dependent component, composition unit, and length unit. In order for the data to be included in the calculation, the column and row definitions in the file must adhere to certain rules of entry.

Only the columns described here are read / used in the calculation. It is important to enter the information exactly as described. It is recommended that the data file is cleaned up before importing / loading it and performing calculations.

	A	B	C	D	E	F	G
1	Distance	Mn	Cr	Ti	dependent_component=fe	composition_unit=mass_pct	length_unit=micrometer
2	0	0	0	0			
3	500	0.1	0.6	1.1			
4	1000	0.2	0.12	1.2			
5	1500	0.5	0.19	1.5			
6	2000	0.1	0.1	1.3			
7	3000	0.1	0.05	1.1			

Figure 2: This is an example of data entered into an Excel spreadsheet (which is then converted to csv format). Columns A to D show the data entered to create the Composition Profile itself. Columns E, F, and G are to define default settings although these can also be defined on the Configuration window.

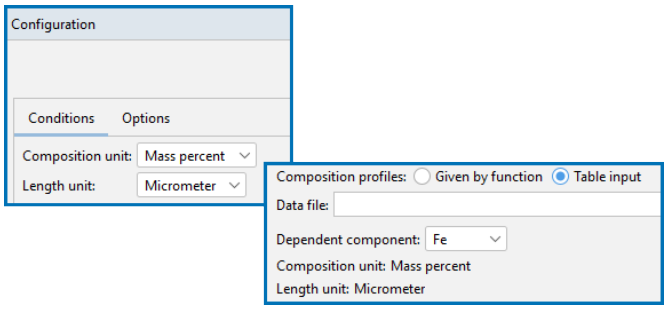

Figure 3: Three columns in the spreadsheet correspond to settings that can either be entered on the Configuration window, or defined in the data file. This is for the dependent component (column E), composition unit (column F), and length unit (column G). When this information is not specified in the data file, the default is taken from the settings defined on the Configuration window.

Distance and Composition/Components Plus Values

- No abbreviations are allowed.
- All header text must be in English, i.e. no translations into other languages will be read correctly by the data file.
- The composition columns MUST match what is already entered on the System Definer or the file will not load.

In the table, `code font` indicates something entered into the data file (or it is an example) and any *<text in italic with angle brackets>* is a generic name for an entry.

Column Heading Requirements and Options	*Row Cell Requirements and Options*
Distance This is column A as in Figure 2 Enter the text `Distance`. No abbreviations allowed but it is not case sensitive.	Valid format and entries for each row in this column: • Any numerical input for the distance e.g. `500`, `0.15`, `8.7`, `1.00E-05`, etc.
<Components / Composition> These are columns B to D as in Figure 2	Valid format and entries for each row in these columns: • A number for the composition e.g. `0.15`, `8.7`, `1.00E-05`, etc.

Column Heading Requirements and Options	*Row Cell Requirements and Options*
Each element of the composition is in a separate heading column using the *<element short name>* This is already included in the table header on the **Configuration** window and based on the entries selected on the System Definer. Enter an *<element short name>* into each column, row 1. e.g. in this example, `Mn`, `Cr`, and `Ti` are entered in columns B, C, and D, respectively. Entries are not case sensitive, so alternatives in this example for Mn can be `mn` or `MN`.	The elements in the file must match what is selected on the System Definer. (1) If it is in the file but not selected on the System Definer, then it is not added to the table, and (2) if the opposite is true, that an element is selected on the System Definer but not included in the file, then an empty column is added and manually you must enter the details.

Composition Unit, Length Unit, and Dependent Component

- The defaults can be selected on the **Configuration** window, or can be entered in its own column in the data file. When this is not specified in the data file, the default is taken from the settings defined on the Configuration window. See Figure 3.
- No abbreviations allowed but it is not case sensitive. For example, it is acceptable to enter `composition_unit` or `Composition_Unit`, or `COMPOSITION_UNIT`, etc.
- All header text must be in English, i.e. no translations into other languages will be read correctly by the data file. For example, do not add the accents to the A and O in the word Angstrom, e.g. Ångström cannot be read correctly.
- Do not enter anything in the rows in each of these columns.

In the table, `code font` indicates something entered into the data file (or it is an example) and any *<text in italic with angle brackets>* is a generic name for an entry.

Column Heading Description	*Column Heading Requirements and Options*
The **Dependent component** in the data file is defined with the heading `dependent_component=<element>`	Valid format and entries of the *<dependent_component>* (the text is added after the = sign):

Column Heading Description	*Column Heading Requirements and Options*
In Figure 3, this is in column E. i.e. `dependent_component=fe`. Add the heading to its own column to set the **Dependent component** to **Fe**.	• Any of the components/elements selected already on the System Definer can be entered.
The **Composition unit** in the data file is defined with the heading `composition_unit=<unit>`. In Figure 3, this is in column F. i.e. `composition_unit=mass_pct`. Add the heading to its own column to set the **Composition unit** to **Mass percent**.	Valid format and entries of the *<composition_unit>* (the text is added after the = sign): • `mass_pct` • `mass_frac` • `mole_pct` • `mole_frac`
The **Length unit** for the distance in the data file is defined with the heading `length_unit=<unit>`. In Figure 3, this is in column G. i.e. `length_unit=micrometer`. Add the heading to its own column to set the **Length unit** for the distance to **Micrometer**.	Valid format and entries of the *<length_unit>* (the text is added after the = sign): • `Meter` • `Millimeter` • `Micrometer` • `Nanometer` • `Angstrom` Enter `Angstrom` without the accents on A and O, e.g. Ångström will not be read correctly.

Diffusion Calculator Thermal Profile

The **Thermal Profile** is set up on the **Configuration** window for a . The isothermal or non-isothermal profile is viewed in the **Visualizations** window. Choose **Isothermal** to do a simulation at constant temperature. Choose **Non-isothermal** to enter or import data for a user-defined temperature profile.

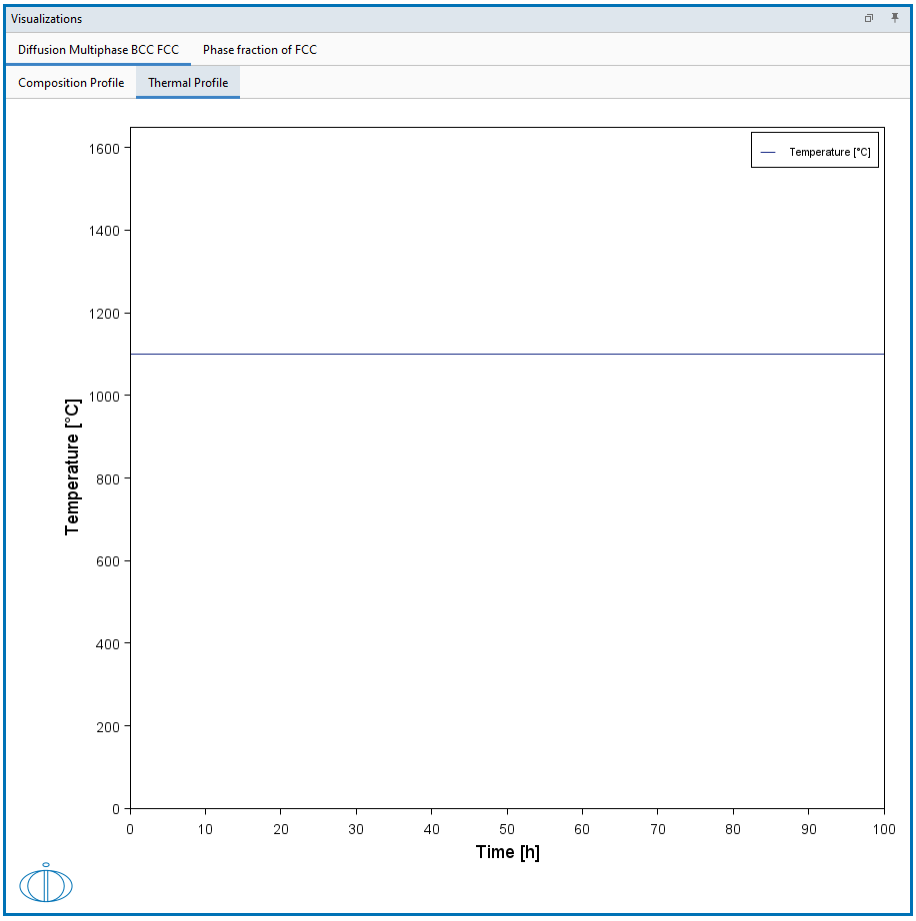
When connected to an **AM Calculator** (see Including Probe Data from an AM Calculator) the **Isothermal** and **Non-isothermal** options are not visible as it is not relevant to that view.

Isothermal Calculations

Many of the Graphical Mode examples for this Add-on Module are isothermal calculations, e.g. D_03: Evolution of an Fe-Cr-Ni Diffusion Couple.

1. On the Diffusion Calculator **Configuration** window, first enter the required settings described in Conditions Tab Settings including the Region Settings, Boundary Conditions, and Composition Profiles.
2. Under **Thermal Profile** click to choose **Isothermal** to do a simulation at constant temperature.
3. Enter a **Temperature** and choose a unit (**Kelvin**, **Celsius**, or **Fahrenheit**.
4. Enter a **Simulation time** and choose a unit: **Seconds**, **Minutes**, **Hours**, or **Days**.

   The **Thermal Profile** is displayed in the **Visualizations** window showing the constant temperature entered.

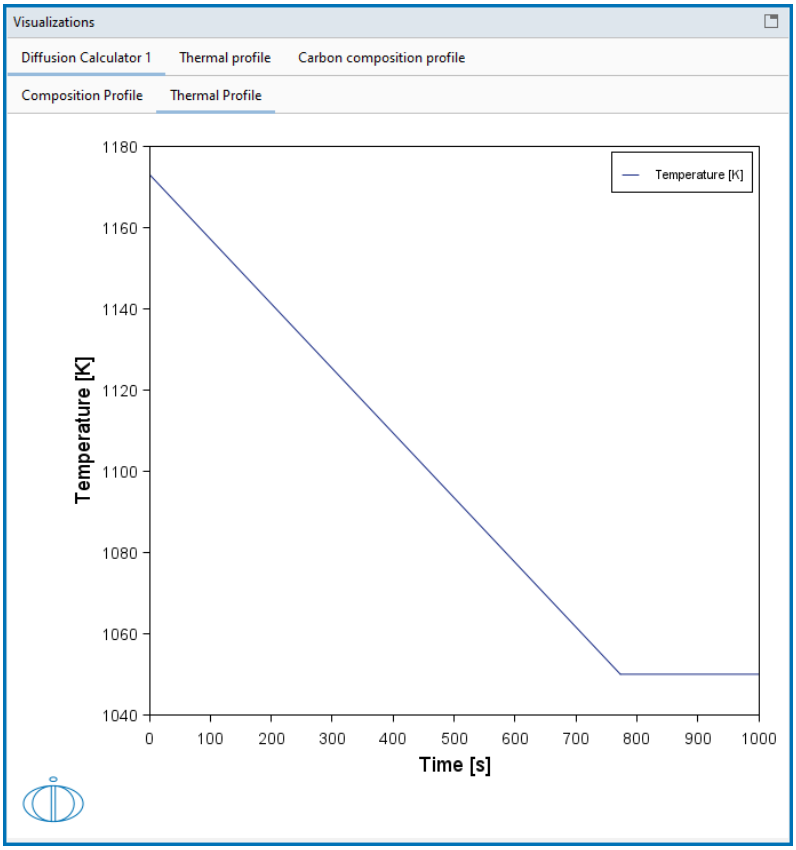


5. For this calculation type this completes the settings you need to enter for the Thermal Profile.

Non-isothermal Calculations

1. On the Diffusion Calculator **Configuration** window, first enter the required settings described in Conditions Tab Settings including the Region Settings, Boundary Conditions, and Composition Profiles.
2. Under **Thermal Profile** click to choose **Non-isothermal** to enter or import data for a user-defined temperature profile.
3. Select a **Temperature unit**: **Kelvin**, **Celsius**, or **Fahrenheit**.
4. Enter an **End time** and choose a unit: **Seconds**, **Minutes**, **Hours**, or **Days**. The *Simulation time* is displayed as text.

5. You can next either directly enter **Time** and **Temperature** coordinates into the table or import the information from a file. A minimum of two points is required.
6. To enter data directly into the table:
    a. Click in each cell under the applicable columns, **Time** and **Temperature** then directly enter the values in the table.
    b. Press `<Enter>` to add rows and use the scroll bars to navigate the table.
7. To import from a file:
    a. Although it is a simple set of data, prepare the data file as in Guidelines for Importing Data Files to Thermal Profiles.
    b. When the data file is ready, to the right of the **Import from file** field, click the file button.
    c. Navigate to a data file such as an MS Excel spreadsheet (with ***.xls** or ***.xlsx** extensions) or a ***.csv** file. You can also use other programs (e.g. Google Sheets) to enter data and export to a CSV format that can be read by the software. Click **Open** to import the data to the **Configuration** window table.
    d. If there are issues with the above import, experiment with choosing the delimiter type that corresponds to the data in the file: **Comma** (`,`), **Colon** (`:`), **Equals sign** (`=`), **Semicolon** (`;`), or **Tab**. Click the **Reload** button. The data is imported to the **Configuration** window table.
8. For this calculation type this completes the settings you need to enter for the **Thermal Profile**, which is displayed in the **Visualizations** window. Make adjustments to the settings as needed and watch it dynamically change in the window.



This is from example D_04: Fe-C Moving Boundary - Austenite to Ferrite.

Including Probe Data from an AM Calculator

When you also have a license for the Additive Manufacturing (AM) Module you can include probe data from the AM Calculator in the set up of the thermal profile.

There is connectivity between the Diffusion Module (DICTRA) or the Precipitation Module (TC-PRISMA) and the Additive Manufacturing (AM) Module when you have full licenses available for all relevant Add-on Modules and databases.

You can add a Diffusion Calculator or Precipitation Calculator as a successor to the AM Calculator and then when probes are included with the AM Calculator this data can be further used with the thermal profile.

Details are in the AM Module documentation. See AM Calculator: Working with Probe Data.

Guidelines for Importing Data Files to Thermal Profiles

The **Thermal Profile** settings are done on the **Configuration** window for a . The profile is then previewed in the **Visualizations** window.

You can import data from a file. There are specific guidelines needed to correctly prepare the data in this file to ensure it imports without errors.

Region Settings, Boundary Conditions, Composition Profiles, and Diffusion Calculator Thermal Profile.

Data File Requirements

For a Thermal Profile you can either directly enter **Time** and **Temperature** coordinates into the table on the **Configuration** window, or import the data from a file. A minimum of two points is required.

Although there are only two columns to define, it is still important to ensure the file is set up correctly. In order for the data to be included in the calculation, the column and row definitions in the file must adhere to certain rules of entry.

General Rules

- No abbreviations are allowed in the header.
- A header is not actually required in this file but in order to know which column is which, it is recommended to include it.
- All header text must be in English, i.e. no translations into other languages will be read correctly by the data file.

Only the columns described here are read / used in the calculation. It is important to enter the information exactly as described. It is recommended that the data file is cleaned up before importing / loading it and performing calculations.

	A	B
1	Time	Temperature
2	0	1173
3	773	1050
4	1000	1075
5	1500	2000

Figure 4: This is an example of data entered into an Excel spreadsheet (which is then converted to csv format). Columns A and B show the data entered to create the Thermal Profile.

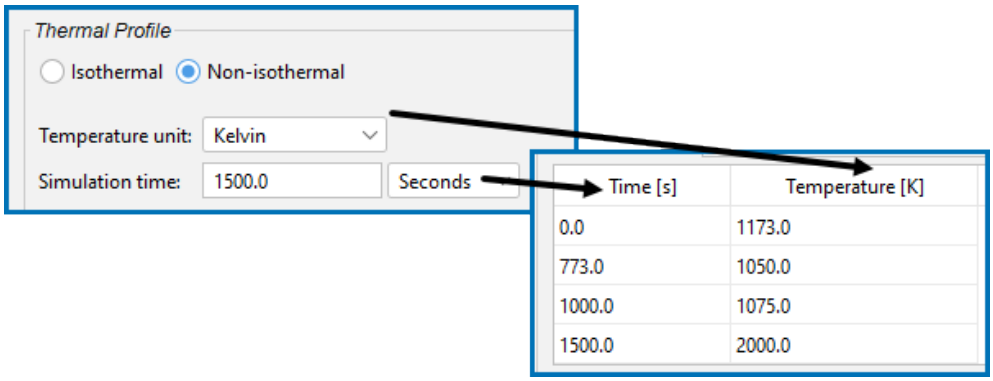


Figure 5: The units shown on the Configuration window for the Time and Temperature correspond to settings that can ONLY be selected on the Configuration window. The data file does not contain any information about the units.

Data File Column and Heading Requirements

Column Heading Requirements and Options	*Row Cell Requirements and Options*
Time This is column A as in Figure 4 Enter the text `Time`. No abbreviations allowed but it is not case sensitive. It is also not required but recommended to include so you know which column of data it applies to.	Valid format and entries for each row in this column: • Any numerical input for the time that corresponds to the unit selected on the Configuration window e.g. `0.0`, `773`, `1000`, `1500`, are times in seconds, which is the unit chosen in the example shown in Figure 5.
Temperature This is column B as in Figure 4 Enter the text `Temperature`. No abbreviations allowed but it is not case sensitive. It is also not required but recommended to include so you know	Valid format and entries for each row in these columns: • Any numerical input for the temperature that corresponds to the unit selected on the Configuration window e.g. `1173`, `1050`, `1075`, are temperatures in Kelvin, which is the unit chosen in the example shown

Column Heading Requirements and Options	*Row Cell Requirements and Options*
which column of data it applies to.	in Figure 5

Pause, Resume, and Cancel Diffusion Calculations

Diffusion calculations are often complex simulations that take some time to complete. Sometimes you may want or need to pause or resume a calculation, or make adjustments to your compositions and start again.

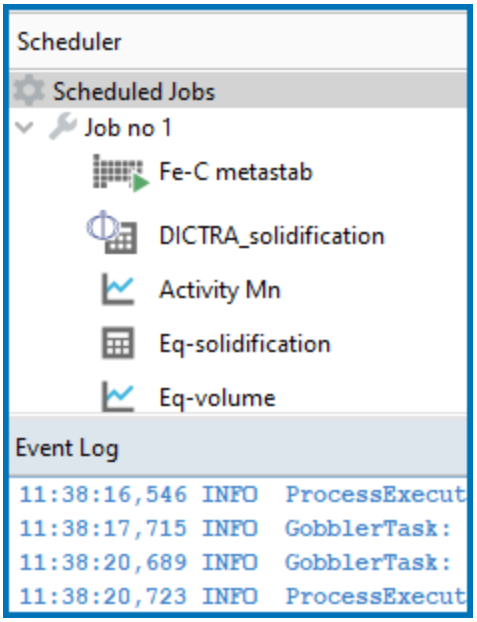
Graphical Mode

In Graphical Mode, you pause and resume when you are on the Diffusion Calculator **Configuration** window. When pausing a Diffusion Calculator calculation, you can make changes to the **Simulation time**, **Left Boundary Condition**, and **Right Boundary Condition**. This is useful, for example, when simulating carburization, where it is common to first have a step with high carbon activity in the furnace for the actual carburization, and then lower it and allow the carbon in the specimen to diffuse without further increased carbon content.

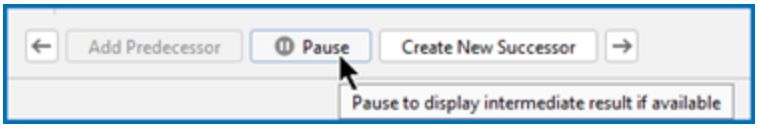
This is also available for the Precipitation Calculator (but not any other calculators). See Pause, Resume, and Cancel Precipitation Calculations.

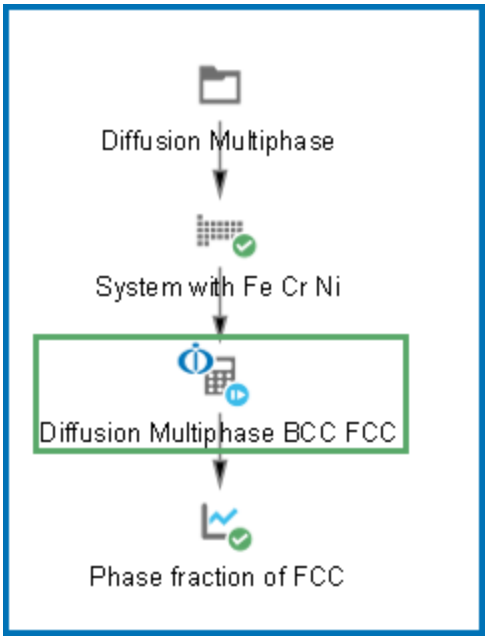
Pausing and Resuming a Job

1. Run the job (i.e. click **Perform Tree**). In the **Scheduler** you can see the job listed and in the **Event Log** you can follow the progress of the calculation.

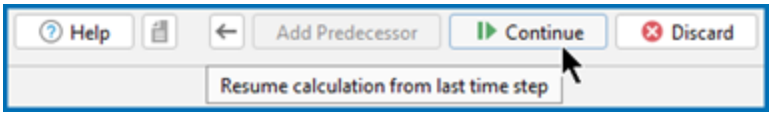


2. In the **Project** window, click the **Diffusion Calculator** node.
3. In the **Configuration** window at the bottom, click **Pause**. Observe that the **Diffusion Calculator** in the **Project** window has a pause indicator. If there are intermediate results available these are listed in the **Event Log**.



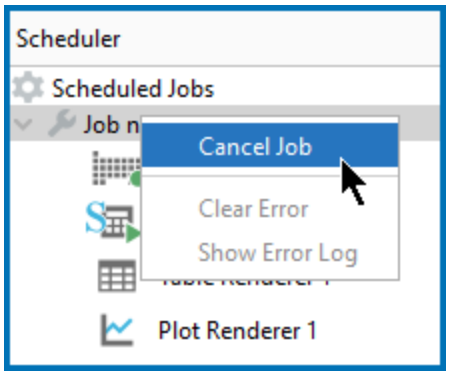


4. As required, make changes to the settings: *Left Boundary Condition*, *Right Boundary Condition*, *Temperature*, and/or *Simulation time*. The rest of the **Configuration** window settings are grayed out and no other editing can be done while paused.
5. When ready, click **Continue** to resume your calculations from the last time step or click **Discard** to discard the calculation (then click **Yes** or **No** on the window that opens).



Cancelling a Job

In the **Scheduler** window, right-click the job you want to cancel and select **Cancel Job**.



Console Mode

In response to a command or a lengthy calculation, Thermo-Calc may display a lot of text in the Console window. Use these keyboard shortcuts to pause, resume, or stop a process.

- To pause the text on printing press <Ctrl+S>.
- To resume the printing on screen, press <Ctrl+Q>.
- When Thermo-Calc is performing a stepping or mapping operation, the results are continuously printed in the Console window. To stop the calculation of the current region of the mapping and stop the output, press <Ctrl-A> (Windows) or <Ctrl-C> (Linux).

Diffusion Module (DICTRA) Graphical Mode Examples Collection

These are the Graphical Mode examples. There are separate Console Mode examples also available.

Examples using up to three elements are available to all users. The other examples require a Diffusion Module (DICTRA) license to calculate and plot results.

The Role of Diffusion in Materials: A Tutorial is available for download on our website. It is intended for engineers interested in using the Diffusion Module (DICTRA), as well as students learning about the role of diffusion in materials. It is designed to be useful at many levels, from undergraduate studies to someone with a PhD and experience in a related field.

These examples use the **Diffusion Calculator**. All examples use demonstration database packages included with your installation no matter what licenses you have.

D_01: Homogenization of a Binary Fe-Ni Alloy

The single phase example simulates the diffusion of Fe and Ni at a temperature of 1400 K in a planar domain. At this temperature the material is fully austenitic, i.e. the only phase present is the so-called fcc (face centered cubic) phase. Initially, there is a linear variation in Ni going from 10 mass-% on the left-hand side to 50 mass-% on the right-hand side.

Project File Information

- Folder: **Diffusion Module - DICTRA**
- File name: `D_01_Diffusion_Single_Phase.tcu`

This example is part of the *Diffusion Module (DICTRA) Quick Start Guide* available to all users. A version of the example is also available for Console Mode.

Visualizations

This example is included as a Diffusion Module (DICTRA) tutorial on our website and as part of the playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Composition Profiles** and **Thermal Profile**: When setting up a calculator on a **Configuration** window you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.

- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

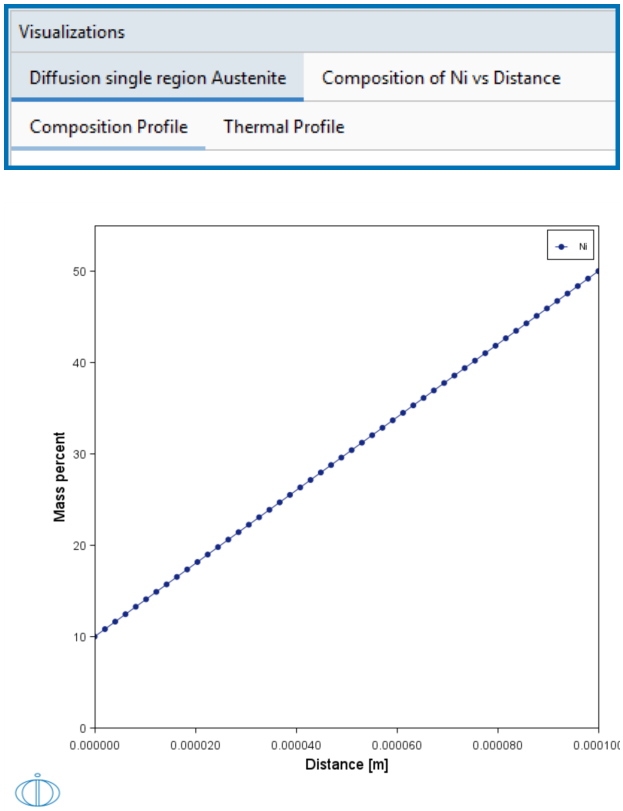

Figure 1: During set up of the calculation, you can preview the Composition Profile (shown) or Thermal Profile. Click the tab(s) in the Visualizations window to switch between these previews and adjust settings on the Diffusion Calculator Configuration window. For an Isothermal Thermal Profile this shows the constant temperature as entered.

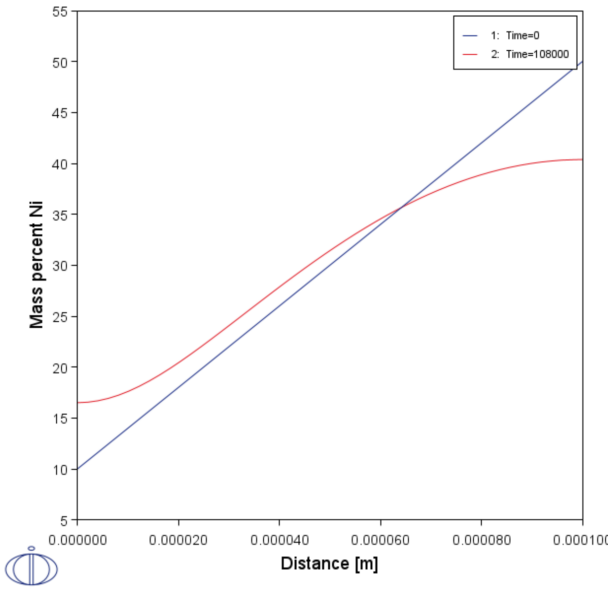

Figure 2: After performing the calculation, you can view the result on the Composition of Ni vs Distance tab, which shows the initial and final Ni profile. In this example, the Plot Renderer is renamed and this matches the tab name in the Visualizations window.

D_02: Ferrite(bcc)/Austenite(fcc) Transformation in a Binary Fe-C Alloy

The moving phase boundary example simulates the growth of ferrite (bcc) into austenite (fcc). The austenite is assumed to be initially homogeneous with the composition Fe-0.15 mass-% C. The transformation temperature is 1050 K. The initial thickness of the austenite is 2 mm and an initially very thin ferrite (1 nm) is also present at the start of the simulation.

Project File Information

- Folder: **Diffusion Module - DICTRA**
- File name: `D_02_Diffusion_Moving_Boundary.tcu`

This example is part of the *Diffusion Module (DICTRA) Quick Start Guide* available to all users. A version of the example is also available for Console Mode.

Visualizations

This example is included as a Diffusion Module (DICTRA) tutorial on our website and as part of the playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Composition Profiles** and **Thermal Profile**: When setting up a calculator on a **Configuration** window you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.
- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

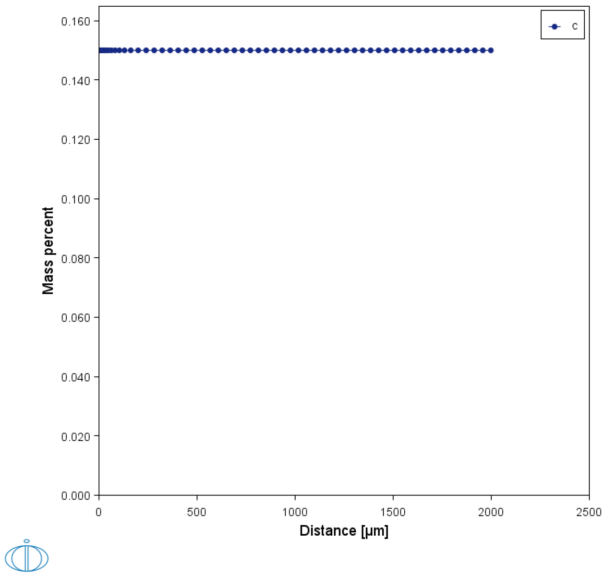

Figure 3: During set up of the calculation, you can preview the Composition Profile (shown) or Thermal Profile. Click the tab(s) in the Visualizations window to switch between these previews and adjust settings on the Diffusion Calculator Configuration window. For an Isothermal Thermal Profile this shows the constant temperature as entered.

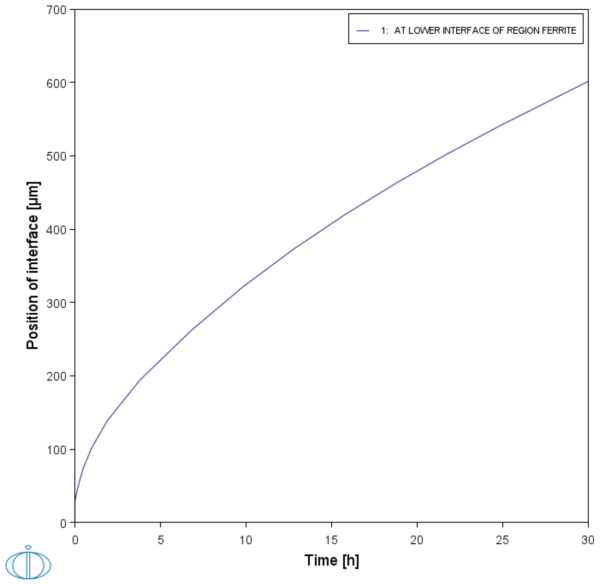

Figure 4: After performing the calculation, you can view the result on the Position of interface vs time tab. In this example, the Plot Renderer is renamed and this matches the tab name in the Visualizations window.

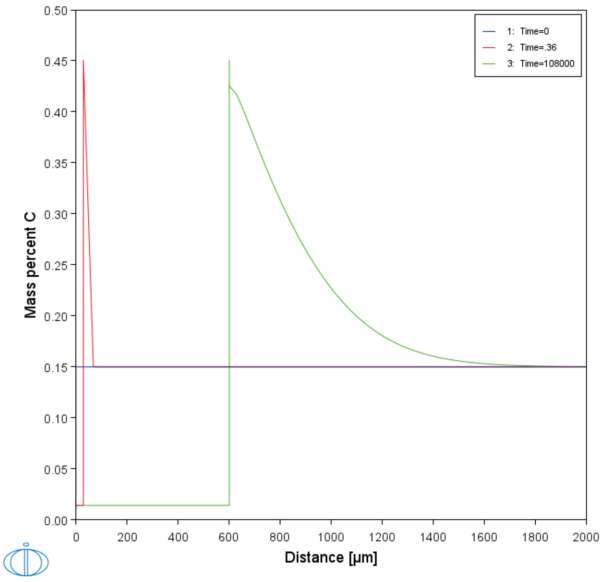

Figure 5: After performing the calculation, you can view the result on the Composition profile C tab. In this example, the Plot Renderer is renamed and this matches the tab name in the Visualizations window.

D_03: Evolution of an Fe-Cr-Ni Diffusion Couple

The multiphase example simulates the evolution of an Fe-Cr-Ni diffusion couple during a 100 hour heat treatment at 1100° C (1373.15 K). Both end members of the diffusion couple are duplex ferrite plus austenite, but the majority phase is ferrite on the left-hand side and austenite on the right.

With this type of simulation it is assumed that the material is fully equilibrated at each grid point, i.e. the local phase fractions, phase compositions and so forth are obtained from an equilibrium calculation with the local overall composition as a condition.

More details about the homogenization model for multiphase simulations can be found in Larsson and Engström [2006Lar] and Larsson and Höglund [2009Lar]. Experimental data is from Engström [1995Eng].

D_04: Fe-C Moving Boundary - Austenite to Ferrite

This example simulates the austenite to ferrite transformation in a Fe-0.01 mass% C steel during continuous cooling. The simulation starts at a temperature where only austenite is stable, ferrite nucleates and grows into the austenite during cooling in the two phase region. Plots of thermal and carbon composition profiles are generated.

D_05: γ/α/γ Diffusion Couple of Fe-Ni-Cr alloys

This example demonstrates the evolution of a ternary Fe-Cr-Ni diffusion couple. A thin slice of ferrite (α phase) (38%Cr,0%Ni) is clamped between two thicker slices of austenite (γ phase) (27%Cr, 20%Ni). The assembly is subsequently heat treated at 1373 K.

This set up corresponds to diffusion couple in Kajihara et al. [1993aKaj] and Kajihara and Kikuchi [1993bKaj].

D_06: Diffusion Through a Tube Wall

This is a simple example of diffusion through a tube wall. The tube material is an Fe-0.06Mn-0.05C alloy. Two plots comparing distance to the U-fraction of manganese and composition of carbon are generated to visualize the austenite region. A *cylindrical* geometry is used with *mixed zero flux and activity* boundary conditions.

On the inside wall a carbon activity of 0.9 is maintained whereas on the outside the carbon activity is very low. This example demonstrates the use of boundary conditions, advanced plotting and tables.

Project File Information

D_07: Multiphase Carburization of an Alloy

This example is based on Engström et al. [1994Eng] and is about carburization of a Ni-25Cr-0.0001C alloy. In this case the M7C3 and M3C2 carbides are entered as spheroid phases in an FCC_A1 matrix. It is similar to Graphical Mode example D_06 except the default simulation condition is automatically set to use the homogenization model.

The isothermal calculation is run for 1000 hours at a temperature of 1123 K using the mixed zero flux and activity left boundary condition. Results are plotted using two Plot Renderers and a Table Renderer.

D_08: Microsegregation During Solidification

This application example, which has some step-by-step instructions available on our website, shows how Thermo-Calc together with the Diffusion Module (DICTRA) can be used to investigate and predict microsegregation (solute redistribution) during solidification.

The example is based on a real case where the elemental distribution of a continuously cast steel was measured revealing the concentration of the elements Si, Mn, and P as sketched in Figure 1. The profile results from the well-known segregation across secondary dendrite arms. The interesting point is that the elements Si and Mn show the expected positive segregation (higher concentrations) in the interdendritic regions. The peak of the P content, on the other hand, is shifted compared to Si and Mn, and, in fact, shows negative segregation in the interdendritic region. This is unexpected and counterintuitive.

The calculations are based on ones performed in the frame of a research project funded by the European Union called VESPISM – Virtual Experiments to Solve Problems in Metallurgy – conducted from 2001 to 2004. Read about the research.

Project File and License Information

- Folder: **Diffusion Module - DICTRA**
- File name: `D_08_Diffusion_Microsegregation_During_Solidification.tcu`

Running this calculation requires licenses for the Add-on Diffusion Module (DICTRA) plus the steels thermodynamic database (TCFE) and mobility database (MOBFE). For best results, TCFE14 and MOBFE8.1 and newer (as of 2025a) are recommended.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Composition Profiles** and **Thermal Profile**: When setting up a calculator on a **Configuration** window you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.

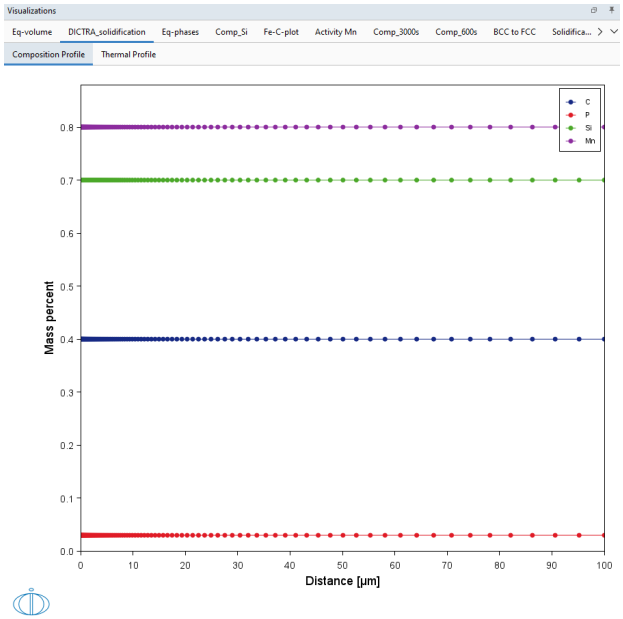

Figure 28: During set up of the calculation, you can preview the Composition Profile. Click the tab in the Visualizations window to switch between these previews and adjust settings on the Diffusion Calculator Configuration window.

D_09: Ni Post Weld Heat Treatment

In this example, a Ni-based alloy (Ni-Al-Co-Cr-Mo-Ti) post weld heat treatment analysis is completed. It shows how to import an initial composition profile from a file into the Diffusion Calculator. Then the calculation is run and plotted to show the composition of Al vs distance compared to experimental data from [2017She]. Such simulations can be used to design the heat treatment such that the desired homogenization of the weld is achieved. The initial composition profile needs to be determined by suitable experimental techniques, for example microprobe.

This example highlights the dual purpose of the **Visualizations** window where you can enter or import *Composition profiles* via the Diffusion Calculator **Configuration** window as well as being able to view and analyze results via the Plot Renderer after a calculation runs.

Project File Information

- Folder: **Diffusion Module - DICTRA**
- File name: `D_09 Ni_Post_Weld_Heat_Treatment_From_File.tcu`

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

On the Diffusion Calculator, when defining its setup, the **Composition profiles** are imported using the **Table input** option. A prepared file, in this case a csv file, is set up with the correct data columns, which then are included on the **Configuration** window. After import the **Composition Profiles** are further able to be seen via the **Visualizations** window, at which point adjustments can be made as needed. In this isothermal example, you can also see that the constant temperature of the **Thermal Profile** is previewed.

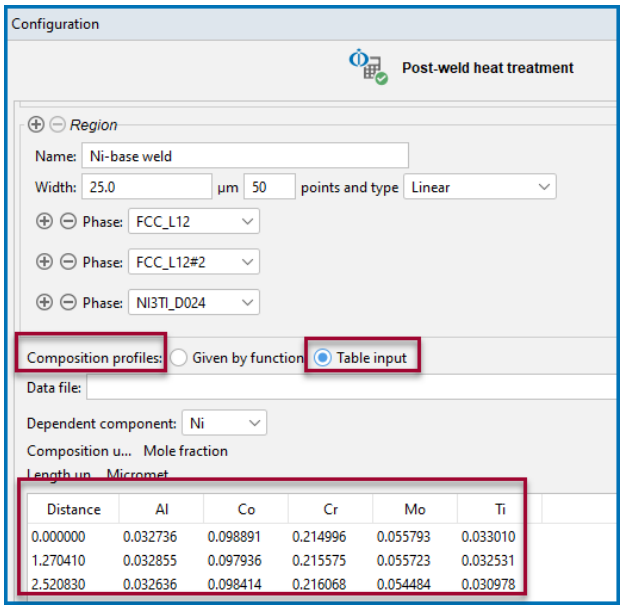

Figure 29: The Diffusion Calculator Configuration window showing the composition profile data, which is then compiled and displayed on the Visualizations window.

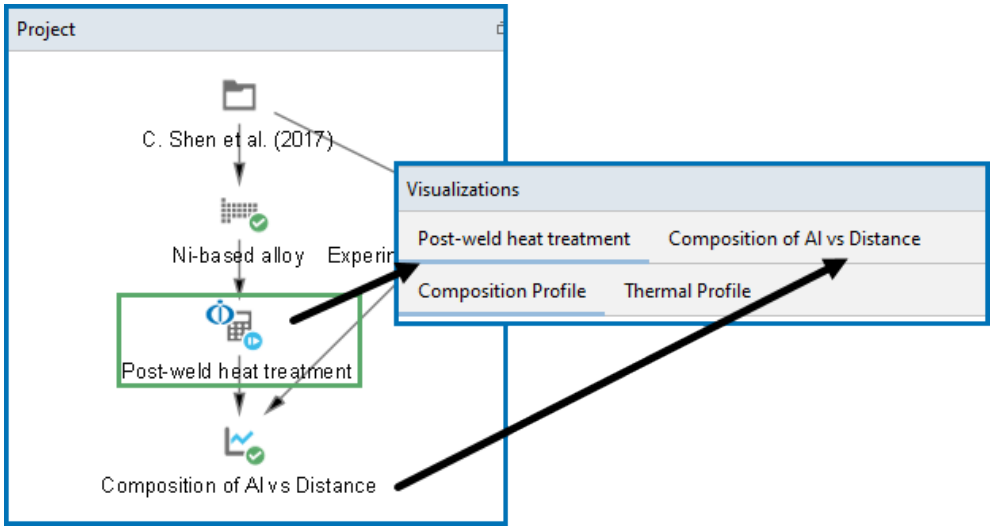

Figure 30: The Visualizations window displays details from both the Diffusion Calculator node (renamed to Post-weld heat treatment) via the Composition Profile and Thermal Profile tabs as well as the Plot Renderer node (renamed to Composition of Al vs Distance).

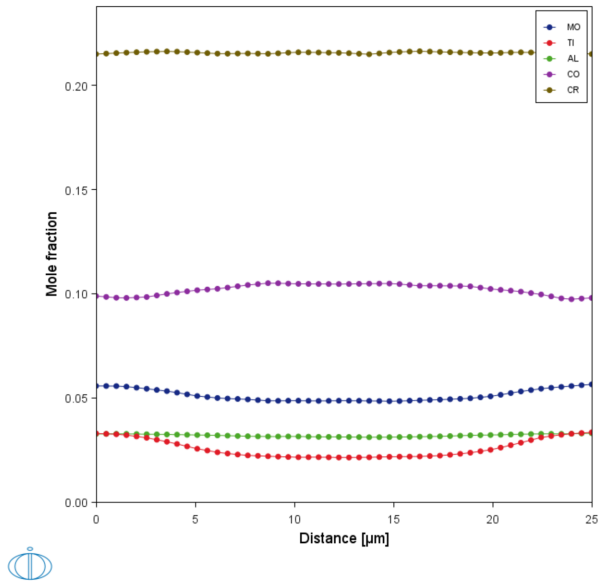

Figure 31: The Composition Profiles as shown in the Visualizations window after data is prepared and then imported into the Diffusion Calculator Configuration window.

An **Experimental File Reader** node is used to supply experimental data from [2017She] to the Plot Renderer to validate the composition of, for example, Al vs distance on the Plot Renderer. The plot shows the content of Al along the cross-section of the weld, both before and after the post weld heat treatment. There is good agreement between the diffusion simulation and the data measured in the literature.

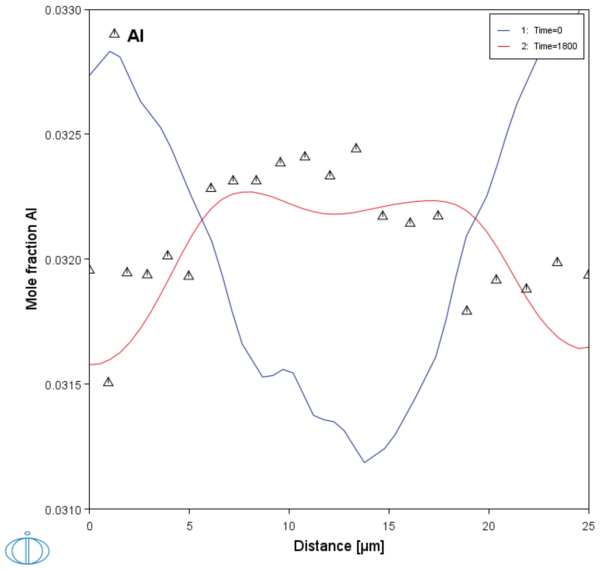

Figure 32: Plot results showing the mole fraction of Al before and after the heat treatment as a function of distance for a Ni-based alloy compared to experimental data [2017She].

Other plots can be added to investigate further details of the simulations, such as phase fractions or compositions.

D_10: Iron (Fe) Homogenization in Scheil

This example models the homogenization of a cast Ni-Cr steel and compares predictions with the experimental data collated by Fuchs and Roósz [1975Fuc]. The conditions studied have a dendritic half spacing of 200 µm and are heat treated to temperatures of 1120 °C and 1235 °C. The data has been un-normalized to allow comparison using wt.% composition values.

The composition of the steel is 0.4C, 0.65Mn, 0.35Si, 0.015S, 0.01P, 1.9Ni, 0.95Cr, and 0.3 Mo (wt.%). The diffusion of Cr and Ni are modeled using a simplified chemistry of 0.4C, 0.65Mn, 1.9Ni, and 0.95Cr.

Project File and License Information

- Folder: **Diffusion Module - DICTRA**
- File name: `D_10_Fe _Homogenization_from_Scheil.tcu`

The Diffusion Module (DICTRA) Console Mode example `exa7` is available to show the use of Scheil segregation profiles in Console Mode.

The FEDEMO thermodynamic and MFEDEMO mobility databases are used with this example. Users with a Diffusion Module (DICTRA) license can run the example. Other users can read the documentation as a DEMO license only allows the use of up to three components.

Setting up a Diffusion Simulation in Graphical Mode **2144**

About this Quick Start Guide

The following introduces you to the basic concepts, steps and theory to start using the Diffusion Module (DICTRA). An understanding of this information is necessary to ensure accurate calculations.

More details about the use of DICTRA can be found in [2002And] and [2000Bor].

If you are not familiar with Graphical Mode, it is recommended you review the documentation and additional resources available on our website.

The Role of Diffusion in Materials: A Tutorial is available for download on our website. It is intended for engineers interested in using the Diffusion Module (DICTRA), as well as students learning about the role of diffusion in materials. It is designed to be useful at many levels, from undergraduate studies to someone with a PhD and experience in a related field.

Diffusion Module Terminology in Graphical Mode

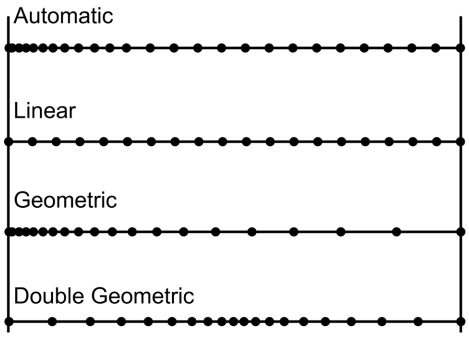
The following definitions are useful to help you understand the examples in this guide. For more detailed information search or browse the online help (press F1 or from the main menu select **Help → Online Help**). These terms are specific to working in Graphical Mode. The overall simulation in Console Mode is comparable but there are some differences in terminology and functionality.

Region

In Graphical Mode, a system consists of one *cell* with one or multiple *regions* in which the diffusion problem is to be solved.

Grid Types

These grid types are used in diffusion simulations: automatic, linear, geometric, and double geometric. When you are setting up the simulation, in either Console Mode or Graphical Mode, a region must have a grid defined.



Phases

Each region must contain at least one *phase*. The so-called *homogenization model* is used if multiple phases are added inside a region, then the average properties of the local phase mixture is used. Phase(s) can also be added to interphases of region(s) and then only participate in the simulation if the driving force for precipitation of the phase exceeds a predefined value. A new region is then created where the name of the region is set to the name of the phase but with `R_` added as a prefix.

Composition

These types of composition variables are used in the configuration of the Diffusion Calculator: *mass (weight) fraction*, *mass (weight) percent*, *mole fraction*, or *mole percent*.

The *u-fractions* are used in the diffusion equations. The u-fraction of a component *k* is defined as

$$\mu_k = \frac{x_k}{\sum_{j \in S} x_j}$$

The summation is only performed over the substitutional elements. The choice of the volume fixed frame of reference in the calculations make it convenient to use a composition variable which is related to the volume. The definition of the u-fraction is based upon the assumption that a species may or may not contribute to the volume of a phase. An interstitial element is assumed to not contribute to the volume. Substitutional elements are assumed to contribute equally to volume. Weight fraction, mole fraction or u-fraction can be used when plotting the results from a simulation.

Geometry and Coordinates

The Diffusion Module (DICTRA) can only handle diffusion problems where compositions vary along one spatial coordinate. The geometry of your system can be *planar*, *cylindrical*, or *spherical*.

The *planar* geometry corresponds to an infinitely wide plate of a certain thickness. If the system has a planar geometry then the lower boundary (the zero coordinate) is at the left side of the system. The upper boundary (the coordinate with the highest value) is at the right side of the system.

Boundary Conditions

Boundary conditions are conditions that define how matter behaves at the boundaries of your system. By default, matter is not allowed to cross the system boundaries.

You can change the setting for both the lower boundary (left side/centre) and the upper boundary (right side/surface) of the system.

Setting up a Diffusion Simulation in Graphical Mode

When you are using the Graphical Mode version of the Diffusion Module (DICTRA), the steps to set up a simulation are a combination of adding *Activity* nodes (the System Definer, Diffusion Calculator, and Plot Renderer) and then defining the applicable settings for each of these nodes in a Configuration window.

The following is a general overview of the steps to set up the simulation.

1. Use the **Diffusion** template to add the System Definer, Diffusion Calculator, and Plot Renderer activity nodes.
2. On the **System Definer**, you select the thermodynamic and kinetic databases, add elements and phases, and generally define the system.
3. On the **Diffusion Calculator**, you set the geometry (by default the geometry is planar), add region(s) and enter grid(s) and phase(s) in the region(s). You then enter composition (s) of phase(s).
4. On the **Plot Renderer** or **Table Renderer**, you choose how to visualize your diagrams, and then run the simulation, i.e. you **Perform** the sequence of nodes you have defined in the tree to produce the output simulation.

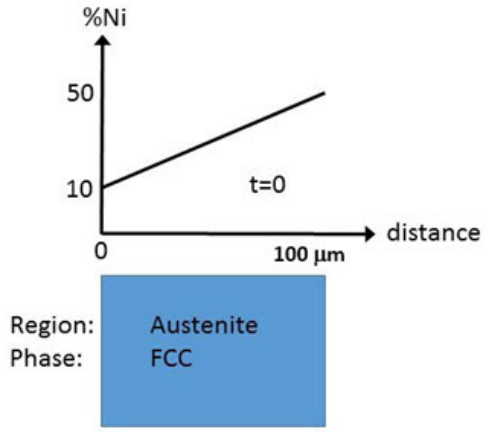
About the Single Phase Simulation

In a 100 µm wide planar domain, the single phase example simulates the diffusion of Fe and Ni at a temperature of 1400 K. At this temperature the material is fully austenitic, i.e. the only phase present is the so-called fcc (face centered cubic) phase (in Thermo-Calc the name of this phase is FCC_A1). Initially, there is a linear variation in Ni going from 10 mass-% on the left-hand side to 50 mass-% on the right-hand side.

The simulation time is slightly different between the modes. For Console Mode it is 10^5 s and for Graphical Mode it is 30 hours.

By default the boundaries are closed. The plot generated shows the initial and final Ni profile.



Schematic view of the initial state of Single Phase Diffusion example. The width of the domain is 100 µm and there is a linear gradient in composition going from 10 to 50 mass-% Ni. There is a single region named Austenite that consists of an fcc phase.

Theory for the Single Phase Simulation

The flux of a component k in the z-direction in an isobarothermal system is in general given by

$$J_k = \sum_{i=1}^{n} L_{ki} \frac{\partial \mu_i}{\partial z}$$

where L_{ki} is a matrix of kinetic coefficients and μ_i is the chemical potential of component i. The correlation effects, i.e. the coupling of the flux of k component to the chemical potential gradients of the other elements, are normally neglected

$$(L_{ki} = 0, k \neq i)$$

and thus

$$J_k = L_{kk} \frac{\partial \mu_k}{\partial z} = M_k c_k \frac{\partial \mu_k}{\partial z}$$

where c_k is the concentration and M_k the mobility of component k.

The equation for the flux is combined with the equation of continuity, which takes the following form in a planar domain,

$$\frac{\partial c_k}{\partial t} = \frac{\partial}{\partial z}(-J_k)$$

which relates the local evolution of the concentration of k to the divergence of the flux.

The expression for the flux can be expanded in terms of concentration gradients

$$J_k = -\sum_{i=1}^{n} M_k c_k \frac{\partial \mu_k}{\partial c_j} \frac{\partial c_j}{\partial z} = -\sum_{i=1}^{n} D_{kj} \frac{\partial c_j}{\partial z}$$

where the diffusion coefficient of component k with respect to the concentration gradient of component j has been introduced.

$$D_{kj} = M_k c_k \frac{\partial \mu_k}{\partial c_j}$$

The flux expressions above are given in the so-called lattice-fixed frame of reference. In practical calculations it is more common to use a volume-fixed frame of reference. For a discussion of these concepts, see Andersson and Ågren [1992And].

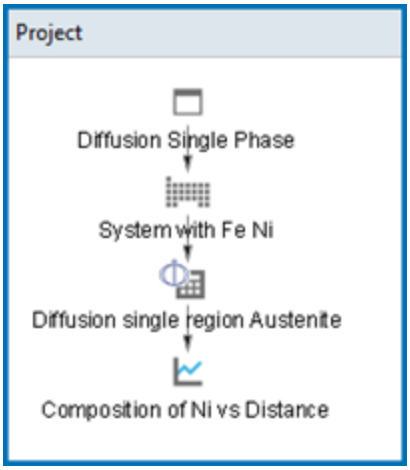
Setting Up the Single Phase Simulation

For the single phase example, you can open the example project file included with your installation to first see how it is set up.

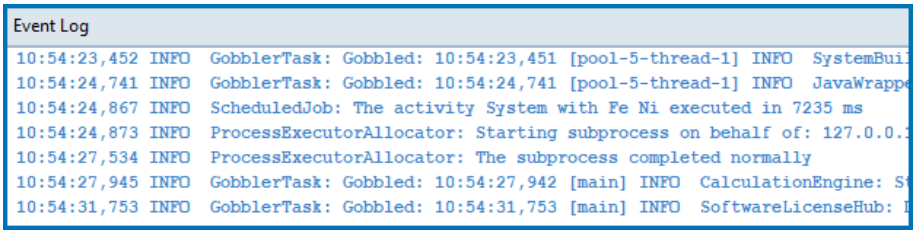
Opening and Running the Single Phase Example

1. Open Thermo-Calc.
2. There are different ways to access the examples.
   - From the main menu, select **File →** or **Help → Examples Files**. The Graphical Mode folder opens by default.
   - Click the **My Project** node and on the **Configuration** window under **Getting Started**, click **Example Files**.
3. Click to open the **Diffusion Module - DICTRA** folder and locate the **D_01_Diffusion_Single_Phase.tcu** file. Double-click to open it.
4. The project opens in Thermo-Calc and adds this tree structure:



5. Click the top Project node (renamed to *Diffusion Single Phase*). At the bottom of the **Configuration** window click **Perform Tree**. You can also right-click the node and select **Perform Now**.

   The **Event Log** shows the progress of the calculations:

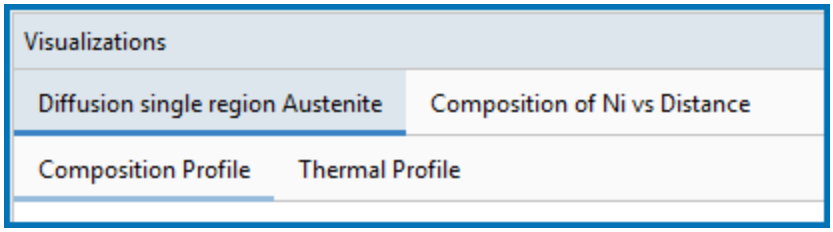


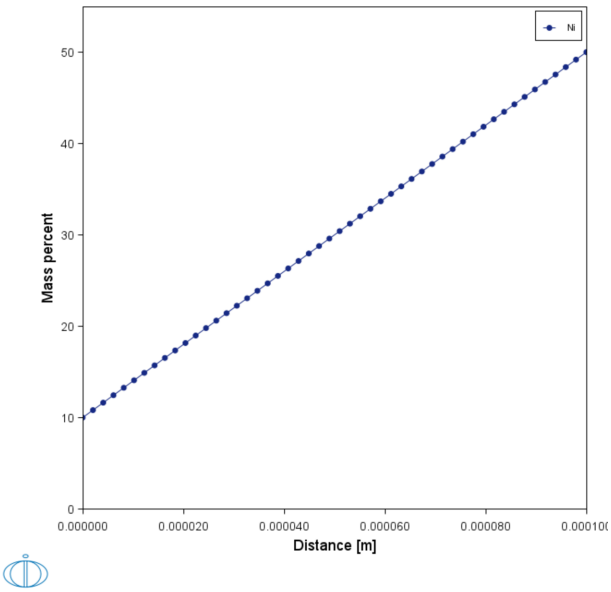
When completed, the results are plotted in the **Visualizations** window as shown below.

Visualizations

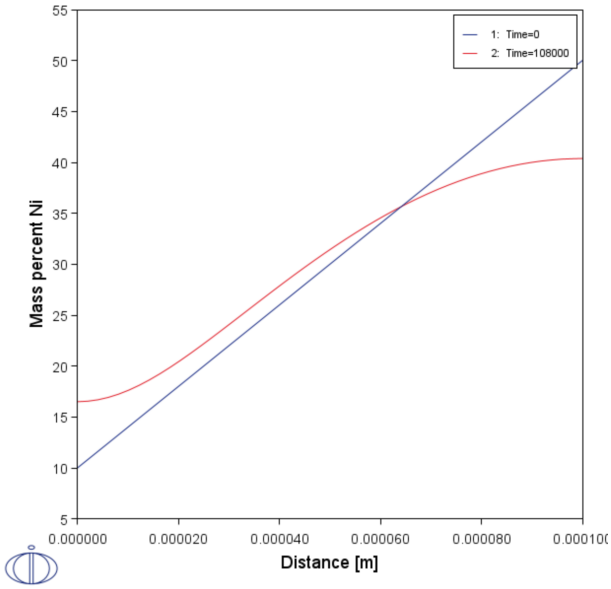
There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Composition Profiles** and **Thermal Profile**: When setting up a calculator on a **Configuration** window you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.
- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.





During set up of the calculation, you can preview the Composition Profile (shown) or Thermal Profile. Click the tab(s) in the Visualizations window to switch between these previews and adjust settings on the Diffusion Calculator Configuration window. For an Isothermal Thermal Profile this shows the constant temperature as entered.



After performing the calculation, you can view the final Plot Renderer result on the Composition of Ni vs Distance tab, which shows the initial and final Ni profile. In this example, the Plot Renderer is renamed and this matches the tab name in the Visualizations window.

For the rest of the exercise, you will learn how to build this example step-by-step.

System Definer Settings

The following describes how to set up the *D_01_Diffusion_Single_Phase.tcu* example from the beginning.

> To learn more about the activity nodes and tree structure see About the Activity Nodes in the help or *Thermo-Calc Software Documentation Set* PDF.

Adding a System Definer Node

1. Open Thermo-Calc.
2. In the **Project** window, right-click **My Project** and select **Create New Activity → System Definer**.
3. In the **System Definer Configuration** window, you select the thermodynamic and kinetic databases to use and select the elements.

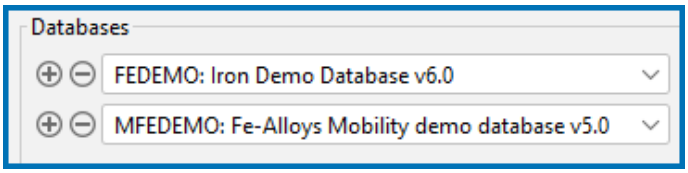
Tip: The Diffusion Template

For this first example the activity nodes are added one at a time. A faster way to add all the nodes you need is to use the **Diffusion** template (click **My Project** node then under **Non-Equilibrium** click **Diffusion**).

Choosing the Databases

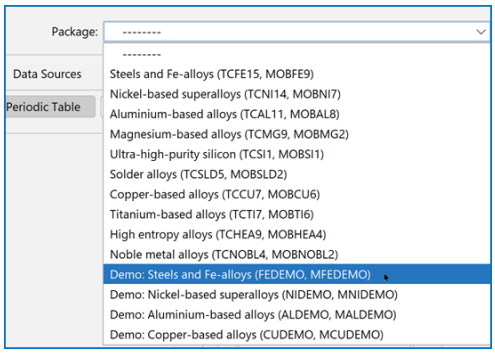
There are databases for different purposes and material types. This example uses two demonstration databases: **FEDEMO** (the thermodynamic steels/Fe-alloys database) and **MFEDEMO** (the kinetic/mobility steels/Fe-alloys database).

1. In the System Definer **Configuration** window click the **Databases** list and select the **FEDEMO** database.
2. Click the **Add a database** button.
3. Select the **MFEDEMO** database.



Tip: Database Packages

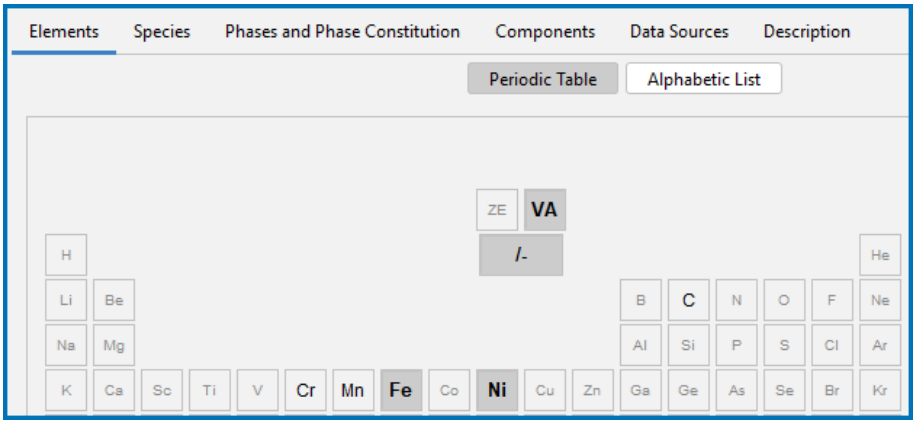
For this first example the databases are added one at a time. A faster way to add both the databases is to add a predefined database **Package**.



Choosing the Elements

On the **Elements** tab, and based on the databases selected, you can select and review elements using a **Periodic Table** or **Alphabetic List** format. The demonstration databases have only a small number of elements to choose from.

1. In the **Periodic Table**, click **Fe**.
2. Click **Ni**.



When using the System Definer with the Diffusion Calculator, you can keep all phases selected on the **Phases and Phase Constitution** tab.

Diffusion Calculator Settings

After you have completed the settings for the System Definer you start defining the diffusion parameters on the Diffusion Calculator.

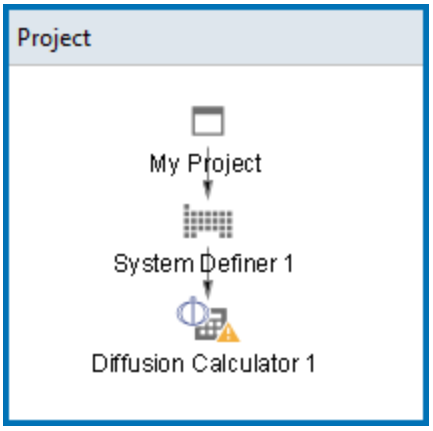
In any simulation at least one *region* must be defined. This is a named container that designates a certain part of the domain. In this case it is the whole domain. The name of a region is arbitrary and specified by you.

> The use of regions becomes clearer in the context of moving phase boundary simulations.

A region must contain a numerical *grid* specified by width and type. In this example, a 10^{-4} m (1e-4 m) wide, linear (i.e. equidistant) grid is used with 50 grid points.

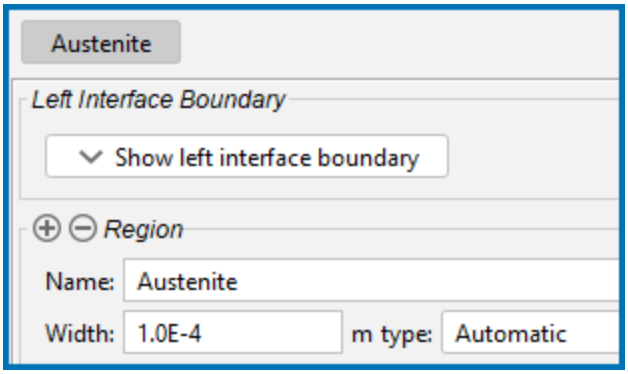
Defining the Region and Composition Profiles

1. In the **Project** window, right click the **System Definer** node and select **Create New Successor → Diffusion Calculator**. A Diffusion Calculator node is added to the tree structure.



> If you used the **Diffusion** template, then this activity node is already there. Click the **Diffusion Calculator** node to access the **Configuration** window settings.

2. You are now going to add the settings to the Configuration window on the **Conditions** tab. Keep the defaults for *Composition unit* (**Mass percent**) and *Length unit* (**Meter**). A **Planar***Geometry* is used for all the examples.
3. In the *Region***Name** field, enter `Austenite`. This name is automatically updated on the tab.

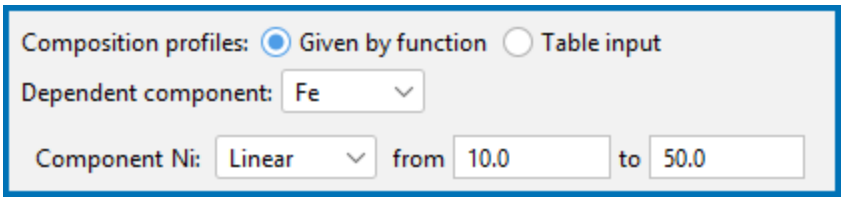


4. In the **Width** field replace the default with `1e-4`. Keep the defaults for number of points (`50`) and type of grid (`Automatic`).
5. From the **Phase** list, select **FCC_A1**.

   In the **Visualizations** window, the **Composition Profile** tab displays a preview. The initial composition profile must be specified for all regions. Since there are only two elements, Fe and Ni, the initial composition profile must only be given for one of them.

6. Next to **Composition profiles** the default selected is **Given by function**. Choose **Fe** as the **Dependent component**.

   There are many ways to specify the composition profile, e.g. an arbitrary position dependent function. In this example, the default *Linear* type is used. The initial profile for Ni is a **Linear** variation. In the **from** field enter `10` and in the **to** field enter `50`. These settings mean that the profile goes from 10 (mass-%) on the lower/left hand side of the system to 50 (mass-%) on the upper/right hand side of the system.

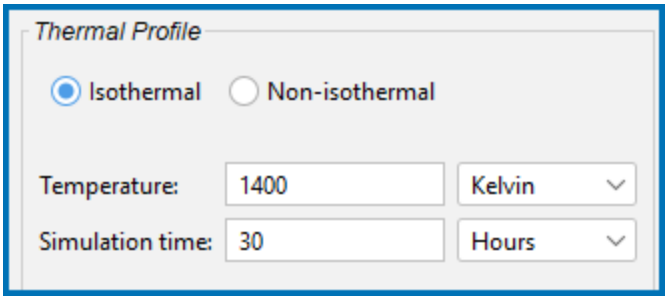


Watch as the **Composition Profile** changes on the **Visualizations** window to match these values.

Defining the Thermal Profile

The default **Isothermal** profile is used for this example. A constant temperature of 1400 K is used during the simulation, which is run for 30 hours. Enter these values in the fields:

1. In the **Temperature** field, enter `1400`. Keep **Kelvin** as the default unit.
2. In the **Simulation time** field, enter `30`. Select **Hours** from the list.



Watch as the **Thermal Profile** tab on the **Visualizations** window updates to match these values.

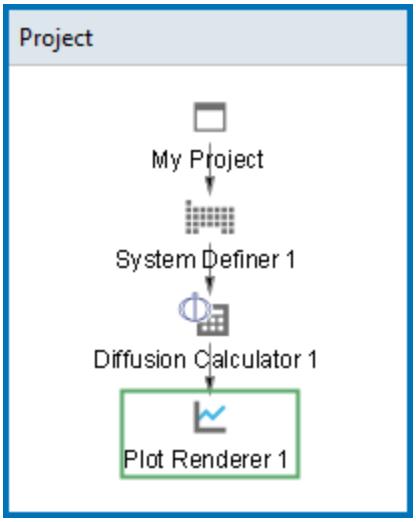
There are no changes to the default settings on the **Options** tab. You can click the tab to see what settings are available and then search the Online Help (press F1) for more information.

Plot Renderer Settings

After you have completed the settings for the System Definer and Diffusion Calculator you define the plot parameters and run (perform) the simulation.

Defining the Plot and Running the Simulation

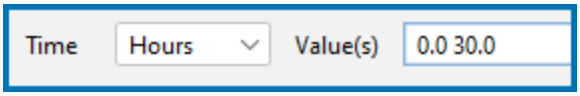
1. In the **Project** window, right click the **Diffusion Calculator** node and select **Create New Successor → Plot Renderer**. A Plot Renderer node is added to the tree structure.



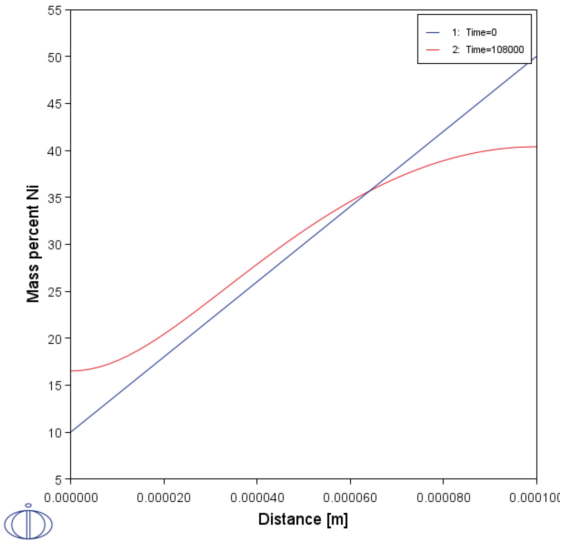
> If you used the **Diffusion** template, then this activity node is already there. Click the **Plot Renderer** node to access the **Configuration** window settings.

For this first example, some of the defaults are kept and there are only two settings to add. In most cases, either a specific position in the domain or one or more specific times must be specified depending on whether time or spatial position is chosen as independent (*X-axis*) variable.

2. In the *Axes* section for *Y* and next to **Composition**, choose **Ni**.
3. In the **Value(s)** field, enter `0.0` before the `30.0`, which is automatically taken from the Diffusion Calculator setting.



4. Click **Perform**. If you have entered everything correctly, you will get this plot showing the composition profile of Ni at the initial (0 hours) and final time (30 hours or 108,000 seconds).



Renaming the Nodes and Saving the Project

You can rename the nodes in the tree at any time during the creation of a project. For this first example it was left until the end so you could become familiar with the System Definer, Diffusion Calculator and Plot Renderer settings. It is also important at this point to save the project. You can do this at any time and it is good practice to save your project often.

Renaming Nodes and Saving Projects

The following renaming can be done to match the example file included with your installation:

When you rename a node, associated tabs are also renamed automatically. For example, when the Plot Renderer is renamed, so is the tab in the **Visualizations** window.

1. Right-click the **My Project** node and select **Rename**.
2. In the **New name** field enter `Diffusion Single Phase`. Click **OK**. Continue renaming the other nodes.
3. Right-click the **System Definer**, select **Rename** and enter `System with Fe Ni`.
4. Right-click the **Diffusion Calculator**, select **Rename** and enter `Diffusion single region Austenite`.
5. Right-click the **Plot Renderer**, select **Rename** and enter `Composition of Ni vs Distance`.
6. Save the project. To do this, click the **Save** button and navigate to a location on your computer where you can easily find this project file.

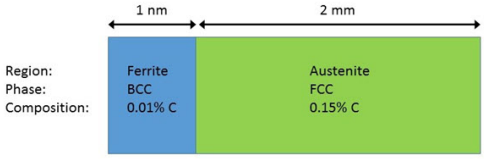
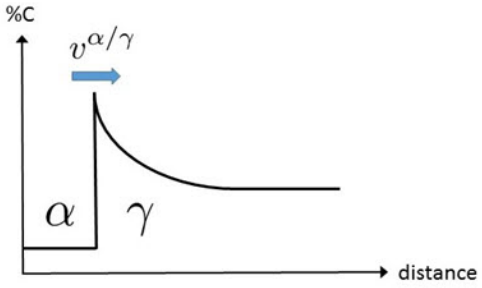
About the Moving Phase Boundary Simulation

The growth of ferrite (bcc) into austenite (fcc) is simulated in this example. The austenite is assumed to be initially homogeneous with the composition Fe - 0.15 mass-% C and the transformation temperature is 1050 K. The initial thickness of the austenite is 2 mm and an initially very thin ferrite (1 nm) is also present at the start of the simulation. The initial state is as below.



The set-up of the Moving Boundary example. There are two regions, Ferrite and Austenite, consisting of bcc and fcc, respectively.

A schematic graph of the carbon profile during the transformation is shown in the image below. Crusius et al. [1992Cru-1] is recommended as further reading.



Schematic view of the carbon profile during the transformation from austenite (γ) to ferrite (α) in the Moving Boundary example.

Reference

[1992Cru-1] S. Crusius, L. Höglund, U. Knoop, G. Inden, J. Ägren, On the Growth of Ferrite Allotriomorphs in Fe - C Alloys / Das Wachstum von allotriomorphem Ferrit in Fe — C-Legierungen. Int. J. Mater. Res. (Zeitschrift für Met. 83, 729–738 (1992).

Theory for the Moving Phase Boundary Simulation

It is assumed that local equilibrium holds at the phase interface, i.e. the chemical potentials of all elements are continuous across the boundary, but the chemical potential gradients are in general discontinuous.

In order to maintain mass balance a set of flux balance equations must be satisfied at the phase interface:

$$v^{\alpha/\gamma}(c_k^\alpha - c_k^\gamma) = J_k^\alpha - J_k^\gamma \qquad k = 1, \ldots, n-1$$

where v is the interfacial velocity. The concentrations and the fluxes c and J are those at the interface on the α and γ sides, respectively.

In the present case there are no degrees of freedom at the interface and the concentrations can be taken directly from a phase diagram. There is only one flux balance equation and the interface velocity can be evaluated once the fluxes at the interface are known. However, for ternary and higher systems the state at the interface must be found by some iterative procedure.

For more information on moving phase boundary problems, see, for example, [1982Ågr], [1992Cru-2], and [1997Hög].

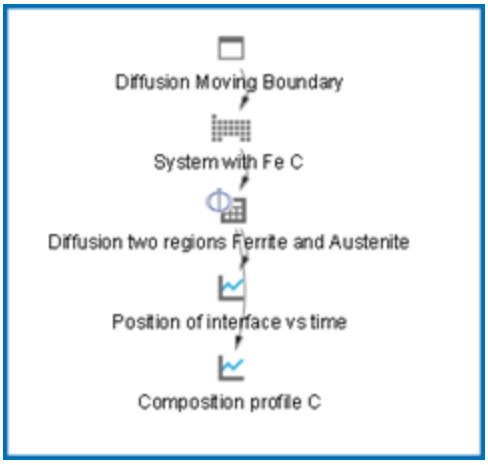
Moving Phase Boundary Example Project

For the moving phase boundary simulation, you can open the example project file included with your installation to see how it is set up.

Opening and Running the Moving Phase Boundary Example

1. Open Thermo-Calc.
2. There are different ways to access the examples.
   - From the main menu, select **File →** or **Help → Examples Files**. The Graphical Mode folder opens by default.
   - Click the **My Project** node and on the **Configuration** window under **Getting Started**, click **Example Files**.
3. Click to open the **Diffusion Module - DICTRA** folder and locate the file **D_02_Diffusion_Moving_Boundary.tcu**. Double-click to open it.
4. The project opens in Thermo-Calc. Click the top Project node (renamed to *Diffusion Moving Boundary*). At the bottom of the **Configuration** window click **Perform Tree**. You can also right-click the node and select **Perform Now**.

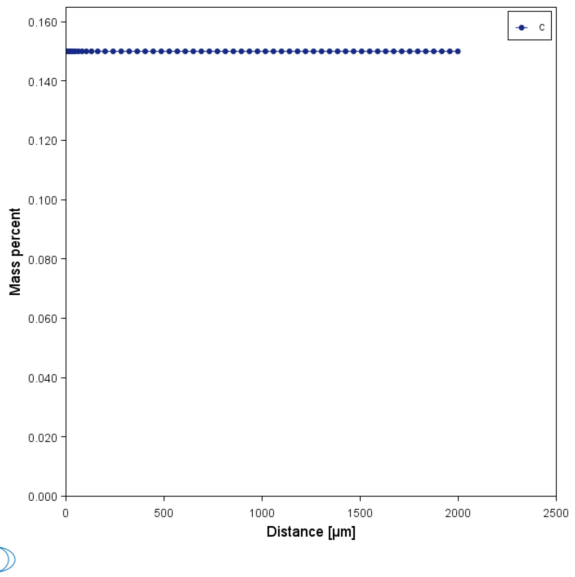


When completed, the results are plotted in the **Visualizations** window.

Visualizations

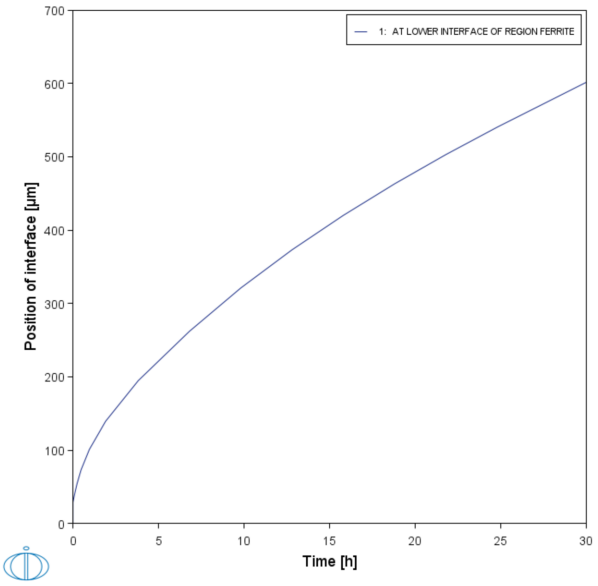
There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Composition Profiles** and **Thermal Profile**: When setting up a calculator on a **Configuration** window you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.
- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

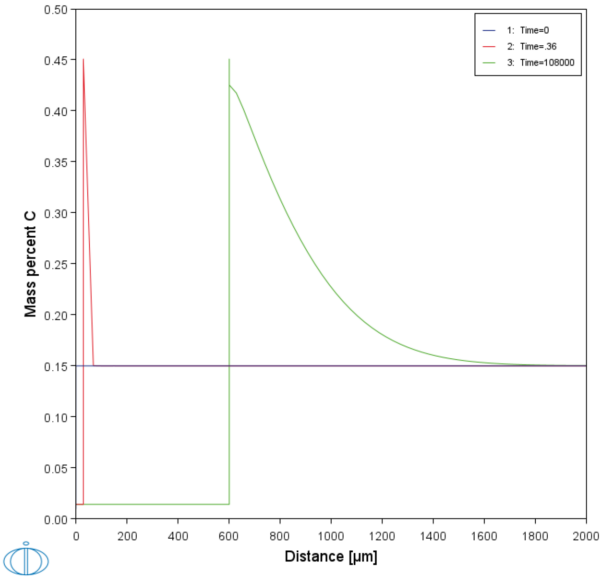


During set up of the calculation, you can preview the Composition Profile (shown) or Thermal Profile. Click the tab(s) in the Visualizations window to switch between these previews and adjust settings on the Diffusion Calculator Configuration window. For an Isothermal Thermal Profile this shows the constant temperature as entered.

There are two plot nodes, which creates two plots: The ferrite/austenite phase interface position as a function of time and the composition profile for Carbon.



After performing the calculation, you can view the final Plot Renderer result on the Position of interface vs time tab. In this example, the Plot Renderer is renamed and this matches the tab name in the Visualizations window.



After performing the calculation, you can view the final Plot Renderer result on the Composition profile C tab. In this example, the Plot Renderer is renamed and this matches the tab name in the Visualizations window.

System Definer Settings

This is a continuation from the Single Phase simulation and it describes how to set up the example file *D_02_Diffusion_Moving_Boundary.tcu*. In this example, the shortcuts explained for the Single Phase System Definer are used.

Adding the Databases and the Elements

1. Open a new instance of Thermo-Calc.
2. Click the **My Project** node and on the **Configuration** window under **Non-Equilibrium**, click the **Diffusion** template icon.
3. In the System Definer **Configuration** window click the **Package** list and choose **Demo: Steels and Fe-alloys (FEDEMO, MFEDEMO)**.
4. In the **Periodic Table**, click **Fe** then **C**.
5. Rename the nodes. Right-click **System Definer** and rename it to **System with Fe C**.
6. Right-click **My Project** and give it the same name as the project e.g. *Diffusion Moving Boundary*.
7. Save the project file with a new name, such as *Diffusion_Moving_Boundary*.

Diffusion Calculator Settings

After you have completed the settings for the System Definer, you define the diffusion calculation parameters.

The phase interface between ferrite and austenite is created by introducing an austenite region that is attached to the ferrite region. Regions are always separated by phase interfaces and must therefore always contain different phases.

In this simulation both the FCC_A1 and BCC_A2 phases are included. Both phases are assumed to be initially homogeneous, the BCC phase having 0.01 mass-% C and the FCC phase 0.15 mass-% C. These settings are entered on the Diffusion Calculator.

As with the single phase example, the **Options** tab keeps all the defaults.

Adding a Ferrite Region

1. In the **Project** window, click the **Diffusion Calculator** node.
2. Keep the default for **Composition unit** (**Mass percent**). Choose **Micrometer** for the **Length unit**. A **Planar** geometry is used for all the examples.
3. Under *Region* in the **Name** field enter `Ferrite` (replace the default text **Region 1**). Press <Enter>.
4. In the **Width** field enter `0.001` µm and change the default number of points to `10`. Keep the default **Automatic** grid type.

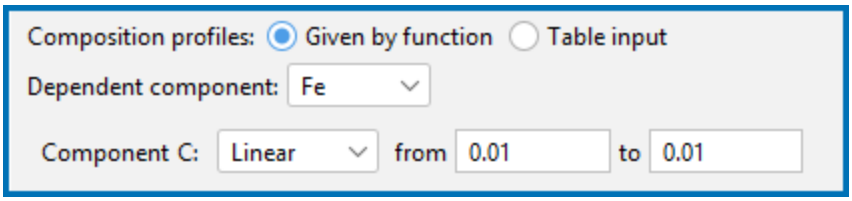
   The grid type for the ferrite region is the same as in the single-phase simulation example, i.e. equidistant.

5. From the **Phase** list select **BCC_A2**.

   In the **Visualizations** window, the **Composition Profile** tab displays a preview. The initial composition profile must be specified for all regions. Since there are only two elements, Fe and C, the initial composition profile must only be given for one of them.

6. Next to **Composition profiles** the default selected is **Given by function**. **Fe** is chosen as the **Dependent component** and the initial profile for **Component C** is a **Linear** variation.

7. Enter `0.01` in both fields to represent C going from 0.01 (mass-%) on the lower, left-hand side of the system to 0.01 (mass-%) on the upper, right-hand side of the system.



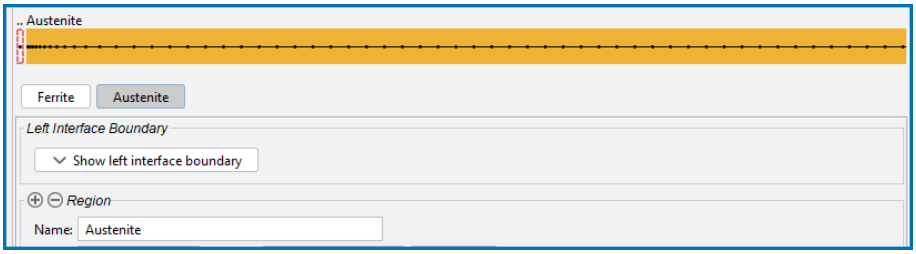
Watch as the **Composition Profile** changes on the **Visualizations** window to match these values.

Adding an Austenite Region

1. Next to *Region*, click the add button ⊕. A new tab called **Region 1** is added.

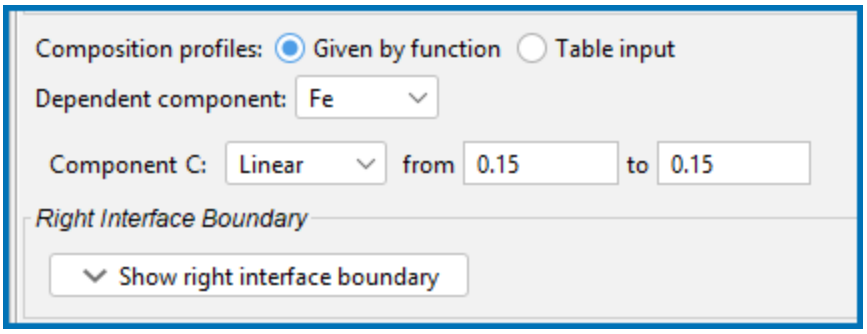
> If you add a region and then need to change the order, right-click the applicable tab and choose **Move left** or **Move right**.

2. In the *Region*__Name__ field, enter `Austenite`. This name is automatically updated on the tab and above the grid points in a new section for the second region.



3. In the **Width** field enter `2000` µm.
4. Select a **Automatic** type of grid and choose **Medium**.
5. From the **Phase** list, select **FCC_A1**.
6. Next to **Composition profiles** the default selected is **Given by function** and **Fe** is the **Dependent component**. Enter `0.15` in both the **from** and **to** fields to represent **Component C** going from 0.15 (mass-%) on the lower, left-hand side of the system to 0.15 (mass-%) on the upper, right-hand side of the system. The Austenite grid shows the points and the **Composition Profile** changes on the **Visualizations** window to

match these values.

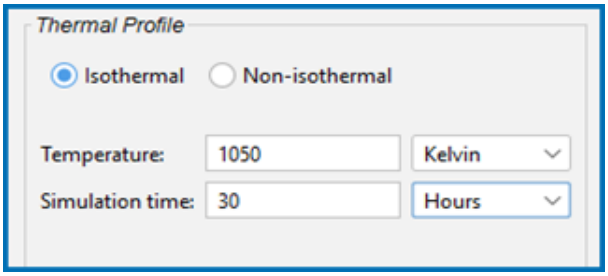


The domain now consists of two regions: Ferrite and Austenite.

Defining the Thermal Profile

The default **Isothermal** profile is used.

1. In the **Temperature** field, enter `1050`. Keep the default unit, **Kelvin**.
2. In the **Simulation time** field, enter `30`. Choose **Hours** from the list.
3. Right-click **Diffusion Calculator** and rename it to `Diffusion two regions Ferrite and Austenite`.



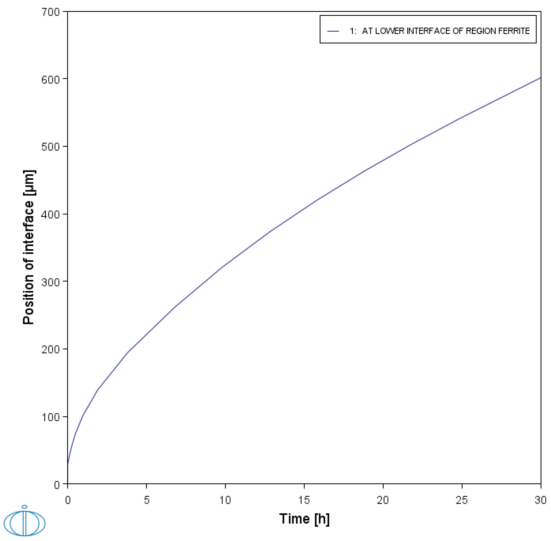
Plot Renderer Settings

After you have completed the settings for the System Definer and Diffusion Calculator you define the plot parameters.

Defining the Plot and Running the Simulation

1. In the **Project** window, click the **Plot Renderer** node.
2. In the *Axes* section, choose **Time** for *X* and select **Hours**.
3. Choose **Position of interface** for *Y*. After you click **Perform**, the **Interface** list is populated.
4. Right-click the **Plot Renderer** and rename it to `Position of interface vs time`.
5. Click **Perform**. If you have entered the same settings the plot shows the ferrite/austenite phase interface position as a function of time. The plot has the parabolic appearance characteristic for many types of diffusion simulations.

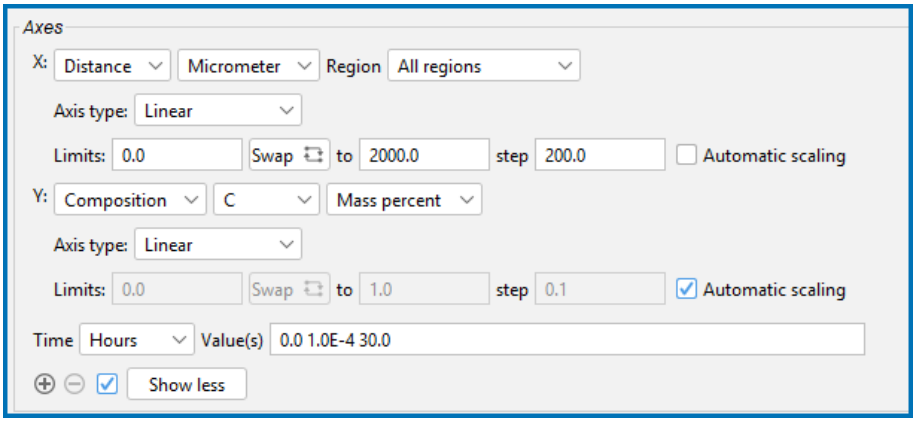
   Plot result from the example showing the phase interface position as a function of time.



Adding a Second Plot

1. Right-click the **Diffusion Calculator** node. Remember it is renamed to *Diffusion two regions Ferrite and Austenite*.
2. From the **Create New Successor** list, click **Plot Renderer**.

3. In the new Plot Renderer node **Configuration** window *Axes* section, for *X*, change the **Distance** units to **Micrometer**.
4. Click **Show more**, then click to clear the **Automatic scaling** checkbox.
5. In the **Limits** fields, keep `0.0` as the lower limit, enter `2000` for the upper limit and `200` for **step**.
6. For *Y*, keep the default **Composition** and choose **C** from the list.
7. Choose **Hours** as the **Time** unit and enter `0.0 1.0E-4 30.0` in the field.



8. Right-click **Plot Renderer** and rename it to `Composition profile C`.
9. Click **Perform** If you have entered the same settings the plot shows the composition profile of C.

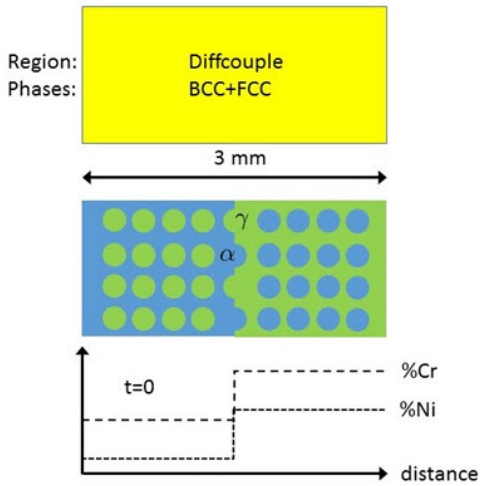
About the Multiphase Simulation

This example simulates the evolution of an Fe-Cr-Ni diffusion couple during a 100 hour heat treatment at 1100° C (1373.15 K). Both end members of the diffusion couple are duplex ferrite plus austenite, but the majority phase is ferrite on the left-hand side and austenite on the right.

With this type of simulation it is assumed that the material is fully equilibrated at each grid point, i.e. the local phase fractions, phase compositions and so forth are obtained from an equilibrium calculation with the local overall composition as a condition.



Schematic view of the initial state of the Multiphase example. Two ternary Fe-Cr-Ni alloys form a diffusion couple. There is a single region (diffcouple) where both the bcc and fcc phases are entered. Both alloys are duplex bcc+fcc, but the majority phase is bcc (α) in the left-hand side alloy and fcc (γ) in the right.

Theory for the Multiphase Simulation

More details about the homogenization model for multiphase simulations can be found in Larsson and Engström [2006Lar] and Larsson and Höglund [2009Lar]. As mentioned in the description of this simulation, it is assumed that the material is locally fully equilibrated and that the local phase fractions, phase compositions and so forth are obtained from an equilibrium calculation with the local overall composition as a condition. From a numerical point of view the homogenization model treats the multiphase material as a single phase having the “average”, or “effective”, properties of the local phase mixture.

When estimating the effective kinetics of a multiphase mixture the product of solubility and mobility in each phase is considered. It is therefore convenient to define

$$\Gamma_k^\phi = M_k^\phi c_k^\phi$$

for each phase ϕ. The effective kinetics of the multiphase mixture is denoted and in this example it was evaluated using the lower Hashin-Shtrikman bound. The default method is a simple rule of mixtures

$$\Gamma^\star = \sum_\phi f^\phi \Gamma_k^\phi$$

where f^ϕ is the volume fraction of ϕ. The flux is obtained as

$$J_k = -\Gamma_k^\star \frac{\partial \mu_k}{\partial z}$$

which replaces the single-phase equation

$$J_k = L_{kk} \frac{\partial \mu_k}{\partial z} = M_k c_k \frac{\partial \mu_k}{\partial z}$$

for multiphase simulations.

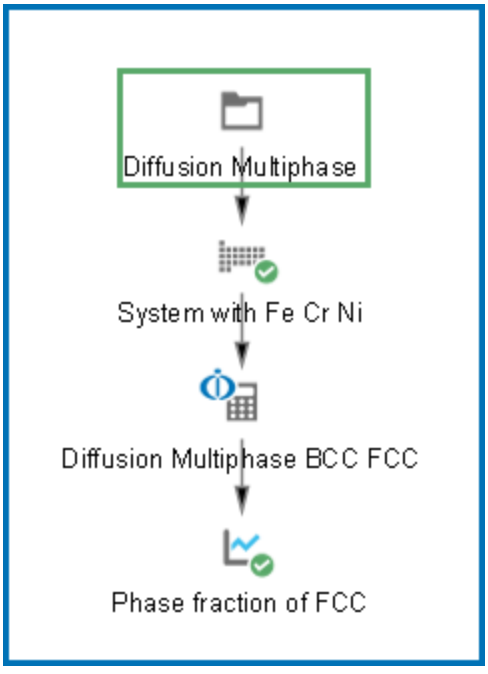
Multiphase Example Project

For the multiphase simulation, you can open the example project file included with your installation to see how it is set up.

Opening and Running the Multiphase Example

1. Open Thermo-Calc.
2. There are different ways to access the examples.
   - From the main menu, select **File →** or **Help → Examples Files**. The Graphical Mode folder opens by default.
   - Click the **My Project** node and on the **Configuration** window under **Getting Started**, click **Example Files**
3. Click to open the **Diffusion Module - DICTRA** folder and locate the **D_03_Diffusion_ Multiphase.tcu** file. Double-click to open it.
4. The project opens in Thermo-Calc. Click the top Project node (renamed to *Diffusion Multiphase*). At the bottom of the **Configuration** window click **Perform Tree**.

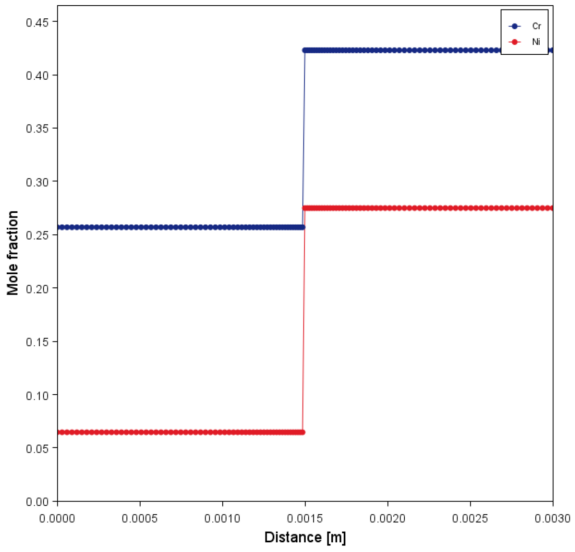


When completed, the results are plotted in the **Visualizations** window.

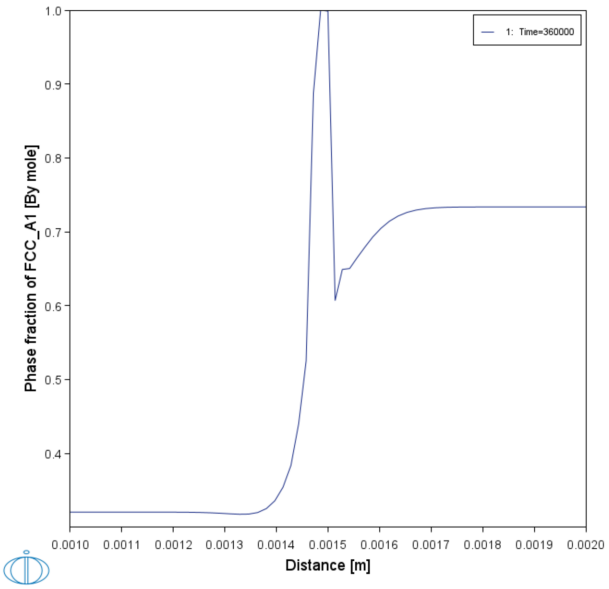
Visualizations

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Composition Profiles** and **Thermal Profile**: When setting up a calculator on a **Configuration** window you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.
- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.



During set up of the calculation, you can preview the Composition Profile (shown) or Thermal Profile. Click the tab(s) in the Visualizations window to switch between these previews and adjust settings on the Diffusion Calculator Configuration window. For an Isothermal Thermal Profile this shows the constant temperature as entered.



After performing the calculation, you can view the final Plot Renderer result on the Phase fraction of FCC tab. In this example, the Plot Renderer is renamed and this matches the tab name in the Visualizations window.

System Definer Settings

This is a continuation from the previous examples and uses the short cuts already described. You can alternatively open a saved project and edit the settings.

Adding the Databases and the Elements

1. Open a new instance of Thermo-Calc.
2. In the **My Project** window under **Non-Equilibrium**, click the **Diffusion** template icon.
3. In the System Definer **Configuration** window click the **Package** list and choose **Demo: Steels and Fe-alloys (FEDEMO, MFEDEMO)**.
4. In the **Periodic Table**, click **Fe**, then **Cr** and **Ni**.
5. Right-click **System Definer** and rename it to `System with Fe Cr Ni`.
6. Save the project file with a new name, e.g. *Diffusion_Multiphase*.

Diffusion Calculator Settings

After you have made the settings to the System Definer, you add the diffusion calculation parameters.

Defining the Ferrite and Austenite Regions

1. In the **Project** window, click the **Diffusion Calculator** node.
2. For **Composition unit** select **Mole fraction**.

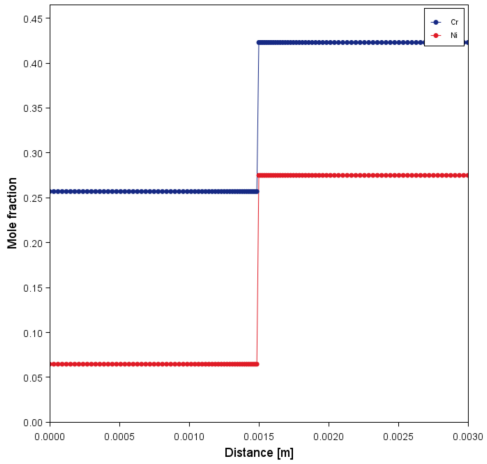
   Keep the default **Length unit** as **Meter**. A **Planar** geometry is used for all the examples.

3. Under *Region* in the **Name** field enter `Diffcouple`.
4. In the **Width** field enter `0.003`.
5. Select **Automatic** as the grid type. Select **Fine**.
6. Choose **FCC_A1** from the **Phase** list.
7. Next to **Phase** click the **Add phase** button. From the **Phase** list select **BCC_A2**.

   In the **Visualizations** window, the **Composition Profile** tab displays a preview of these changes.

8. Next to **Composition profiles** the default selected is **Given by function**. **Fe** is chosen as the **Dependent component**.
   a. Define **Component Cr** and **Component Ni**. Choose **Step** for both the Cr and Ni elements.
   b. In each of the fields for Cr (**from**, **to**, **step at**) enter `0.257`, `0.423` and `0.0015`, respectively.
   c. In each of the fields for Ni (**from**, **to**, **step at**) enter `0.0647`, `0.275` and `0.0015`, respectively.

   In the **Visualizations** window, the **Composition Profile** tab displays a preview of these changes.



During set up of the calculation, you can preview the Composition Profile (shown) or Thermal Profile. Click the tab(s) in the Visualizations window to switch between these previews and adjust settings on the Diffusion Calculator Configuration window. For an Isothermal Thermal Profile this shows the constant temperature as entered.

The resulting Cr profile is thus 0.257 on the left half of the domain and 0.423 on the right with a sharp step at the center (as shown in About the Multiphase Simulation).

Defining the Thermal Profile

The default **Isothermal** profile is used for this example.

1. In the **Temperature** field, enter `1100` and choose **Celsius** as the unit from the list.
2. In the **Simulation time** field, enter `100` and choose **Hours** from the list.
3. Right-click **Diffusion Calculator** and rename it to `Diffusion Multiphase BCC FCC`.

Choosing the Homogenization Function

The local kinetics of the multiphase mixture must be estimated by means of some function that may depend on the local phase fractions, phase compositions, and the mobilities of the individual phases.

There are many such homogenization functions to choose from. In this particular example the **General lower Hashin–Shtrikman bound** is a good choice [1962Has].

1. To choose this homogenization function, click the **Diffusion Calculator** and then click the **Options** tab.
2. Under *Simulation Conditions*, select **Homogenization** as the **Default solver**.
3. Under *Homogenization Model Specific*, from the **Homogenization function** list, select **General lower Hashin–Shtrikman bound**.

[1962Has] Z. Hashin, S. Shtrikman, A Variational Approach to the Theory of the Effective Magnetic Permeability of Multiphase Materials. J. Appl. Phys. 33, 3125–3131 (1962).

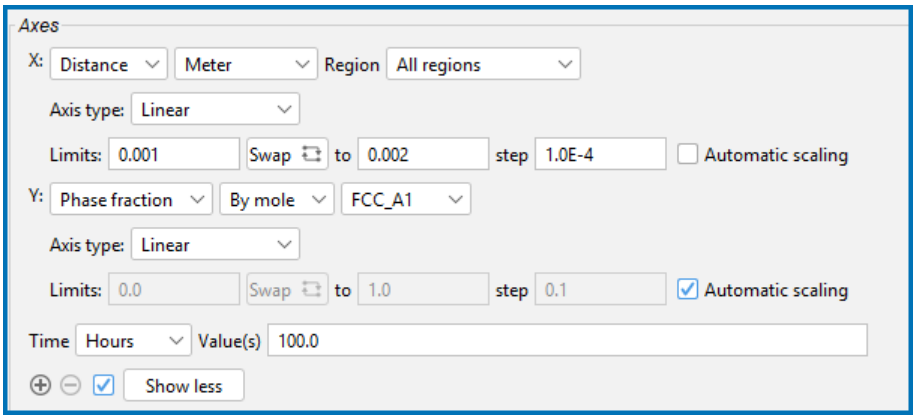
Plot Renderer Settings

After you enter the settings for the System Definer and Diffusion Calculator, you define the plot parameters. For this example you want to plot the mole fraction fcc phase as a function of distance at the end of the heat treatment.

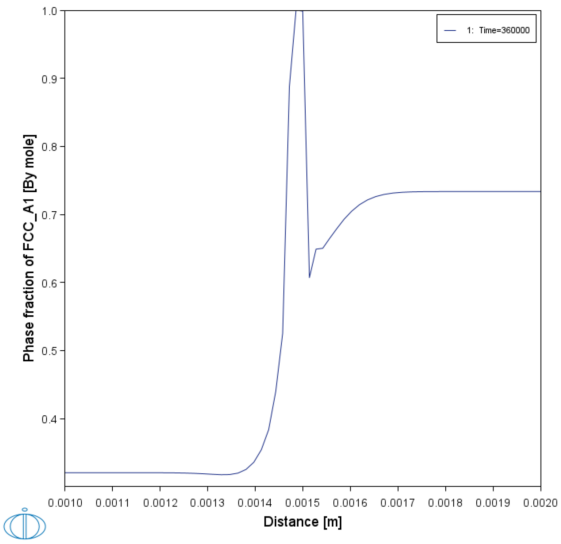
The plot of phase fraction vs distance shows that a single phase fcc zone has formed and this was also observed experimentally, see [1995Eng].

Defining the Plot and Running the Simulation

1. Click the **Plot Renderer** node.
2. Click **Show more**. Then under *Axes* for *X*, click to clear the **Automatic scaling** checkbox.
3. Enter the **Limits**: `0.001` **to** `0.002` **step** `1.0E-4`.
4. For *Y*, choose **Phase fraction** and **FCC_A1**.



5. Click **Perform** If you have entered the same settings you will get this plot result.



6. Right-click **Plot Renderer** and rename it to `Phase fraction of FCC`.

Next Steps

Below are suggestions for you to learn more about using the Diffusion Module (DICTRA).

- Browse the locally installed Help (press F1) or go the web version via the website that matches the most recently released version of Thermo-Calc.
- Open the *Thermo-Calc Software Documentation Set* PDF included with your installation (**Help → Manuals Folder**).
- You can also go to the Thermo-Calc website to see if there are other options suited to you, such as a course or video tutorials. To go to the web page, in the **Project** window, click the top **My Project** node and then click **Video Tutorials**. Or from the main menu, select **Help → Video Tutorials**.

There are several resources available on our website to help you learn how to use Thermo-Calc and other Add-on Modules. Go to the Getting Started Guides page and choose one of the guides that provides new users an introduction to setting up simple calculations in Graphical Mode. The information there is also in this help documentation.

The Role of Diffusion in Materials: A Tutorial is available for download on our website. It is intended for engineers interested in using the Diffusion Module (DICTRA), as well as students learning about the role of diffusion in materials. It is designed to be useful at many levels, from undergraduate studies to someone with a PhD and experience in a related field.

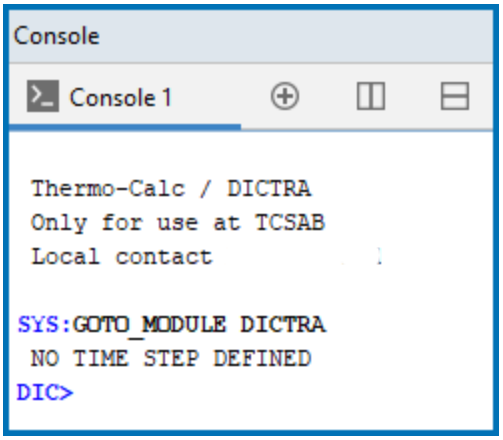
Opening DICTRA in Console Mode

1. Open Thermo-Calc in Console Mode.

> By default, Thermo-Calc opens in the most recently used state. If it opens in Graphical Mode, on the toolbar, click **Switch to Console Mode**.

2. In the `SYS` module, type `GOTO_MODULE DICTRA`. For a list of all the available commands in the current module, at the prompt type a question mark (?) and press <Enter>. For a description of a specific command, type `Help` followed by the name of the command.



About the Console Mode File Formats

The Diffusion Module (DICTRA) in Console Mode uses different file formats: *log* files (*.TCM), *macro* files (*.DCM) and *workspace* files (*.DIC).

Also see Graphical Mode vs Console Mode. If you are working with Thermo-Calc in Console Mode, see Working with the Console Mode File Types.

Log Files

Log files (*.TCM) are plain text files and are just macro files used to save a sequence of commands. These files can be edited in a text editor.

- To start saving your input into a file, in the SYS module type `SET_LOG_FILE`, followed by the name of the file that you want to save your command sequence to.
- When creating a command sequence, and if you want to save the output in the log file, type `SET_ECHO` before SET_LOG_FILE. This is useful if you later want to use the log file as a macro file because the macro file lists the full commands instead of only the short names.

Macro Files

Macro files (*.DCM) are plain text files used to save a sequence of commands that can be loaded and executed. Macro files can be edited in a text editor. When creating a command sequence, you add comments to the file by starting a line with @@.

- To run a macro file, in the SYS or DICTRA module type `MACRO_FILE_OPEN`, followed by the name of the macro file. DICTRA runs the MACRO_FILE_OPEN sequence that the file contains.
- To remain in the console and keep working in the DICTRA module, in the SYS, DICTRA, POLY, or POST module add the command SET_INTERACTIVE at the end of the macro file. Alternatively, use `EXIT` as the final command.

Workspace Files

Workspaces files for the Diffusion Module (DICTRA) have the file extension *.DIC, which allow you to save all the data in your current workspace. A workspace contains all the data, specified settings and the result of any calculations performed. The saved data includes original and

modified thermodynamic data, the last set of conditions and options, and the results of any simulations.

- At the `DIC` prompt use SAVE_WORKSPACES .
- To load the data and calculation results of a workspace file, at the `DIC` prompt use READ_WORKSPACES.

Opening a Macro File in Console Mode

You can open the macro files (*.TCM or *.DCM files) in different ways.

- From the main menu,
- Using a command,
- By dragging and dropping the file into the Console window, or
- Navigate to the file location on your computer and double-click to open it. If you already have Thermo-Calc open, the macro opens in a new tab. Otherwise a new instance of Thermo-Calc is launched.

> If you are using the advanced pipe or redirect option (Technical Note: Pipe or Redirect Output Data from Console Mode) then a new instance of Thermo-Calc is always started.

- You can also read the commands listed in the macro file using a text editor.

> If you only open and read the macro file in a text editor, you do not see the output that Thermo-Calc gives in response to the commands stored in the macro file.

Opening an Example Macro

To open a specific macro file from the Examples folders included with your installation:

1. Open Thermo-Calc.
2. Confirm you are in Console Mode. If not, click the **Switch to Console Mode** button.
3. From the main menu, select **File** → or **Help** → **Examples Files**. The Console Mode folder opens.
4. Double-click the **Diffusion Module - DICTRA** folder to view the subfolders.

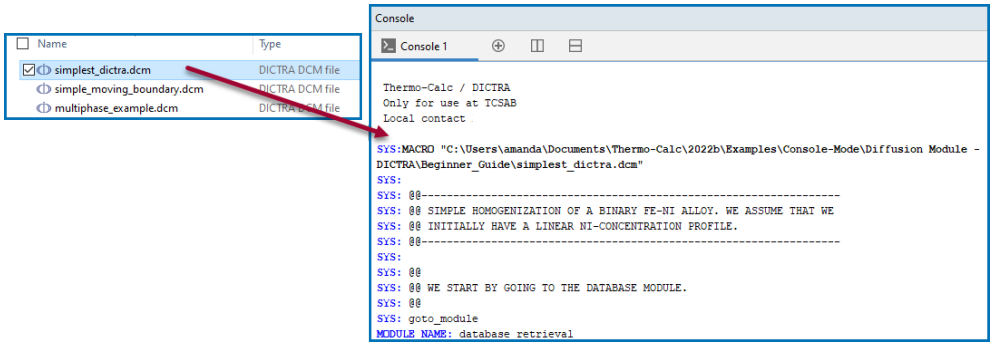
> The three Quick Start example macros are in the first folder called **Beginner Guide**.

Opening a Macro with a Command

At the `SYS` prompt, type MACRO_FILE_OPEN and press <Enter>. In the file dialogue window that opens, locate and select the macro file on your computer.

Opening a Macro File by Dragging and Dropping it into Console Mode

For example, navigate to the **Beginner Guide** folder and then drag the file from its location into Thermo-Calc Console window. The macro automatically runs after you drop it into the Console window.



Double-clicking to Open a File

Navigate to the macro file location, for example where each set of file examples is in its own folder. If you already have Thermo-Calc open, the macro opens in a new tab. Otherwise a new instance of Thermo-Calc is launched.

Typical Console Mode Workflow

The basic work flow in Console Mode is as follows.

1. You are in the **SYS** module when you start Thermo-Calc in Console Mode.
2. In the **DATA** module you define the system. Before performing a calculation, you must define your system and retrieve thermodynamic and kinetic data. The data is retrieved from the database files.
3. The data needed to describe a system is sent to the **GIBBS** module. When the data is in GIBBS, the software can access the retrieved data. The retrieved data is accessible to the **POLY** module, which is involved in simulations that require that equilibrium calculations are performed.
4. In the **DICTRA_MONITOR** you:
    a. Set the initial state of the system and define its geometry and boundary conditions. The simplest system has one cell that contains one region, but you may put additional regions in a cell and put additional cells in your system.
    b. Define the phases each region contains.
    c. Set various parameters for the numerical calculations.
    d. Run the simulation from within the DICTRA_MONITOR.
5. In the **POST** module you plot and visualize your data.
    a. Choose the data to plot
    b. Change the appearance of the diagram
    c. Save the diagram as an image file (available in several formats).

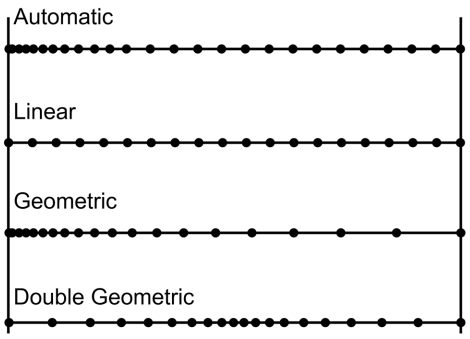
About Regions and Grids

This section or topic is specific to Console Mode.

A *region* contains one or more phases. If a region contains several phases one of those must be entered as a *matrix phase* whereas the others are entered as *spheroid*.

A region must also contain a number of *grid points*. The composition is only known at these grid points and the software assumes that the composition varies linearly between them. The amount and composition of all the phases present at a single grid point in a certain region are those given by thermodynamic equilibrium keeping the over-all composition at the grid point fixed.

These grid types are used in diffusion simulations: automatic, linear, geometric, and double geometric. When you are setting up the simulation, in either Console Mode or Graphical Mode, a region must have a grid defined.



Learn More

For Graphical Mode, see Diffusion Module Terminology in Graphical Mode.

Also see Creating Regions and Gridpoints.

About System, Cells and Regions

This section or topic is specific to Console Mode.

A system normally consists of one *cell*. This cell contains one or several *regions* in which the diffusion problem is to be solved. A system of diffusion equations is solved for each region. The size of the system is the sum of sizes of all the regions in all the system's cells.

The interface between two regions typically moves as the result of a simulation, that is, the regions grow or shrink. Such an interface is called an *inner interface*. The boundary of a cell is called an *outer interface* and the condition of this type of interface may be affected by the choice of boundary conditions.

For some simulations it is useful to have several cells in a system. Matter can move between cells. However, it is assumed that there is diffusional equilibrium between all cells (this means that there are no differences in diffusion potentials between cells). In other words, the size of a cell is fixed during the simulation.

By default this is a *closed system*, which means that matter cannot move across its boundaries. However, you can change this setting for both the *lower boundary* (left side/centre) and the *upper boundary* (right side/surface) of the system. You can also set these boundary conditions to vary as a function of time, temperature and/or pressure.

For Graphical Mode, see Diffusion Module Terminology in Graphical Mode.

About Phases

This section or topic is specific to Console Mode.

Each region contains one or more *phases*. A phase can be of the *matrix*, *spheroid* or *lamellar* type. A phase can be introduced with the status *active* (the default) or *inactive*.

An inactive phase is a phase which does not participate in the calculations until it is stable. If a phase is inactive, then the driving force for precipitation of the phase is continuously monitored. When the driving force exceeds a predefined positive value, the phase take parts in the simulation and the phase automatically becomes active. A new region is then created and the formerly inactive phase is entered as the matrix phase of the new region. The name of the region is set to the name of the phase that just became active but with `R_` added as a prefix.

Region Phase Types

Phase type	*Description*
Matrix	The region's primary phase. If there is only one phase in a region, then that phase is automatically a matrix.
Spheroid	Used to treat one or several dispersed phases in a matrix. Unless the homogenization model is invoked, which happens automatically when a spheroid phase is entered, then diffusion is only considered in the matrix phase; the spheroid phases then only act as sources and sinks of the diffusing elements.
Lamellar	Used to simulate the growth of a eutectic or eutectoid region. The software only treats the growth, not the dissolution, of such a region. The *pearlite calculation model* is used for a phase that is lamellar.

Learn More

For Graphical Mode, see Diffusion Module Terminology in Graphical Mode.

Also see Entering Phases in Regions and Specifying Phase Compositions in a Region.

About Composition Variables

Two types of composition variables are used within the program: site-fractions and u-fractions, although you can also use weight fraction or mole fraction, for example.

The *site-fractions* are used to set up the problem and interface with POLY-3 (in Console Mode). The site fraction of a species *k*, y_k, is the fraction of equivalent lattice sites occupied by species k. It is the only concentration variable that uniquely defines the composition and the constitution of a phase and it is necessary to use the site fraction in the storage of the data during a simulation.

The *u-fractions* are used in the diffusion equations. The u-fraction of a component *k* is defined as

$$u_k = \frac{x_k}{\sum_{j \in S} x_j}$$

The summation is only performed over the substitutional elements. The choice of the volume fixed frame of reference in the calculations make it convenient to use a composition variable which is related to the volume. The definition of the u-fraction is based upon the assumption that a species may or may not contribute to the volume of a phase. An interstitial element is assumed to not contribute to the volume. Substitutional elements are assumed to contribute equally to volume.

About Global Conditions

This section or topic is specific to Console Mode.

There are several global parameters that influence the diffusion rate in simulations: temperature, pressure and heat content removal. These parameters are defined as functions of time. The temperature can also be a function of the spatial position, and heat content removal can be a function of temperature or pressure.

For heat content removal, the amount of extracted heat per time unit is normalized and the size of the system is normalized to one mole of atoms.

Setting Global Conditions

About Boundary Conditions in Console Mode

Boundary conditions are conditions that define how matter behaves at the boundaries of your system. By default, matter is not allowed to cross the system boundaries.

You can change the setting for both the lower boundary (left side/centre) and the upper boundary (right side/surface) of the system.

SET_CONDITION

Boundary Condition Descriptions

Boundary Condition	*Description*
FIX_FLUX_VALUE	Enter functions that yield the flux times the molar volume for the independent components. Can be a function of time, temperature and pressure. Use this boundary condition with caution as it may cause unrealistic compositions.
STATE_VARIABLE_VALUE	A legal equilibrium condition expression in POLY-3 syntax that reduces the degrees of freedom. This type should be used with care as no checks are done in advance to determine if it is a legal expression. Do not specify the conditions for temperature and pressure here as these are taken from the global conditions.
POTENTIAL_FLUX_ FUNCTION	Use to take into account the finite rate of a surface reaction. The flux for the independent components must be given in the format: $$J_k * V_m = f_k(T,P,TIME)*\left[POTENTIAL_k^N - g_k(T,P,TIME)\right]$$ The functions f and g may have time (TIME), temperature (T), and/or pressure (P) as arguments. N is an integer. The potentials are those with user defined reference states.
ACTIVITY_FLUX_ FUNCTION	Use to take into account the finite rate of a surface reaction. The flux for the independent components must be given in the format: $$J_k * V_m = f_k(T,P,TIME)*\left[ACTIVITY_k^N - g_k(T,P,TIME)\right]$$ The functions f and g may have time (TIME), temperature (T), and/or pressure (P) as arguments. N is an integer. The activities are those with user-defined reference states.

Boundary Condition	*Description*
ITERATIVE_ACTIVITY_ FLUX_ FUNCTION	Same as ACTIVITY_FLUX_FUNCTION but an iterative scheme is used to determine the flux. Use this if the other command encounters problems.
CLOSED_SYSTEM	Corresponds to a fix flux value, which is set to zero at all times. This is the default boundary condition.
MIXED_ZERO_FLUX_AND_ ACTIVITY	The flux of selected components is set to zero and the activity of others may be set to a prescribed value.
GAS	This option can cause a change in system volume. The flux of selected components is set to zero and the activity of others can be set to a prescribed value. Use this to treat an expanding system, e.g. the growth of an external oxide scale.

About Geometry and Coordinates

This section or topic is specific to Console Mode.

Specifying the Geometry

Geometry and Coordinates

The Diffusion Module (DICTRA) can only handle diffusion problems where composition vary along one spatial coordinate. The geometry of your system can be *planar*, *cylindrical* , or *spherical*.

Planar Geometry

This geometry corresponds to an infinitely wide plate of a certain thickness. If the system has a planar geometry then the lower boundary (the zero coordinate) is at the left side of the system. The upper boundary (the coordinate with the highest value) is at the right side of the system.

Cylindrical and Spherical Geometries

- Cylindrical geometry corresponds to an infinitely long cylinder of a certain radius.
- Sypherical geometry corresponds to a sphere with a certain radius.

By default for both geometries, the lower boundary (the zero coordinate) is at the centre of the cylinder/sphere. The upper boundary (the coordinate with the highest value) is at the *surface* of the cylinder/sphere. You can enter a left most coordinate that is larger than zero to allow for tube and hollow sphere geometries.

About Operators and Functions

Sometimes you need to specify functions when setting up a system. For example, to make global and boundary conditions vary as a function of time.

The following operators can be used in writing functions. Use a semi-colon (;) to mark the end of a function.

Available Operators for Writing Functions

Operator	*Description*
+, -, *, /	Addition, subtraction, multiplication, division
**	Exponentiation, raising one quantity to the power of another, e.g. x^2.
ABS()	Absolute value
ERF(X)	Error function
EXP(X)	Exponential
LOG(X)	Natural logarithm
LOG10(X)	Base 10 logarithm
SIGN(X)	Sign function SIGN(X) is -1 when X<0, is 0 when X=0 and is 1 when X>0.
SIN(X), COS(X), TAN(X), ASIN(X), ACOS(X), ATAN (X)	• Trigonometric functions: sine, cosine, tangent • Inverse trigonometric functions: arcsine, arccosine, arctangent
SINH(X), COSH(X), TANH(X), ASINH(X), ACOSH (X), ATANH(X)	• Hyperbolic trigonometric functions • Inverse hyperbolic functions

Operator	*Description*
SQRT(X)	Square root

Defining a System in Console Mode

This section or topic is specific to Console Mode.

Define your system with as few elements (components) and phases as possible; keep the simulation as simple as possible to avoid making the simulation unsolvable.

In order to perform a simulation in the Diffusion Module, both a thermodynamic database and a kinetic database is needed. The thermodynamic database is a normal Thermo-Calc database, whereas the kinetic database contains information about the atomic mobility of individual elements in various phases.

1. Open Thermo-Calc in Console Mode. At the `SYS` prompt, type `GOTO_MODULE DATA`.
2. Use SWITCH_DATABASE to select databases. Unless you directly specify the name of the database as a parameter to the command, the available databases are listed. Specify the one to use.
3. Use DEFINE_ELEMENTS followed by a list of the elements that you want in your system. (To list the elements available in the current database, type `LIST_DATABASE Elements`.)
4. Use REJECT with the keyword, `Phases` to make sure that unnecessary phases are not retrieved from the database.
5. Use RESTORE with the keyword, `Phases` to restore any phases that have been excluded.
6. Use GET_DATA to read from the database and send the thermodynamic data about your system to the GIBBS and DICTRA workspace.
7. Use APPEND_DATABASE to select the database from which you want to retrieve kinetic data.
8. Define your elements and specify whether to reject and restore any phases. Do this in exactly the same way as you would for the thermodynamics data (see steps 2, 3 and 4).
9. Use GET_DATA to read from the database and add the kinetic data to the thermodynamic data that already exists in the GIBBS and DICTRA module workspace.
10. Use APPEND_DATABASE again to add thermodynamic or kinetic data from another database. When all the data needed is retrieved, you can start using the DICTRA module.

Setting Up and Running a Simulation

This section or topic is specific to Console Mode.

1. Before you can set up and start a simulation, you must have retrieved thermodynamic and kinetic data and defined your system. See Defining a System in Console Mode.
2. Set conditions that hold globally in the system using SET_CONDITION `Global`. Normally, this is the temperature condition.
3. Enter a region into the current cell using ENTER_REGION. Give the region an arbitrary name. If the region that you create is not the cell's first region, then by default it is attached to the right side of the last region created in the cell.
4. For each region, use ENTER_GRID_COORDINATES to specify the region's size (width) as well as the type of grid and the number of grid points to be used in the region. The size is specified in meters.
5. Use ENTER_PHASE_IN_REGION to enter a phase into a region. Specify whether the phase is active/inactive, which type of phase it is, and what the name of the phase is.
6. Use ENTER_COMPOSITIONS to specify the initial composition of a phase that you have entered in a region. You can specify the composition in terms of site fraction, mole fraction, mole percent, weight fraction, weight percent or u-fraction. The composition profile may be entered by a user or be read from a file.
7. Use SET_CONDITION `Boundary` to set non-default boundary conditions.
8. Use ENTER_GEOMETRICAL_EXPONENT to enter the geometrical exponent that defines the geometry of the system. If you do not specify the geometrical exponent, then it is assumed that the system has a planar geometry.
9. Use SET_SIMULATION_TIME to set the simulation time.
10. If you want to use a specific model for the simulation calculations, then set the DICTRA module to use a COARSENING_MODEL, PARA_EQUILIBRIUM_MODEL, HOMOGENIZATION_MODEL or GB_MODEL. Also see About the Pearlite Model.
11. You are now ready to run the simulation. However, it is recommended that you use SAVE_WORKSPACES to save the setup before running the simulation.
12. Use SIMULATE_REACTION to start the simulation. To ensure that the simulation is run with default settings (answer `Y`), otherwise you may be prompted to specify certain values during the running of the simulations (if phases appear or disappear in the simulation).

Setting Global Conditions

This section or topic is specific to Console Mode.

Use SET_CONDITION and choose `Global`. Global conditions include temperature (T), heat content removal (Q) and pressure (P), and these reduce the degrees of freedom for equilibrium calculations.

About Global Conditions

If the heat content removal is specified then only the initial temperature should be entered with the SET_INITIAL_TEMPERATURE command.

- In practice, the pressure is rarely specified. By default the pressure is assumed to be constant and equal to 1 bar.
- For each condition, you can define a profile over time that consists of several intervals of time, or *ranges*, with each range having its own function to define the value of the condition.
- Temperature can be entered as a function of time (TIME) and/or spatial coordinate (X). The pressure condition can be defined as a function of time (TIME). The heat content removal can be defined as a function of temperature (T), pressure (P) and/or time (TIME).

  For example, the following function could specify a cooling rate if it is used to specify how the global condition temperature (T) changes with time (TIME) during a certain range: `1900-1*TIME;`

- Temperature can also be entered as time/temperature pair values.

Specifying Time-Dependent Profiles

This section or topic is specific to Console Mode.

In the DICTRA module you are often prompted to specify a time-dependent profile for a condition.

Settings

To define the profiles or intervals, enter information as follows:

LOW TIME LIMIT

To determine the time when the function starts to apply.

HIGH TIME LIMIT

To determine the time when the function stops applying. Use an asterisk (*) to set the high limit to the time when the simulation ends.

ANY MORE RANGES

Enter `Y` to specify an additional range with a time-dependent function, which starts to apply at the time step after the high time limit of the previous range is reached.

Creating Regions and Gridpoints

This section or topic is specific to Console Mode.

Enter a new region by specifying its name and, unless it is the first region, how it should be located with respect to one already existing region. The size of a region is determined when a grid is entered into the region.

Creating a Region

1. Complete Defining a System in Console Mode.
2. Use ENTER_REGION to enter a region into the system.
3. Enter an arbitrary name for the region at the `Region name` prompt.
4. If this is the first region you create in your system, then you are finished. Otherwise, continue to the next step.
5. Enter the name of an already existing region to which the new region is attached.
6. Specify whether the new region should be `Attached to the right of` the existing region. Enter `Y` to attach to the existing region's right side or `N` to attach it to its left side.
7. If the system has a cylindrical or spherical geometry, then this is a question of whether to put the new region outside the existing region, so that the new region surrounds the existing one, or to put it at the existing region's centre, so that the existing region surrounds the new region.

Adding Gridpoints to a Region

This topic describes how you specify the size and grid point distribution to use in a region.

1. Complete Defining a System in Console Mode and Creating a region.
2. Use ENTER_GRID_COORDINATES followed by the name of the region.
3. Specify the width of the region in meters.
4. At the `Number of points` prompt enter the number of grid points for the region.

5. Specify the type of grid point distribution to have in the region.
    - `Linear` for an equally spaced grid.
    - `Read_Point_by_Point` to read a number of specific grid points from a data file.
    - `Geometric` for a grid that yields a varying density of grid points in the region. Enter the `Value of R in the geometrical series`, which determines the distribution. A geometrical factor larger than one yields a higher density of grid points at the lower end of the region and a factor smaller than one yields a higher density of grid points at the upper end of the region.
    - `Double_Geometric` to have a high number of grid points in the middle or at both ends of a region. Specify two geometrical factors. `Value of R in the geometrical series for lower part of region` for the distribution in the lower (left) part of a region, and `Value of R in the geometrical series for upper part of subregion` for the distribution in the upper (right) part of a region.

Learn More

About System, Cells and Regions and About Regions and Grids

Entering Phases in Regions

When defining a region you need to enter one or more phases into the region. The number and type of phases depends on the simulation you want to run.

- To simulate diffusion of components within one phase, enter one matrix phase into the region.
- To simulate how an interface between regions moves, enter two regions with at least one phase in each.
- To simulate growth of one or more dispersed phases in a matrix phase, enter one matrix phase and one or more spheroid phases.

There is no supersaturation locally within a given region.

Entering Phases in a Region

1. Complete Defining a System in Console Mode and Creating Regions and Gridpoints.
2. Use ENTER_PHASE_IN_REGION. Specify whether the phase is to be `Active` or `Inactive`.
3. For an inactive phase, specify the following:
   - Enter the name of the region and the side of that region which the phase is attached to.
   - Enter the required driving force (evaluated as DGM (where DGM is the POLY variable for the driving force that is already divided by RT), and it is dimensionless (phase) in POLY-3) to be used for determining whether an inactive phase is stable.
   - Enter the `CONDITION TYPE` that the phase boundary condition should be set to if the inactive phase becomes stable. (Inactive phases are only considered in the simulation calculations once it is stable.)
4. For an active phase specify the following:
   - `REGION NAME` for the region in which the phase is to be entered.
   - `PHASE TYPE`: `Matrix`, `Lamellar` or `Spheroid`. `SPHEROID` is only available if a `MATRIX` phase is created first. You can only enter one matrix phase in each region.

- Enter the `PHASE NAME`. You can append a hash sign (`#`) and a digit at the end of the phase name to designate the composition set number (e.g. `FCC#2`). If you do not append this and the phase has more than one composition set, then you are prompted to specify a composition set number.

Learn More

About Phases

Specifying Phase Compositions in a Region

This section or topic is specific to Console Mode.

When you specify the composition of a phase, you do this by specifying the composition of the phase within its region—a composition profile.

Steps to Specify Phase Compositions in a Region

1. Complete Defining a System in Console Mode, Creating Regions and Gridpoints and Entering Phases in Regions.
2. Use ENTER_COMPOSITIONS to enter a composition of a phase in a certain region.
3. Enter the `Region name` of the region in which the phase has previously been entered.
4. Enter the `Phase name` of the phase whose composition you want to specify.
5. If the phase is spheroid, then for `Use equilibrium value` enter `Y` to automatically calculate the equilibrium fractions of the phase and its constitution at the start of the simulation. Specify the initial `Volume fraction of` the spheroid phase.
6. Enter the `Dependent component`. Sometimes the dependent component is automatically set and there is no prompt.
7. Enter a `Composition type` for the constitution of the phase. The options are: SITE_FRACTION, MOLE_FRACTION, MOLE_PERCENT, WEIGHT_FRACTION, WEIGHT_PERCENT, and U_FRACTION.
8. Enter the `Type` of composition profile (that is, the type of composition profile). The options are:

- `Linear` to have an equally spaced composition distribution. Specify the composition at the first (leftmost) grid point (`Value of first point`) and at the last (rightmost) grid point (`Value of last point`).
- `Read_point_by_point` to read the composition at each grid point. The specification of these can either be read from a DATA-file that you are prompted to select or entered directly at the terminal. If you want to enter them at the terminal, then enter `READ_POINT_BY_POINT` and press <Enter>.
- `Geometric` for a distribution that yields a higher concentration of the component at the lower end of the region if a geometrical factor larger than one is given and a higher concentration at the upper end of the region if the factor is smaller than one. You are prompted to specify the `Value of R in the geometrical series` which determines the distribution.

- `Function` for the global distance denoted ‘gd’. Useful functions include the error function (`erf(gd)`) and the heavy-side step function (`hs(gd)`). For example, the function `3+2hs(x-1e-4)` specifies a concentration of 3 at the region’s left side and 5 at the region’s right side, with a sharp step in the concentration profile at 1e-4m=100µm.

Specifying the Geometry

This section or topic is specific to Console Mode.

By default a DICTRA module system has a planar geometry. To change the geometry of the system, use ENTER_GEOMETRICAL_EXPONENT followed by a number `0` (planar), `1` (cylindrical) or `2` (spherical).

With a cylindrical or spherical geometry, the system's zero coordinate (left boundary) is at the centre of the cylinder or sphere. The highest coordinate (right boundary) is defined by the cylinder or sphere radius. If you want a geometry corresponding to a tube or a hollow sphere, then use SET_FIRST_INTERFACE to locate the system's left boundary at a coordinate that is greater than zero.

About Geometry and Coordinates

Setting Boundary Conditions

This section or topic is specific to Console Mode.

Boundary conditions are conditions that define how matter behaves at the boundaries of your system. By default, matter is not allowed to cross the system boundaries.

You can change the setting for both the lower boundary (left side/centre) and the upper boundary (right side/surface) of the system.

Steps to Set Boundary Conditions

1. Complete Defining a System in Console Mode and Creating Regions and Gridpoints.
2. Use SET_CONDITION and choose `Boundary`. Then specify whether you want to set the LOWER or the UPPER boundary.
3. Specify which condition type you want to set the boundary to.
4. Enter any parameter values that are necessary for the condition type you have chosen.
5. Specify the `LOW TIME LIMIT`, when the function you define starts to apply.
6. If required, enter the function that is applied during the time interval. For most condition types, the function may have time, temperature and pressure as arguments.
7. Enter the `HIGH TIME LIMIT` for the interval.
8. If you want to define a different function for another time interval, then enter `Y` when prompted with `ANY MORE RANGES`. Then enter another function for the next range.
9. When you have defined functions for all the ranges you want, enter `N` at the `ANY MORE RANGES` prompt.

Adding (Creating) Cells

This section or topic is specific to Console Mode.

If you add cells to a system, then each new cell is always placed next to the system's right outer boundary. Use the command CREATE_NEW_CELL.

Importing a Scheil Segregation Profile

You can import a previously calculated Scheil segregation profile into the Diffusion Module (DICTRA). A Scheil calculation is a conservative estimate of the segregation that occurs during solidification and is useful when estimating the necessary time/temperature for a homogenizing heat treatment.

From a practical point of view it is also a simple and fast calculation compared to a more accurate, but computationally more difficult, diffusion simulation.

In order to limit the computational effort, this feature cannot be combined with the fast diffusers option in the Scheil module.

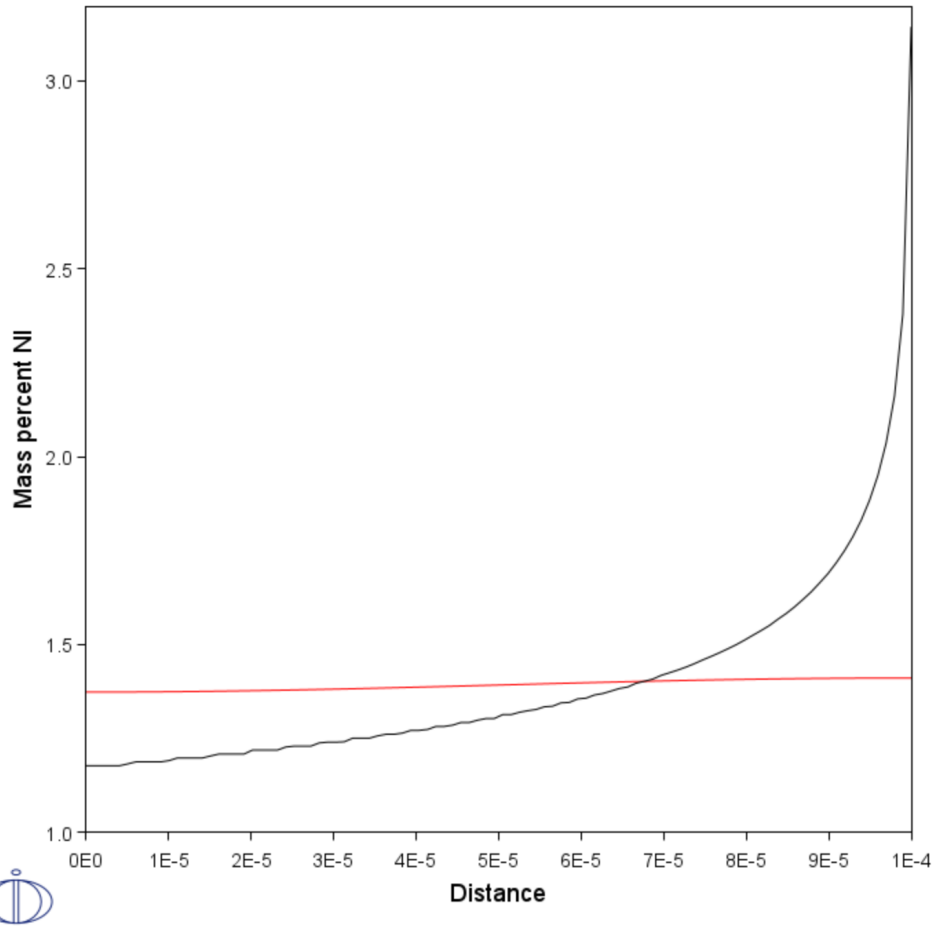
This is available in Graphical Mode using the **Homogenization** template. Also see Graphical Mode example *D_10_Fe _Homogenization_from_Scheil.tcu*.

Example exa7

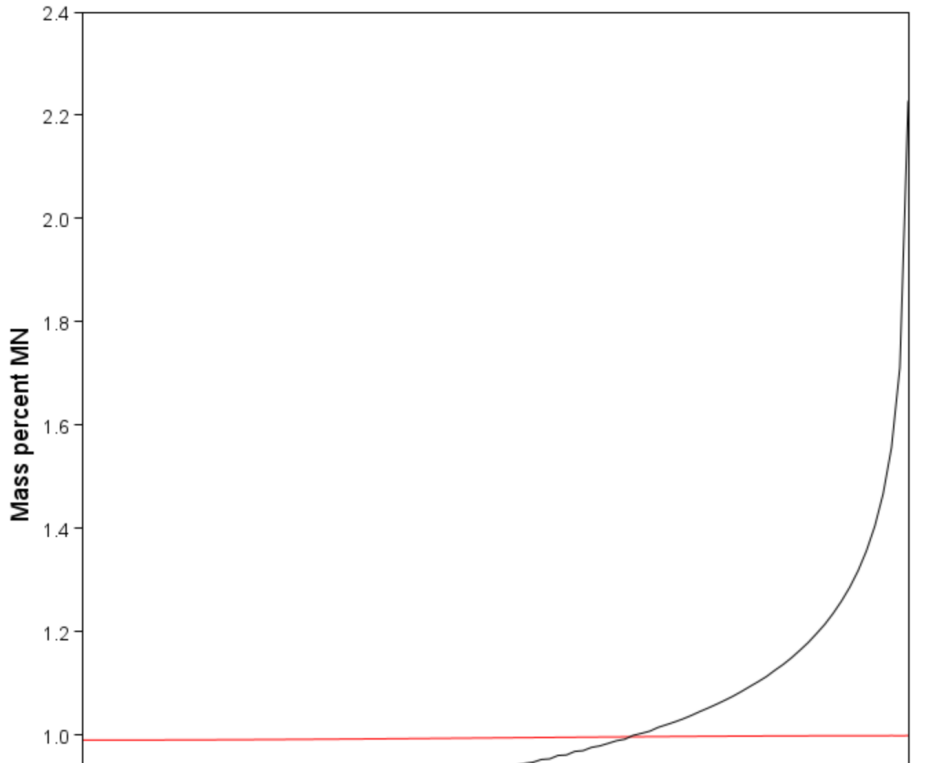
In the following example, taken from the Diffusion Module example collection (see About the Examples in the Thermo-Calc documentation), the Scheil segregation profile for a ferritic stainless steel (Fe-17Cr-1.4Ni-1Mn) was calculated in the Scheil module in Thermo-Calc.

The profile was then imported into the DICTRA module and a one hour homogenizing heat treatment at 1200° C was simulated. For the simulation a domain size of 100 µm was assumed, which approximately corresponds to the secondary dendrite arm spacing.

2021.11.27.10.23.44
Time = 0,3600
CELL #1



2021.11.27.10.16.48
Time = 0,3600
CELL #1



The plots show the initial (left) and final (right) Ni profile.

About the Homogenization Model

This section or topic is specific to Console Mode.

If you enter a spheroid phase when you configure your calculation, then the homogenization model is automatically used. This is useful when you want to simulate long-range diffusion through a multiphase mixture, under the assumption that local equilibrium holds at each node point.

You can also explicitly set the DICTRA module to use the HOMOGENIZATION_MODEL. This way, you can use it when calculating a one phase or a moving boundary simulation.

When the homogenization model is used, simulations are run using an implicit finite volume method to increase numerical stability. Because of this, and other factors, homogenization model simulations generally run slower than other comparable simulations. You can increase or decrease the `Degree of implicity when integrating PDEs` with the command SET_SIMULATION_CONDITION.

There are several special commands for use with this model.

If you have entered a spheroid phase in a region and want to use the older so-called dispersed system model, then you must explicitly disable the Homogenization Model after all phases have been entered.

- ADVANCED_HOMOGENIZATION_OPTIONS
- UTILITIES_HOMOGENIZATION
- SOLVE_IN_LATTICE_FIXED_FRAME
- DEPENDENT_ELEM_BALANCE_FLUXES
- BC_FOR_DEPENDENT_ELEMENT
- USE_TWO_TYPES_OF_BOUNDARY_CON

About the Disperse Model

This section or topic is specific to Console Mode.

This model can be used to calculate diffusion of a phase that is dispersed in a matrix phase. However, it is recommended that you use the HOMOGENIZATION_MODEL for this type of calculation instead.

There is no specific command to activate this model. It is only available if a phase of type "spheroid" is entered in a region.

The disperse model has the following limitations:

- There must be a continuous matrix phase otherwise the simulation breaks down.
- There is no implicit integration of the partial differential equations (PDEs), leading to a lower accuracy.
- Only diffusion in the matrix phase can be simulated. It is assumed that no diffusion occurs in the dispersed phase.

After a spheroid phase is entered, the homogenization model must explicitly be *inactivated* in order to run the simulation with the dispersed model. To do this, enter the command HOMOGENIZATION_MODEL and then choose N to make it inactive.

About the Para Equilibrium Model

The model allows you to calculate a moving phase boundary simulation while assuming that para-equilibrium conditions hold at the boundary. You must explicitly set the DICTRA module to use this model with the PARA_EQUILIBRIUM_MODEL command.

When this model is used, it implies that the local equilibrium assumption is no longer valid and that substitutional components are regarded as one composite component. You can only simulate a single moving boundary in one cell.

About the Thermomigration Model

This section or topic is specific to Console Mode.

The thermomigration model allows you to simulate thermally induced diffusion in temperature gradients. To use the model, you must set the temperature to depend on the spatial coordinate (x) in your calculation. In addition, you must also enter the heat of transport quantity (Q*) using the ENTER_HEAT_TRANSFER_PARAMETER command. You must enter this parameter separately for each element in each phase.

The model is automatically used once this is done.

See Console Mode example exh3.

About the Grain Boundary Model (GB_Model)

This section or topic is specific to Console Mode.

You must explicitly set the DICTRA module to use this model with GB_MODEL. This model allows you to simulate grain-boundary and dislocation-assisted diffusion.

The grain boundaries and the dislocations contribute to the total amount of diffusion according to the weighted fractions. The parameters are entered separately for each region in order to allow for different expression for different phases.

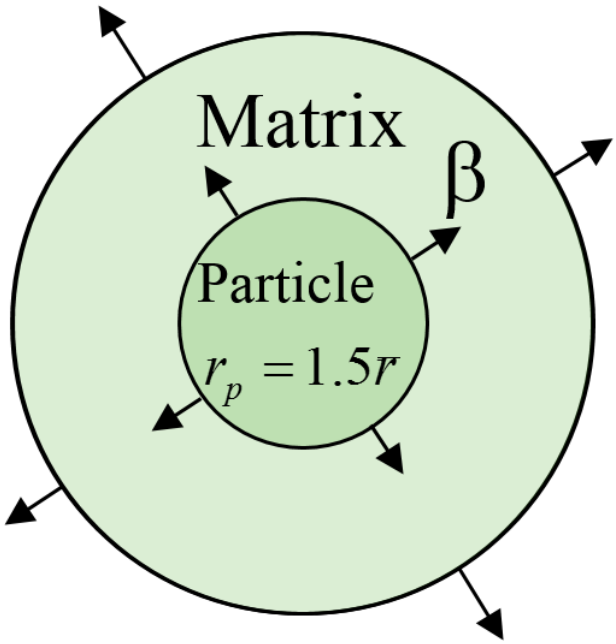
See the *TCNI Examples Collection* for an example using this model.

Coarsening Processes

This type of simulation is available for Console Mode. See About the Coarsening Model for more information.

You can run a simulation of a coarsening process. In accordance with Lifshitz-Slyozov-Wagner theory, this is done by assuming that the coarsening can be simulated by calculating the growth of a single particle of the maximum size in the particle size distribution.

Simulate a coarsening process



About the Coarsening Model

This section or topic is specific to Console Mode.

The model is based on LSW theory (after Lifshitz and Slyozov [1961Lif] and Wagner [1967Wag]. The model is also described in Gustafson, Höglund, and Ågren [1998Gus] and Björklund, Donaghey, and Hillert [1972Bjo].

LSW theory is strictly only valid for low volume fractions of the particle phase. The theory predicts that the normalized particle size distribution obtains a constant shape where the largest particles have a radius equal to 1.5 times the average particle radius.

The calculations are performed in one cell on a maximum size particle which thus is assumed to be 1.5 times the size of the average particle size. The matrix phase is on one side in contact with the maximum size particle and on the other the matrix phase is in local equilibrium with an average sized particle. The effect of the surface energy is such that both the maximum size particle as well as the matrix phase grows.

The model allows you to perform coarsening simulations. You must explicitly set the DICTRA module to use this model with the command COARSENING_MODEL.

To use this mode, configure the calculation as follows:

- Have one cell only, with a single particle that is 1.5 times larger than the average particle size.
- The matrix phase should be in contact with the maximum size particle on the left/lower side, and then the model specifies a local equilibrium with an average sized particle on the right/upper side.
- The surface energy then results in growth of both the maximum size particle and the matrix phase. Use the SET_SURFACE_TENSION command to enter the surface energy to enable coarsening.

About the Pearlite Model

This section or topic is specific to Console Mode.

The pearlite model is automatically used if there is lamellar phase in a region.

About Cooperative Growth

This section or topic is specific to Console Mode.

You can simulate the growth of pearlite in alloyed steels by calculating the Eutectoid reaction γ→α+β, where α and β grow cooperatively as a lamellar aggregate into the γ matrix.

About Using Volume in the Diffusion Module (DICTRA)

This section or topic is specific to Console Mode.

The following is applicable to the use of the classic models in the Diffusion Module (DICTRA). That is, all models *except* the homogenization model.

DICTRA uses a simplified treatment of volume, i.e. DICTRA does not use volume data from the thermodynamic databases. This implementation in the original software development was because most databases did not contain volume data at that time.

The basic rule to use when applying the classic model is that only substitutional phase constituents contribute to volume and the partial molar volume of such constituents are assumed to be constant and equal. The partial molar volume of interstitial phase constituents are assumed to be zero. The actual value used as partial molar volume of substitutional phase constituents is 10-5 [m^3/mol] and this is entered in databases as a constant `VS`.

The databases contain definitions of *zero volume species* and these species can then be interstitial phase constituents. Typically, C, N and O are entered as zero volume species.

There is, however, a rule that supersedes the basic rule, that is, for a phase that consists of a single sublattice, such as graphite, all constituents are considered to be substitutional. Another case is the liquid, which in most databases is described with a single sublattice. In such a liquid all constituents are then considered to be substitutional.

Thus, a given species can be interstitial in one phase but substitutional in another.

For the homogenization model the treatment of volume is, unfortunately, but for good reason, slightly different. The homogenization model only considers the elements of the system and regards each element as being either substitutional or interstitial. This status is the same in all phases. For many cases this treatment yields the same result as the rules for the classic model described above. However, it does not work for graphite, which has zero volume.

Plotting Simulations in the POST Module

You can plot or tabulate the results of your simulation in the POST_PROCESSOR module, also called the POST module and accessed within the DICTRA module. The resulting diagram is on a plot tab in the Console Results window. Once the simulation results are plotted, you can then change its appearance in the Plot Properties window.

Purpose and Methodology **2240**

Plot Condition and Independent Variable **2241**

Legal Plot Conditions *2241*

Legal Independent Variables *2241*

Plotting Simulation Results **2242**

Editing the Plot Properties **2244**

Tabulating Simulation Results **2245**

Purpose and Methodology

The purpose of the POST PROCESSOR is to read and process data from the internal data structure of the DICTRA module in order to present the result of a simulation in either* GRAPHICAL (command PLOT_DIAGRAM) or* TABULAR FORM (command MAKE_EXPERIMENTAL_DATAFILE).

Before plotting/printing, you have to specify what variables should be plotted on the diagram axis or printed in the table columns. For this purpose there is a command SET_DIAGRAM_AXIS. After having SET both X- and Y-axis variables, you have to SET also plot condition and independent variable. It is also possible to specify a Z-axis. Its values appear as tick marks on the XY-curve.

Plot Condition and Independent Variable

There are two free variables after a simulation is done by the DICTRA module. One is the simulation TIME and the other is a DISTANCE in the system.

In general, when plotting a diagram you MUST set either type as fixed, i.e. the *plot condition*, use command SET_PLOT_CONDITION. The plot condition chosen is printed on a separate line above the diagram.

The other variable is then the independent variable, use command SET_INDEPENDENT_VARIABLE. The independent variable is used as stepping variable. It varies along the calculated curve.

Legal Plot Conditions

- `TIME`: Integration time
- `DISTANCE`: Distance in the system. It can be a GLOBAL distance counted from the rightmost interface of the system. A LOCAL distance is counted from the LOWER interface of the specific region prompted for.
- `INTERFACE`: At a certain interface. An interface is identified by the NAME of the adjacent region, with the addition that you will be prompted to specify if the interface is at the upper or lower end of the region.
- `INTEGRAL`: Is automatically SET when using an INTEGRAL VARIABLE as axis variable.
- `TIE_LINE`: At a certain interface. Allows you to plot a certain quantity from both sides of an interface. The typical application is for plotting tie-lines.

Legal Independent Variables

- `TIME`: Integration time. Is automatically SET when using an INTEGRAL VARIABLE' or TIME as axis variable.
- `DISTANCE`: Space coordinate. It may be GLOBAL. It is then counted from the rightmost interface of the system. Alternatively, it may be LOCAL. The distance is then counted from the LOWER interface of the specific region prompted for.

Plotting Simulation Results

Saving and Printing the Output in Console Mode

Plotting a diagram is to graphically represent how a dependent variable varies with an independent variable. The independent variable is either distance or time.

1. Complete all the steps to run your simulation.
2. At the `DIC` prompt type `POST_PROCESSOR` (or just `POST`).
3. Use SET_DIAGRAM_AXIS to specify the variables to plot on the X- and Y-axes of the diagram. One of the axes must be set to either TIME or DISTANCE.

   For example, to set the X-axis to plot the distance from the lower boundary of the calculation (rather than from the lower boundary of the current region) and the Y-axis to plot the weight-percent composition of the Si element, at the `POST` prompt type:

   ```
   SET_DIAGRAM_AXIS X DISTANCE GLOBAL
   SET_DIAGRAM AXIS Y WEIGHT-PERCENT SI
   ```

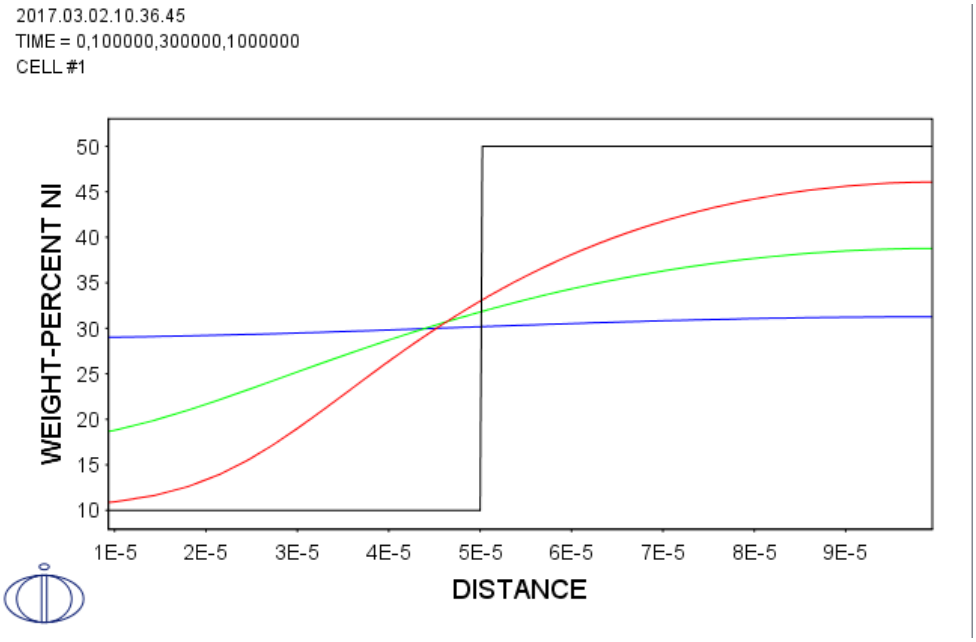
4. You can specify a Z-axis, which is represented as tick marks on the curve in the XY-plane.
5. When one of the axes is set to TIME or DISTANCE, the variable automatically becomes the independent variable. If you do not want the independent variable plotted along an axis, use SET_INDEPENDENT_VARIABLE and set it to `Time` or `Distance`.
6. Simulation calculations depend on both time and a spatial coordinate; these variables must be fixed during the plotting process. Use SET_PLOT_CONDITION to set the variable to keep fixed. These variables can be set as the fixed plot condition:
   - `Time`: The integration time. More than one value can be entered using commas or spaces to separate the values. One graph is plotted for each value.
   - `Distance`: The distance in the system (from the lower boundary).
   - `Interface`: At the location of a certain interface between two phases.
   - `Intergral`: The value of the plot condition is integrated over the phase, region or system volume.

7. Use PLOT_DIAGRAM to plot the results. The plot is added as a tab to the **Console Results** window.

The plot example below is from example exa2a, which is part of the Diffusion Module example collection (see About the Examples in the Thermo-Calc documentation). Distance is set as the independent variable and the weight-percent of Ni is on the Y-axis. The plot condition is `TIME`: the plot shows four graphs, each with the spatial distribution of Ni in the region at the time steps 0, 1e5, 3e5, and 10e5.

8. To print the plotted graphs direct to a postscript-file, type `Plot` and a file name.
9. In the **Plot** window, right click the diagram and choose **Properties** to adjust its appearance and colors.

Editing the Plot Properties.



Editing the Plot Properties

To change the appearance of a plotted diagram, right click the diagram and select **Properties**. In the **Plot Properties** window you can change the fonts and colours, and add a title, for example.

You can also change the colour, stroke (solid/dashed/dotted/dash_dot) and line width of a particular series of lines in the plot by double-clicking one of the lines in the series. In this way, you can also toggle whether data points should be shown or not for a series of lines. The crosshair cursor turns into a cursor resembling a pointing hand when it is placed over a line that can be clicked but if you hold down the <Ctrl> key, this does not happen (the cursor continues to be shown as a crosshair).

To configure the default settings for plotting, go to the **Options** window and on the Console Mode tab click the **Plotting** node in the tree.

Tabulating Simulation Results

1. Complete all the steps to run your simulation.
2. At the DIC prompt type `POST_PROCESSOR` (or just `POST`).
3. Use ENTER_SYMBOL `Table` to specify the variables to be shown in the table columns. Separate the variables by commas (,).
4. Use SET_INDEPENDENT_VARIABLE to specify the variable that the rows in the table should represent.
5. Use TABULATE to generate the table.

Troubleshooting

These topics contain general advice to consider in order to avoid having your simulation fail to converge when you calculate different kinds of simulations in the Diffusion Module (DICTRA).

Cooperative Growth **2253**

Tips for a Successful Diffusion Simulation

The following tips are useful to help you fine-tune the design of your simulation.

Simplify Your Simulation

For example, if you have an alloy with five or six elements, first run a simulation with only the main elements. When this simulation works, you can then add more elements as necessary.

Start with a Low Accuracy and Refine It

If you start with a high accuracy setting, then computing the simulation takes much longer, and problems are more likely. Check the profiles and the overall mass balance, and if the accuracy is insufficient then you can improve the accuracy values.

To change the accuracy:

In Console Mode use SET_ACCURACY and increase or decrease `Max relative error` and `Max absolute error`.

In Graphical Mode the setting is on the Diffusion Calculator in the section *Time step control*.

Modify the Grid or Time Step

If you get large fluctuations in the composition or phase boundary profiles, then you can try modifying the grid or the time step of the simulation. You can increase the time step by lowering the accuracy if automatic time step control is used (the default).

If you increase the tolerated relative and/or absolute error then the automatic time step control increases the time step.

In Console Mode use the SET_ACCURACY command.

In Graphical Mode the setting is on the Diffusion Calculator in the section *Time step control*.

Integrate the PDEs

The composition or phase boundary profiles can often also be improved if the partial differential equations (PDEs) are integrated fully implicitly (i.e. Euler backward).

To integrate the PDEs in this way:

In Console Mode use SET_SIMULATION_CONDITION to set the parameter `Degree of Implicity when Integrating PDEs` to a value of `1`.

In Graphical Mode, the setting is on the Diffusion Calculator on the **Options** tab. Under *Simulation Conditions*, you can try a different **Time integration method**. The default method is Trapezoidal, which is equivalent to a 0.5 numerical setting in Console Mode. If you choose Euler backward, this is equivalent to a 1.0 numerical setting in Console Mode.

Debug (Console Mode)

If your Console Mode simulation fails to converge, then debugging may give you some clues about the source of the failure. To receive more detailed information about what is happening during the simulation use the command DEBUGGING.

Moving Boundary Simulations

Moving Boundary Examples

Grid Distribution

Check the grid distribution at the interfaces. If the grid is too coarse or too fine-grained then the fluxes may not be defined well.

Use Activities Instead of Potentials

Use activities instead of potentials when the content of one or more of the elements becomes very low. If you do this, then the activity approaches zero, which is easier to handle than a potential that approaches infinity.

In Console Mode, use SET_SIMULATION_CONDITION to set the parameter `Vary potentials or activities` to `Activities`.

In Graphical Mode the setting is on the Diffusion Calculator in the section *Classic model specific*. From the list, choose **activity** [**Use the activity of a component in order to find the correct tieline at the phase interface**].

Starting Values

Use the automatic starting values when you run the simulation the first time. If the first time step does not converge try decreasing the starting values for the velocities. Alternatively, increase the duration of the first time step.

If the simulation fails during the first time step, then check how the starting values affect the residuals.

In Console Mode, use the command SET_SIMULATION_CONDITION and set the parameter `NS01A PRINT CONTROL` to `1`.

When you adjust this setting, the software then prints the tried unknown value and the residual for each flux balance equation in each iteration. The equations are organized so that

the first unknown value is always the migration rate of the phase interfaces followed by the unknown potentials. All unknown values are scaled by the starting value or the calculated value in the previous time step.

Cell Calculations

This section or topic is specific to Console Mode.

In cell calculations, determine start values for each cell separately and thereafter connect the individual cells. You can even start out simulating in planar and/or cylindrical geometry in order to determine sufficient starting values if you want to use a spherical geometry.

Cell Calculation Examples

Diffusion in Dispersed Systems

This section or topic is specific to Console Mode.

If you simulate diffusion in a dispersed system and the homogenization model is turned off, then time integration is explicit. The maximum time step allowed, or the highest time step actually taken in the calculation, affects the final result of the simulation. This effect is most evident if one or more of the diffusing species have low solubility in the matrix phase. When this is the case, a supersaturation is created in the matrix phase during a diffusion step and if too large a time step is allowed, then too much supersaturation is created. Consequently, always check your results by performing a second simulation with a maximum time step that is ten times lower than in the first run. If there is large difference in results between the first and the second run, then decrease the time step again with a factor of ten and perform a third run. Repeat this process until the results can be trusted.

If a simulation fails because the program is not able to calculate an equilibrium, then try to calculate the initial equilibrium yourself using Thermo-Calc and enter the composition and fraction of each phase separately instead of having the DICTRA module calculate it. Also enter starting values for each phase with the command SET_ALL_START_VALUES. Alternatively, you may force the software to use certain start values using SET_SIMULATION_CONDITION.

Diffusion in Dispersed Systems Examples

Cooperative Growth

This section or topic is specific to Console Mode.

If your simulation fails to converge, try calculating the A1e temperature with Thermo-Calc and start your simulation at a temperature slightly below that temperature. Use the equations given in the interactive help in order to estimate S0 and the growth rate.

State Variables in Console Mode DICTRA

Also see SET_DIAGRAM_AXIS and ENTER_SYMBOL in the DICTRA POST module.

State variables in the DICTRA POST module are similar to those defined in Thermo-Calc POLY-3 module. Examples of state variables are temperature, mole fraction, enthalpy, etc. In POLY-3 a general notation method based on character mnemonics is designed for a predefined set of state variables.

The numerical values of some state variables, e.g. activity, chemical potential, and the energetic extensive properties, are given relative to some reference state which has been defined in the thermodynamic database file. Sometimes you may have specified a reference state using SET_REFERENCE_STATE. To get numerical values relative to the user-defined reference state, append an R to the mnemonic names as defined.

For all extensive properties a suffix can be added to the mnemonic name to indicate a normalized extensive property. The extensive properties tables describe each mnemonic.

Intensive Properties

Mnemonic	Description
T	temperature
P	pressure
AC(component)	activity
MU(component)	chemical potential

Extensive Property `Z at Each Grid Point

Mnemonic	Description
Z	Extensive property `Z at each grid point.
ZM	Extensive property `Z per moles of atoms.
ZW	Extensive property `Z per mass (gram).
ZV	Extensive property `Z per volume (m^3).

Extensive Property `Z for a Phase at Each Grid Point

Mnemonic	Description
Z	Extensive property `Z for the current amount of the phase.
ZM	Extensive property `Z per mole of atoms of the phase.
ZW	Extensive property `Z per mass (gram) of the phase.
ZV	Extensive property `Z per volume (m^3) of the phase.
ZF	Extensive property `Z per mole formula unit of the phase.

Energetic Extensive Properties

Suffixes M, W, V and F can be applied.

Mnemonic	Description
S	entropy
S(phase)	entropy of a phase
V	volume
V(phase)	volume of a phase
G	Gibbs energy
G(phase)	Gibbs energy of a phase
H	enthalpy
H(phase)	enthalpy of a phase
A	Helmholtz energy
A(phase)	Helmholtz energy of a phase

Extensive Property: Amount of Components

Suffixes M, W and V can be applied.

Mnemonic	Description
N(component)	Number of moles of a component.
N(phase,component)	Number of moles of a component in a phase.
B(component)	Mass of a component.
B(phase,component)	Mass of a component in a phase.

Extensive Property Total Amount

Suffixes M, W and V can be applied.

Mnemonic	Description
N	Number of moles
B	Mass The legal combination BW is not very interesting as it will always be unity. BV is the density

Extensive Property: Amount of a Phase

Suffixes M, W and V can be applied.

The normalizing properties are calculated at each grid point.

Mnemonic	Description
NP(phase)	Number of moles of a phase.
BP(phase)	Mass of a phase.
VP(phase)	Volume of a phase.
Y(phase,species#sublattice)	site fraction

Mnemonic	Description
	This quantity is dependent upon the model chosen for the phase.

Extensive Property: Constitution

This quantity is dependent upon the model chosen for the phase.

Mnemonic	Description
Y(phase,species#sublattice)	site fraction

Integral Variables

An integral variable is a quantity that has been obtained by integration in space over the whole system or over a specific region. In a planar geometry values are given per unit area, in a cylindrical geometry they are given per unit length, and in a spherical geometry they are absolute values.

SET_DIAGRAM_AXIS and ENTER_SYMBOL commands in the DICTRA POST module.

The variable mnemonics are constructed in the following way.

- The first letter is always I for INTEGRAL VARIABLE.
- The second letter specifies quantity.
- The third letter is OPTIONAL and specifies the normalizing quantity.

First and Second Letter

Class	Quantity	Description
I	N	for number of moles
I	W	for mass
I	V	for volume
I	U	for number of moles of volume-contributing elements
II	S	for entropy
II	H	for enthalpy
II	G	for Gibbs energy
II	A	for Helmholtz energy

Class I

Integral quantities of CLASS=I may take 0-3 arguments.

The arguments MUST be given in 'falling' order of significance.

1. Region name
2. Phase name
3. Component name

Class II

Integral quantities of CLASS=II may take 0-2 arguments.

The arguments MUST be given in 'falling' order of significance.

1. Region name
2. Phase name

Third Letter - Normalizing Quantity

Quantity	Description
N	for total number of moles in system
W	for total mass of system
V	for total volume of system
U	for total number of moles of volume-contributing elements in system

Examples

Variable	Definition
`IW(PEARLITE,BCC,CR)`	The mass of CR in the BCC phase in region PEARLITE.
`IW(PEARLITE,BCC)`	The mass of BCC phase in region PEARLITE. IW is the total mass in the system.
`IVV(Austenite)`	The volume fraction of Austenite in a single cell calculation.

Variable	Definition
`IVV(2, Austenite)`	The volume fraction of Austenite in Cell 2 for a multi cell calculation.

Auxiliary Variables

The following table lists auxiliary variables that are associated with both names and mnemonics.

SET_DIAGRAM_AXIS and ENTER_SYMBOL in the DICTRA POST module.

Interface names are the same as the region names with the addition that you also have to specify if the interface is at the U(pper) or L(ower) end of the regions.

Name and Mnemonic Auxiliary Variables

Name	*Mnemonic*	*Argument*
ACTIVITY	AC(component)	component
DISTANCE		
FLUX	JV(component)	component
LAMELLAR-SPACING	LS(name)	region name
LAMELLAR-THICKNESS	LT(name)	phase name
MOLE-FRACTION	X(component)	component
MOLE-PERCENT		component
POSITION-OF-INTERFACE	POI(name,U/L)up*)	interface name
TEMPERATURE-KELVIN	T	
TEMPERATURE-CELSIUS	-	
U-FRACTION	UF(component)	component
VELOCITY-OF-INTERFACE	VOI(name,U/L)up*)	interface name
WEIGHT-FRACTION	W(component)	component

Name	*Mnemonic*	*Argument*
WEIGHT-PERCENT		component

Mnemonic Auxiliary Variables

There are also auxiliary variables that are only associated with a mnemonic.

Mnemonic	Description
GD	global distance
LD	local distance
M(phase,J)	mobility coefficient where J=diffusing species
LOGM(phase,J)	^{10}log of the mobility coefficient
DT(phase,J)	tracer diffusion coefficient where J=diffusing species
LOGDT(phase,J)	10log of the tracer diffusion coefficient
DC(phase,J,K,N)	chemical diffusion coefficient where K=gradient species, and N=reference species
LOGDC(phase,J,K,N)	^{10}log of chemical diffusion coefficient
DI(phase,J,K,N)	intrinsic diffusion coefficient
LOGDI(phase,J,K,N)	^{10}log of intrinsic diffusion coefficient
JV(phase and/or species)	flux in volume fixed frame of reference
JL(phase and/or species)	flux in lattice fixed frame of reference
QC(phase,J,K,N)	Q=R(ln (DC{T1}) - ln (DC{ T1+e}))/(1/(T1+e) - 1/ T1)
QT(phase,J)	Q=R(ln (DT{T1}) - ln (DT{T1+e}))/(1/(T1+e) - 1/ T1)

Mnemonic	Description
QI(phase,J,K,N)	Q=R(ln (DI{T1}) - ln (DI{T1+e}))/(1/(T1+e) - 1/T1)
FC(phase,J,K,N)	D0=exp(ln (DC{T1})+Q/R/ T1)
FT(phase,J)	D0=exp(ln (DT{T1})+Q/R/T1)
FI(phase,J,K,N)	D0=exp(ln (DI{T1})+Q/R/T1)

DICTRA Console Mode Examples

To learn more about how to use the add-on software you can open and run the example files. These macro files (with the extension *.DCM) include comments, which you can either run in the Thermo-Calc program or open and read in a text editor.

If you read the macro file in a text editor, you do not see the output that Thermo-Calc gives in response to the commands stored in the macro file.

All the DICTRA Console Mode macro files and the outputs are also combined into one file that you can search and read. This is available as a PDF on our website. For the current version of the PDF, navigate to *Current Documentation > Examples > Diffusion Module (DICTRA) Console Mode*. A direct link to the PDF is here. The PDF is also found in the Archive and saved by release version.

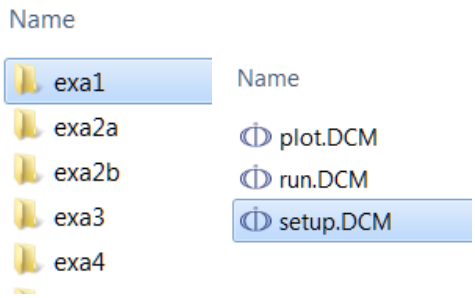
Opening the Setup, Run, and Plot Macro Files

For the main set of examples (this is different for the Quick Start examples), there are three macro files: a **setup**, **run** and a **plot**. You must run these macros in order.



To begin, double-click the **setup.DCM** file to open it. It launches a new session of Thermo-Calc and opens in Console Mode.

All the DICTRA Console Mode macro files and the outputs are also combined into one file that you can search and read. This is available as a PDF on our website. For the current version of the PDF, navigate to *Current Documentation > Examples > Diffusion Module (DICTRA) Console Mode*. A direct link to the PDF is here. The PDF is also found in the Archive and saved by release version.

Quick Start Guide Examples

These examples are used in the *Diffusion Module Quick Start Guide (Console Mode)*. It is recommended you review this guide before going to the additional examples.

File Name	Description
simplest_dictra.dcm	Simple homogenization of a binary Fe-Ni alloy. Initially it is assumed to have a linear Ni-concentration profile.
simple_moving_ boundary.dcm	Calculating a ferrite(bcc)/austenite(fcc) transformation in a binary Fe-C alloy
multiphase_ example.dcm	Shows the use of the homogenization model for multiphase simulations. It is taken from [2006Lar]. Experimental data is from [1995Eng].

References

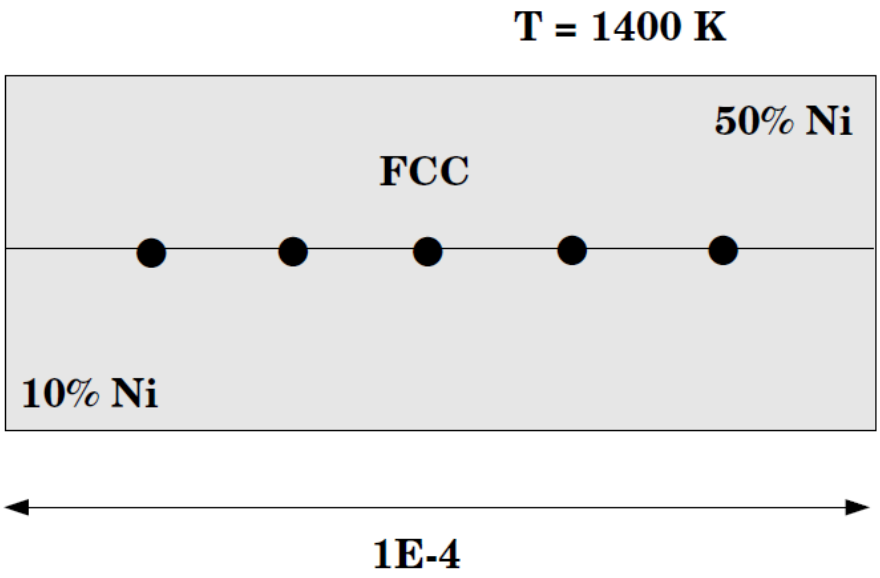
One Phase Examples

Example exa1

Homogenization of a binary Fe-Ni alloy: Linear concentration profile

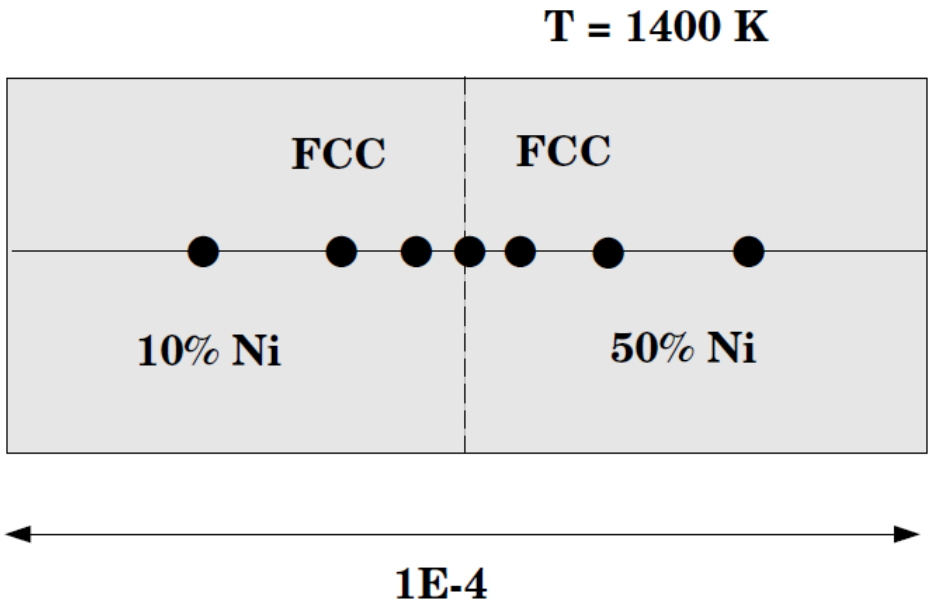
Simple homogenization of a binary Fe-Ni alloy. It is assumed there is initially a linear Ni-concentration profile.



Example exa2a and exa2b

Homogenization of a binary Fe-Ni alloy

- Example exa2a **Step Profile:** Simple homogenization of a binary Fe-Ni alloy. A Ni rich and a Ni lean alloy are put together and initially there is a step profile.
- Example exa2b **Time Integration:** This example is identical to a2a but instead it uses implicit time integration instead of the trapezoidal method for solving the PDEs.



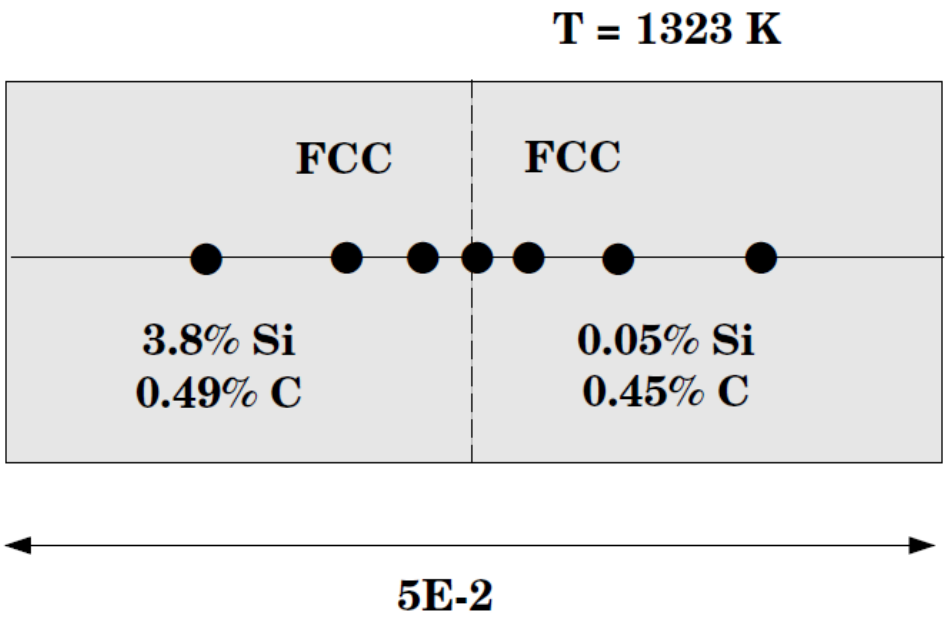
Example exa3

Uphill diffusion in an Fe-Si-C alloy

This is an example to simulate uphill diffusion in a ternary single phase austenite matrix due to the classical Darken experiment published by Darken, 1949 [1949Dar].

In this example, two pieces of austenite (3.80 wt%Si, 0.49 wt%C) and (0.05 wt%Si, 0.45 wt%C) are put together and are subsequently annealed at 1050 C for 13 days. As both pieces are austenite they must be entered into the same region. This is done by individually giving the compositions of Si and C in each grid point. These data are then stored to file.

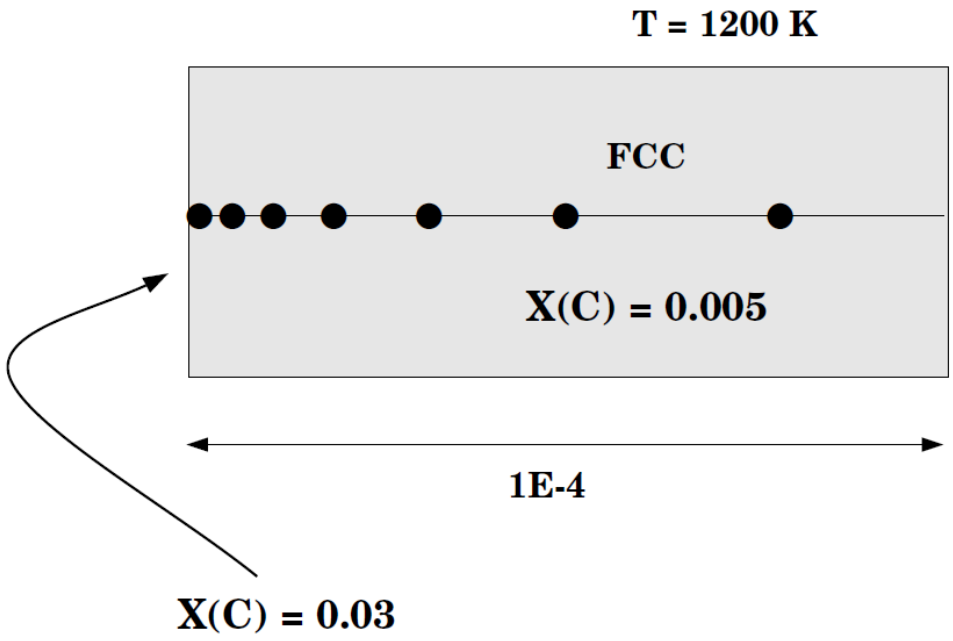
This example uses the TCFE and MOBFE databases. These licenses are required to run the example.



Example exa4

Carburization of binary Fe-C alloy: Comparison to an analytical erf solution

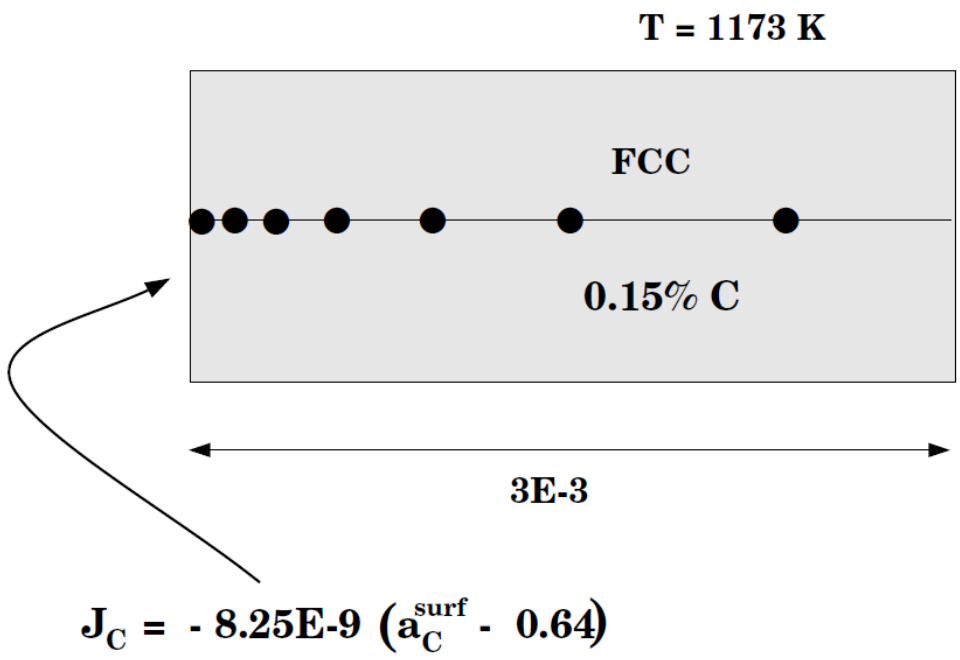
This is a simple binary simulation with one single phase region. The numerical simulation is compared with an analytical erf-solution. A special database is created (*erf.tdb*) where the diffusion coefficient is set to a concentration independent value.



Example exa5

Carburization of a binary Fe-0.15 wt% C alloy

A mixture of 40% N2 and 60% cracked methanol is used as carrier gas. The carburizing "carbon potential" in the gas is 0.85 wt% and a surface reaction controls the flux of C at the surface.

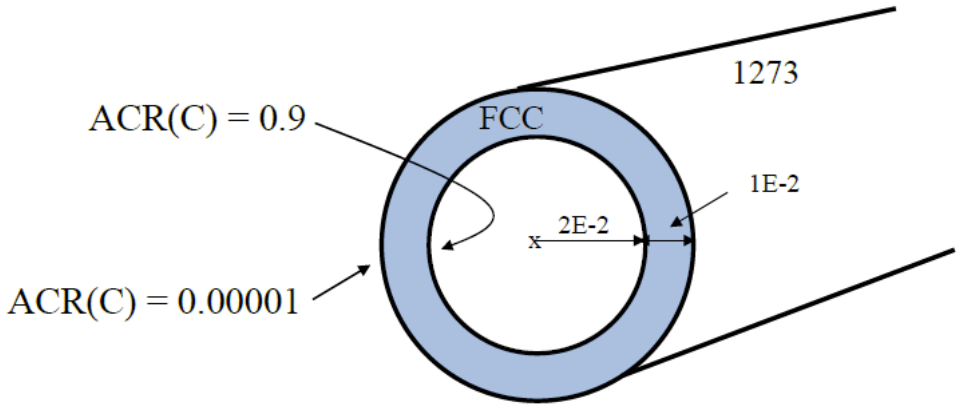


Example exa6

Diffusion through a tube wall

A simple example of diffusion through a tube wall. The tube material is an Fe-0.6%Mn-0.7%Si-0.05%C alloy. On the inside wall a carbon activity of 0.9 is maintained whereas on the outside the C-activity is very low. This example demonstrates the use of the command SET-FIRST-INTERFACE as well as the use of MIXED boundary conditions.

This example uses the TCFE and MOBFE databases. These licenses are required to run the example.



A modified version of this example is also available in Graphical Mode as example D_06. For Graphical Mode you do not need a Diffusion Module (DICTRA) license. You can open the example from Thermo-Calc when in Graphical Mode (**File → Examples Files → Diffusion Module**).

Example exa7

Homogenization heat treatment

The initial segregation profile is created from a Scheil calculation (see `macro create_initial_profile.TCM`). The command INPUT_SCHEIL_PROFILE in the DICTRA monitor performs most of the setup. Only time and temperature must be entered after the INPUT_SCHEIL_PROFILE command is executed.

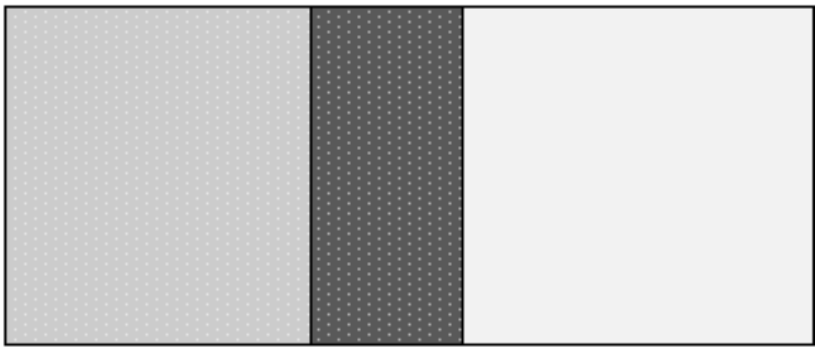
Moving Boundary Examples



Example exb1a

Austenite (γ) to ferrite (α) transformation in a binary Fe-C alloy

This example calculates a ferrite (BCC)/austenite (FCC) transformation in a binary Fe-C alloy. The initial state is an austenite of 2 mm thickness. The composition of the austenite is Fe-0.15wt%C. After austenitization the specimen is quenched down to 1050K. The system is assumed closed, so no boundary conditions are set (a closed system is the default). Ferrite is expected to grow into the austenite. For this reason you start with a thin region with ferrite adjacent to the austenite.

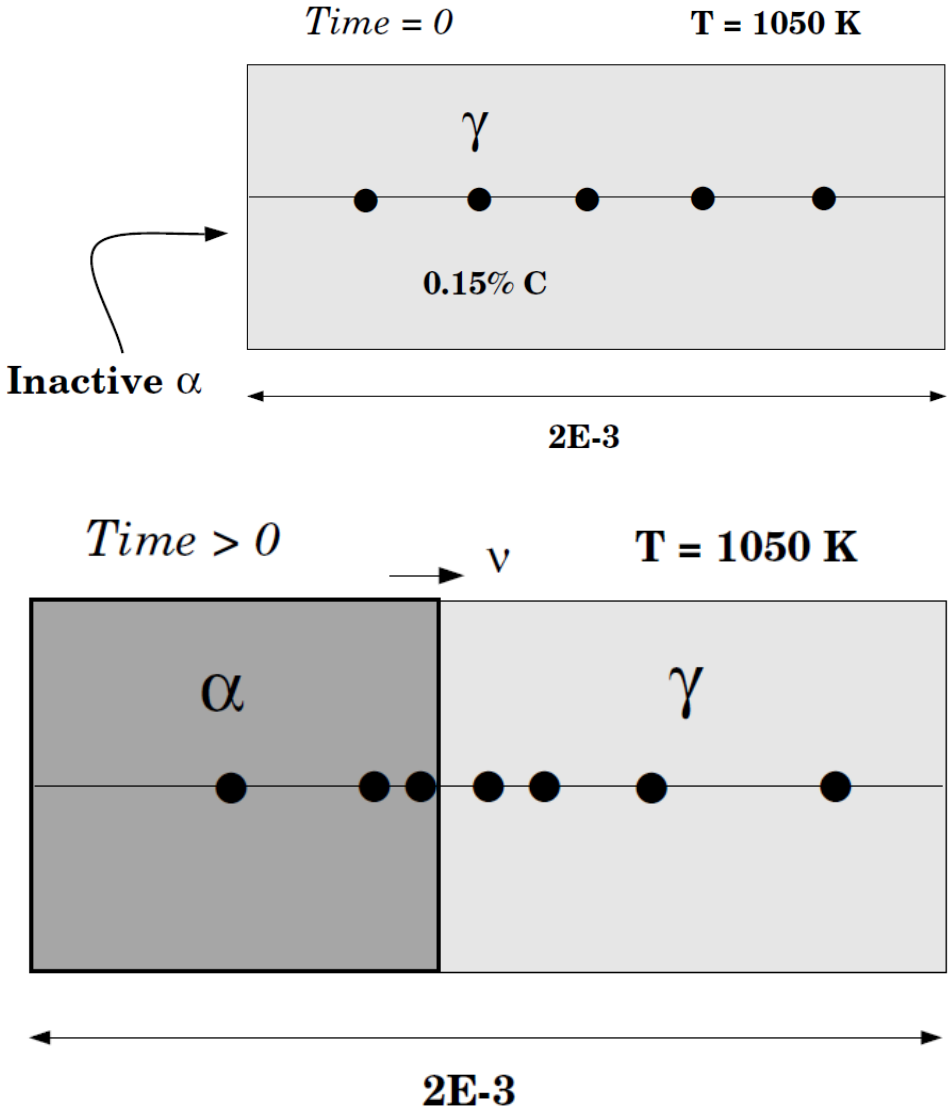
Example exb1b

Austenite (γ) to ferrite (α) transformation in a binary Fe-C alloy: Inactive α

This is the same example as in exb1a but now the problem is with ferrite as an inactive phase adjacent to the initial austenite.

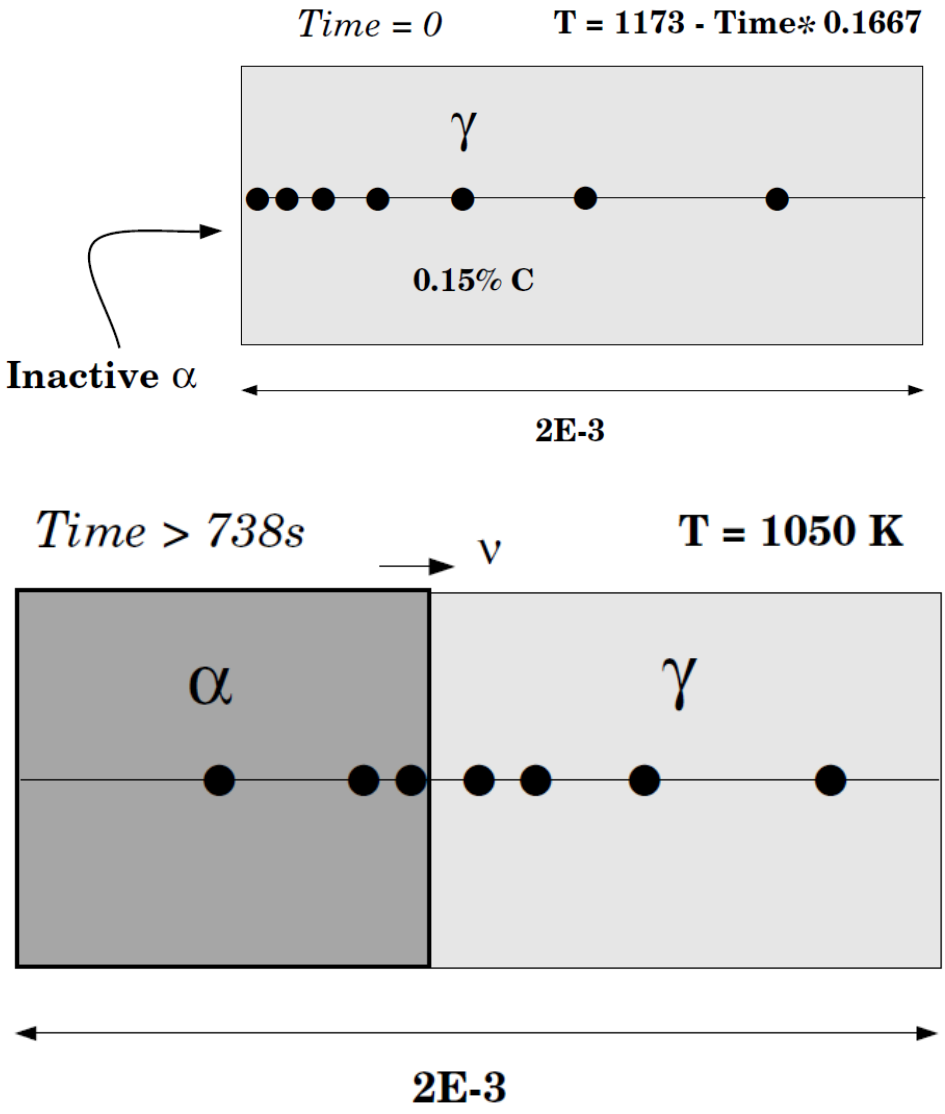


Example exb1c

Austenite (γ) to ferrite (α) transformation in a binary Fe-C alloy: Gradual cool down to 1050K

This is the same example as in exb1a and exb1b but now the simulation starts at a higher temperature and assumes a gradual cooling down to 1050 K.

When 1050 K is reached, the temperature is kept constant and thus has an isothermal transformation. As in exb1b, ferrite is in an inactive phase adjacent to the initial austenite.

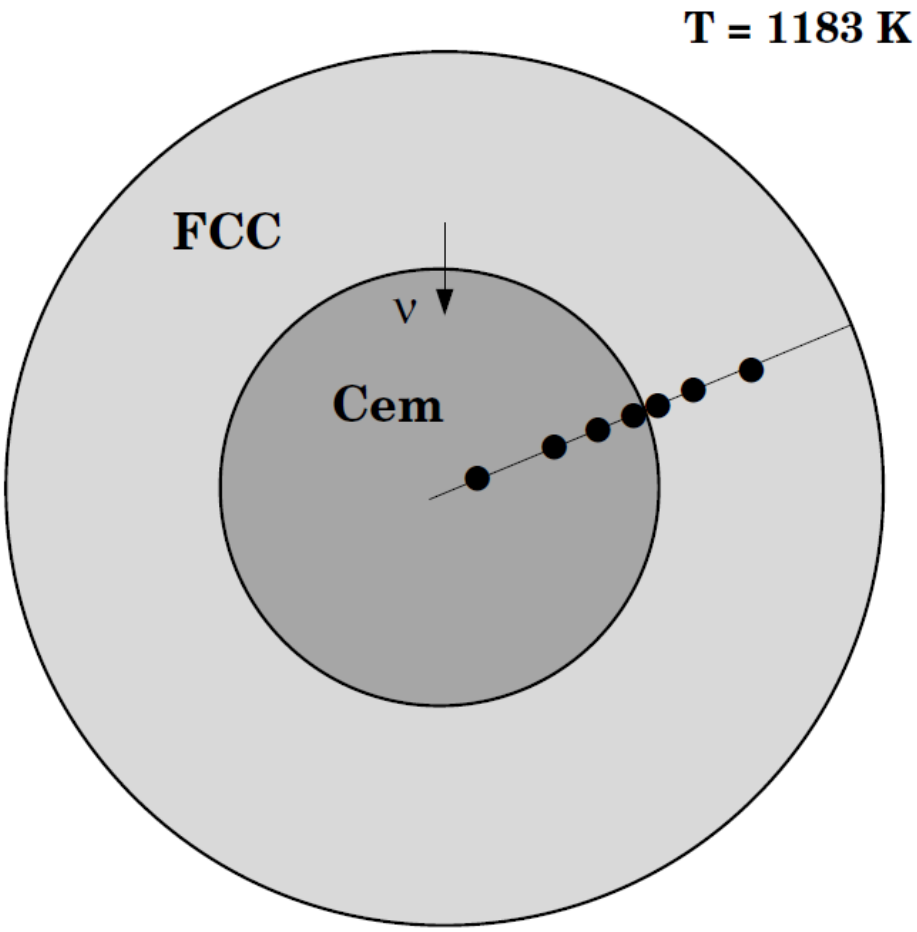


Example exb2

Cementite dissolution in an Fe-Cr-C alloy

This example calculates the dissolution of a spherical cementite particle in an austenite matrix. This case is from [1991Liu].

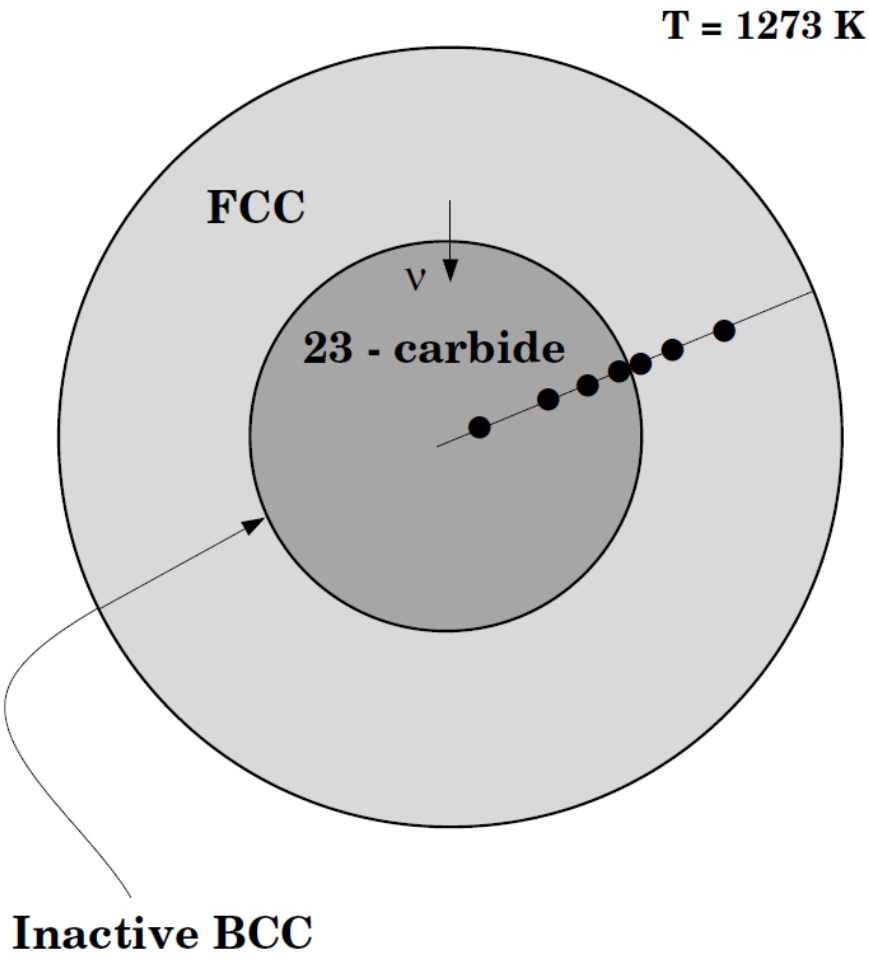
In order to achieve the correct average composition in the calculation it is necessary to take into account the fact that the calculation is set up using the volume fraction of the phases. To calculate the initial state at the heat treatment temperature we need first to determine the state at the normalizing temperature. To calculate the volume fraction of the phases we need to enter a number of functions that calculate these quantities.



Example exb3

Dissolution of 23-carbide in an austenitic matrix

This example calculates the dissolution of an M23C6 particle in an austenite matrix. A film of ferrite is allowed to nucleate around the carbide during the precipitation.

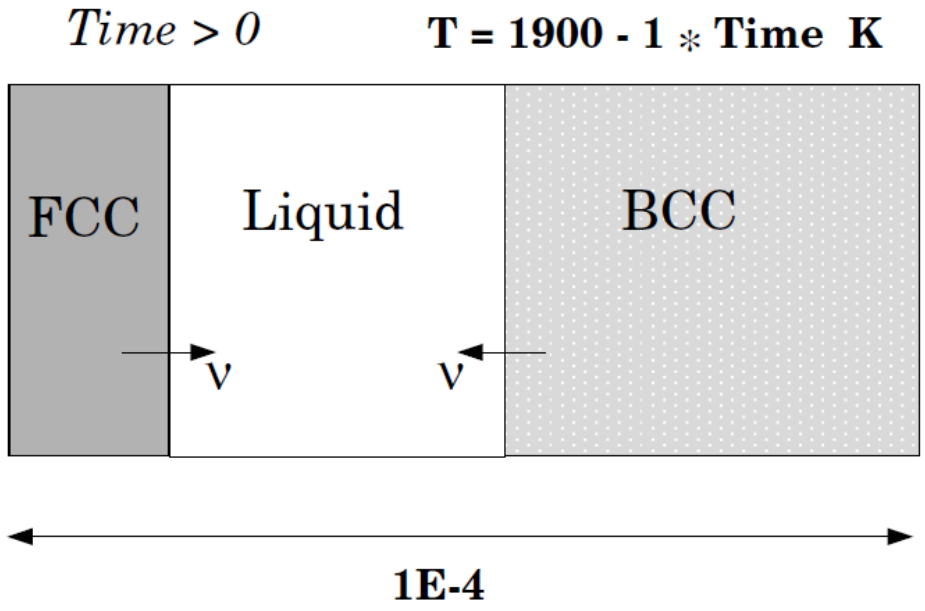


Example exb4a

Solidification path of an Fe-18%Cr-8%Ni alloy: Eutectic reaction

This example demonstrates the solidification path of an Fe-18%Cr-8%Ni alloy. A eutectic reaction is assumed, LIQUID -> BCC + FCC. Hence the BCC and FCC regions should be on separate sides of the liquid region. Comparison is made with both a Scheil-Gulliver simulation and equilibrium solidification conditions, both done in Thermo-Calc.

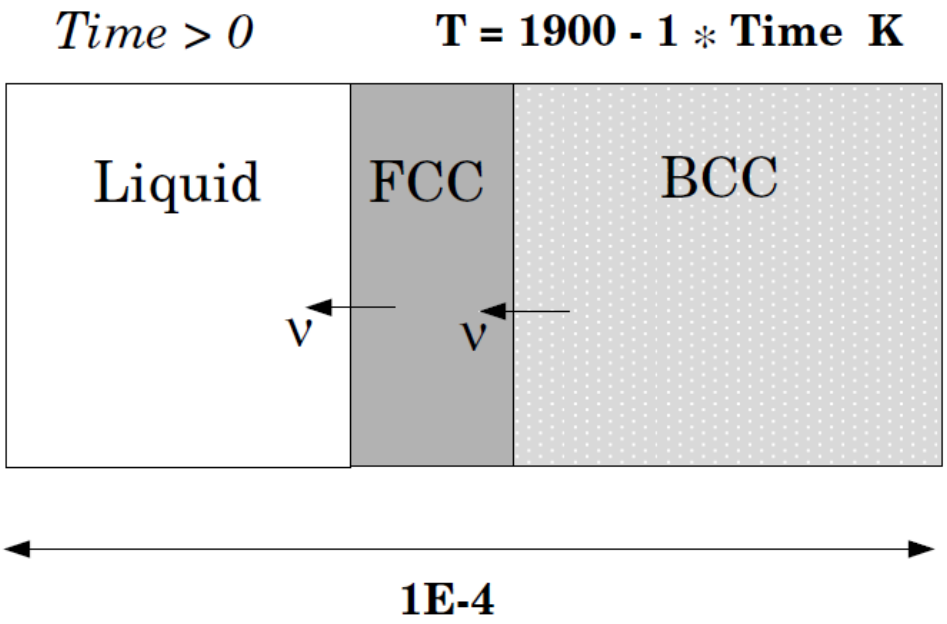
This example uses the TCFE and MOBFE databases. Licenses are required to run the example.



Example exb4b

Solidification path of an Fe-18%Cr-8%Ni alloy: Peritectic reaction

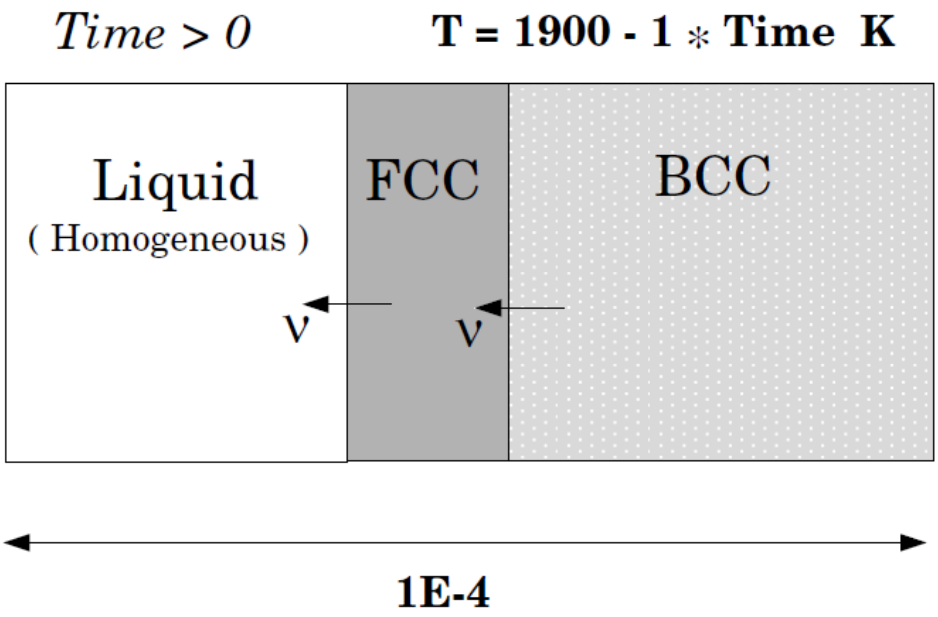
This example is the same as exb4a but now a peritectic reaction is assumed: LIQUID + BCC -> FCC. Hence the FCC region should appear in between the LIQUID and the BCC. Comparison is made with both a Scheil-Gulliver simulation and equilibrium solidification conditions, both done in Thermo-Calc.



Example exb4c

Solidification path of an Fe-18%Cr-8%Ni alloy: Peritectic reaction, homogeneous liquid

This example is the same as exb4b but now the diffusivity data is amended for the LIQUID and a very high value for the diffusivity is used in order to simulate a case where we assume that the composition in the LIQUID is always homogeneous. This case should be considered less realistic than exb4b. Comparison is made with both a Scheil-Gulliver simulation and equilibrium solidification conditions, both done in Thermo-Calc.

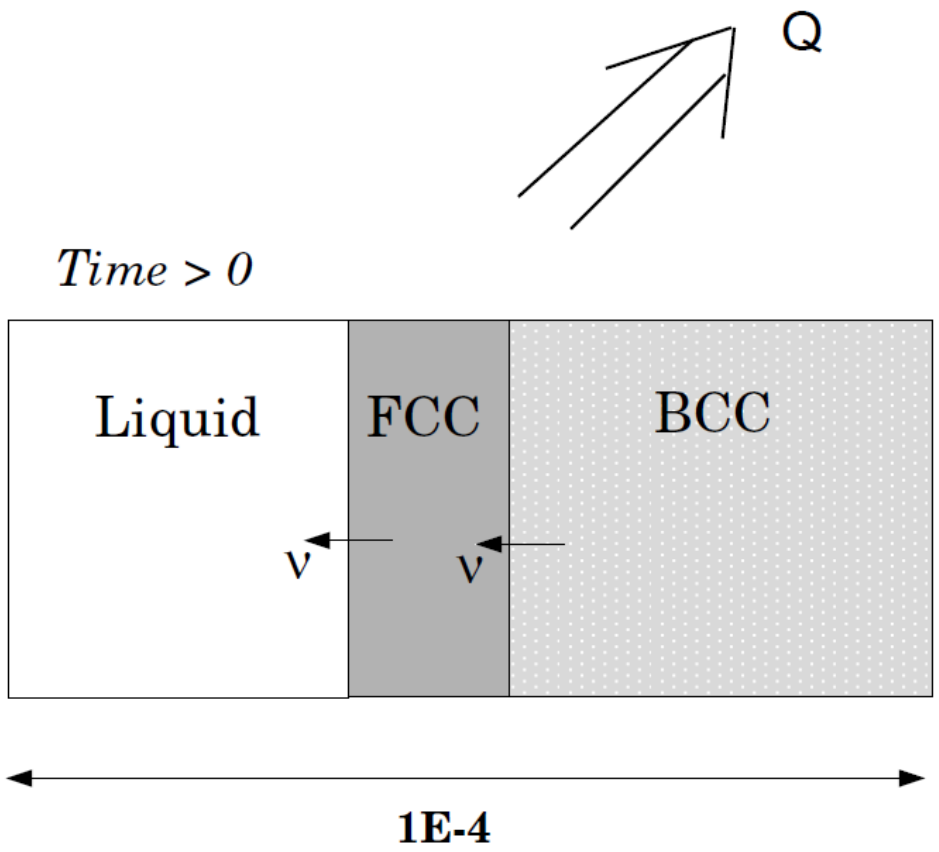


Example exb4d

Solidification path of an Fe-18%Cr-8%Ni alloy: Peritectic reaction, heat-flux controls the temperature

This example is the same as exb4b but instead of controlling the temperature the amount of heat extracted is given. Comparison is made with both a Scheil-Gulliver simulation and equilibrium solidification conditions, both done in Thermo-Calc.

This example uses the FEDEMO and MOBFE2 database. A license is required for the MOBFE database to run the example.

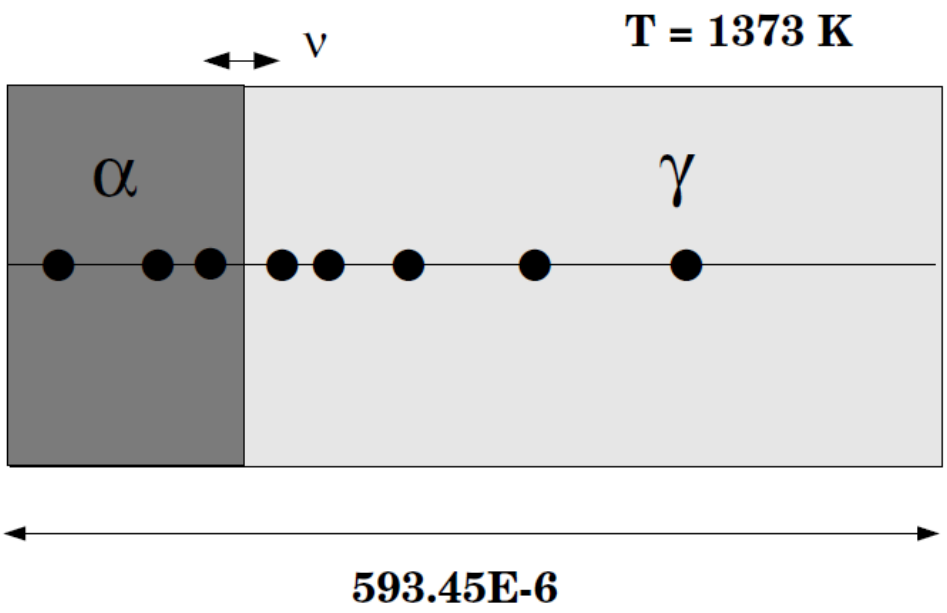


Example exb5

γ/α/γ Diffusion couple of Fe-Ni-Cr alloys

This example demonstrates the evaluation of a ternary Fe-Cr-Ni diffusion couple. A thin slice of α phase (38%Cr,0%Ni) is clamped between two thicker slices of γ phase (27%Cr, 20%Ni). The assembly is subsequently heat treated at 1373K.

This set up corresponds to diffusion couple in [1993Kaj-1]. Also see [1993Kaj-2].



Example exb6

Microsegregation of phosphorus

This example illustrates the effect of microsegregation of phosphorus during peritectic solidification in steel.

This example uses the TCFE and MOBFE databases. These licenses are required to run the example.

Example exb7

Moving boundary problem with multiple phases on each side of the boundary

This example shows how to enter dispersed phases on either side of a phase interface. The particular case shows how the kinetics of a ferrite to austenite transformation is affected by simultaneous precipitation of niobium carbide. The transformation is caused by carburization.

This example uses the TCFE, SSUB and MOBFE databases. These licenses are required to run the example.

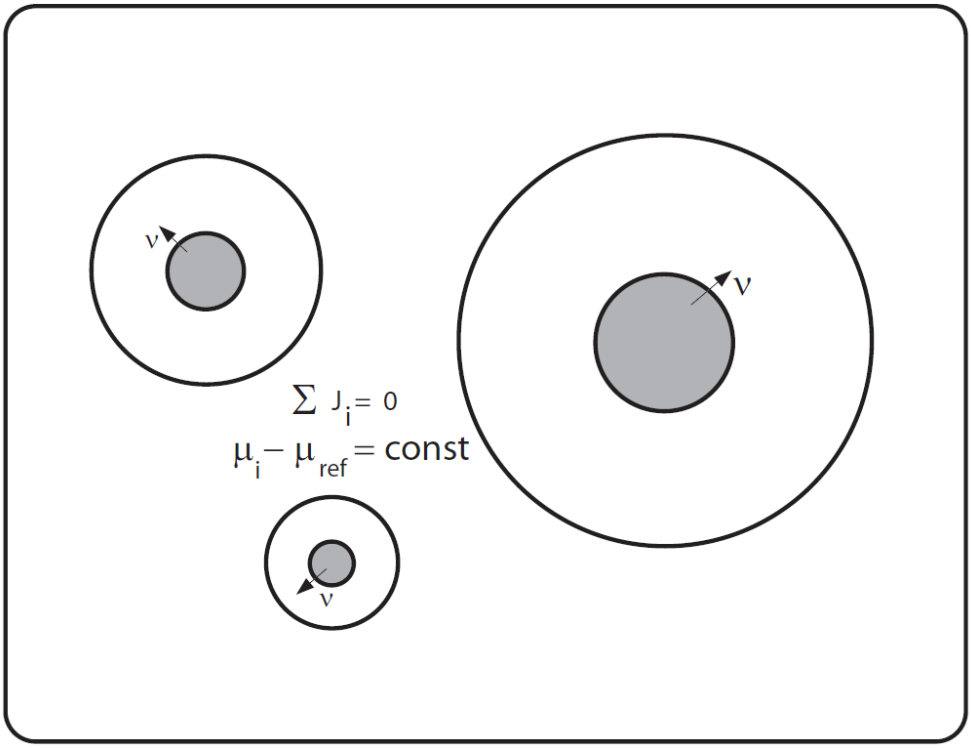
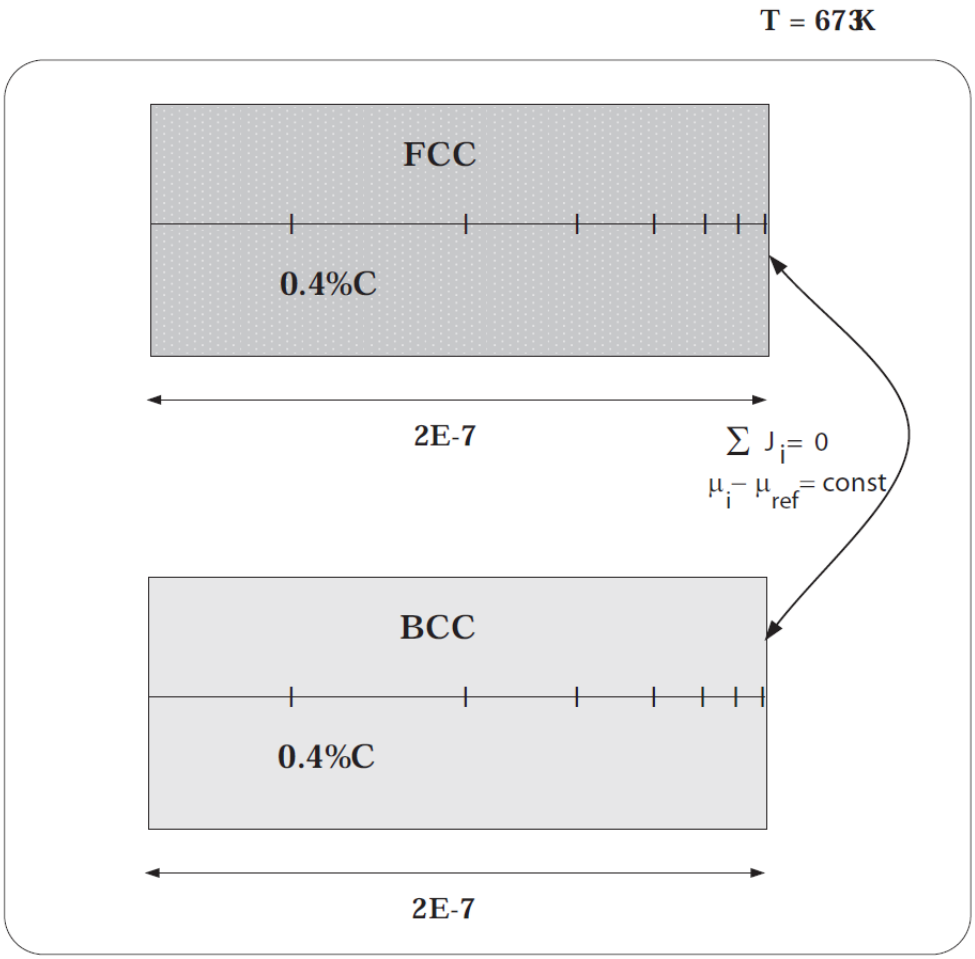
Cell Calculation Examples



Example exc1

Carbon cannon in ferrite/austenite (α/γ): Fe-C system, two-cell calculation

This example simulates what happens to a ferrite plate that has inherited the carbon content of its parent austenite. The ferrite plate formed is embedded in an austenite matrix. This setup corresponds to a proposed mechanism for formation of Widmannstätten ferrite or for the ferrite phase of the bainite structure. It is assumed that the phase boundary between ferrite and austenite is immobile, this is achieved in the simulation by putting the ferrite and the austenite in two different cells. Also see [1993Hil].



Example exc2

Cementite dissolution in an Fe-Cr-C alloy: Three particle sizes and three different cells

This example calculates the dissolution of cementite particles in an austenite matrix. This is the same as exc1 except that there are three particle sizes. Altogether six particles are considered using three different cells. This is to be able to represent some size distribution among the cementite particles. Also see [1991Liu].

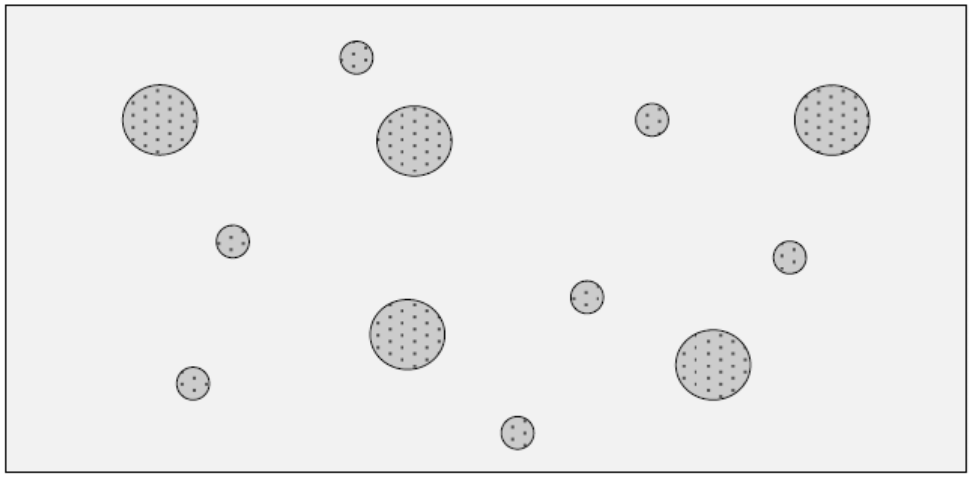
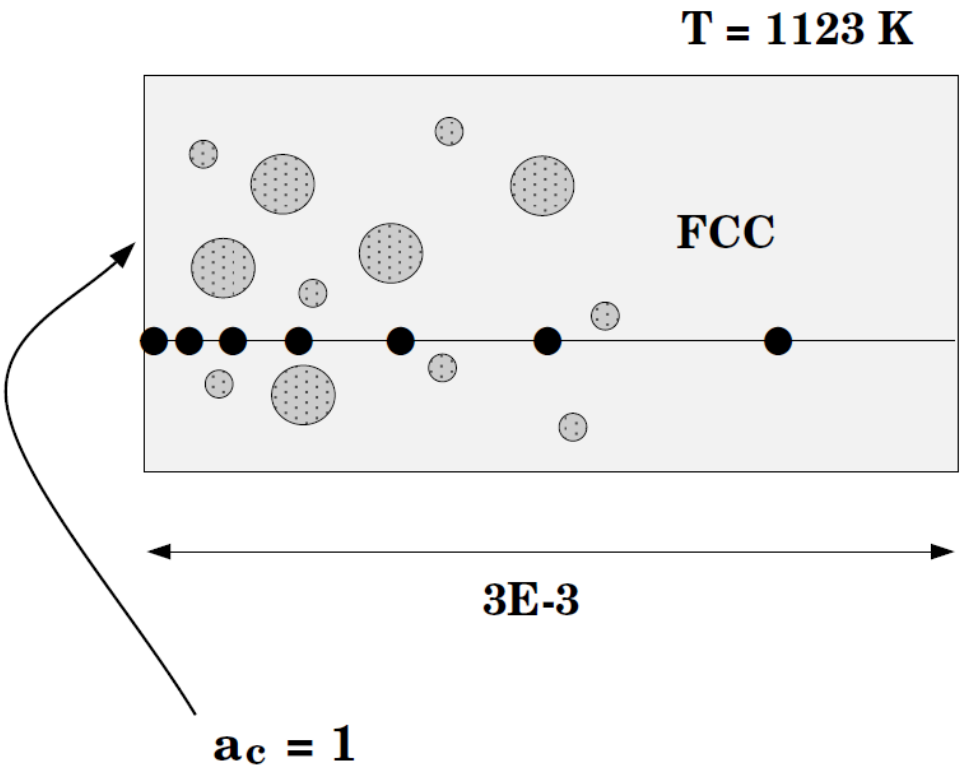
Diffusion in Dispersed Systems Examples



Example exd1a

Carburization of Ni-25%Cr alloy: Dispersed system model

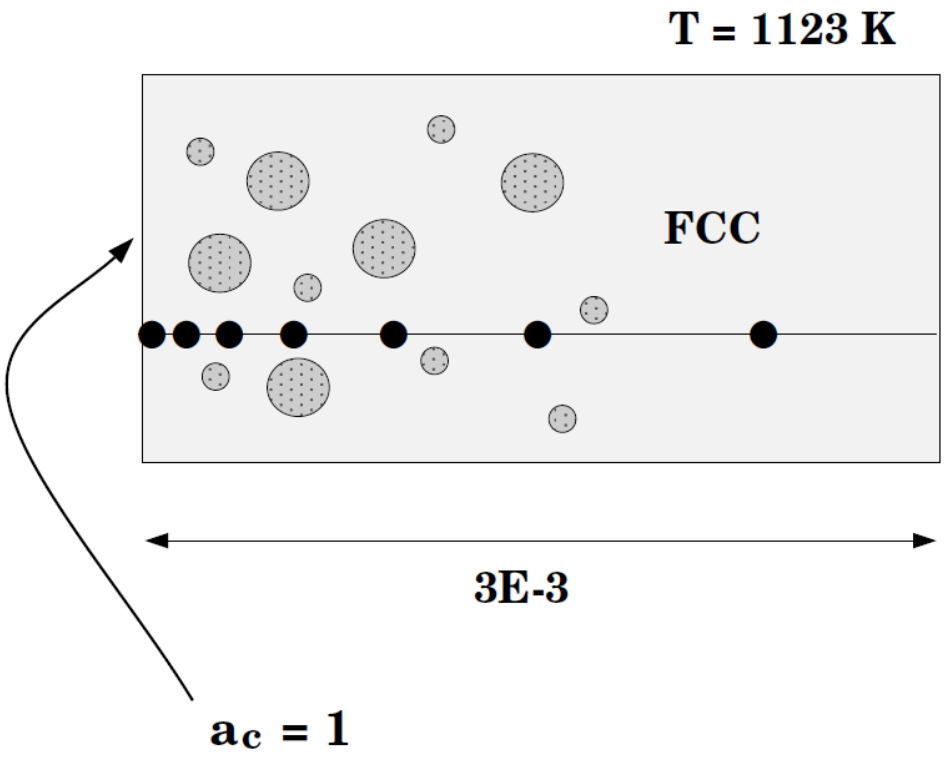
This example is about carburization of a Ni-25Cr alloy. In this case the M3C2 and M7C3 carbides are entered as spheroid phases in a FCC matrix. This simulation can be run with either the DISPERSED SYSTEM MODEL or the HOMOGENIZATION MODEL. In this example the DISPERSED SYSTEM MODEL is used. This case is from [1994Eng].



Example exd1b

Carburization of Ni-25%Cr alloy: Homogenization model

This example is about carburization of a Ni-25Cr alloy. In this case the M3C2 and M7C3 carbides are entered as spheroid phases in a FCC matrix. It is similar to exd1a except the default HOMOGENIZATION MODEL is used and then ENTER_HOMOGENIZATION_FUNCTION should be used instead of ENTER_LABYRINTH_FUNCTION. This case is from [1994Eng].

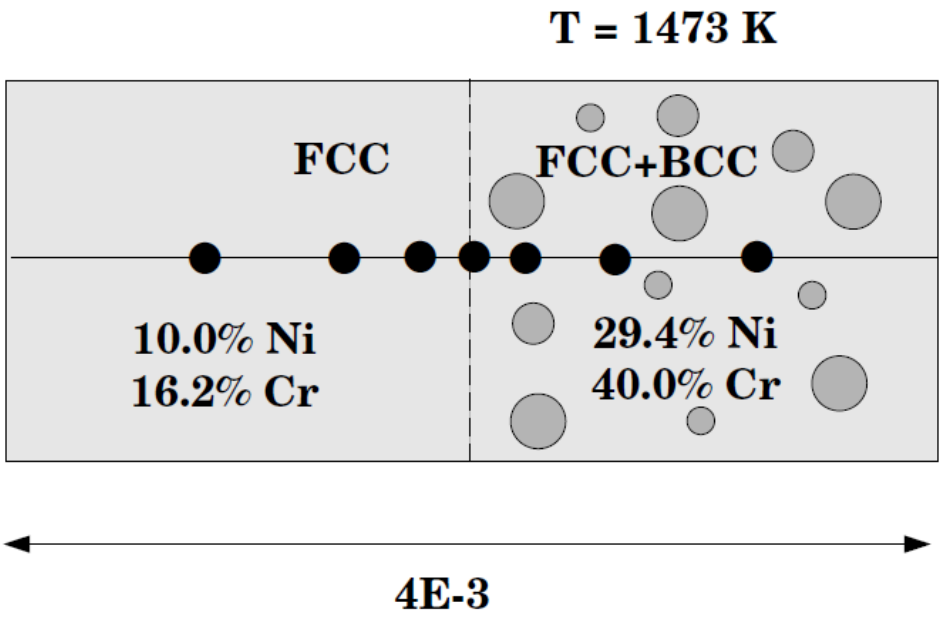


A modified version of this example is also available in Graphical Mode as example D_07. For Graphical Mode you do not need a Diffusion Module (DICTRA) license. You can open the example from Thermo-Calc when in Graphical Mode (**File →Examples Files → Diffusion Module**).

Example exd2a

Diffusion couple of Fe-Cr-Ni alloys: Dispersed system model

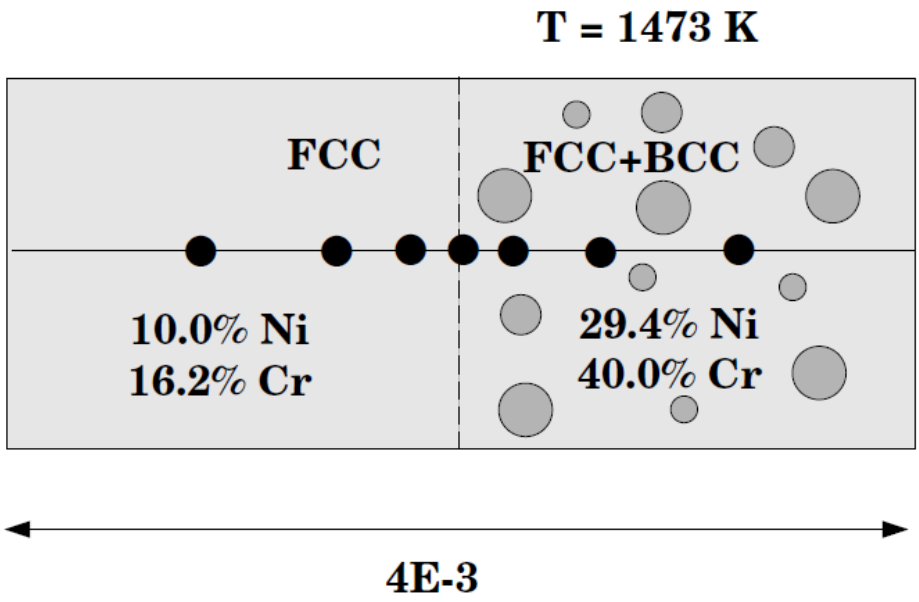
This example calculates the interdiffusion in a diffusion couple between a two-phase (FCC+BCC) and a single-phase (FCC) Fe-Ni-Cr alloy. Initially it has a step profile. This simulation can be run with either the DISPERSED SYSTEM MODEL or the HOMOGENIZATION MODEL. In this example the DISPERSED SYSTEM MODEL is used. This case is from [1995Eng].



Example exd2b

Diffusion couple of Fe-Cr-Ni alloys: Interdiffusion and the Homogenization Model

This example calculates the interdiffusion in a diffusion couple between a two-phase (FCC+BCC) and a single-phase (FCC) Fe-Ni-Cr alloy. Initially it has a step profile. It is similar to exd2a except the default HOMOGENIZATION MODEL is used and then ENTER_ HOMOGENIZATION_FUNCTION is used instead of ENTER_LABYRINTH_FUNCTION. This case is from [1995Eng].



Example exd3

Diffusion couple of Fe-Cr-Ni alloys: Homogenization model

This example uses the homogenization model. It is taken from [2006Lar]. Experimental data is from[1995Eng].

The homogenization model can be used for multiphase simulations like the dispersed system model, but unlike the dispersed system model there is no need to have a single continuous matrix phase and, furthermore, there is no need to limit the size of time-steps. The set-up is performed in the same manner as for the dispersed system model, which means that a certain phase is entered as the matrix phase and the other phases are entered as spheroidal, but the choice of matrix phase does not affect the simulation.

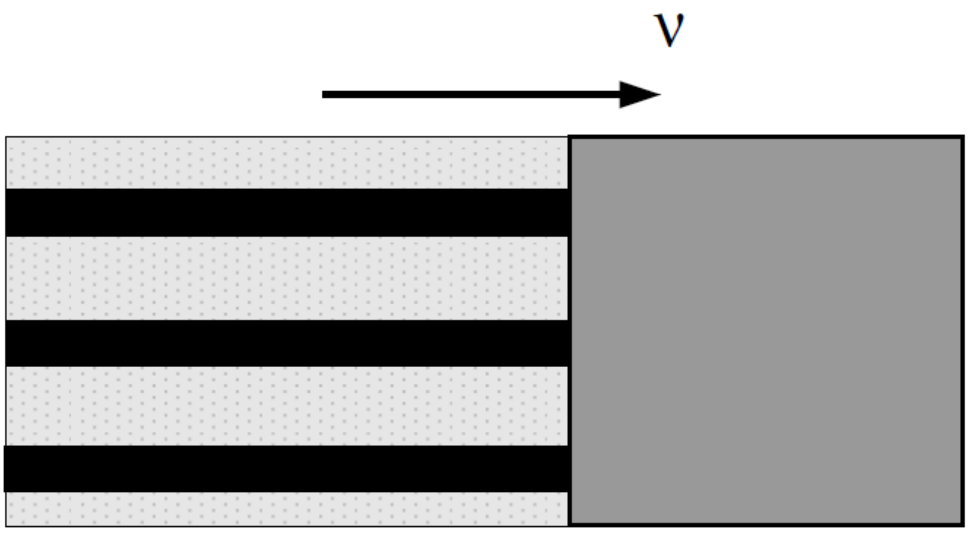
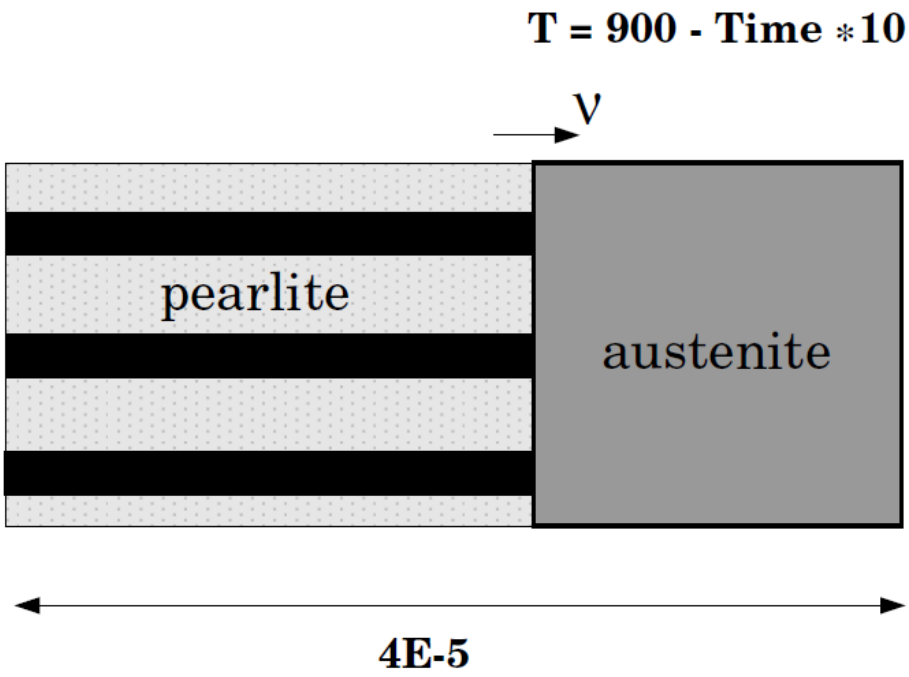
Cooperative Growth Example



Example exe1

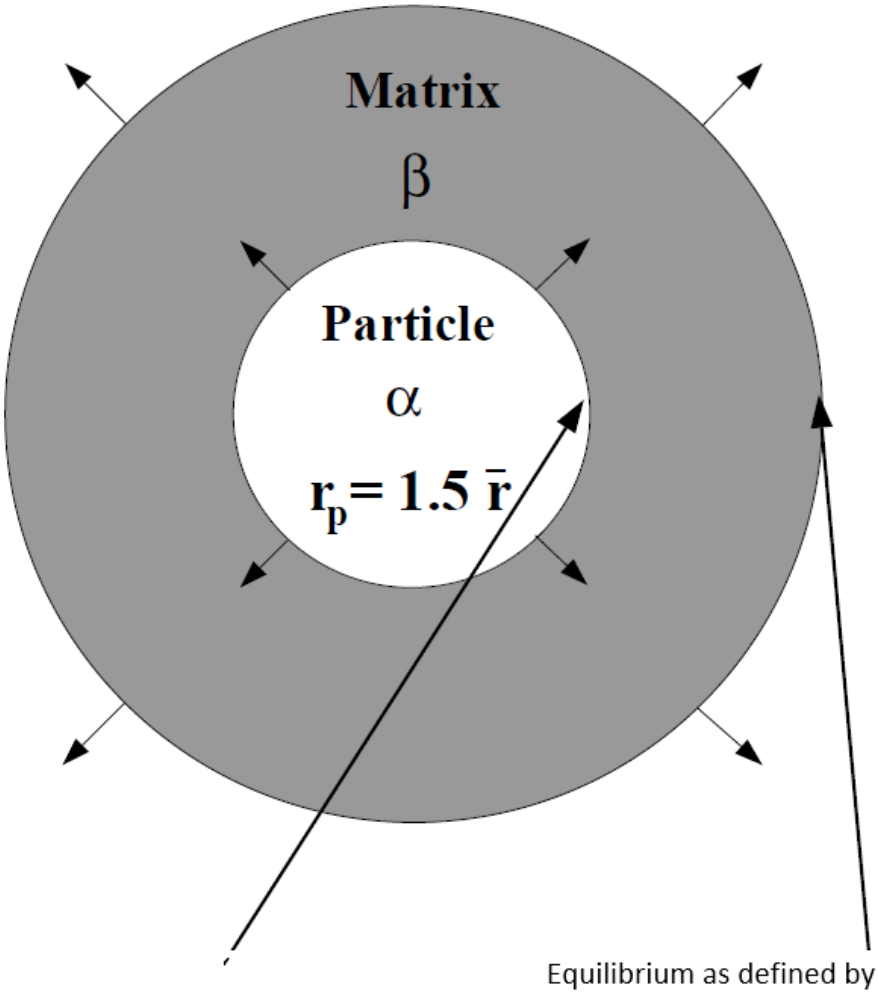
Growth of pearlite in an Fe-Mn-C alloy

This is an example of pearlite growth in an Fe-0.50wt%C-0.91wt%Mn steel.



T = 900 - Time ∗10
V
pearlite
austenite
4E-5

Coarsening Example



Moving phase interface with α and β in local equilibrium.

$\frac{2\sigma V_m}{r}$ Interfacial energy contribution for α phase

Equilibrium as defined by the average composition in the system.

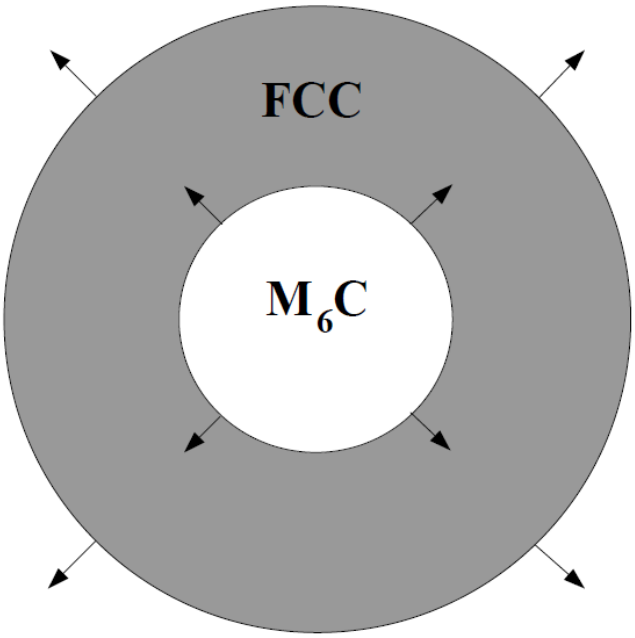
$\frac{2\sigma V_m}{r_p}$ Interfacial energy contribution for α phase

Example exf1

Coarsening of M6C precipitate in an Fe-Mo-C alloy

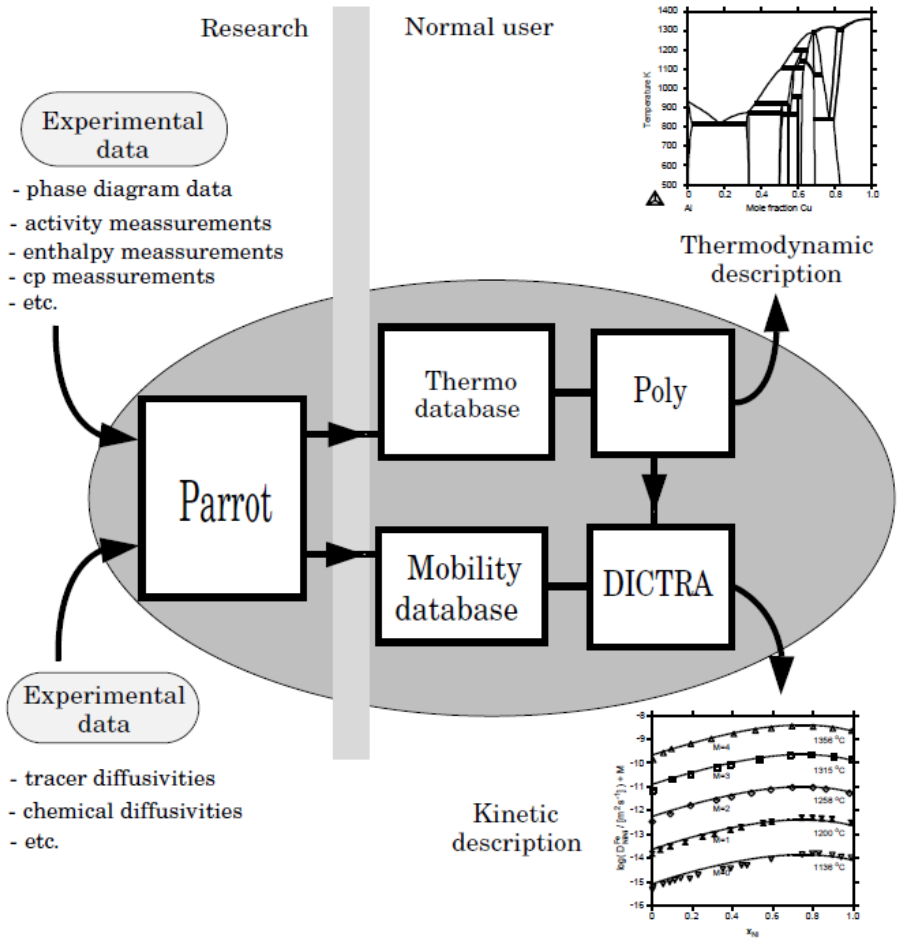
This example calculates the Ostwald-ripening of a spherical M6C carbide in an austenite matrix.

This example uses the TCFE and MOBFE databases. These licenses are required to run the example.



$T = 1173K$ $r_p = 0.228\ \mu m$

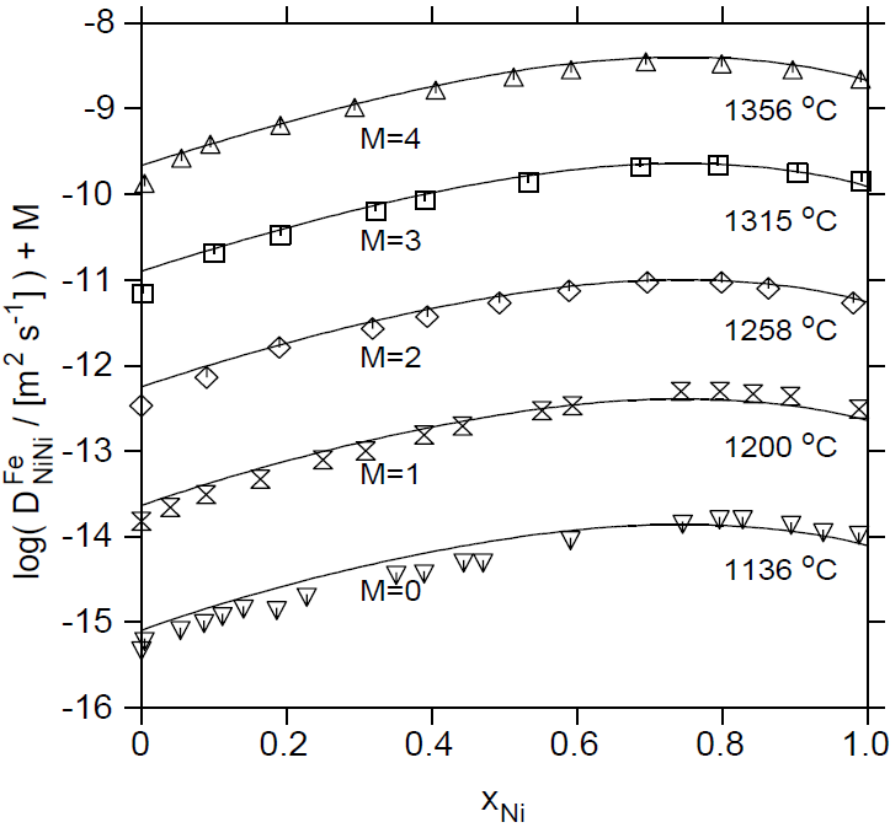
Kinetic Data Examples



Example exg1

Checking mobilities and diffusivities in an Fe-Ni alloy

This is an example file to check the mobilities and diffusivities in an Fe-Ni alloy.



Example exg2

Optimization of mobilities in Ni-Al fcc alloys

A file for reading thermodynamic data and setting up the kinetic parameters that are needed for an optimization of the FCC phase in the binary Ni-Al system. Also see [1996Eng].

This example uses the MOB2 database. This license is required to run the example.

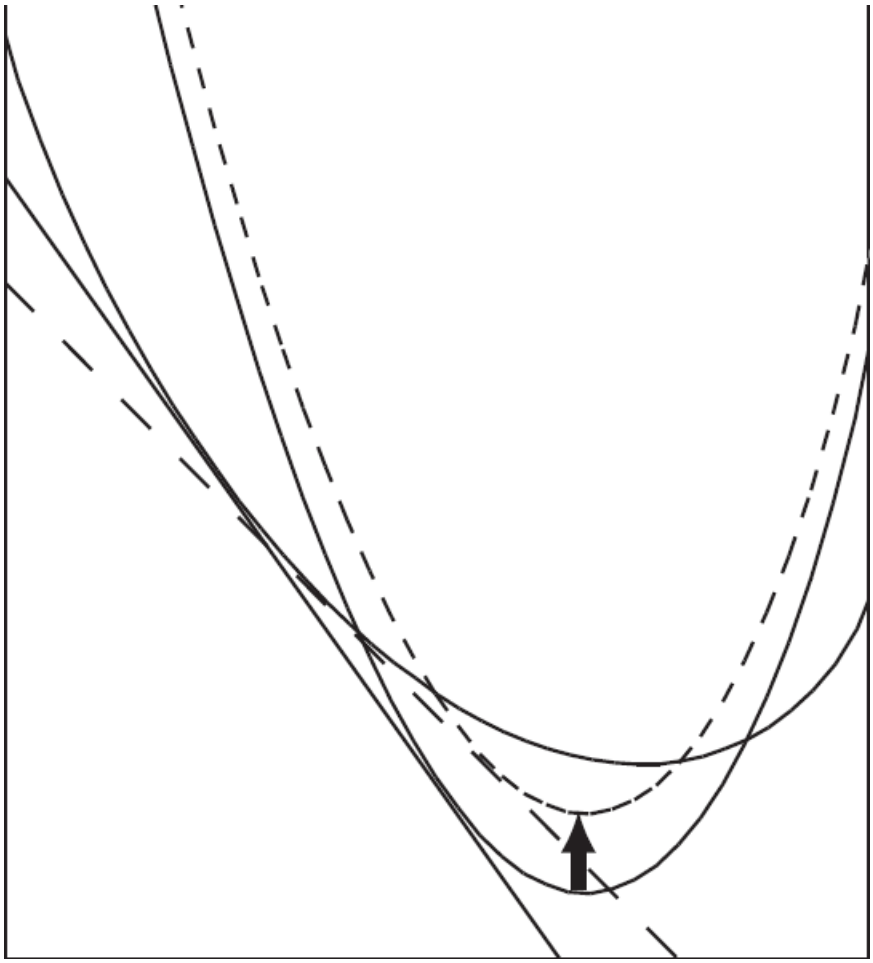
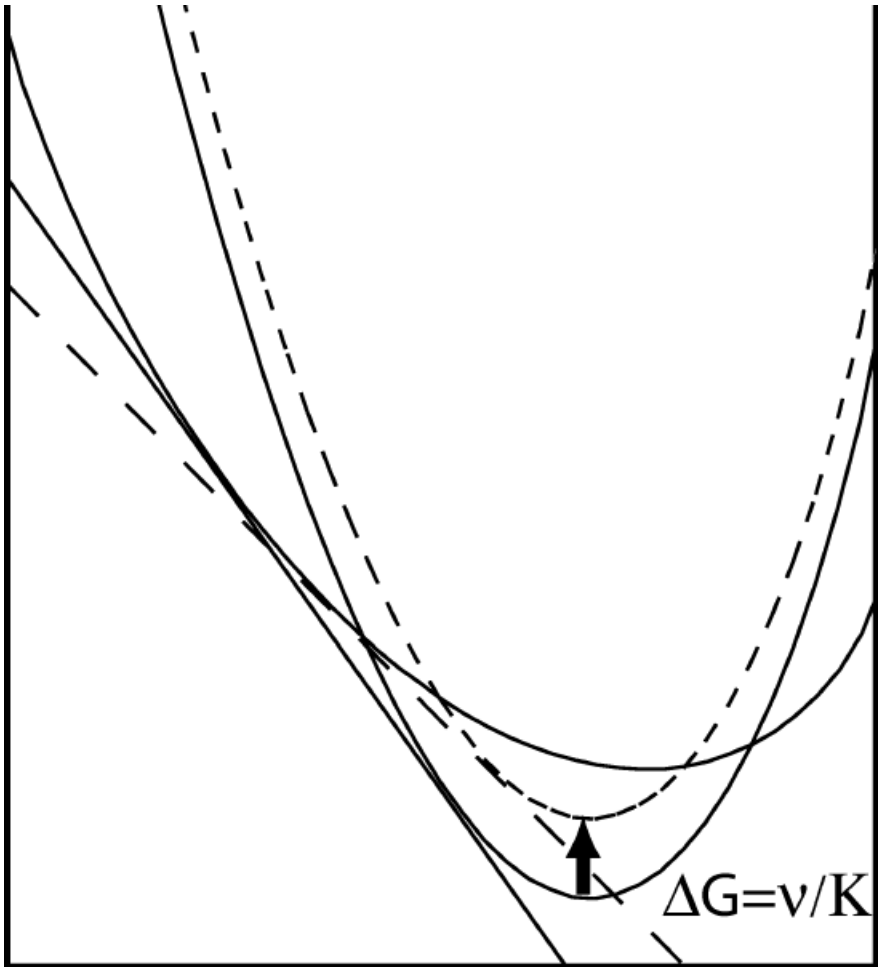
Deviation from Local Equilibrium Examples



Example exh1

Ferrite/austenite (α/γ) diffusion couple with interface mobility

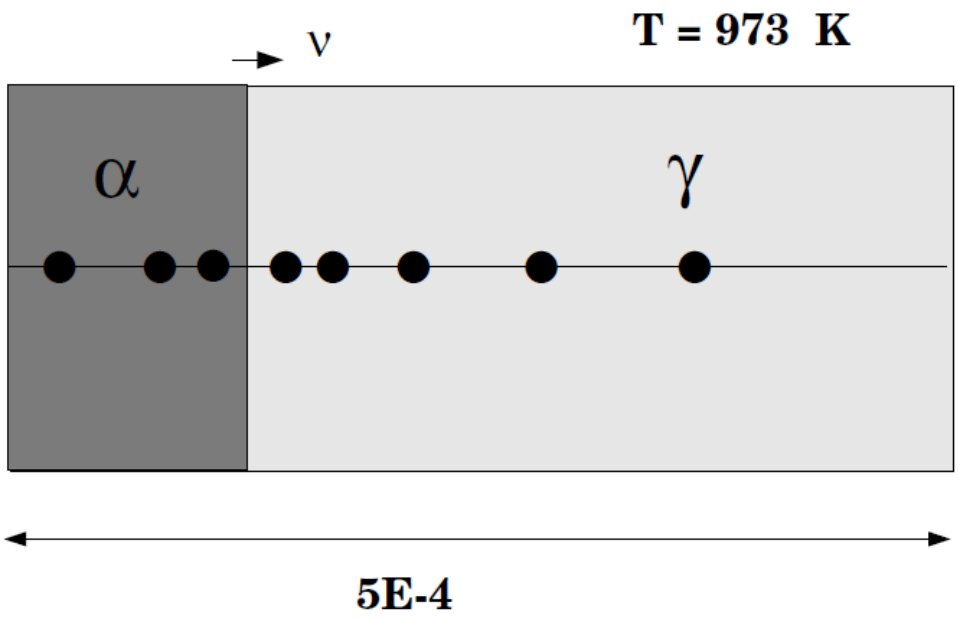
This example calculates the growth of ferrite (α) into austenite (γ) with a limited interface mobility. This is done by adding a Gibbs-energy contribution to the ferrite using the SET-SURFACE-ENERGY command.



Example exh2

Ferrite/austenite (α/γ) para-equilibrium in an Fe-Ni-C alloy

This example calculates the growth of ferrite (α) into austenite (γ) in an Fe-2.02%Ni-0.0885%C alloy using the para-equilibrium model. The results are compared with experimental information from Hutchinson, Fuchsmann, and Brechet [2004Fuc].



Example exh3

Diffusion induced by a temperature gradient (thermomigration)

This calculation shows how a temperature gradient induces diffusion.

$$J_C = -\frac{u_C}{V_e} y_{Va} M_{CVa} \left(\frac{\partial \mu_C}{\partial x} + \frac{Q_C^*}{T} \frac{\partial T}{\partial x} \right)$$

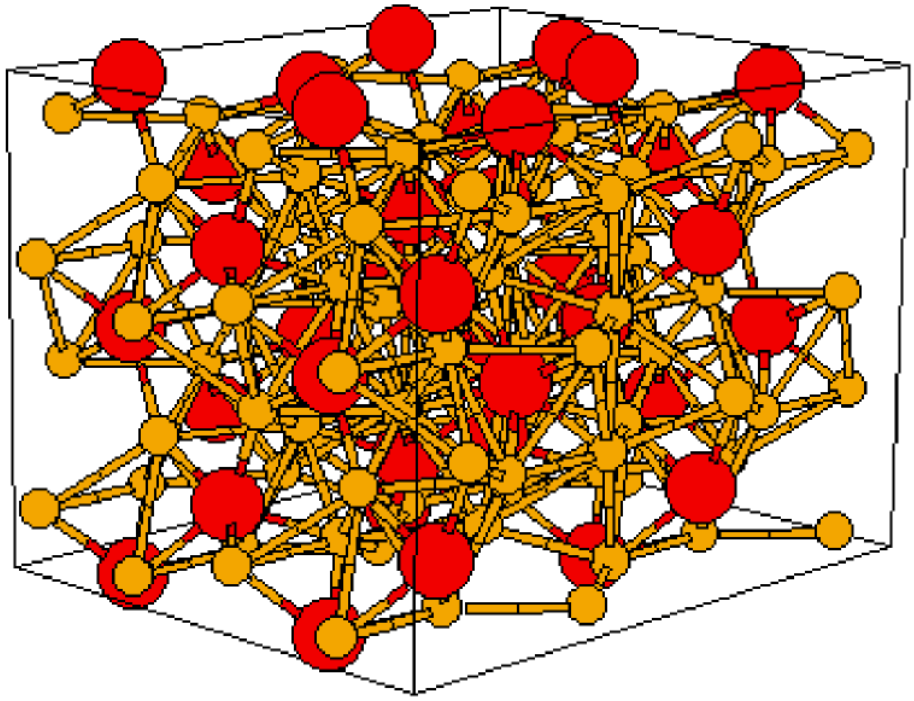
Diffusion in Complex Phases Examples



Example exi1

Diffusion in a system with B2 ordering

In this example folder, there is also a datafile `AlFeNi-data.TDB`, which contains both a thermodynamic and kinetic description for the ordered and disordered bcc.

Example exi2

Diffusion of carbon in cementite

This example demonstrates the use of the model for calculation of diffusion through a stoichiometric phase. The flux of a component in the stoichiometric phase is assumed to be proportional to the difference in chemical potential at each side of the stoichiometric phase multiplied with the mobility for the component in the phase. The mobility is assessed from experimental information and is basically the tracer diffusivity for the component.

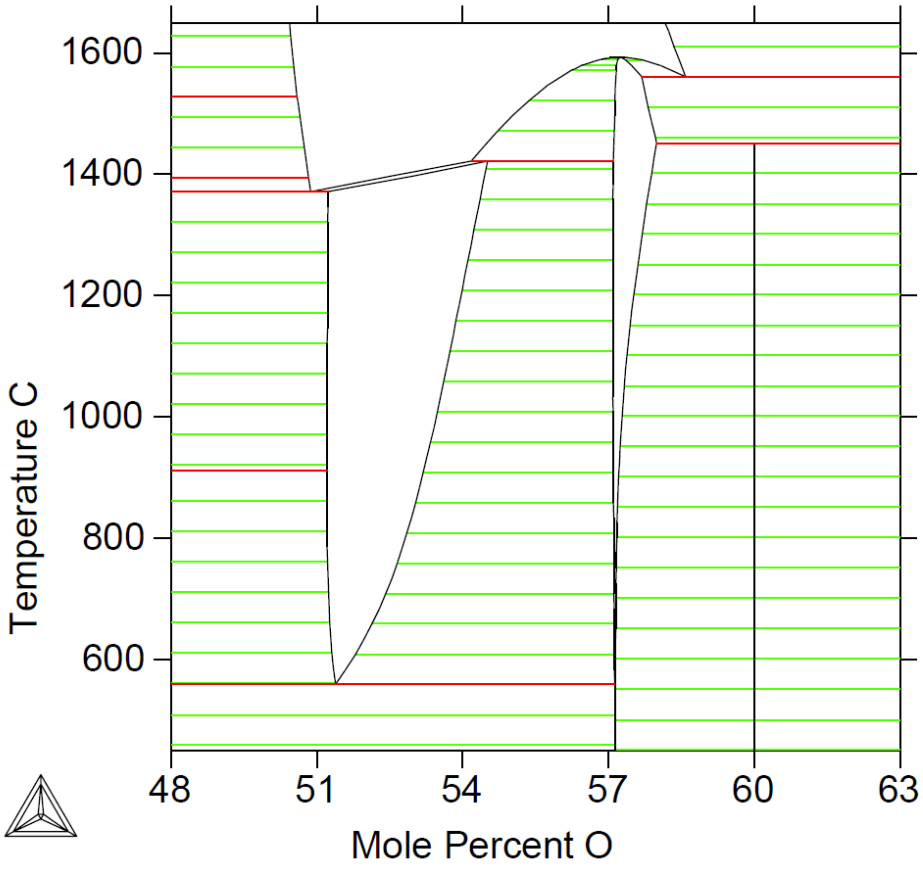
This calculation is compared with experimental data where a sample of pure iron has been exposed to a gas atmosphere with a certain carbon activity. The weight gain is then measured as a function of time. The experimental data is obtained from [1982Ozt].

$J \sim \Delta\mu$

Example exi3a

Diffusion in iron oxide (FeO)

This example shows the oxidation of an iron sample and the consequent growth of an oxide layer.



Example exi3b

Diffusion in iron oxide (FeO) with a grain boundary contribution

This example shows the oxidation of an iron sample and the consequent growth of an oxide layer using the grain boundary diffusion contribution model.

About the DICTRA Commands

These topics, starting with DICTRA Module Commands, are for users already familiar with Console Mode and it includes all the commands applicable to the Diffusion Module (DICTRA). It is a supplement to the commands described for Thermo-Calc (see Commands by Module to navigate).

How you proceed depends on your experience with the software as well as your level of expertise with diffusion problems. The following supplemental resources can help you work with the Diffusion Module (DICTRA) in Console Mode.

Learn More

The Role of Diffusion in Materials: A Tutorial is available for download on our website. It is intended for engineers interested in using the Diffusion Module (DICTRA), as well as students learning about the role of diffusion in materials. It is designed to be useful at many levels, from undergraduate studies to someone with a PhD and experience in a related field.

Discover more or refresh your skills with an Advanced Lecture Series on Fundamentals of Thermodynamics, created by Professor John Ågren, one of the original developers of Thermo-Calc.

General Commands

These commands are universal in Console Mode.

Command/Syntax	Description and Prompts
BACK	Return to the previous module. From the POST-processor you go back to the DICTRA-MONITOR module.
EXIT	Terminates the program and returns to the operating system. Unless a SAVE_WORKSPACES command has been given before all data entered is lost.
GOTO_MODULE	`Module name` Select and go to another module. The name of the module must be given. In order to obtain a list of available modules give a return.
HELP ?	Enter HELP or ? to either a list of all commands or specific help for a command by giving the command (abbreviated) `Command` The command for which a description is wanted should be given. If the abbreviation is not unique a list of all matching commands are given.

ADD_STOP_CRITERION

The ADD_STOP_CRITERION command is available to use once there is data included with a simulation. Use this command to add an alternative criteria (instead of the final time) to terminate the simulation.

SET_PLOT_CONDITION and Plot Condition and Independent Variable

Most of the "plot-conditions" in the post-processor can now be used as termination criteria for a DICTRA simulation.

Syntax	ADD_STOP_CRITERION
Prompts	`TYPE OF STOP CONDITION /INTEGRAL/:` An overall condition corresponding to the PLOT_CONDITION used in the post-processor to define where/how the criteria for termination is defined. Enter one of the following: • `DISTANCE`: Distance in the system. It defines a local or global position where the value of a state variable defines if the simulation should be terminated. • `INTERFACE`: At an interface where the value of a state variable defines if the simulation should be terminated. • `INTEGRAL`: Value is integrated over the phase/region/system volume (the default). An INTEGRAL VARIABLE value should be used to define the termination. See below for additional prompt details.

If `DISTANCE` is entered, then	`TYPE OF DISTANCE /GLOBAL/:`
	Fixed distance in the system. Enter one of the following:
	• `GLOBAL`: i.e. counted from the leftmost interface (the default).
	• `LOCAL`: i.e. counted from the interface to the left of the region. If this is entered then also enter,
	  • `NAME OF REGION`
	  • `DISTANCE`

If `INTEGRAL` is entered then	`INTEGRAL VARIABLE:` Enter the integral variable used to define the termination criteria. Integral Variables details how to construct the value.
If `INTERFACE` is entered then	Enter the interface of the system. Enter ? to list the options based on the set up. Options are: • Region name

Syntax	ADD_STOP_CRITERION

	• FIRST
	• LAST
	
	If a "region name" is entered, then you are further prompted:
	
	`UPPER OR LOWER INTERFACE OF REGION:`
	
	This then defines the position at as the interface at the UPPER or LOWER part of the named region.
	
	`STATE VARIABLE:`
	
	Enter the state variable used to define the termination criteria.
	
	See State Variables in Console Mode DICTRA for details about how to construct the value.

For either the `INTEGRAL VARIABLE` or `STATE VARIABLE`	`TERMINATION VALUE:` The criteria for the value of the variable that should trigger a termination of the simulation. Valid answers are for a numeric value.

ADVANCED_HOMOGENIZATION_OPTIONS

UTILITIES_HOMOGENIZATION

Use the ADVANCED_HOMOGENIZATION_OPTIONS command and its subcommands with the HOMOGENIZATION_MODEL. Go to each command listed below for details.

Syntax	ADVANCED_HOMOGENIZATION_OPTIONS
Prompts	`Which option?` Enter ? to list the available commands as below. • BC_FOR_DEPENDENT_ELEMENT • SOLVE_IN_LATTICE_FIXED_FRAME • DEPENDENT_ELEM_BALANCE_FLUXES • USE_TWO_TYPES_OF_BOUNDARY_CON • CHECK_PHASE_SET

AMEND_CELL_DISTRIBUTION

Use the AMEND_CELL_DISTRIBUTION command to amend the cell distribution factor of the currently selected cell.

Syntax	AMEND_CELL_DISTRIBUTION
	`Cell distribution factor /1/`
Prompt	A parameter that determines the weight of the cell, it can be used to simulate a distribution of different cell sizes. The default value is 1, i.e. a single copy of the same cell. Integer values are not required.

AMEND_MOBILITY_DATA

Use the AMEND_MOBILITY_DATA command to change an existing parameter.

Also see ENTER_MOBILITY_DATA for information about the parameter names and prompts.

Syntax	AMEND_MOBILITY_DATA
Prompt	`Parameter name <Identifier> (<Phase>, <Component array>; <Digit>)` Enter `?` to get an overview

APPEND_EXPERIMENTAL_DATA

Use the APPEND_EXPERIMENTAL_DATA command to add experimental data and text on a calculated diagram. The experimental data and text are added to a file prepared according to the syntax of the DATAPLOT graphical language. The picture generated from the data is superimposed on the ordinary graphical output from the POST PROCESSOR. The experimental data file can be created with an ordinary text editor. Another use of the APPEND_EXPERIMENTAL_DATA command is to superimpose plots from several independent calculations. For this purpose, there is a command MAKE_EXPERIMENTAL_DATAFILE which dumps a calculated diagram on a file according to the DATAPLOT syntax. With the aid of a basic text editor many such files may be merged. Remember to have only one prologue section on the file (see below).

About DATAPLOT Files

Syntax	APPEND_EXPERIMENTAL_DATA
Prompts	`Use experimental data (Y or N) /N/:` By default, no experimental data is plotted.
	`Experimental datafile` Specify the name of the file with the experimental data. Default file extension is exp.
	`Prologue number` Select which prologue to use. In a prologue one may e.g. give the scaling of an axis, the axis texts, and so on. -1 gives a list of all prologues on the file. Read more about prologues below.
	`Dataset number(s)` Select from which dataset(s) data should be read. Several datasets may be given separated with commas or spaces. -1 gives a list of all datasets on the file.

BC_FOR_DEPENDENT_ELEMENT

Use the BC_FOR_DEPENDENT_ELEMENT command to allow an "active" boundary condition (BC) for a dependent element. It is available with the HOMOGENIZATION_MODEL as a command within the ADVANCED_HOMOGENIZATION_OPTIONS.

The command enables you to enter a “fix flux” or an “activity-/potential-flux function” type of boundary condition for the dependent substitutional element if such a boundary condition is already entered for the independent elements.

Use of this command automatically ensures that the flux of the dependent element is not used to balance the independent fluxes, i.e. the feature “dependent element balance fluxes” is set to NO.

Syntax	BC_FOR_DEPENDENT_ELEMENT
Prompts	`Enter BC for dependent element on lower boundary /NO/` If YES is entered, the subsequent prompts are the same as when the boundary condition was entered for the independent elements on the lower boundary; it is a prerequisite that such a boundary condition is already entered. This feature is only allowed with a “fix flux” or an “activity/potential flux function” type of boundary condition.
	`Enter BC for dependent element on upper boundary /NO/` If YES is entered, the subsequent prompts are the same as when the boundary condition was entered for the independent elements on the upper boundary; it is a prerequisite that such a boundary condition is already entered. This feature is only allowed with a “fix flux” or an “activity/potential flux function” type of boundary condition.

CHECK_DIFFUSION_MATRIX

Use the CHECK_DIFFUSION_MATRIX command to display the diffusion coefficient matrix for a phase at a given composition, pressure and temperature.

Syntax	CHECK_DIFFUSION_MATRIX
Prompts	`Output to screen or file /Screen/`
	`Phase name` Name of the phase for which the diffusion coefficient matrix is to be displayed.
	`Concentration of` Concentration of the component in U-fraction for which the diffusion coefficient matrix is to be displayed.
	`Pressure` Pressure for which the diffusion coefficient matrix is to be displayed.
	`Temperature` Temperature at which diffusion coefficient matrix is to be displayed. Use one or several of the options: • `D`: reduced diffusion matrix • `L:L` matrix (diagonal) • `P:L'` matrix • `B:L"` matrix • `M:MU(k)` array • `X:dMU(k)/dCj` matrix • `0`: unreduced diffusion matrix • `E`: Eigen values of matrix

CHECK_PHASE_SET

This command is available with the HOMOGENIZATION_MODEL as a command within the ADVANCED_HOMOGENIZATION_OPTIONS.

This command is only available with single region simulations.

One difficulty with single region multiphase simulations is to choose which phases should take part in the simulation, i.e. which phases should be entered in the region; what phases are stable, or become stable, is often a part of the question and the diffusion path is not known *a priori*. With the CHECK_PHASE_SET command it may be checked which, if any, phases read from the database but not entered in the region have become stable. The interval at which checks are made can be set to some extent. Whether a simulation should be terminated when a non-entered phase become stable can also be set. Finally, it can also be set whether some phases should be excluded from the check, if for example a phase has been read only to be used to define a reference state.

Syntax	CHECK_PHASE_SET
Prompt	CHECK SET OF PHASES ENTERED INTO SIMULATION (Y/N): USE THIS FEATURE WITH DEFAULT SETTINGS? (Y/N): if NO, the following settings can be made: OPTIONS FOR CHECK INTERVAL: 1. BEGINNING AND END OF SIMULATION 2. EVERY TIME RESULTS ARE SAVED 3. AS #2, BUT TERMINATE SIMULATION IF NON-ENTERED PHASE BECOME STABLE CHOOSE OPTION 1-3: PERFORM CHECK USING GLOBAL MINIMIZATION? (Y/N): SHOULD ANY PHASE BE EXCLUDED FROM THE CHECK? (Y/N): if YES, then those phases are prompted for.

COARSENING_MODEL

About the Coarsening Model

The model allows you to perform coarsening simulations. Use the COARSENING_MODEL command to explicitly set the DICTRA module to use this model.

Enable or disable the use of the simplified model for calculating Ostwald-ripening in multicomponent systems. This also must be used together with the SET_SURFACE_TENSION command.

To use this mode, configure the calculation as follows:

- Have one cell only, with a single particle that is 1.5 times larger than the average particle size.
- The matrix phase should be in contact with the maximum size particle on the left/lower side, and then the model specifies a local equilibrium with an average sized particle on the right/upper side.
- The surface energy then results in growth of both the maximum size particle and the matrix phase. Use SET_SURFACE_TENSION to enter the surface energy to enable coarsening.

Syntax	COARSENING_MODEL
Prompt	`Enable coarsening model /N/` By default the coarsening model is not used. Enter Y to enable the use of this model.

CREATE_NEW_CELL

Use the CREATE_NEW_CELL command to create a new cell and attach it to the list of current existing cells.

Syntax	CREATE_NEW_CELL
Prompt	`Cell distribution factor` A parameter that determines the weight of the cell, this parameter can be used in order to simulate a distribution of different cell sizes. This value can be viewed as the number of copies of the same cell. When modeling a particle size distribution it is useful to be able to enter different number of copies of different sized particles. However, it is not required to use integer values.

DEBUGGING

Use the DEBUGGING command to determines the debugging level. Depending on the value given, different amounts of information are written onto the output device. This can be used to determine what causes the program to crash during a simulation.

Syntax	DEBUGGING
Prompt	`Debug level (Yes, No, 0, 1, 2, 3, 4) /N/` The level of debugging information to be displayed.

DELETE_REGION

Use the DELETE_REGION command to delete a region and all its associated data from the current cell.

Syntax	DELETE_REGION
Prompt	`Region name` The region name to delete.

DEPENDENT_ELEM_BALANCE_FLUXES

Use the DEPENDENT_ELEM_BALANCE_FLUXES command to set whether the dependent element should balance fluxes at the boundaries. This command is available with the HOMOGENIZATION_MODEL as a command within the ADVANCED_HOMOGENIZATION_OPTIONS.

For most boundary conditions (the notable exception being the “gas” type of boundary condition) the default behavior is that the boundary flux of the dependent substitutional element balances the fluxes of all other substitutional elements such that the size of the domain is preserved. This generally means that the flux of the dependent element equals minus the sum of all other substitutional elements.

This feature allow the balancing of boundary fluxes to be turned off and consequently the domain may change its size as a result of the boundary condition.

Syntax	DEPENDENT_ELEM_BALANCE_FLUXES
Prompt	`Dependent element balance the fluxes /Yes/:` The input for this feature is `Yes` or `No`, where `No` mean that the balancing of boundary fluxes is turned off.

ENTER_COMPOSITIONS

Use the ENTER_COMPOSITIONS command to enter the composition into the phases in a region.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	ENTER_COMPOSITIONS
Prompts	`Region name` Name of the region into which the compositions are to be entered.
	`Phase name` Name of the phase in a region into which the compositions are to be entered.
	`Use equilibrium value` This is only for spheroid phases in simulations with dispersed phases. If this option is used the program automatically calculates the equilibrium fractions of the spheroid phase and its constitution at the start of the simulation.
	`Dependent substitutional species` A dependent substitutional species is required in order to be able to determine which species are independent. The program only queries for the compositions of the independent species. Sometimes the dependent species is chosen by the program and thus this question is never given. This may be due to stoichiometric constraints or to the fact that it has been set already in the kinetics database due to the model selected for the diffusion.
	`Dependent interstitial species` A dependent interstitial species is required in order to be able to determine which species are independent. The program only queries for the compositions of the independent species. Vacancies are always regarded as dependent and therefore if vacancies are present in the phase then this question is never given.
	`Composition type` Type of composition used for the constitution of the phase. Options are: SITE_FRACTION, MOLE_FRACTION, MOLE_PERCENT, WEIGHT_FRACTION, WEIGHT_PERCENT and U_FRACTION.
	`Type` Type of composition profile to be entered, options are: LINEAR, READ_POINT_BY_POINT, FUNCTION,

Syntax	ENTER_COMPOSITIONS
	and GEOMETRIC. • If READ_POINT_BY_POINT is chosen note the following. When compositions are read from a file it may often be the case that both grid coordinates and the composition at the grid points are given on the same line, e.g. the grid coordinates in the first column, the mole fraction of the first element at that grid point in the second column and so on. The column that contain the composition of a given element can then be specified in a macro file by, for example, having a line "read_point_by_point foo.dat 2". The "2" mean that the grid coordinates are in the 2nd column in the file foo.dat. In a corresponding manner the column that contain the grid point coordinates can be specified (see ENTER_GRID_COORDINATES). • If FUNCTION is chosen the composition profile can be given as a function of the global distance denoted X. Some useful functions are the error function denoted `erf(X)` and the Heaviside step-function denoted `hs(X)`. For example the function `3+2hs(x-1e-4)` provides a concentration of 3 at the left side and 5 at the right side with a sharp step in the concentration profile at 1e-4m=100µm.
	`Value of first point` Composition in the first gridpoint. Values in between are interpolated linearly if a LINEAR type of profile is specified.
	`Value of last point` Composition for the last gridpoint. Values in between are interpolated linearly if a LINEAR type of profile is specified.
	`Input file` The input source from which to read the points when entering values point by point, default is TERMINAL.
	`Value of point` The value of the point when entering values point by point.
	`Value of R in the geometrical serie` Use the same geometrical factor as for the geometrical grid.
	`Volume fraction of` Initial volume fraction of a spheroid phase.

ENTER_ENHANCEMENT_FACTOR

Use the ENTER_ENHANCEMENT_FACTOR command to change the mobility of a specific element in a specific phase. The mobility of the element in the phase is multiplied by a factor which is specified as an argument to the command. You can use the `TIME` and `T` (temperature) functions with the command. For example, `1E-4*EXP(-5000/T)` is a function for including T.

A full example of the string you enter at the prompt is

```
ENTER_ENHANCEMENT_FACTOR FCC_A1 C 1200-T;
```

Syntax	ENTER_ENHANCEMENT_FACTOR
Prompts	`MOBILITY ENHANCEMENT FACTOR FOR PHASE` e.g. enter `FCC_A1`
	`ELEMENT` e.g. enter `C`
	`MEF[FCC_A1,C](T,TIME)=` e.g. enter `1200-T;`

ENTER_GEOMETRICAL_EXPONENT

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Use the ENTER_GEOMETRICAL_EXPONENT command to enter the geometrical exponent which defines the geometry of the system. The program handles one-dimensional geometries defined by the geometrical exponent. These geometries are:

- **Planar**. This corresponds to an infinitely wide plate of a certain thickness.
- **Cylindrical**. This corresponds to an infinitely long cylinder of a certain radius.
- **Spherical**. Sphere with a certain radius.

Syntax	ENTER_GEOMETRICAL_EXPONENT
Prompt	`Geometrical exponent` Enter an integer value between 0 and 2.

ENTER_GRID_COORDINATES

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Use the ENTER_GRID_COORDINATES command to enter the size and gridpoint distribution of the grid in each region separately. The size of the region is specified in the units that the diffusion data is entered in. The grid in a specific region may also be subdivided into several parts, where the type of each part is chosen independently, by first entering SUB_REGION as the overall grid type.

SET_AUTO_GRID_OPTION

Syntax	**ENTER_GRID_COORDINATES**
Prompts	`Region name` Name of the region into which a grid is to be entered.
	`Width of region /1/` The actual size of the region is entered. The size of the region is specified in units compatible with those of the diffusion data.
Options	**Description**
`TYPE` of grid	`Type /Automatic/` Type of grid to enter, options are: • `AUTOMATIC`: Use this for automatic grid point distribution. An appropriate grid is generated at the start of the simulation where the grid points are automatically distributed according to the entered composition profile and boundary conditions. • `LINEAR`: For an equally spaced grid. • `READ_POINT_BY_POINT`: Can be done either from the keyboard or from a predefined file. When grid coordinates are read from a file it may often be the case that both grid coordinates and the composition at the grid points are given on the same line, e.g. the grid coordinates in the first column, the mole fraction of the first component at that grid point in the second column and so on. The column that contain the grid coordinates can then be specified in a macro file by, for example, having a line "read_point_by_point 30 foo.dat 1". The "1" mean that the grid coordinates are in the 1st column in the file foo.dat (and "30" is the total number of grid points). In a corresponding manner the column that contain the composition of a specific component can be specified (see ENTER_COMPOSITIONS).

Syntax	ENTER_GRID_COORDINATES
	• GEOMETRIC: Yields a higher number of gridpoints at the lower end of the region if a geometrical factor larger than one is given and a higher number of gridpoints at the upper end of the region if the factor is smaller than one. • DOUBLE_GEOMETRIC: Divides the region in two halves and generates a separate geometrical grid in each half. It gives a high number of gridpoints in the middle or at both ends of a region, two geometrical factors should be entered.
Sub_region	If SUB_REGION is entered when you are prompted to enter the grid type, then the next prompt is `End coordinate in Sub-Region /1/` Enter a value equal to or less than the total width of the region. You are then prompted for the number of grid points and the grid type to be used between the left-hand side of the region and the end coordinate. As long as the end coordinate is less than the total width of the region you are prompted for an end coordinate and the grid to be used in the sub region starting at the end of the former sub region. Thus, progressively higher end coordinates must be entered and the final end coordinate must be equal to the total width of the region.
	`Number of points /50/` The number of points present in the region. Please consider the interspacing of the grid when determining the number of points.
	`Input file` The input source from which to read the points when entering values point by point, default is TERMINAL.
	`Value of point` The value of the point when entering values point by point.
	`Value of R in the geometrical series` Value in the geometrical factor in the series determining the distribution of the grid points. A geometrical factor larger than one yields a higher density of gridpoints at the lower end of the region and a factor is smaller than one yields a higher density of gridpoints at the upper end of the region.
	`Value of R in the geometrical serie for lower part of region` The geometrical factor in the series for the lower (left) part of a region in a double geometrical grid
	`Value of R in the geometrical serie for upper part of region` The geometrical factor in the series for the upper (right) part of a region in a double geometrical grid.

ENTER_HEAT_TRANSFER_PARAMETER

A model for thermos-migration simulates the thermal induced diffusion in temperature gradients. This model requires that the temperature depends on the length coordinate in the system and that the quantity `heat of transport` (`Q*`), is entered using the ENTER_HEAT_TRANSFER_PARAMETER command.

The implementation and functionality of this model is described in [2010Hög].

Syntax	ENTER_HEAT_TRANSFER_PARAMETER
Prompt	`Heat transfer parameter for phase` The phase for which the parameter is to be entered. This parameter is entered separately for each component in each phase.

Reference

[2010Hög] L. Höglund, J. Ågren, Simulation of Carbon Diffusion in Steel Driven by a Temperature Gradient. J. Phase Equilibria Diffus. 31, 212–215 (2010).

ENTER_HOMOGENIZATION_FUN

Use the ENTER_HOMOGENIZATION_FUN command with the homogenization model for multiphase simulations. The homogenization model is based on the assumption of local equilibrium at each node point, which yields the local chemical potentials at each node point from which the local chemical potential gradients may be estimated. The chemical potential gradients are the driving forces for diffusion. The local kinetics must also be evaluated by some averaging procedure, the choice of which is determined by this command. The local kinetics is evaluated by considering the product of mobility times u-fraction for each component in each phase and the volume fraction of each phase.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	ENTER_HOMOGENIZATION_FUN
Prompt	`Enter homogenization function # /5/` Enter a digit between 1 and 14 (default is 5). The options corresponding to the numbers are listed below.

Homogenization Functions

Enter a digit between 1 and 14 (default is #5) to assign the homogenization function then follow the prompts. The homogenization functions are:

No.	Function name
1	General lower Hashin-Shtrikman bound*
2	General upper Hashin-Shtrikman bound*
3	Hashin-Shtrikman bound with prescribed matrix phase*
4	Hashin-Shtrikman bound with majority phase as matrix phase*
5	Rule of mixtures (upper Wiener bound)
6	Inverse rule of mixtures (lower Wiener bound)
7	Labyrinth factor f with prescribed matrix phase
8	Labyrinth factor f**2 with prescribed matrix phase

No.	Function name
9	General lower Hashin-Shtrikman bound with excluded phase(s) *
10	General upper Hashin-Shtrikman bound with excluded phase(s) *
11	Hashin-Shtrikman bound with prescribed matrix phase with excluded phase(s) *
12	Hashin-Shtrikman bound with majority phase as matrix phase with excluded phase(s) *
13	Rule of mixtures (upper Wiener bound) with excluded phase(s)
14	Inverse rule of mixtures (lower Wiener bound) with excluded phase(s)

* For the Hashin-Shtrikman bounds, see [1962Has]

About the Homogenization Functions

The geometrical interpretation of the Hashin-Shtrikman bounds are concentric spherical shells of each phase. For the general lower Hashin-Shtrikman bound the outermost shell consists of the phase with the most sluggish kinetics and vice versa for the general upper bound. The geometrical interpretation of the Hashin-Shtrikman bounds suggest further varieties of the bounds, viz. *Hashin-Shtrikman bound with prescribed matrix phase* and *Hashin-Shtrikman bound with majority phase as matrix phase*, where the outermost shell consist of a prescribed phase or the phase with highest local volume fraction, respectively.

The geometrical interpretation of the Wiener bounds are continuous layers of each phase either parallel with (upper bound) or orthogonal to (lower bound) the direction of diffusion.

The labyrinth factor functions (described below) are available in Console Mode and when using TC-Python.

The labyrinth factor functions implies that all diffusion takes place in a single continuous matrix phase. The impeding effect on diffusion by phases dispersed in the matrix phase is taken into account by multiplying the flux with either the volume fraction (*Labyrinth factor f with prescribed matrix phase*), or the volume fraction squared (*Labyrinth factor f**2 with prescribed matrix phase*), of the matrix phase.

The varieties with excluded phases (described below) are available in Console Mode and when using TC-Python.

The varieties with excluded phases are useful in several respects. First, if a phase is modeled as having zero solubility for a component, the mobility of that component in that phase is undefined, which causes a (non-terminal) error. Setting a phase as excluded causes the mobility of all components in that phase to be set to zero. Second, often there are some major matrix solid solution phases and some minor precipitate phases. If the mobilities in the minor precipitate phases are zero the lower Hashin-Shtrikman bound is useless as it produces a kinetic coefficient of zero. However, using *General lower Hashin-Shtrikman bound with excluded phase(s)* the excluded phases are not considered when evaluating what phase has the most sluggish kinetics.

Reference

[1962Has] Z. Hashin, S. Shtrikman, A Variational Approach to the Theory of the Effective Magnetic Permeability of Multiphase Materials. J. Appl. Phys. 33, 3125–3131 (1962).

ENTER_LABYRINTH_FUNCTION

Use the ENTER_LABYRINTH_FUNCTION command to enter a constant value or a function of temperature, pressure, or the volume fraction of the phase where diffusion occurs. This function increase or reduces the diffusion coefficient matrix. This function is primarily used when spheroid phases have been entered into a region. It may also be used for increasing or decreasing all diffusion coefficients in a certain matrix phase by a constant factor.

Syntax	ENTER_LABYRINTH_FUNCTION
Prompt	`Region` `f(T,P,VOLFR,X)=`

ENTER_MOBILITY_DATA

Use the ENTER_MOBILITY_DATA command to enter previously non-existing mobility parameters. If there is already a function is defined for the same parameter, it is deleted.

You can also use:

- ENTER_ENHANCEMENT_FACTOR to enter a factor by which element mobilities are multiplied with.
- ENTER_MOBILITY_ESTIMATE to enter a rough mobility estimate for elements in specific phases. This can be useful for phases where there is no data in the database.

A valid parameter should have the general form of:

```
<Identifier> ( <Phase name> , <Component array> ; <Digit> )
```

The `identifier` must be followed by an opening parenthesis, a phase name, a comma and a component array. Optionally, the component array can be followed by a semicolon and a digit. The parameter name is terminated by a closing parenthesis.

These identifiers are legal:

- `MQ` (activation energy for mobility)
- `MF` (frequency factor for mobility)
- `DQ` (activation energy for diffusivity)
- `DF` (frequency factor for diffusivity)
- `OQ` (activation energy for mobility, ordered part)
- `OF` (frequency factor for mobility, ordered part).

The `phase name` must be followed by an & and directly following that the name of the diffusing species.

The `component array` consists of a list of constituent names. Interaction parameters have two or more constituents separated by a comma. If the phase has sublattices at least one constituent in each sublattice must be specified. The constituents in different sublattices must be given in sublattice order and are separated by a colon.

After the component array a subindex `digit` can be specified after a semicolon. This digit must be in the range 0 to 9. The interpretation of the subindex depends on the excess model used for the phase. If no semicolon and digit is given the subindex value is assumed to be zero.

Syntax	ENTER_MOBILITY_DATA
Prompt	`Parameter: <Parameter name>`

Syntax	ENTER_MOBILITY_DATA

	As explained above, specify a correct and complete parameter name, which should contain all the necessary parts of the general form:
	`<Identifier>(<Phase>,<Component array>;<Digit>)`
	If a parameter name is not acceptable or <Enter>, is pressed, the error message displays:
	`*** Error, please re-enter each part separately`
	Examples
	• `MQ(FCC&C,Fe:Va)` Mobility of C in fcc Fe with interstitials.
	• `MQ(FCC&C,Fe,Cr;0)` The regular parameter for Fe and Cr in fcc.
	• `MQ(FCC&C,Fe,Cr;1)` The subregular interaction parameter (Redlish-Kister model).

`Identifier`	`Identifier /MQ/ <MQ, MF, DQ, Df, OQ, OF>` If this command is used one or more times, the previous value on this prompt is set as default. Press <Enter> for the same type identifier or specify a new type.
`Phase Name`	`Phase name /FCC&C/` Each parameter is valid for a specific phase. The name of that phase must be supplied. The name must not be abbreviated. The phase name must be followed by an '&' and directly following that, the name of the diffusion species.

ENTER_MOBILITY_ESTIMATE

Use the ENTER_MOBILITY_ESTIMATE command to enter a function yielding a mobility estimate for a specific element in a specific phase.

LIST_MOBILITY_ESTIMATES

Syntax	ENTER_MOBILITY_ESTIMATE
Prompt	`Mobility estimate for phase` Interactively enter a function yielding a mobility estimate for a specific element in a specific phase. This can be used to enter mobility estimates in phases for which there is no assessed data. Estimates entered here override database values.

ENTER_PHASE_IN_REGION

Use the ENTER_PHASE_IN_REGION command to enter a phase into a previously defined region.

Syntax	ENTER_PHASE_IN_REGION
Prompts	`Active or Inactive phase` Type of phase entered. An inactive phase is a phase which does not participate in the calculations until it is stable. This is done by regarding the driving force for precipitation of the phase in an equilibrium calculation. The program then automatically retransforms the inactive phase into an active one.
	`Region name` Name of the region into which the phase is to be entered.
	`Phase type` Type of phase entered. Legal types are: • MATRIX • LAMELLAR (see ENTER_PHASE_IN_REGION - Lamellar Prompts). • SPHEROID: requires that a MATRIX phase has been previously entered.
	`Phase name` Name of the phase that is to be entered. A #-sign and a digit may append the phase name in order to specify the composition set number, e.g. FCC#2.
	`Composition set` Number of the composition set. This is needed if the phase has been amended to have more than one composition set and the number was not given directly on the phase name, see above.
	`Attach to region named` Enter the name of the region onto which the inactive phase is to be attached.
	`Attached to the right of` Enter Y to attach the inactive phase on the right side of the region. Enter N to attach on the left side.
	`Required driving force for precipitation` The required driving force (evaluated as DGM (phase) in POLY-3) to be used for determining whether an inactive phase is stable.
	`Condition type` Boundary condition used if the inactive phase becomes stable.

ENTER_PHASE_IN_REGION - Lamellar Prompts

The following are the ENTER_PHASE_IN_REGION subprompts for Lamellar.

For a LAMELLAR type of phase as a subprompt for the ENTER_PHASE_IN_REGION command, the pearlite calculation model is invoked. The following is displayed:

```
eutectoid reaction is "gamma" ==> "alpha" + "beta"
```

This is to clarify what is meant with GAMMA, ALPHA, and BETA in the specific sub-prompts that display as follows.

Syntax	ENTER_PHASE_IN_REGION > LAMELLAR
	`Enter name of "alpha" phase` Enter the GES phase name for the ALPHA phase of the eutectic/eutectoid decomposition product.
	`Enter name of "beta" phase` Enter the GES phase name for the BETA phase of the eutectic/eutectoid decomposition product.
	`Enter name of "gamma" phase` Enter the GES phase name for the GAMMA matrix phase.
	`Enter "alpha"/"beta" surface tension:` Enter function for the surface tension between the ALPHA and BETA phases, $\sigma^{\alpha/\beta}$
	`Enter "alpha"/"gamma" surface tension:` Enter function for the surface tension between the ALPHA and GAMMA phases,$\sigma^{\alpha/\gamma}$
	`Enter "beta"/"gamma" surface tension:` Enter function for the surface tension between the BETA and GAMMA phases,$\sigma^{\beta/\gamma}$
	`Optimum growth condition factor /2/:` Enter the Optimum-growth-rate-factor. Due to Zener's maximum growth rate criteria this factor has a value of 2 for volume controlled growth and 3/2 for boundary controlled growth. Due to Kirkaldy's extreme in entropy production criteria the values are 3 and 2, respectively.
	`Name of dependent element` Enter the name of the substitutional element to consider as the dependent one.
	`Growth model (Volume/Boundary/Kirkaldy) for element x` Select growth model to be used for element X. Choose between: • `Volume` diffusion model • `Boundary` diffusion model • `Kirkaldy`'s mixed mode diffusion model. Implies MIXED, see below.

Syntax	ENTER_PHASE_IN_REGION > LAMELLAR

	`df(x) = /Value/Automatic/Mixed/TDB/`
	Either input a numerical value on the pre-exponential factor DF or select one of the keywords:
	• AUTOMATIC
	• MIXED
	• TDB
	AUTOMATIC is only available for element Carbon. It implies a mixed type of calculation where the volume diffusion part is calculated due to [1986Ågr] (volume diffusion of C in Austenite) and the boundary diffusion part due to [1982Ågr] (boundary diffusion of C is assumed to be the same as C diffusion in Ferrite).
	The k' or k'', as appropriate, are given by [1992Jön]. MIXED means a mixed mode calculation using an effective diffusion coefficient. Coefficient k' or k'' is asked for, see below. TDB means calculate the diffusion coefficient for volume diffusion for element X from the parameters stored in the database.
	`DQ(X)=`
	Input a numerical value on the activation energy DQ for element X.
	`k'=`
	`k''=`
	Input a numerical value on the k coefficient used to calculate the effective diffusion coefficient, use in MIXED mixed mode calculations, see B. Jönsson, 1992“On the Lamellar Growth of Eutectics and Eutectoids in Multicomponent Systems.” Trita-Mac 478 (January): 27.

	`DF_boundary(x)=` Input a numerical value on DF for boundary diffusion of element X in a mixed mode calculation.
	`DQ_boundary(x)=` Input a numerical value on DQ for boundary diffusion of element X in a mixed mode calculation.
	`DF_volume(x)=` Input a numerical value on DF for volume diffusion of element X in a mixed mode calculation. N.B. key word TDB may also be used, see TDB above.
	`DQ_volume(x)=` Input a numerical value on DQ for volume diffusion of element X in a mixed mode calculation.
	`Automatic start values for the s0 determination /Y/:` Enter `Y` if you want automatic start values for the unknown parameters in the S0 determination else enter `N`. S0 is the critical lamellar spacing for which the growth rate is zero.
	`Critical thickness of "alpha" lamella:` If you answered `N` this prompt displays. The critical thickness of ALPHA is about 0.9 of S0, which in turn is about 1/3 to 1/2 of the observed lamellar spacing S. For binary Fe-C alloys the observed pearlite lamellar spacing is approximately given by $$S = 1.75 \cdot 10^{-5}(A_{1e} - T)^{-1}$$ The equation may be used as a start value approx. for alloyed steels. However, use the $\mathbf{A_{1e}}$

Syntax	ENTER_PHASE_IN_REGION > LAMELLAR
	temperature of the steel.
	`Critical thickness of "beta" lamella:` The critical thickness of BETA is about 0.1 of S0, see above.
	`Automatic start values on potentials /Y/:` By default, automatic start values for the unknown potentials are used. Choose N to enter your own start values.
	`Give potentials for "alpha"/"gamma" equil.` Enter start values for the unknown potentials, MU, at the ALPHA/GAMMA phase boundary.
	`Give potentials for "beta"/"gamma" equil.` Enter start values for the unknown potentials, MU, at the BETA/GAMMA phase boundary.
	`Growth rate v:` Enter a start guess on the growth rate. As a hint on what value to choose we recognize that for binary Fe-C alloys the pearlite growth rate is approximately given by: $$v = 8 \cdot 10^{-9}(A_{1e} - T)^2$$ The equation may be used as a start value approx. for alloyed steels. However, use the A_{1e} of the steel.
	`Automatic start values on other variables /Y/:` By default there are automatic start values for the unknowns in the determination of the growth rate.
	`Fraction of "alpha" phase:` Enter a guess on the fraction of the ALPHA phase. For pearlite it is about 0.9.
	`Give potentials for "alpha"/"gamma" equil.` Enter start values for the unknown potentials, MU, at the ALPHA/GAMMA phase boundary.
	`Give potentials for "beta"/"gamma" equil.` Enter start values for the unknown potentials, MU, at the BETA/GAMMA phase boundary.

ENTER_REGION

Use the ENTER_REGION command to enter a region into the system. Enter this before entering a grid or any phases.

Syntax	ENTER_REGION
Prompts	`Region name` Name of a region to be entered. The name of the region can be arbitrarily chosen.
	`Attach to region named` Name of a region to which the new region should be attached.
	`Attached to the right of` Relative position of the new region. Enter Y to attach the inactive phase on the right side of the region. Enter N to attach on the left side.

GB_MODEL

Grain-boundary and dislocation assisted diffusion is implemented with the GB_MODEL command by assuming that these contributed to the diffusion by using the same frequency factor and a modified bulk activation energy. The grain-boundaries and the dislocations contribute to the total amount of diffusion according to the weighted fractions.

Syntax	GB_MODEL
	The parameters are entered separately for each region in order to different expression for different phases.
	The used expressions for the grain-boundary and dislocation contributions are: $$M^{gb} = M_0^{bulk} \cdot \exp(F_{redGB} \cdot Q^{bulk}/R/T)$$ $$M^{disl} = M_0^{bulk} \cdot \exp(F_{redDisl} \cdot Q^{bulk} R/T)$$ where • M_0^{bulk} : frequency-factor in the bulk • Q^{bulk} : activation energy in the bulk • F_{redGB} : bulk diffusion activation energy multiplier (typical value 0.5) • $F_{redDisl}$: bulk diffusion activation energy multiplier (typical value 0.8) The weighted calculated value for the mobility M^{new} is then evaluated from: $$M^{new} = \delta/d \cdot M^{gb} + \rho \cdot b^2 \cdot M^{disl} + (1 - \delta/d - \rho \cdot b^2) \cdot M^{bulk}$$ where • δ: grain boundary thickness (typical value $0.5 \cdot 10^{-9}$ or $0.5 \cdot 10^{-10}$) • d: grain size as a function of time and temperature (typical value $25 \cdot 10^{-6}$) • ρ: dislocation density as a function of time and temperature • b: burgers vector (typical value $1 \cdot 10^{-10}$) • M^{bulk}: mobility in the bulk (δ/d being the fraction of grain boundaries in the bulk and $\rho \cdot b^2$ being the fraction of dislocations in the bulk)

HOMOGENIZATION_MODEL

UTILITIES_HOMOGENIZATION

ADVANCED_HOMOGENIZATION_OPTIONS

The HOMOGENIZATION_MODEL command enables or disables the use of the homogenization model and its default settings. The homogenization model is used for multiphase simulations assuming that local equilibrium holds at each node point. When entering phases into a region one of them is entered as MATRIX phase and all other phases as SPHEROID, but it does not matter which one is entered as matrix phase and it does not affect simulations. Homogenization model simulations differs from all other DICTRA module simulations in that it is implemented using an implicit finite volume method in order to increase numerical stability (degree of implicity can be chosen using the SET_SIMULATION_CONDITION command). Because of this, and other factors, homogenization model simulations generally run slower than other comparable simulations.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	HOMOGENIZATION_MODEL
Prompts	`Enable homogenization model:` Enter `Y` to enable the homogenization model. If it is already enabled, you can enter `N` to disable it.
	`Use default settings /Y/:` Press <Enter> to keep the default settings for the homogenization model. Otherwise enter N and follow the prompts.

	`Add ideal flux contribution /N/:`
	If you enter `Y` you are prompted as follows:
	`Fractional ideal contribution(0->1) /.01/:`
	Enter a number between zero and one. In multiphase regions the system loses degrees of freedom which may cause fluctuations in the composition profiles. This can be amended by adding a small ideal contribution to the fluxes. The ideal flux contribution should normally not be used.

	`Use interpolation scheme /Y/:`
	By default the interpolation scheme is used and it normally speeds up simulations. You are then prompted with the following:
	`Enter number of steps between XMin and XMax /10000/:`
	Enter the number of steps in composition space. In the limit where an infinite number of steps are used, exactly the same solution is obtained as without the interpolation scheme. However, excellent

Syntax	HOMOGENIZATION_MODEL

	results can be obtained with a reasonable discretization.
	`Linear or logarithmic discretization /Log/:`
	The discretization can be either linear or logarithmic (the default). For the linear discretization the scheme is not used at node points where the content of one or more solutes fall below a certain critical value. For such cases, where a good discretization is required for very low solute contents, the logarithmic discretization can be tried.
	`Fraction of free physical memory to be used /.1/:`
	Enter the fraction of free physical memory to be used by the interpolation scheme. If a value larger than one (1) is entered it is interpreted as the number of MB to be used for the interpolation scheme.

	`Use global minimization /N/:` By default global minimization is not used in equilibrium calculations. In general, using global minimization significantly increases the simulation time, but there is also a significantly reduced risk for non-converged equilibrium calculations.
	`Refresh Jacobian every iteration /N/:` If there are convergence problems, enter Y to see if this solves the issue. This does increase computational demand for each iteration.
	`Default grid parameter values /Y/:` These settings only affect simulations where the grid changes during the simulation. If you enter N, you are prompted with the following.
	`Geometrical coefficient (0+ -> 1) /.98/:` The geometrical coefficient used in each region.
	`Fixed interface width (<0 DISABLES) /-1/:` A value larger than zero makes interface widths fixed to that value.
	`Grid fineness away from interface /1/:` A value other than one causes the grid away from the interface to be coarser (>1) or finer (<1) than what would be obtained just by the geometrical coefficient.
	`Interface width fraction (0+ -> 0.1) /.005/:` If the interface width is not fixed the program aims for a width equal to this factor times the cell width.
	`Consecutive critical time-steps (DT) to delete region /20/:` If the width of a region falls below a certain critical value and shrinks monotonically for this number of time-steps it is deleted.

INPUT_SCHEIL_PROFILE

As per normal procedure, and before entering the DICTRA monitor, you need to read thermodynamic and kinetic data to use this command.

The INPUT_SCHEIL_PROFILE command takes a previously calculated Scheil segregation profile and performs most of the setup needed to use that profile in a simulation, for example a homogenizing heat treatment.

The command creates a region called SCHEIL_REGION. You then create a linear grid and enter the composition read from the file containing the segregation profile.

After issuing this command, you specify simulation time (SET_SIMULATION_TIME) and simulation temperature (SET_CONDITION, enter `GLOBAL` and variable `T`) to finalize setup.

In order to limit the computational effort, this feature cannot be combined with the fast diffusers option in the Scheil module.

Press F1 in Thermo-Calc to search the online help for detailed information about Scheil simulations.

Syntax	INPUT_SCHEIL_PROFILE
Prompts	`Enter file location of Scheil segregation profile` In interactive mode (the command line), a file dialogue window opens. Navigate to the file containing the Scheil profile. Alternately, if you are working from a macro file, the line should contain the name of the file. An XF.txt file can be created with the EVAL_SEGR command in the Thermo-Calc SCHEIL module. The file is available after the Scheil simulation is finished and contains one line per grid point. See EVAL_SEGREGATION_PROFILE for more information and to make sure to use the same number of grid points in the DICTRA region for both commands.
	`Enter width of region` Enter the width of the region [m] that contains the Scheil profile. This typically corresponds to the secondary dendrite arm spacing.

Syntax	INPUT_SCHEIL_PROFILE
	`Enter main solid solution phase` Enter the name of one of the main solid solution phases. In the next prompt you can enter other phases that enter the simulation.
	`Should more phases be entered in the region` Enter Y to enter more phases then enter the phase name as prompted next.
	`Enter phase name` Enter the name of another phase that should be entered into the region.

INTERFACE_SURFACE_TENSION

The INTERFACE_SURFACE_TENSION command enters a distance- and velocity-dependent function that is added to the Gibbs energy of the phase at left side of a specified interface. This can then be used to emulate the effect of surface tension on the equilibrium between at the phase interface or limited phase mobility. This command is similar to the SET_SURFACE_TENSION command but more flexible because if there is more than one interface in a cell, the user can add different Gibbs energy expressions to different interfaces, each specified by the two neighboring phases.

For detailed syntax for the function, see the SET_SURFACE_TENSION command.

Syntax	INTERFACE_SURFACE_TENSION

Prompt	`PHASE ON LEFT SIDE OF INTERFACE`
	The name of the phase on the left side of the specified interface.
	`PHASE ON RIGHT SIDE OF INTERFACE`
	The name of the phase on the right side of the specified interface.
	`Function F(X,V,TIME,T):`
	Enter a function which adds to the Gibbs energy expression for the phase located at the lower (left) side of the interface. The expression is multiplied with the volume per mole substitutional atoms (10-5m^3/mole). This command is also used to simulate a limited interfacial mobility control where the energy function is a function of the interface velocity.
	It is used to enter the surface energy to enable coarsening. However, it can also be used to simulate a case with a limited interfacial mobility.

LIST_CONDITIONS

Use the LIST_CONDITIONS command to lists the conditions defined with the SET_CONDITION command.

Syntax	LIST_CONDITIONS
Prompt	`Output file` File where the information is to be written.

LIST_MOBILITY_DATA

This command does not work for encrypted databases.

The LIST_MOBILITY_DATA command lists the mobility data from the database or entered interactively by the ENTER_MOBILITY_DATA command.

Syntax	LIST_MOBILITY_DATA
Prompt	`Output file` File where the information is to be written.

LIST_MOBILITY_ESTIMATES

Use the LIST_MOBILITY_ESTIMATES command to list on screen the mobility estimate entered interactively using the ENTER_MOBILITY_ESTIMATE command.

LIST_PROFILES

Use the LIST_PROFILES command to list the concentration profiles and grid coordinates in the cell.

Syntax	LIST_PROFILES
Prompts	`Name of region` Name of region(s) in which the profiles are to be listed.
	`Output file` File where the information is to be written.
	`Composition type` Composition type in which the profiles are to be written. Legal composition types are: • SITE_FRACTION • MOLE_FRACTION • WEIGHT_FRACTION • U_FRACTION
	`Components` The output information may be limited to the specified components.
	`Constituents` The output information may be limited to the specified constituents.

LIST_REGION

Use the LIST_REGION command to list the names of the defined regions, active and inactive phases and the global coordinates of the interfaces.

Syntax	LIST_REGION
Prompt	`Output file` File where the information is to be written.

LIST_TIMESTEPS

This for the DICTRA module. Also see LIST_TIME_STEPS for the POST module.

Use the LIST_TIMESTEPS command to list the time steps in the workspace and those stored on file during a simulation.

MACRO_FILE_OPEN

Use the MACRO_FILE_OPEN command to predefine sequences of commands on a file and then execute them with the MACRO command. This is useful when the same calculation is made often with just small changes. One good case for applying this is when calculating diagrams from an assessment. With a macro file all commands can be stored on a file and you just type `MACRO <filename>`.

The macro file can contain any legal DICTRA module commands. The macro must be terminated with EXIT or in the SYS, DICTRA, POLY-3 or POST module with the command SET_INTERACTIVE_MODE.

Syntax	MACRO_FILE_OPEN
Prompt	`Macro filename` Give the name of the file with the macro commands. Default extension is DCM.

PARA_EQUILIBRIUM_MODEL

Use the PARA_EQUILIBRIUM_MODEL command to turn on the para-equilibrium model in the simulation. Using this model implies that the local equilibrium assumption is no longer valid and that substitutional components are regarded as one composite component.

The model is limited to treating only one single moving interface in one cell.

See the Diffusion Module (DICTRA) example EXH2, which is briefly described in Deviation from Local Equilibrium Examples

Syntax	PARA_EQUILIBRIUM_MODEL
Prompts	`Enable paraeq` Enables or disables the use of this model by using one of the key words YES or NO.
	`Auto` Choose this to set it to the value at the region's lower or upper boundary.
	`Value %` Enter a value followed by a percentage sign (%) to set it to a certain percentage from the moving boundary inside the region.
	`-Value` Enter a hyphen (-) followed by a value to set it to a fixed distance from the moving boundary.
	`Value` Enter a value to set the composition to that specific value,

POLY_COMMAND

The POLY_COMMAND command sends a string to the POLY-3 module interpreter where it is then executed.

An example of the use of this command is as follows. There are some differences in the default settings for equilibrium calculations based on whether the equilibrium calculation is performed from the DICTRA module or POLY. The changes in the defaults are performed automatically every time the DICTRA module is entered. By using this command it is possible to override those changes.

Syntax	POLY_COMMAND
Prompt	`To POLY` Command line sent to the POLY-3 module.

POST_PROCESSOR

Use the POST_PROCESSOR command to "give control" to the post processor. Then you can start using the commands.

READ_WORKSPACES

Both GES6 and GES5 data are saved to/read from a dic-file. For information about GES versions, see About the Gibbs Energy System (GES) Module.

When you use the READ_WORKSPACES command, the DICTRA, POLY-3 and GES workspaces can be read from a file where they must be already saved with a SAVE command. This file is not printable.

Syntax	READ_WORKSPACES
Prompt	`File name` Name of the file where the workspaces shall be read from. The default file extension is `dic`.

REINITIATE_MODULE

Use the REINITIATE_MODULE command to reset the state of the DICTRA module to what it was when you first entered the workspace.

REMOVE_STOP_CRITERION

The REMOVE_STOP_CRITERION command can be used as long as you have already set up the simulation and included a stop criterion using the ADD_STOP_CRITERION command.

There are no prompts. You enter arguments, either a number referring to a specific criterion (as shown inLIST_CONDITIONS) or a wildcard * referring to all criteria.

ADD_STOP_CRITERION

SAVE_WORKSPACES

Both GES6 and GES5 data are saved to/read from a dic-file. For information about GES versions, see About the Gibbs Energy System (GES) Module.

When you use the SAVE_WORKSPACES command, the workspaces in DICTRA, POLY-3 and GES are saved in a file. Return to the state before the SAVE command by entering a READ command. The SAVE command should normally be given before starting a simulation with SIMULATE_REACTION.

Syntax	SAVE_WORKSPACES
Prompts	`File name` Name of the file where the workspaces shall be saved on. The default file extension is DIC.
	`Overwrite current file content`
	`Proceed with save` If there is already a file with this name and if you answer Y the previous content is overwritten. If you have results from SIMULATE_REACTION these are lost when SAVE is used. You may append several results by the SIMULATE_REACTION command without destroying the previous results but SAVE erases them all.

SELECT_CELL

Use the SELECT_CELL command to select the current cell from the list of existing cells and enables you to enter and display data into that cell. This command is for the DICTRA.

See also POST PROCESSOR prompt of the same name SELECT_CELL.

Syntax	SELECT_CELL
Prompt	`Number` Specify the cell number by giving an integer or one of the key words NEXT or PREVIOUS.

SELECT_TIMESTEP

Use the SELECT_TIMESTEP command to select a time step from those stored on file during a simulation. The profiles can be listed and simulation can be continued from this time step.

Syntax	SELECT_TIMESTEP
Prompt	`Timestep` The time step to be selected, legal syntax is: • `FIRST` • `LAST` • `time` • `#nnn` • `#?` When selecting a time no interpolation is performed but the time step closest to the time entered is selected. #nnn can be obtained from the number given by LIST_TIMESTEPS or by typing `#?`.
	`Delete all other timesteps` Clears the current workspace from all other time steps except the one selected. This is necessary if the simulation is to be continued from this time step.

SET_ACCURACY

Use the SET_ACCURACY command to enter the accuracy requirements to use in the determination of the time step when using the automatic time step procedure. It may also be necessary to modify the parameters to control the removal of grid points and set manual starting values for velocities and potentials at the phase interfaces.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	SET_ACCURACY
Prompts	`Max relative error` The maximum allowed relative error of the profile during one time step integration.
	`Max absolute error` Maximum allowed absolute error of the profile during one time step integration. This parameter must be chosen with some relation to the smallest concentration in the profiles.

SET_ALL_START_VALUES

Use the SET_ALL_START_VALUES command to enter starting values for various quantities, such as velocities and potentials.

Syntax	SET_ALL_START_VALUES
Prompts	`Start value for velocity of interface` A starting value for velocity at the named interface is required.
	`Start value for potential` A starting value for a potential at the named interface is required. If an AUTOMATIC value is specified the program attempts to determine a starting value and also selects a suitable component for which the potential is varied.
	`Varying species in interface` The species which potential is treated as unknown.
	`Automatic starting values for phase compositions` Compositions used as starting values in the equilibrium calculations using POLY-3. When using automatic starting values the compositions are taken from the entered profiles.

SET_AUTO_GRID_OPTION

Use the SET-AUTO-GRID-OPTION command to set the number of equidistant points in a region (e.g. maximum distance between two adjacent grid points is the size of the region divided by this number) and the maximum factor that is allowed in the geometric series defining the initial grid.

HOMOGENIZATION_MODEL

Syntax	SET_AUTO_GRID_OPTION
Prompt	`GRID ACCURACY/MEDIUM/:` Press enter to accept the default (MEDIUM), or enter FINE, COARSE, or CUSTOM. The values for the Grid Accuracy settings for each option differ when calculated by Thermo-Calc based on whether it is the Classic or Homogenization model. • If you are using a Classic model: Fine 75/1.25, Medium 50/1.2, Coarse 25/1.15 (Number of points/Max geometric factor) • If you are using the Homogenization model: Fine 100/1.03, Medium 80/1.02, Coarse 60/1.01 (Number of points/Max geometric factor)
Custom	If CUSTOM is entered then further define these settings. MAX NUMBER OF EQUIDISTANT POINTS IN A REGION: /50/: This value must be more than 2. VALUE OF R IN THE GEOMETRICAL SERIE : /1.2/: Value in the geometrical factor in the series determining the distribution of the grid points. A geometrical factor larger than one yields a higher density of gridpoints at the lower end of the region and a factor is smaller than one yields a higher density of gridpoints at the upper end of the region.

SET_CONDITION

Use the SET_CONDITION command to define conditions to reduce the degrees of freedom at equilibrium or defines the boundary conditions at the outer rims of the system. Use it to set the temperature, pressure or heat extracted from the system.

Conditions can be a function of time and different time-dependent functions can be specified at different time intervals. The syntax for this is approximately the same as used in the GES to specify temperature ranges for thermodynamic parameters.

DICTRA uses a constant molar volume, which is included in the flux, i.e. the unit of flux as entered in boundary conditions is:

$$\text{flux*molar volume} = \text{mol*m}^{-2}\text{*s}^{-1}\text{*m}^{3}\text{*mol}^{-1} = \text{m*s}^{-1}$$

Syntax	SET_CONDITION
Prompts	`Global or Boundary Condition /Global/` Type of condition to be specified. A global condition is either pressure (P), temperature (T) or heat content removal (P) and may be specified as a function of time. Boundary conditions determine how the cell interacts with the world outside the cell.

	`Variable`
	Legal variables are pressure (P), temperature (T) or heat extracted (Q) as a function of time (TIME), TIME_TEMPERATURE_PAIRS (T-T-P) that specifies temperature at a specific time and lets the program calculate the cooling or heating rate, or LOOKUP_TABLE_TEMPERATU that reads a file with time-temperature pairs. For Q the amount of extracted heat per time unit is normalized and the size of the system is normalized to 1 mole of atoms.
	For example, if you enter T-T-P at the Variable prompt then at the next prompt:
	`TIME,TEMPERATURE`
	Specify temperature and time pairwise such as e.g.:
	`0 1400`
	`60 1200`
	`* 1200`
	Where entering an asterisk(`*`)" is required in order to indicate the end time of a simulation.
	For LOOKUP_TABLE_TEMPERATU the file should look similar except for the end time:
	`0 1473`
	`60 1273`
	`1000 1173`
	For the lookup table some optimization is done. Redundant pairs are removed when reading the data.
	Tips to Determine the Temperature as a Function of Time

Syntax	SET_CONDITION
	The two methods to determine the temperature as a function of time, TIME_TEMPERATURE_PAIRS and LOOKUP_TABLE_TEMPERATU, are used in different ways based on the type of simulation. • TIME_TEMPERATURE is a shortcut to the ordinary temperature condition and is translated into a series of different temperature conditions. For example, they appear as a series of conditions if the conditions are listed. This sets some limits on the time-step that is used, occasionally overriding the limit set in the SET_SIMULATION_TIME command. The time-step is also adjusted to always coincide with the time giving in the time-temperature pair. Therefore it is recommended that this option is only used for a limited number of pairs, e.g. a linear approximation of a heat-treatment cycle. For the input to be valid, the last time in the set of pairs must be given as a wildcard *. • LOOKUP_TABLE stores the time and temperature pairs and interpolates within the table in order to obtain the correct temperature for a certain time. The time-step is limited by how much the temperature is allowed to change over the time-step besides the maximum limit provided by the SET_SIMULATION_TIME command. This allows for the use of a very large dataset containing several hundred values, e.g. a measured temperature from a solidification. Should the simulation exceed the last time given in the table, an error message is shown but the simulation will continue using the last temperature in the list.
	`Boundary` Defines on which side of the system the boundary conditions are to be specified. Options are UPPER (the rightmost side of the system) and LOWER (the leftmost side of the system).
	`Condition type` Defines the type of boundary condition to be specified. The options may in most cases be functions of both TIME, T (temperature) and P (pressure). The default is CLOSED_SYSTEM which is equivalent to setting the fluxes of all components to zero at the boundary. Options are: • `FIX_FLUX_VALUE`: Enter functions that yield the flux times the molar volume for the independent components. May be a function of time, temperature and pressure. • `STATE_VARIABLE_VALUE`: A legal expression in POLY-3 syntax that reduces the degrees of freedom. This type of boundary condition should be used with the uttermost care as no checks are done if it is a legal expression in advance. • `ACTIVITY_FLUX_FUNCTION` or `POTENTIAL_FLUX_FUNCTION`: These types of boundary conditions are used to take into account the finite rate of a surface reaction. The flux for the independent components must be given in the format: $$J_k * V_m = f_k(T,P,TIME)^* \left[ACTIVITY_k^N - g_k(T,P,TIME)\right]$$ or $$J_k * V_m = f_k(T,P,TIME)^* \left[POTENTIAL_k^N - g_k(T,P,TIME)\right]$$ where *f* and *g* may be functions of time (TIME), temperature (T), and pressure (P), and N is an integer.

Syntax	SET_CONDITION
	The activities are those with user defined reference states. The function f_k is the mass transfer coefficient, g_k is the activity of the corresponding species in the gas and *N* is a stoichiometric coefficient. For more details see [1988Spr]. • `ITERATIVE_ACTIVITY_FLUX_FUNCTION`: Same as activity flux function above. However, an iterative scheme is used to determine the flux. This method may be used instead of activity flux function when the latter has problems. • `CLOSED_SYSTEM`: Corresponds to a fix flux value, which is set to zero at all times. • `MIXED_ZERO_FLUX_AND_ACTIVITY`: The flux of selected components is set to zero and the activity of others may be set to a prescribed value. • `GAS`: The flux of selected components is set to zero and the activity of others may be set to a prescribed value. This option is used for treating an expanding system, e.g. the growth of an external oxide scale.
	`Low time limit` The lower time limit to be used when entering a time dependent function.
	`High time limit` The upper time limit to be used when entering a time dependent function. An asterisk * indicates the high limit as infinity.
	`Any more ranges` To specify whether any additional time dependent functions exists or not.
	`Type of condition for component` The type of condition when setting a boundary condition of the type MIXED. Options are ZERO_FLUX and ACTIVITY.

Reference

[1988Spr] L. Sproge, J. Ågren, Experimental and theoretical studies of gas consumption in the gas carburizing process. J. Heat Treat. 6, 9–19 (1988).

SET_FIRST_INTERFACE

Use the SET_FIRST_INTERFACE command to set the coordinate of the first interface in the cell, when a value other than zero is required, for instance when simulating diffusion through a tube wall or a hollow sphere. The default value is zero.

Syntax	SET_FIRST_INTERFACE
Prompt	`Coordinate for first interface` The coordinate to which the first interface is to be set.

SET_INITIAL_TEMPERATURE

The SET_INITIAL_TEMPERATURE command is only used when the heat removal rate from the system is specified. It yields the initial temperature of the system. How the temperature then varies during the simulation is a result of the heat removed from the system.

Syntax	SET_INITIAL_TEMPERATURE
Prompt	`Initial temperature /2000/`

SET_LOG_LEVEL

Use the SET_LOG_LEVEL command to choose the amount of output to the logs during a homogenization model simulation. The default (2) keeps the log output to a minimum and thus limits the possibility of slowing down a calculation.

Syntax	SET_LOG_LEVEL
Prompt	`HOMOGENIZATION MODEL LOG LEVEL(1=NORMAL, 2=MINIMAL): /2/:` Choose 1 to set the amount of logging to normal and 2 to set it to a minimal amount (the default).

SET_NUMERICAL_LIMITS

Use the SET_NUMERICAL_LIMITS command to set parameters to control the integration, the solution of the flux balance equations, diffusion equations and the equilibrium calculation during the simulation.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	SET_NUMERICAL_LIMITS
Prompts	`Required sum of squares in NS01A` Required accuracy during the solution of the flux-balance equations.
	`Max number of calls to Calfun of NS01A` The maximum number of iterations when solving the flux-balance equations. This number acts as a *safety valve*, a moderate choice is 10*(number_of_interfaces *(number_of_components - 1)) but use a larger value if necessary.
	`Step used by NS01A` A user supplied parameter which is used to calculate the estimates of the partial derivatives numerically when solving the flux-balance equations.
	`Max step used by NS01A` A parameter which must be set to a generous estimate of the 'distance' between the initial approximation and the required solution of the flux-balance equations.
	`Max number of equidistant points in a region` The number of equidistant parts in which a region is divided into that is required to describe the profile. This parameter is used by the procedure that removes unnecessary gridpoints from the profile during the simulation; the number of gridpoints is normally not allowed to be less than this number if a linear grid is used.
	`Fraction of region assigned to the interface` Fraction of a region at the region border that is to be regarded as part of the interface. This parameter is used by the procedure that removes unnecessary gridpoints from the profile during the simulation.
	`Smallest number used in scaling flux equations` The flux-balance equations are scaled by the velocities calculated in the previous time step. This number may however decrease to such a small value so that convergence may be affected. The scaling factor is therefore not allowed to decrease below this value.
	`Default driving force for inactive phases` Sets the necessary driving force needed before an inactive phase is allowed to start to precipitate.

Syntax	SET_NUMERICAL_LIMITS
	This is also available as a shortcut via SET_OPTION

SET_OPTION

The SET_OPTION command is a short cut to other commands to set a variety of parameters. It is a short cut to quickly apply commands and settings that also continue to be included with the SET-SIMULATION-CONDITION and SET_NUMERICAL commands. The intent is just to save time and reduce key strokes to get to the actions.

Syntax	SET_OPTION
Prompts	`Option /None/` Choose from these short cuts . • ALLOW_AUTOMATIC_SWITCHING_OF_VARYING_ELE • CHECK_INTERFACE_POSITION • DEFAULT_DRIVING_FORCE_FOR_INACTIVE_PHASE • DEGREE_OF_IMPLICITY_WHEN_INTEGRATING_PDE • SAVE_WORKSPACE_ON_FILE • VARY_POTENTIALS_OR_ACTIVITIES_OR_LNAC Except for one, all short cuts are connected to the command SET_SIMULATION_CONDITION
	`ALLOW AUTOMATIC SWITCHING OF VARYING ELEMENT : /YES/:` Or enter No to return to the prompt. Determines whether the program is allowed to itself switch the component that is used to reduce the degrees of freedom at the local equilibrium. The scheme used is that of choosing the components which activities or potentials varied most during the previous timestep.
	`CHECK INTERFACE POSITION /NO/:` This parameter determines whether the timestep in addition to the accuracy also should be controlled by the distance with which the phase interface is displaced during the simulation.
	`DEFAULT DRIVING FORCE FOR INACTIVE PHASES : /.01/:` Sets the necessary driving force needed before an inactive phase is allowed to start to precipitate. This is a short cut connected to the command SET_NUMERICAL_LIMITS
	`DEGREE OF IMPLICITY WHEN INTEGRATING PDEs (AUTO, 0 -> 0.5 -> 1): /1/:` Normally a value of 0.5 (trapezoidal rule) should be used. If however, large fluctuations occur in the profiles it may be necessary to use the value 1.0 (Euler backwards). • `0.0` Euler forwards • `0.5` Trapezoidal rule • `1.0` Euler backwards
	`SAVE WORKSPACE ON FILE (YES,NO,0-999) /YES/:`

Syntax	SET_OPTION
	This parameter determines whether the workspaces are to saved on file during the course of the simulation. Legal alternatives are • `YES` Always save on file • `NO` Never save on file • `##` Save every n:th time on file (## is a integer value ranging from 0 to 99.)
	`VARY POTENTIALS OR ACTIVITIES OR LNAC : /ACTIVITIES/:` Determines whether the program should use the potential or the activity of a component in order to find the correct tieline at the phase interface. The potential or the activity is varied by the program and is set in order to reduce the degrees of freedom at the local equilibrium.

SET_REFERENCE_STATE

When using the SET_REFERENCE_STATE command there are some important things to know. The reference state for a component is important when using activities, chemical potentials, and enthalpies and it is determined by the data. For each component the data must be referred to a selected phase, temperature and pressure the *reference state*. All data in all phases where this component dissolves must use the same reference state. However, different datasets may use different reference states for the same element. Thus one must mix data from different databases with caution.

By default activities etc. are computed relative to the reference state used by the database and this may thus differ depending on the database. You can select the reference state of a component if the reference state in the database is not suitable.

Syntax	**SET_REFERENCE_STATE**
Prompts	`Component` The name of the component must be given.
	`Reference state` The name of a phase that must be either entered or dormant must be given. The component must be a constituent of this phase of course. A subtle problem is if the component exists in several species in the phase, for example oxygen as O, O2 and O3 in a gas. Normally one would like to have the most stable species as reference state of oxygen, i.e. O2 in this case. Therefore the program calculates the Gibbs energy of all possible states with the phase with the pure component at the current temperature and selects the most stable one.
	`Temperature` Select the temperature for the reference state. The value * means the temperature used for the calculation.
	`Pressure` Select the pressure for the reference state.

SET_SIMULATION_CONDITION

Use the SET_SIMULATION_CONDITION command to set parameters used to control output and certain parameters during the simulation.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	SET_SIMULATION_CONDITION
Prompts	`NS01A print control` Determines whether data should be printed about the iterative procedure to solve flux-balance equations. This parameter is normally set to 0 but can be set to 1 when difficulties with convergence occur. NS01A prints out the values used in the iterations and the residuals.
	`Flux correction factor` This parameter controls if the flux correction scheme should be used in the calculations. The value should normally always be 1.
	`Number of delta timesteps in calling MULDIF` This parameter specifies the number of equally large time steps that one time step should be subdivided into.
	`Check interface position` This parameter determines whether the time step is to be controlled by the phase interface displacement during the simulation. The default is `Auto`. This is also available as a shortcut via SET_OPTION
	`Vary potentials or activities or LNAC` Determines whether the program should use the potential or the activity of a component in order to find the correct tie-line at the phase interface. The potential or the activity is varied by the program and is set in order to reduce the degrees of freedom at the local equilibrium. The default is `Activities`. This is also available as a shortcut via SET_OPTION
	`Allow automatic switching of varying element` Determines whether the program is allowed to itself switch the component that is used to reduce the degrees of freedom at the local equilibrium. The scheme used is that of choosing the components which activities or potentials varied most during the previous time step. The default is `Yes`.

Syntax	SET_SIMULATION_CONDITION
	This is also available as a shortcut via SET_OPTION
	`Save workspace on file` This parameter determines whether the workspaces are to be saved to file during the course of the simulation. Options are `Yes` (the default) to always save to file, `No` to never save to file, or `##` to save every n^{th} time to file where ## is a integer value ranging from 0 to 99. This is also available as a shortcut via SET_OPTION
	`Degree of implicity when integrating PDEs` The default is `Auto` where the default degree of implicity corresponds to trapezoidal (0.5) for classic and Euler Backward (1.0) for the homogenization model. If large fluctuations occur in the profiles it may be necessary to use the value 1.0 (Euler backwards). • `Auto` • `0.0` Euler forwards • `0.5` Trapezoidal rule • `1.0` Euler backwards This is also available as a shortcut via SET_OPTION
	`Max timestep change per timestep` Factor specifying the maximum increase in the time step taken from one time step to another. For example, if the default, `2` is used the maximum time step is twice as long as the previous time step taken.
	`Use forced starting values in equilibrium calculation` This concerns the calculation of the equilibrium when using the disperse model where the equilibrium calculations sometimes fail due the abrupt changes in the composition over the region. The default `Auto` means it always sets forced starting values for composition and phase amounts before preforming the equilibrium calculation.
	`Always calculate stiffness matrix in MULDIF` This determines how often the diffusion coefficient matrix is calculated when solving the partial differential equations (PDE) of diffusion problem. The default setting `Yes` calculates the diffusion coefficient matrix, yielding the stiffness matrix, at each iteration. However, when setting this parameter to `No`, it is only calculated at the first iteration and a constant stiffness matrix is used to obtain the solution to the PDEs. This then leads to an implicit solution and therefore the degree of implicitly is automatically set to 1.
	`Calculate residual for dependent component /No/`

Syntax	SET_SIMULATION_CONDITION
	Keep the default.

SET_SIMULATION_TIME

Use the SET_SIMULATION_TIME command to enter the time specific conditions for a simulation.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	SET_SIMULATION_TIME
Prompts	`Eend time for integration` The time up to which the simulation is to be carried out.
	`Automatic timestep control` Determines whether the time step should be controlled by an automatic procedure or not. If you answer `N` you are prompted for the fixed time step to use during the simulation. The time step determined by the automatic time step control procedure is controlled by the parameters set by the command SET_ACCURACY.
	`Max timestep during integration` The maximum time step allowed during the simulation. This is required when using the automatic procedure to determine the time step.
	`Timtestep during integration` Fixed time step used when the automatic time step procedure is disabled.
	`Initial timestep` Time step used as the initial time step.
	`Smallest acceptable timestep` The smallest time step allowed during the simulation. This is required when using the automatic procedure to determine the time step.

SET_SURFACE_TENSION

The SET_SURFACE_TENSION command enters a distance- and velocity-dependent function which is added to the Gibbs energy of the phase at left side of each phase interface. This can then be used to emulate the effect of surface tension on the equilibrium between at the phase interface or limited phase mobility.

Syntax	SET_SURFACE_TENSION
Prompt	`Function`

About Entering the Function

Enter a surface energy function which adds to the Gibbs Energy expression for the phase located at the lower (left) side of the interface. The expression is multiplied with the volume per mole substitional atoms. This command is also used to simulate a limited interfacial mobility control where the energy function is a function of the interface velocity.

It is used to enter the surface energy to enable coarsening. However, it can also be used to simulate a case with a limited interfacial mobility.

This function should only be used in spherical geometries if the function is solely dependent of the interface position.

Function describing how the (surface) energy function varies with the particle radius and/or the interface velocity.

The classical expression for the surface energy contribution has the form of $\frac{2\sigma V_m}{r}$.

The molar volume should be given relative to the molar volume used by default in DICTRA, 1 x 10^{-5} (m^3/mole). The volume should also be given per mole of substitutional atoms. For a precipitate of type M_xC_y this means multiplying with a factor (y+x)/x. If we use M_6C as an example with surface tension 0.5 (J/m^2) and molar volume of 0.71 x 10^{-5} (m^3/mole), the entered function should be 2*0.5*0.71*(7/6)/X;

Commonly the surface tension function is defined as:

```
delta-G = 2 * SIGMA * Vm / R
```

The function to be entered will then be:

```
2*SIGMA/X;
```

A limited interface mobility can be expressed as:

```
delta-G = v * Vm /const
```

The function to be entered is then:

```
v/"const";
```

The expression is multiplied by the partial molar volume of the substitutional components.

SIMULATE_REACTION

The SIMULATE_REACTION command starts the simulation. All default values (if there are any) are used during simulation and no user input can be entered. This is especially useful when using batch mode.

If, however, you want to manually enter any of the values during the simulation, then you need to add NO to the command line. Then you are prompted for certain values during simulations where phases appear or disappear.

Syntax	SIMULATE_REACTION

Prompt	`Simulate_Reaction`
	All default values are automatically used.
	`Simulate_Reaction No`
	If you want to be able to manually adjust any of the values during the simulation, then you need to add NO to the command line.

SOLVE_IN_LATTICE_FIXED_FRAME

Use the SOLVE_IN_LATTICE_FIXED_FRAME command to solve a diffusion problem in the lattice-fixed frame of reference. This command is available with the HOMOGENIZATION_MODEL as a command within the ADVANCED_HOMOGENIZATION_OPTIONS.

Syntax	SOLVE_IN_LATTICE_FIXED_FRAME
Prompts	`Solve in the lattice-fixed frame of reference /NO/` Enter `Yes` to enable this feature.

About the SOLVE_IN_LATTICE_FIXED_FRAME Command

By default, DICTRA solves diffusion problems in a volume-fixed frame of reference under the assumption that the partial molar volume of all substitutional elements is constant and equal and that the partial molar volume of interstitial elements is zero. When you enable this command, the diffusion problem will instead be solved in a lattice fixed frame of reference. In addition, this option forces the use of the assessed molar volumes read from the current thermodynamic database.

Simulations with moving boundaries as well as cell simulations are currently not available with this feature.

For all geometries the leftmost/lower coordinate is fixed during a simulation (by default it is zero). This command also enforces some constraints for planar and cylindrical geometry. For a planar geometry the size of the domain in the plane orthogonal to the direction of diffusion is fixed. For a cylindrical geometry the length of the cylinder is fixed. For all geometries there may be changes in the size of the domain as a result of the diffusion process, even with closed boundaries, since the assessed molar volumes of the thermodynamic database is used.

All elements are set as substitutional. Though the notion of substitutional/interstitial elements has no meaning when running a simulation with this feature turned on, it does have implications in the POST processor.

The DICTRA POST processor does not use assessed molar volumes, which means that certain plots will be erroneous. There may for example be changes in the total domain size even for a single phase simulation with a closed system due to changes in the molar volume. A plot of the total number of moles in the domain would then, erroneously, show a change over time. Other axis quantities that in general will be incorrect are, for example, IV(*) and VP(*).

Further, when solving in the lattice-fixed frame of reference the unit of the flux is $mol*m^{-2}s^{-1}$, which differs from the default unit wherein the assumed constant substitutional molar volume (10^{-5} m^3*mol^{-1}) is included in the flux. This must be taken into account for certain types of boundary conditions, that is, the conditions of type

- FIX_FLUX_VALUE
- POTENTIAL_FLUX_FUNCTION
- ACTIVITY_FLUX_FUNCTION
- ITERATIVE_ACTIVITY_FLUX_FUNCTION

See SET_CONDITION for details about the above commands.

In order to roughly get the same result for these boundary conditions the evaluated flux must be a factor 10^5 higher when solving in the lattice-fixed frame of reference compared to simulations with the default setting.

STORE_HOMOGENIZATION_DATA

Use the STORE_HOMOGENIZATION_DATA command to read/write the interpolation scheme data to file. The interpolation scheme is an option of the homogenization model that is used to speed up simulations. Use if this option can speed up simulations further.

Syntax	STORE_HOMOGENIZATION_DATA
Prompt	`Store/Read homogenization model interpolation data <Y/N>` Answering `Y` or `N` enables/disables read/write of interpolation scheme data to file.

SWITCH_MODEL

Use the SWITCH_MODEL command to use the HOMOGENIZATION_MODEL to solve a problem if the classic model fails.

There are two solvers for moving phase boundary problems. The classic computationally efficient model and the more robust, but computationally more demanding, homogenization model. By default, the classic solver is tried first. If this fails, then the new solver is tried for a few time-steps before switching back to the classic solver, and so on.

The Diffusion Module (DICTRA) in Graphical Mode uses a Diffusion Calculator instead of the Console Mode commands. Most of the Console Mode functionality is available on the Diffusion Calculator, described in the *Thermo-Calc User Guide*. However, you cannot use both Graphical Mode and Console Mode in the same simulation.

Syntax	SWITCH_MODEL
Prompts	`Enable automatic switch of model (Y/N)` Determine if automatic switching from the classic solver to the homogenization model is allowed.

USE_INTERPOLATION_FOR_D

In Graphical Mode, `Complex` is the default and cannot be changed.

An interpolation scheme can be used to calculate the chemical diffusivities of complex phases. If this is enabled, the performance gain from this ranges in orders of magnitude. This is ON by default for complex phases and can be set to OFF with the USE_INTERPOLATION_FOR_D command.

Syntax	USE_INTERPOLATION_FOR_D

Prompts	`The following phases will be affected if complex is selected:`
	When there are phases in the system that will be affected, these are listed. The phases are based on the thermodynamic model.
	`Interpolate diffusivities in /None/Complex/All phases /Complex/`
	The default is `Complex`. A complex phase means that an equilibrium calculation is needed in order to determine the site-fractions in a phase with converting from *u*-fraction (or any other type of composition variable).

	`Enter number of steps between Xmin and Xmax /10000/:` Enter what is essentially the number of steps in each dimension in composition-P-T space for each equilibrium condition (Nk, P, T). In the limit where an infinite number of steps are used, exactly the same solution is obtained as without the interpolation scheme. However, excellent results can be obtained with a reasonable discretization.
	`Linear or Logarithmic discretisation /Log/:` The discretization can be either linear or logarithmic. For the linear discretization the scheme will not be used at node points where the content of one or more solutes fall below a certain critical value. For such cases, where composition span many orders of magnitude, the logarithmic discretisation can be tried.

	The system confirms the discretization setting and displays the amount of free memory available for the calculation. You are prompted to enter how much of this memory to use for the simulation.
	`Discretisation set as Logarithmic (or Linear)`
	`Free physical memory (mb): 8535`
	`Fraction of free physical memory to be used /.1/:`
	The fraction of free physical memory to be allocated for the interpolation scheme.

USE_TWO_TYPES_OF_BOUNDARY_CON

The USE_TWO_TYPES_OF_BOUNDARY_CON command enables you to use two types of boundary conditions (BC). This command is available with the HOMOGENIZATION_MODEL as a command within the ADVANCED_HOMOGENIZATION_OPTIONS. During the simulation one arbitrary boundary will be closed, but for the other open boundary and for each element, you can select which of the two entered boundary conditions should apply.

Syntax	USE_TWO_TYPES_OF_BOUNDARY_CON
Prompts	`Use two types of boundary conditions /NO/` Enter `Yes` to define the boundary conditions further.
	`Close the upper boundary /YES/` Select whether the upper or lower boundary should be closed during the simulation.
	`For <element>, use lower boundary BC: /YES/` You are prompted for each element whether the boundary condition entered for the lower or the upper boundary should apply.

UTILITIES_HOMOGENIZATION

ADVANCED_HOMOGENIZATION_OPTIONS

Use the UTILITIES_HOMOGENIZATION command with the HOMOGENIZATION_MODEL for the available utilities.

Syntax	UTILITIES_HOMOGENIZATION
Prompts	`Set temperature according to solidus temperature /N/:` Set the global temperature such that it goes to a certain value T_{target}=T_{sol}-X, where X is an entered value. Also enter the rate by which the temperature approaches T_{target}. The solidus temperature is determined with a +/- 1 K accuracy. Input guesses of the minimum and maximum temperature to occur during the simulation. This utility can be useful to optimize homogenization heat treatments. The liquid phase must be entered into the system.
	`Dump results to text files /N/:` Enter `Y` to save simulation results to various text files. The names of these files are fixed and are saved to the current working directory.
	`Read initial composition from text file /N/:` Enter `Y` to read initial composition from a text file `XF.TXT` that must be present in the working directory. The file should contain the mole fractions of all elements, in alphabetical order, starting from the first grid point, in the first region, in the first cell.
	`Enter ghost phase /N/:` Enter `Y` to force the so-called ghost phase to be created. This phase has full solubility of all components and zero diffusivity. The Gibbs energy surface of the ghost phase is set above all other phases. The name of this phase is ZZDICTRA_GHOST. It can be used for numerical reasons. It is created automatically if there is a phase that lack solubility range of one or more components and then used internally by the program.
	`Enter inactive phases into one region /N/:` Enter `Y` to make all inactive phases at a given interface to be entered into a single multiphase region when any one of the phases becomes stable.
	`Explicitly set substitutional/interstitial /N/:` Enter `Y` to explicitly select for each element whether it should be substitutional or interstitial. There must be at least one substitutional element in each region. These settings only have effect for the homogenization model and results viewed in the post processor must be interpreted with care; use `DUMP RESULTS TO TEXT FILES` to get results corresponding to the settings entered here.
	`Save average finite volume composition /N/:` Save the average finite volume composition instead of a converted piece-wise linear composition.
	`Set constant phase addition /N/:`

Syntax	UTILITIES_HOMOGENIZATION
	Add constant Gibbs energy contributions to phases (in J/mol formula unit).
	`Use element mobility prefactor /N/:` Enter constant factors which the mobilities of elements are multiplied with in all phases.
	`Enter element mobility constant value /N/:` Interactively enter a constant mobility estimate for specific elements in specific phases. This can be used to enter mobility estimates in phases for which there is no assessed data. Estimates entered here override database values.
	`Enter minimum save interval /Y/:` Enter a minimum time interval (in seconds) that must pass between subsequent saved time-steps. This is useful in cases where a large number of small time-steps may occur in order to keep down the size of the result file.
	`Simplified evaluation of activity boundary condition /N/:` Enter `Y` to evaluate the fluxes on boundaries directly from the activity gradient, i.e. without taking into account the change of state on the boundary caused by the prescribed boundary activities.
	`Enter explicit limits on composition /N/:` Use this setting with caution to explicitly enter upper and lower limits on composition for all components (in mole fraction).
	`Enter chemical potential contribution /N/:` Enter a function (in valid POLY-3 syntax) that is evaluated separately at all grid points and added to the chemical potential of all elements. The contribution affects the flux between grid points.
	`Do not balance external boundary fluxes /N/:` For all boundary conditions except type GAS, the flux of substitutional elements into the domain is balanced with the flux of the dependent substitutional elements such that the size of the domain is preserved. Enabling this setting disables the balancing of the substitutional fluxes. This feature is now available under the ADVANCED_HOMOGENIZATION_OPTIONS command. The use of this feature under the command UTILITIES HOMOGENIZATION is deprecated.
	`Fix external boundary flux of dependent component /N/:` This feature is disabled. A more general version is available under the ADVANCED_HOMOGENIZATION_OPTIONS command. It is still visible for backwards compatibility reasons.
	`Modified kinetics on boundary /N/:` Use this to modify the kinetics on the boundary and enter a factor. If the factor is greater/smaller than one, the mobilities of all elements on the boundary is set equal to the maximum/minimum mobility of all elements times the factor. This can be useful in order to quickly saturate an outermost finite volume.

APPEND_EXPERIMENTAL_DATA

Use the APPEND_EXPERIMENTAL_DATA command to add experimental data and text on a calculated diagram. The experimental data and text are added to a file prepared according to the syntax of the DATAPLOT graphical language. The picture generated from the data is superimposed on the ordinary graphical output from the POST PROCESSOR. The experimental data file can be created with an ordinary text editor. Another use of the APPEND_EXPERIMENTAL_DATA command is to superimpose plots from several independent calculations. For this purpose, there is a command MAKE_EXPERIMENTAL_DATAFILE which dumps a calculated diagram on a file according to the DATAPLOT syntax. With the aid of a basic text editor many such files may be merged. Remember to have only one prologue section on the file (see below).

About DATAPLOT Files

Syntax	APPEND_EXPERIMENTAL_DATA
Prompts	`Use experimental data (Y or N) /N/:` By default, no experimental data is plotted.
	`Experimental datafile` Specify the name of the file with the experimental data. Default file extension is exp.
	`Prologue number` Select which prologue to use. In a prologue one may e.g. give the scaling of an axis, the axis texts, and so on. -1 gives a list of all prologues on the file. Read more about prologues below.
	`Dataset number(s)` Select from which dataset(s) data should be read. Several datasets may be given separated with commas or spaces. -1 gives a list of all datasets on the file.

DETERMINE_KIRK_PLANE

To use the DETERMINE_KIRK_PLANE command a certain time must be set as plot condition. You are prompted for the position of a plane at time zero. The position of the plane at the plot condition time is then calculated. The difference in position is equal to the Kirkendall shift, i.e. how much an inert marker would drift in the material due to a net flux of vacancies.

Syntax	DETERMINE_KIRK_PLANE
Prompt	`Initial zero plane /-1/`

DIFFERENTIATE_VALUES

Use the DIFFERENTIATE_VALUES command to determine differences between values in a plotted curve.

DUMP_DIAGRAM

Use the DUMP_DIAGRAM command as an alternative way to create plots. Supported graphical formats are PNG, BMP, PDF, JPEG, and TIFF. The plot is saved to a file.

Syntax	DUMP_DIAGRAM
Prompt	`Output format (PNG,BMP,PDF,JPEG,TIFF)` Specifies which graphical format to use.
	`Resolution (Low, Medium, High)` Specifies the resolution of the plot.

ENTER_SYMBOL

The information about this command is specific to the Diffusion Module (DICTRA) Console Mode. The ENTER_SYMBOL command is also available in the GIBBS, POLY3 and POST modules in Thermo-Calc.

Use this ENTER_SYMBOL command to define a symbolic name to represent either a table or an 'arbitrary' function.

Legal variables in functions and columns in tables are described in the sections state variables, auxiliary variables, integral variables or can be previously defined functions. Functions are a useful feature of the POST PROCESSOR to define quantities.

Auxiliary Variables, Integral Variables, and State Variables in Console Mode DICTRA for details and examples of the short names (mnemonics).

Syntax	ENTER_SYMBOL
Prompts	`Function or table /Function/` Select what kind of symbol to enter.
	`Name` Each symbol has a unique name that must start with a letter and can have maximum 8 characters. If one wishes to enter the name and the value on the same line they must be separated with an equal sign =.

	`Function`
	Functions are evaluated from an expression of state variables, auxiliary variables, integral variables or previously defined functions. The expression is a Fortran-like expression and operators +, -, *, / and ** can be used (** only with integer powers). Unary functions like LOG, LOG10, EXP, SIN, COS, ABS and ERF can also be used. An expression can be continued on more than one line. An expression should be terminated by a semicolon or an empty line.
	
	Examples of Functions
	
	`POI(CEM,U)-POI(CEM,L);`
	The thickness of the region named CEMENTITE
	
	`AC(CR)/X(FCC,CR);`
	The activity coefficient for Cr in phase FCC
	
	`SQRT(TIME);`
	The square root of the simulation time
	
	`&`
	The ampersand & sub-prompt displays if the function was not terminated by a semicolon. It allows a user to continue to write the function on the new line if one line is not enough for the function. If one has finished the function just press return again.

Syntax	ENTER_SYMBOL
	`Variable(s)` When entering a table, specify what variables are to be in the various columns. Separate the variables with commas or space characters. At present a maximum of 15 columns are allowed. The independent variable is always printed in the first column.

INFORMATION

Some general information about the POST PROCESSOR module is given when you use the INFORMATION command.

Syntax	INFORMATION
Prompt	`Which subject` Select which subject you want additional information about. Type ? to get a list of topics. • PURPOSE • STATE VARIABLES • INTEGRAL VARIABLES • AUXILIARY VARIABLES • PLOT CONDITION AND INDEPENDENT VARIABLE • BASIC METHODOLOGY

INTEGRATE_VALUES

Use the INTEGRATE_VALUES command to mathematically integrate the plotted curve.

LABEL_CURVES

Use the LABEL_CURVES command to create labels. Each label is explained with to the right of the diagram.

Syntax	LABEL_CURVES
Prompt	`Label curves` Enter Y or N. For example: *1. X: X(CR); Y: TIME; PC:3* is read as *1 is a curve with X(CR) on the x-axis, TIME on the y-axis and plot condition PC according to value 3 specified on the plot condition line printed above the diagram*.

LIST_PLOT_SETTINGS

Use the LIST_PLOT_SETTINGS command to list on screen the present values of most parameters specifying the type of diagram to be plotted.

LIST_REGION_NAMES

All region names have a #-sign and the cell number appended.

Use the LIST_REGION_NAMES command to list all region names that are defined.

LIST_SYMBOLS

Use the LIST_SYMBOLS command to list a specific symbol or enter an asterisk (*) to list all defined symbols.

Syntax	LIST_SYMBOLS
Prompt	`Name` Give the name of a symbol or an asterisk * to list all defined symbols.

LIST_TIMESTEPS

This for the DICTRA module. Also see LIST_TIME_STEPS for the POST module.

Use the LIST_TIMESTEPS command to list the time steps in the workspace and those stored on file during a simulation.

MAKE_EXPERIMENTAL_DATAFILE

Use the MAKE_EXPERIMENTAL_DATAFILE command to save graphical information in a file with the DATAPLOT format. To merge two or more diagrams from separate calculations, use the command to export it and add them together with a normal text editor.

APPEND_EXPERIMENTAL_DATA and About DATAPLOT Files

Syntax	MAKE_EXPERIMENTAL_DATAFILE
Prompt	`Output file` File where the graphical information is written. Default file extension is `exp`

PLOT_DIAGRAM

Use the PLOT_DIAGRAM command to plot graphical information on the specified device using the plot format set by SET_PLOT_FORMAT.

Syntax	PLOT_DIAGRAM
Prompt	`Plot file` The name of the file or graphical device.

PRINT_DIAGRAM

This command is only available for Windows operating systems.

Use the PRINT_DIAGRAM command to print a plot or diagram using the printers defined in Windows.

QUICK_EXPERIMENTAL_PLOT

Use the QUICK_EXPERIMENTAL_PLOT command to define a pair of axes, sets the axis labels to X and Y, and scale both x- and y-axis between 0.0 and 1.0 unless a prologue is read from the data file. It is similar to the APPEND_EXPERIMENTAL_DATA command but can be used when there is no graphical information to be plotted in the DICTRA module workspace.

See APPEND_EXPERIMENTAL_DATA about the format of the data file.

REINITIATE_PLOT_SETTINGS

Use the REINITIATE_PLOT_SETTINGS command to give all parameters describing the diagram as default values.

SELECT_CELL

Use the SELECT_CELL command to select the current cell from the list of existing cells and enables you to enter and display data into that cell. This command is for the DICTRA.

See also POST PROCESSOR prompt of the same name SELECT_CELL.

Syntax	SELECT_CELL
Prompt	`Number` Specify the cell number by giving an integer or one of the key words NEXT or PREVIOUS.

SET_AXIS_LENGTH

Use the SET_AXIS_LENGTH command to change the relative length of an axis, i.e. the number of tic-marks on the axis. The default number of tic-marks on an axis is 10 when the relative length is 1. The number of units per tic-mark must be a multiple of 1, 2, or 5 to obtain a reasonable scaling of an axis.

Syntax	SET_AXIS_LENGTH
Prompts	`Axis` Specify the axis to set the axis length.
	`Axis length` Specify the relative axis length. The relative length 1 corresponds to 10 tic-marks on the axis.

SET_AXIS_PLOT_STATUS

Use the SET_AXIS_PLOT_STATUS command to specify to plot a diagram axis. Use it to merge different diagrams on a pen-plotter or to obtain the diagram faster. The default to plot the axes.

Syntax	SET_AXIS_PLOT_STATUS
Prompt	`Axis plot` `Y` or `N` to plot axis.

SET_AXIS_TEXT_STATUS

Use the SET_AXIS_TEXT_STATUS command to change the axis text from the automatic text given by the axis specification to another text.

Syntax	SET_AXIS_TEXT_STATUS
Prompts	`Axis (X, Y or Z)` Specify which axis text status to change (if the axis type is INVERSE, X2 or Y2 may be used to set the corresponding opposite linear axis text).
	`Automatic axis text (Y or N)` Specify if automatic axis text is to be used or not.
	`Axis text` Enter axis text.

SET_AXIS_TYPE

Use the SET_AXIS_TYPE command to select a linear, logarithmic, or inverse axis.

Syntax	SET_AXIS_TYPE
Prompts	`Axis (X, Y or Z)` Specify which axis to change the axis type.
	`Axis type` Specify which axis type to set. Select `LIN`ear (default), `LOG`arithmic or `INV`erse. Only the three first characters are needed.

SET_COLOR

Use the SET_COLOR command on devices that support colors/(line types) to select different colors/(line types).

- Text and axis Color
- Diagram Color
- DATAPLOT Color

SET_DIAGRAM_AXIS

Use the SET_DIAGRAM_AXIS command to specify the axis variables of a plot. At least two axis variables (x and y) must be specified.

Also see Auxiliary Variables, Integral Variables, and State Variables in Console Mode DICTRA for lists of variables including its abbreviated name (i.e. the mnemonic) as well of the names of these variables.

Syntax	SET_DIAGRAM_AXIS
Prompts	`Axis (X,Y or Z)` Specifies the axis to set a variable.
	`Variable` Specifies the variable to plot along this axis. A variable is specified by its mnemonic (i.e. its abbreviated name) or by name. The variable types are None, Integral Variables, Functions, Auxiliary Variables or State Variables. • `NONE`: Use this variable to clear an axis setting. • `INTEGRAL VARIABLES`: A quantity obtained by integration in space over the whole system or over a specific region. In a planar geometry values are given per unit area, in a cylindrical geometry they are given per unit length, and in a spherical geometry they are absolute values. See Integral Variables for examples. • `FUNCTIONS`: These are identified by a name which is entered with the ENTER_FUNCTION command. Use the LIST_SYMBOLS command to get a list of valid function names. • `AUXILIARY VARIABLES`: As a complement to state variables and integral variables the auxiliary variables are defined. The variables can be called by their mnemonic names, which are shown in the rightmost column. These are useful in user-defined functions. See Auxiliary Variables for examples. • `STATE VARIABLES`: State variables in the DICTRA POST module are similar to those defined in POLY-3. Examples of state variables are temperature, mole fraction, enthalpy, etc. In POLY-3 a general notation method based on character mnemonics is designed for a predefined set of state variables. See State Variables in Console Mode DICTRA for examples. Depending on the axis variable some sub-prompts may be available.
	`For component` When an activity, flux, mole-, weight- or U-fraction or percent is plotted the name of the component must be supplied.
	`In region` When the lamellar spacing, e.g. for pearlite, is plotted the name of the region must be supplied.
	`For phase` When the lamellar thickness, e.g. for ferrite in pearlite, is plotted the name of the phase must be supplied.
	`Interface`

Syntax	SET_DIAGRAM_AXIS
	When the velocity or the position of an interface is plotted the name of the interface must be given. An interface is identified by the name of the region on its upper side.
	`Type` When choosing distance as variable one has additionally to specify what type of distance. A distance may be GLOBAL, i.e. counted from the leftmost interface, or LOCAL, i.e. counted from the interface to the left of the region whose name you are prompted for.
	`Region name` Name of the region wherein the local distance is measured.

SET_DIAGRAM_TYPE

Use the SET_DIAGRAM_TYPE command to set the diagram to a square (the default) or triangular plot (Gibbs triangle).

Syntax	SET_DIAGRAM_TYPE
Prompts	`Triangular diagram` Select `Y` for a triangular plot.
	`Plot 3rd Axis` For triangular plots is selected specify if a 3:rd axis, connecting the end points of the x- and y-axis is plotted.
	`Clip along the 3rd axis` Remove all lines outside the region limited by a line joining the end points of the X- and Y-axis.

SET_FONT

Use the SET_FONT command to select the font to use for labels and numbers when plotting the diagram. For some devices (e.g. PostScript) there may be other fonts available and these are selected by the SET_PLOT_FORMAT command.

Syntax	SET_FONT
Prompts	`Select Font number` Give the number for the font to select. Type ? to get an online list of the available fonts.
	`Font size` A value of 0.3 is recommended.

SET_INDEPENDENT_VARIABLE

There are two free variables after a simulation is done in theDiffusion Module (DICTRA). One is the simulation TIME, the other is a DISTANCE in the system. When plotting a diagram use the SET_INDEPENDENT_VARIABLE to choose one to vary along the curve, i.e. the independent variable, then the other one is the plot condition.

When plotting integral quantities TIME should be the independent variable.

Syntax	SET_INDEPENDENT_VARIABLE
Prompts	`Variable` Select which variable TIME (integration time) or DISTANCE (space coordinate) to treat as the independent variable.
	`Type` When choosing distance as independent variable specify the type of distance. A distance may be GLOBAL, i.e. counted from the leftmost interface, or LOCAL, i.e. counted from the interface to the left of the region whose name you are prompted for.
	`Name of region` For a LOCAL distance supply the name of the region within which the distance is measured. Type a ?, to get a list of valid region names.

SET_PLOT_CONDITION

There are two free variables after a simulation is done in theDICTRA module. One is the simulation TIME, the other one is a DISTANCE in the system. In general, when plotting a diagram use the SET_PLOT_CONDITION command to choose a type as fixed (i.e. the plot condition), then the other one is the independent variable. However, when plotting integral quantities, plot condition is automatically set to INTEGRAL and TIME is chosen as independent variable.

You cannot mix different kinds of plot conditions. However, for TIME and DISTANCE you can give up to 15 different condition values, see sub-prompt VALUE(S) below. The plot condition chosen is printed on a separate line above the diagram.

Plot Condition and Independent Variable

Syntax	SET_PLOT_CONDITION
Prompts	`Condition` Specify the type of condition to set. Valid conditions are: • `NONE`: Condition not set. • `TIME`: Integration time. • `DISTANCE`: Distance in system. • `INTERFACE`: At a certain interface. • `INTEGRAL`: Value is integrated over the phase/region/system volume • `TIE_LINE`: Pair of values from both sides of certain interface. Depending on the condition some or none of these sub-prompts may display.
	`Interface` Specify at which interface the condition should be set. FIRST and LAST refer to the leftmost and the rightmost interface of the system, respectively. Type ? to get a full list of relevant region names.
	`Type` When distance is chosen as plot condition specify the type of distance. A distance may be GLOBAL, i.e. counted from the leftmost interface, or LOCAL, i.e. counted from the interface to the left of the region whose name you are prompted for.
	`Name of region` Give the name of the region within which the distance is measured.
	`At upper interface of region` Give the name of the region which upper interface is specified for the TIE_LINE plotting. This plot-

Syntax	SET_PLOT_CONDITION
	condition allows you to plot a certain quantity from both sides of an interface. The typical application is for plotting tie-lines.
	`Upper or lower interface of region` Specify if the condition is at the LOWER or UPPER interface of a region. The LOWER interface is placed on the left side of a region and the UPPER interface on its right side.
	`Value(s)` Supply up to 15 numerical values separated by commas or spaces for the condition set. If plot condition TIME was chosen FIRST, LAST or #n (where n is an integer number) may be specified. #? provides a list of time steps.

SET_PLOT_FORMAT

Use the SET_PLOT_FORMAT command to adjust the format of the graphical output to another graphical device. This default can be changed with the SET_PLOT_ENVIRONMENT command in the SYSTEM MONITOR.

Syntax	SET_PLOT_FORMAT
Prompt	`Graphic device number /#/: <Number of the device>` Specify a graphic device number. Depending on the hardware, different plot formats (graphic devices) may be available. These are listed online by giving a question mark `?`. For some formats there can be additional sub-prompts (Y or N) about the available fonts being used for the chosen format. Also enter Y for further specifications, e.g. font type and size.

SET_PLOT_OPTIONS

Use the SET_PLOT_OPTIONS command to toggle on/off the plotting options on the diagram.

Syntax	SET_PLOT_OPTIONS
Prompts	`Plot header` Toggle the plot of the text above the diagram.
	`Plot logo` Toggle the plot of the logo at lower-left corner of the diagram.
	`Plot footer` Toggle the plot of the footer identifier text (only on postscript devices).
	`White contoured PS CHARS` Toggle the option of having a thin white contour around postscript characters (only on postscript devices).
	`Plot remote exponents` Toggle the plot of the remote exponents on the axis.
	`Plot cell #` Toggle the plot of the cell number text at the upper-right corner of the diagram.
	`Plot condition status` Toggle the plot of the plot-condition status line above the diagram.

SET_PLOT_SIZE

Use the SET_PLOT_SIZE command to specify a relative scale factor to change the size of the diagram. The default value of the scaling factor depends on what output device is chosen by the SET_PLOT_FORMAT command. The default plot size is adjusted to the chosen device.

Syntax	SET_PLOT_SIZE
Prompt	`Relative plot size` Enter the relative scaling factor.

SET_PREFIX_SCALING

When prefix scaling is enabled using the SET_PREFIX_SCALING command, the remote exponent for an axis is automatically chosen to have a value, which is a multiple of three, i.e. ..., -6, -3, 0, 3, 6, etc.

Syntax	SET_PREFIX_SCALING
Prompts	`Axis (X or Y)` Specify `X`- or `Y`- axis.
	`Use prefix scaling` Enables or disables prefix scaling, `Y` or `N`. Give an integer value to select a prefix power of your own.

SET_RASTER_STATUS

Use the SET_RASTER_STATUS command to set to have a raster plotted in the diagram. Default is no raster plotted.

Syntax	SET_RASTER_STATUS
Prompt	`Raster plot (Y or N) /Y/` Enables (`Y`) or disables (`N`) the raster plot.

SET_SCALING_STATUS

Use the SET_SCALING_STATUS command to choose between manual or automatic scaling on a specified axis. If manual scaling is chosen specify a minimum and a maximum value. Manual scaling can be used to magnify interesting parts of a diagram. When an axis variable is selected by the SET_DIAGRAM_AXIS command the scaling status for the axis is always set to automatic scaling.

Syntax	SET_SCALING_STATUS
Prompts	`Axis (X, Y or Z)` Specify what axis to set the scaling status.
	`Automatic scaling (Y or N)` Automatic (`Y`) and manual (`N`) scaling.
	`Min value` For manual scaling specify the value of the starting point of the specified axis.
	`Max value` For manual scaling specify the value of the end point of the specified axis.

SET_TIC_TYPE

Use the SET_TIC_TYPE command to change the size of the tic marks and the placement either inside or outside of the axis.

Syntax	SET_TIC_TYPE
Prompt	`TIC type` Place on either the inside or the outside of the diagram axis. The absolute value of TIC TYPE determines the length. • `TIC TYPE > 0` (outside the axis) • `TIC TYPE < 0` (inside the axis)

SET_TITLE

Use the SET_TITLE command to specify a title that displays on all listings and diagrams from the POST PROCESSOR.

Syntax	SET_TITLE
Prompt	`Title` Enter the title to include on all output. There is a maximum length of about 60 characters.

SET_TRUE_MANUAL_SCALING

Use the SET_TRUE_MANUAL_SCALING command to turn manual scaling on and off. The default is where the tic marks on the axis are placed in even intervals using the whole axis length. The scaling routine adjusts the given minimum and maximum values slightly to accomplish this.

Syntax	SET_TRUE_MANUAL_SCALING
Prompt	`Axis (X or Y)` Specify the axis you want to toggle between automatic adjustment or avoiding the adjustment of the given maximum and minimum values.

DATPLOT Files

About DATAPLOT Files **2453**

Example of DATAPLOT Files *2453*

Keywords for Prologues **2454**

Keywords for Datasets **2455**

Available Graphical Operation Codes (GOCs) **2457**

About DATAPLOT Files

A DATAPLOT file can be divided into two sections. The prologue, which contains directives for manipulating the default settings on the diagram layout, and the dataset, which contains the actual data and any text to be plotted in the diagram. The sections may contain multiple PROLOGUE and DATASET statements, respectively.

- All prologues must be placed before the first DATASET statement. See Keywords for Prologues and Keywords for Datasets.
- The syntax must be used for the DATAPLOT file.
- In general, each line in a DATAPLOT file must consist of a legal keyword plus its parameters or an XY coordinate pair.
- An XY coordinate pair is two real numbers and an optional graphical operation code (GOC). See Available Graphical Operation Codes (GOCs).

Example of DATAPLOT Files

```
700 2.54
50 1.91 WRDS
1.1 0.9 NS3
100 20'This is a text
BLOCK GOC=C3,MWAS; X=C1+273.15; Y=C2*4.184;
600 -1400 S1'text
700 -1500
BLOCKEND
```

Keywords for Prologues

Keyword	Parameters
PROLOGUE	inumb text
XSCALE	min max
YSCALE	min max
XTEXT	text
YTEXT	text
XTYPE	LIN, LOG or INV
YTYPE	LIN, LOG or INV
XLENGTH	rnumb
YLENGTH	rnumb
DIAGRAM_TYPE	TRIANGULAR or SQUARE
TIC_TYPE	rnumb
TITLE	text

Keywords for Datasets

Keyword	Parameters
DATASET	inumb text
FONT	inumb
CHARSIZE	rnumb
COLOR	inumb
GLOBALSIZE	rnumb
LFSIZE	rnumb
LINETYPE	inumb
BLOCK GOC=C3,DEFGOC; X=C1+273.15; Y=LOG10(C2);	Select one X and one Y variable
BLOCK GOC=C3,DWR; X1=C1+273.15; X2=C1; Y=C1+C2*4.184;	or multiple X and one Y variable
BLOCK GOC=C4,MWAS; X=C1+273.15; Y1=C2*4.184; Y2=C3;	or one X and multiple Y variables
BLOCK GOC=C5,DWA; X1=C1; X2=C4; Y1=C2*4.184; Y2=C3;	or multiple XY pairs
BLOCKEND	
DRAWLINE	x,y x,y
TEXT	text or ~name (of a string, see below)
ATTRIBUTE	TOP, CENTER or BOTTOM
STRING	name text The text string may contain text formatting codes namely: ^S# to set font size, ^G for Greek font, ^F# to set font type, ^U# for positioning the text upwards, ^D# for positioning the text downwards, ^R#for positioning the text to the right, ^L# for positioning the text to the left, and finally ^N for printing without updating current position to the end of the character. These text formatting codes only work for soft fonts not hardcopy postscript fonts.
INCLUDE	filename
CLIP	ON or OFF

Keyword	Parameters
SYMBOLSIZE	rnumb
FUNCTION Y=203 (X); or X=203 (Y);	<start end steps GOC> The < > denotes an optional parameter.
PAINT	<code> <video> <mode> The <> denotes optional parameters. Paint the area enclosed by the current path in the current pattern. The current path starts at the last 'moveto' given and includes all subsequent 'draws'. Also see PCFUNCTION below. Default is <code>=0, <video>=NORMAL and <mode>=TRANSPARENT. To set a new current pattern supply any or all of the optional parameters. <code> is a single letter 0-9, A-Z or a-t (if <code>=t supply also a number in the range 0.00 - 1.00, e.g. PAINT t 0.25.) <video> is a string reading NORMAL or INVERSE. <mode> is a string reading TRANSPARENT or OPAQUE.
PCFUNCTION Y=203 (X); or X=203 (Y);	<start end steps GOC> The <> denotes an optional parameter. May be used to add a function to the current path.

Available Graphical Operation Codes (GOCs)

These are the available GOCs:

- `W`: World coordinates (* DEFAULT)
- `V`: Virtual coordinates
- `N`: Normalized plot box coordinates (NPC)
- `M`: Move to this XY (*)
- `D`: Draw to this XY
- `A`: XY is absolute values (*)
- `R`: XY are relative values
- `S`: Plot current symbol at XY
- `B`: Apply soft spines on the drawn curve (use only on BLOCK data)
- `S2`: Change current symbol to 2 and plot at XY
- `'`: Plot the following text at XY

About this Quick Start Guide

The following introduces you to the basic concepts, steps and theory to start using the Diffusion Module (DICTRA). An understanding of this information is necessary to ensure accurate calculations.

More details about the use of DICTRA can be found in [2002And] and [2000Bor].

If you are not familiar with Graphical Mode, it is recommended you review the documentation and additional resources available on our website.

The Role of Diffusion in Materials: A Tutorial is available for download on our website. It is intended for engineers interested in using the Diffusion Module (DICTRA), as well as students learning about the role of diffusion in materials. It is designed to be useful at many levels, from undergraduate studies to someone with a PhD and experience in a related field.

About the DICTRA File Formats

The Diffusion Module (DICTRA) in Console Mode uses different file formats: *log*, *macro*, and *workspace* files.

When working with the DICTRA module in Graphical Mode, the file formats are the same as when using Thermo-Calc.

Log Files

Log files (*.TCM) are plain text files and are just macro files used to save a sequence of commands. These files can be edited in a text editor.

- To start saving your input into a file, in the SYS module type `SET_LOG_FILE`, followed by the name of the file that you want to save your command sequence to.
- When creating a command sequence, and if you want to save the output in the log file, type `SET_ECHO` before SET_LOG_FILE. This is useful if you later want to use the log file as a macro file because the macro file lists the full commands instead of only the short names.

Macro Files

Macro files (*.DCM) are plain text files used to save a sequence of commands that can be loaded and executed. Macro files can be edited in a text editor. When creating a command sequence, you add comments to the file by starting a line with @@.

- To run a macro file, in the SYS or DICTRA module type `MACRO_FILE_OPEN`, followed by the name of the macro file. DICTRA runs the MACRO_FILE_OPEN sequence that the file contains.
- To remain in the console and keep working in the DICTRA module, in the SYS, DICTRA, POLY, or POST module add the command SET_INTERACTIVE at the end of the macro file. Alternatively, use `EXIT` as the final command.

Workspace Files

Workspaces files for the Diffusion Module (DICTRA) have the file extension *.DIC, which allow you to save all the data in your current workspace. A workspace contains all the data, specified settings and the result of any calculations performed. The saved data includes original and modified thermodynamic data, the last set of conditions and options, and the results of any simulations.

- At the `DIC` prompt use SAVE_WORKSPACES .
- To load the data and calculation results of a workspace file, at the `DIC` prompt use READ_WORKSPACES.

Opening the Module and Macro Files

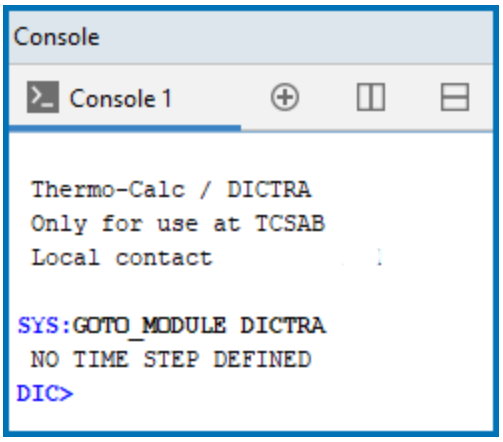
You can go to into the Console Mode to explore the command options, or continue with this quick start guide, which uses macro files to demonstrate how to use the software.

Opening the DICTRA Module in Thermo-Calc

1. Open Thermo-Calc in Console Mode.

   By default, Thermo-Calc opens in the most recently used state. If it opens in Graphical Mode, on the toolbar, click **Switch to Console Mode**.

2. In the `SYS` module, type `GOTO_MODULE DICTRA`. For a list of all the available commands in the current module, at the prompt type a question mark (?) and press <Enter>. For a description of a specific command, type `Help` followed by the name of the command.



Opening the Beginner Guide Examples

For the Console Mode examples included with your installation, you can open the .DCM files from the main menu. You can also open any macro file with a command or by dragging it into the Console window.

Opening a Macro File from the Examples Folder

To open a specific macro file from the Examples folders included with your installation:

1. Open Thermo-Calc.
2. Confirm you are in Console Mode. If not, click the **Switch to Console Mode** button.
3. From the main menu, select **File →** or **Help → Examples Files**. The Console Mode folder opens (these are the Thermo-Calc macro files).
4. Double-click the **Diffusion Module - DICTRA** folder and navigate to an example folder.

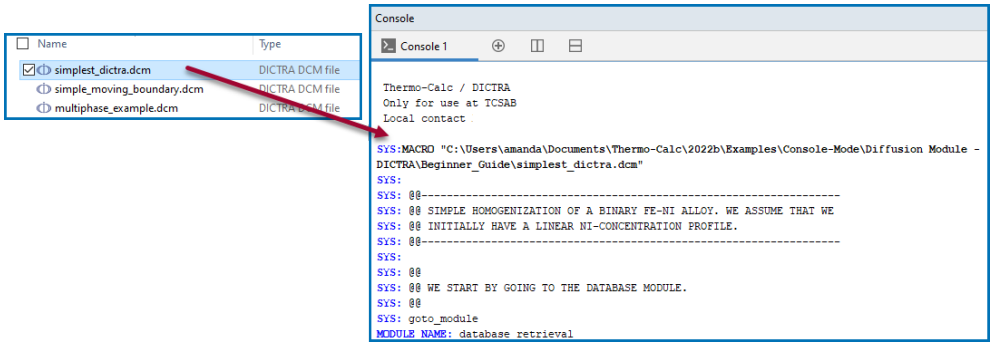
The three Quick Start example macros are in the first folder called **Beginner Guide**.

Using a Command in Console Mode

At the `SYS` prompt, type MACRO_FILE_OPEN and press <Enter>. In the file dialogue window that opens, locate and select the macro file on your computer.

Dragging and Dropping a Macro File into Console Mode

For example, navigate to the **Beginner Guide** folder and then drag the file from its location into Thermo-Calc Console window. The macro automatically runs after you drop it into the Console window.



Double-click to Open a File

Navigate to the macro file location, for example where each set of file examples is in its own folder. If you already have Thermo-Calc open, the macro opens in a new tab. Otherwise a new instance of Thermo-Calc is launched.

Basic Terminology

The following definitions are useful to help you understand the examples and commands in this guide. For more detailed information search or browse the online help (**Help →Online Help**).

Cells and Regions in a System

A system normally consists of one *cell*. This cell contains one or several *regions* in which the diffusion problem is to be solved. A system of diffusion equations is solved for each region. The size of the system is the sum of sizes of all the regions in all the system's cells.

The interface between two regions typically moves as the result of a simulation, that is, the regions grow or shrink. Such an interface is called an *inner interface*. The boundary of a cell is called an *outer interface* and the condition of this type of interface may be affected by the choice of boundary conditions.

For some simulations it is useful to have several cells in a system. Matter can move between cells. However, it is assumed that there is diffusional equilibrium between all cells (this means that there are no differences in diffusion potentials between cells). In other words, the size of a cell is fixed during the simulation.

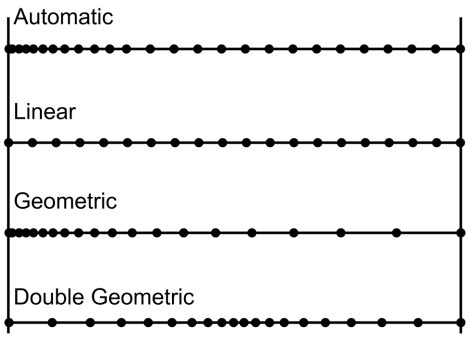
By default this is a *closed system*, which means that matter cannot move across its boundaries. However, you can change this setting for both the *lower boundary* (left side/centre) and the *upper boundary* (right side/surface) of the system. You can also set these boundary conditions to vary as a function of time, temperature and/or pressure.

Regions and Grids

A *region* contains one or more phases. If a region contains several phases one of those must be entered as a *matrix phase* whereas the others are entered as *spheroid*.

A region must also contain a number of *grid points*. The composition is only known at these grid points and the software assumes that the composition varies linearly between them. The amount and composition of all the phases present at a single grid point in a certain region are those given by thermodynamic equilibrium keeping the over-all composition at the grid point fixed.

These grid types are used in diffusion simulations: automatic, linear, geometric, and double geometric. When you are setting up the simulation, in either Console Mode or Graphical Mode, a region must have a grid defined.



Phases

Each region contains one or more *phases*. A phase can be of the *matrix*, *spheroid* or *lamellar* type. A phase can be introduced with the status *active* (the default) or *inactive*.

An inactive phase is a phase which does not participate in the calculations until it is stable. If a phase is inactive, then the driving force for precipitation of the phase is continuously monitored. When the driving force exceeds a predefined positive value, the phase take parts in the simulation and the phase automatically becomes active. A new region is then created and the formerly inactive phase is entered as the matrix phase of the new region. The name of the region is set to the name of the phase that just became active but with `R_` added as a prefix.

Composition

Two types of composition variables are used within the program: site-fractions and u-fractions, although you can also use weight fraction or mole fraction, for example.

The *site-fractions* are used to set up the problem and interface with POLY-3 (in Console Mode). The site fraction of a species *k*, y_k, is the fraction of equivalent lattice sites occupied by species k. It is the only concentration variable that uniquely defines the composition and the constitution of a phase and it is necessary to use the site fraction in the storage of the data during a simulation.

The *u-fractions* are used in the diffusion equations. The u-fraction of a component *k* is defined as

$$u_k = \frac{x_k}{\sum_{j \in S} x_j}$$

The summation is only performed over the substitutional elements. The choice of the volume fixed frame of reference in the calculations make it convenient to use a composition variable which is related to the volume. The definition of the u-fraction is based upon the assumption that a species may or may not contribute to the volume of a phase. An interstitial element is assumed to not contribute to the volume. Substitutional elements are assumed to contribute equally to volume.

Geometry and Coordinates

The Diffusion Module (DICTRA) can only handle diffusion problems where composition vary along one spatial coordinate. The geometry of your system can be *planar*, *cylindrical* , or *spherical*.

Planar Geometry

This geometry corresponds to an infinitely wide plate of a certain thickness. If the system has a planar geometry then the lower boundary (the zero coordinate) is at the left side of the system. The upper boundary (the coordinate with the highest value) is at the right side of the system.

Cylindrical and Spherical Geometries

- Cylindrical geometry corresponds to an infinitely long cylinder of a certain radius.
- Sypherical geometry corresponds to a sphere with a certain radius.

By default for both geometries, the lower boundary (the zero coordinate) is at the centre of the cylinder/sphere. The upper boundary (the coordinate with the highest value) is at the *surface* of the cylinder/sphere. You can enter a left most coordinate that is larger than zero to allow for tube and hollow sphere geometries.

Boundary Conditions

Boundary conditions are conditions that define how matter behaves at the boundaries of your system. By default, matter is not allowed to cross the system boundaries.

You can change the setting for both the lower boundary (left side/centre) and the upper boundary (right side/surface) of the system.

Learn More

See Diffusion Module Terminology in Graphical Mode.

Also see Entering Phases in Regions and Specifying Phase Compositions in a Region.

Setting up a Simulation in Console Mode

Although there are several commands to learn to correctly set up a DICTRA module simulation, the sequence in which to proceed is basically the same.

Defining and Running a Simulation

1. Define and read **thermodynamic** and **kinetic** data.
2. Set **global conditions** (i.e. temperature, *T*, and pressure, *P*).
3. Enter **region(s)**.
4. Enter **grid(s)** in region(s).
5. Enter **phase(s)** in region(s).
6. Enter **composition(s)** of phase(s).
7. Set **geometry** (optional – by default, the geometry is planar).
8. Set **boundary conditions** (optional – by default, the boundaries are closed).
9. Set the simulation **time**.
10. **Run** the simulation.

For definitions of the above, see Basic Terminology.

The following sections describe each step in more detail for these simulation types:

- About the Single Phase Simulation
- About the Moving Phase Boundary Simulation
- About the Multiphase Simulation

Single Phase - Specifying the Thermodynamic System *2478*

Setting up the Single-Phase Simulation *2479*

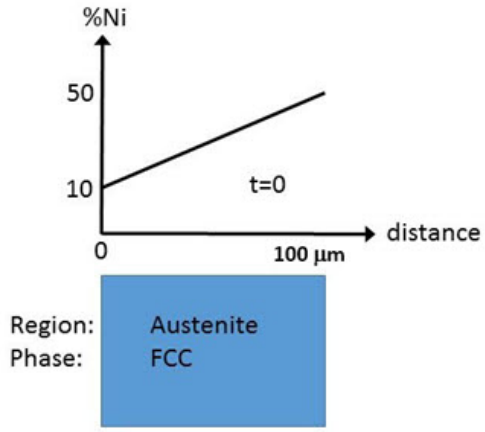
Running and Plotting the Simulation *2483*

About the Single Phase Simulation

In a 100 µm wide planar domain, the single phase example simulates the diffusion of Fe and Ni at a temperature of 1400 K. At this temperature the material is fully austenitic, i.e. the only phase present is the so-called fcc (face centered cubic) phase (in Thermo-Calc the name of this phase is FCC_A1). Initially, there is a linear variation in Ni going from 10 mass-% on the left-hand side to 50 mass-% on the right-hand side.

The simulation time is slightly different between the modes. For Console Mode it is 10^5 s and for Graphical Mode it is 30 hours.

By default the boundaries are closed. The plot generated shows the initial and final Ni profile.



Schematic view of the initial state of Single Phase Diffusion example. The width of the domain is 100 µm and there is a linear gradient in composition going from 10 to 50 mass-% Ni. There is a single region named Austenite that consists of an fcc phase.

Theory for the Single Phase Simulation

The flux of a component k in the z-direction in an isobarothermal system is in general given by

$$J_k = \sum_{i=1}^{n} L_{ki} \frac{\partial \mu_i}{\partial z}$$

where L_{ki} is a matrix of kinetic coefficients and μ_i is the chemical potential of component i. The correlation effects, i.e. the coupling of the flux of k component to the chemical potential gradients of the other elements, are normally neglected

$$(L_{ki} = 0, k \neq i)$$

and thus

$$J_k = L_{kk} \frac{\partial \mu_k}{\partial z} = M_k c_k \frac{\partial \mu_k}{\partial z}$$

where c_k is the concentration and M_k the mobility of component k.

The equation for the flux is combined with the equation of continuity, which takes the following form in a planar domain,

$$\frac{\partial c_k}{\partial t} = \frac{\partial}{\partial z}(-J_k)$$

which relates the local evolution of the concentration of k to the divergence of the flux.

The expression for the flux can be expanded in terms of concentration gradients

$$J_k = -\sum_{i=1}^{n} M_k c_k \frac{\partial \mu_k}{\partial c_j} \frac{\partial c_j}{\partial z} = -\sum_{i=1}^{n} D_{kj} \frac{\partial c_j}{\partial z}$$

where the diffusion coefficient of component k with respect to the concentration gradient of component j has been introduced.

$$D_{kj} = M_k c_k \frac{\partial \mu_k}{\partial c_j}$$

The flux expressions above are given in the so-called lattice-fixed frame of reference. In practical calculations it is more common to use a volume-fixed frame of reference. For a discussion of these concepts, see Andersson and Ågren [1992And].

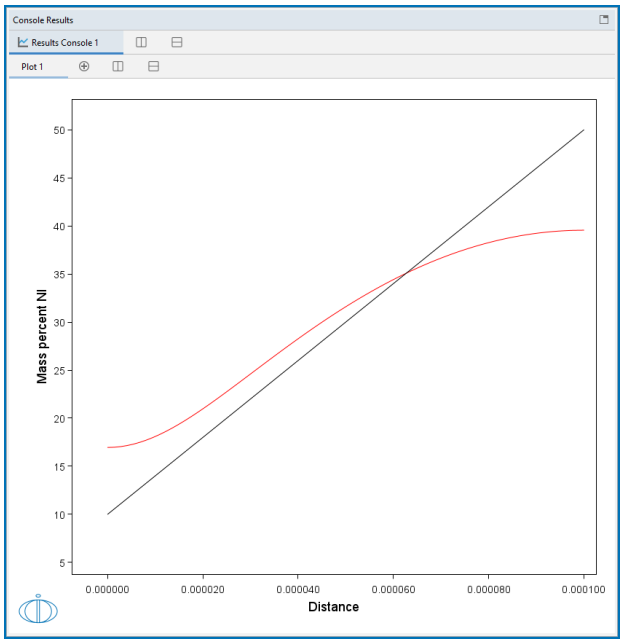
Running the Single Phase Simulation

For the single phase simulation, you use an example macro file called `simplest_dictra.dcm`. Open this file in in Console Mode as described in Opening the Module and Macro Files.

The simulation should automatically be set up, executed and finished within a matter of seconds. Results are plotted in the **Console Results** plot window.

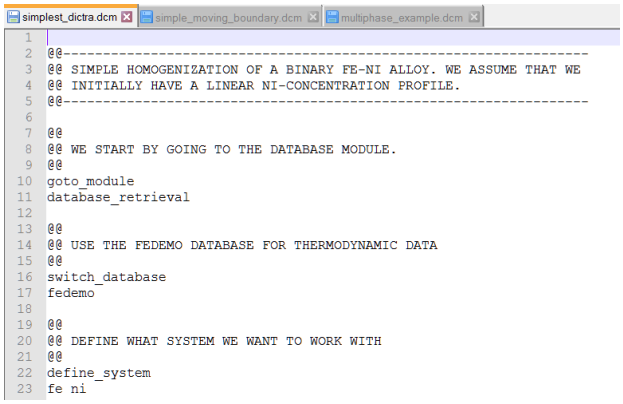


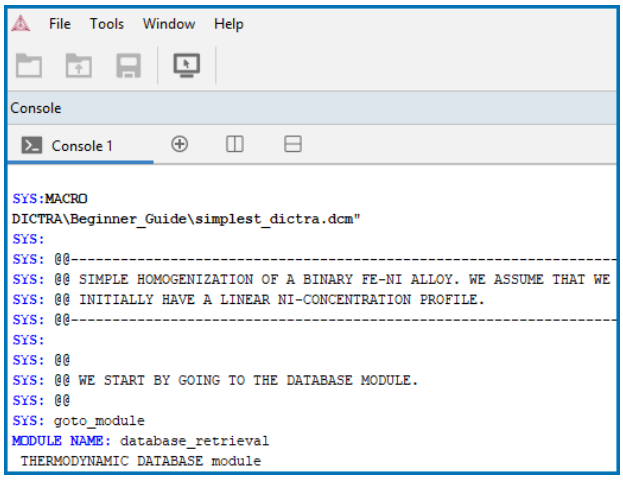
Output from the Single Phase example showing the initial and final Ni profile.

For the rest of the exercise, you will learn how to build this example step-by-step.

Single-Phase Command Details

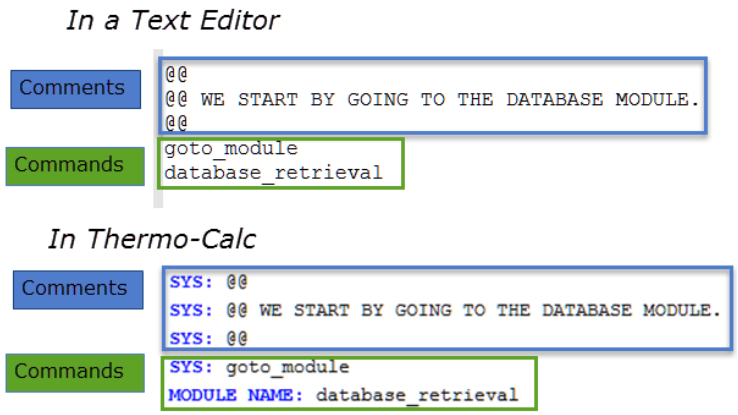
To examine the commands in the macro file, you can either open the file `simplest_dictra.dcm` in a text editor or scroll to the top of the **Console** window.





In the following sections, the commands are discussed in the order they are executed. The first time a command appears it is listed in its general form in UPPERCASE and then using `code font` to detail the specific form of the example. For subsequent examples, only the new commands are detailed. All commands may be abbreviated as long as they are unambiguous.

You can also review the comments included in the example files. The first command you will use is shown in the macro file as follows:



Single Phase - Specifying the Thermodynamic System

Thermo-Calc Console Mode has several modules used for different purposes. In order to define the thermodynamic system the DATABASE_RETRIEVAL module is used.

GOTO_MODULE <MODULE>

```
goto_module database_retrieval
```

There are many databases for different purposes and material types. In this example the *fedemo* database is used. This is the thermodynamic iron demonstration database.

SWITCH_DATABASE <DATABASE>

```
switch_database fedemo
```

Determine what elements to use in the simulation, in this case `Fe` and `Ni`.

DEFINE_SYSTEM <LIST OF ELEMENTS>

```
define_system fe,ni
```

Only the FCC_A1 phase takes part in this simulation and therefore all phases are initially rejected (the wildcard * means *all phases* in this context) and then, with the next command, the FCC_A1 phase is restored.

REJECT <ELEMENTS, SPECIES, PHASES, CONSTITUENT OR SYSTEM> <LIST OF THE RELEVANT TYPE>

```
reject phases *
```

RESTORE <ELEMENTS, SPECIES, PHASES OR CONSTITUENTS> <LIST OF THE RELEVANT TYPE>

```
restore phases fcc_a1
```

The thermodynamic system now consists of the elements `Fe` and `Ni` and the `fcc_a1` phase.

To actually read the data from file into computer memory the GET_DATA command must be executed.

GET_DATA

```
get_data
```

At this stage only the thermodynamic data is defined and read. The kinetic data (mobilities) are, in this case, stored in another database. This is normally the case though it is possible to have both thermodynamic and kinetic data in a single database.

To add data from a different database the APPEND_DATABASE command is used. The kinetic data in this example is stored in the *mfedemo* database. This is the kinetic iron demonstration database.

APPEND_DATABASE <DATABASE>

```
append_database mfedemo
```

The same sequence of commands used for thermodynamic data is used to read kinetic data from this database.

```
define_system fe,ni
reject phases *
restore phases fcc_a1
get_data
```

Setting up the Single-Phase Simulation

The simulation set-up is performed in the DICTRA_MONITOR module.

```
goto_module
dictra_monitor
```

In this example only one *global* condition is set, temperature. The other global condition that can be set is pressure, but that is rarely done as the default value (1 atm) is set automatically and usually accepted.

SET_CONDITION <GLOBAL OR BOUNDARY>

```
set_condition global
```

The SET_CONDITION command is immediately followed by these sub-prompts:

<T OR P>

```
T
```

The T is for temperature. Then follows a standard procedure for entering temporally piece-wise functions:

<LOW TIME LIMIT> <FUNCTION> <HIGH TIME LIMIT> <Y/N> <IF Y, THEN NEXT FUNCTION> <...>

```
0 1400; * N
```

These prompts start with the *low time limit*, here zero (`0`), then the *function* (here the constant value `1400`) closed by a semicolon (`;`), then the *high time limit* (here a wildcard `*` is entered), then a `Y` or a `N` depending on whether more functions will be entered (in this case `N` because only a single function is entered).

The wildcard * used for the upper time limit means that the entered function is valid for the whole simulation. What this means is that a constant temperature equal to 1400 K is used during the whole simulation.

In any simulation at least one *region* must be defined. This is a named container that designates a certain part of, in this case the whole, domain. The name of a region is arbitrary and specified by you.

ENTER_REGION <NAME OF REGION>

```
enter_region austenite
```

The use of regions becomes clearer in the context of so-called moving phase boundary simulations (see About the Moving Phase Boundary Simulation).

A region must contain a numerical *grid* specified by width and type.

ENTER_GRID_COORDINATES

<NAME OF REGION FOR WHICH GRID IS TO BE ENTERED>

<WIDTH OF REGION>

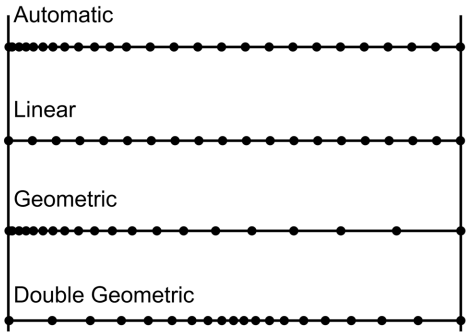
<TYPE OF GRID>

<NUMBER OF GRID POINTS>

```
enter_grid_coordinates
austenite
1e-4
auto
```

In the entries above, a 10^{-4} m wide (`1e-4`), `auto`. There are many types of grids, and a good choice is the automatic (`auto`) grid point distribution. An appropriate grid is generated at the start of the simulation where the grid points are automatically distributed according to the entered composition profile and boundary conditions.

These grid types are used in diffusion simulations: automatic, linear, geometric, and double geometric. When you are setting up the simulation, in either Console Mode or Graphical Mode, a region must have a grid defined.



A region must contain one *active* phase of type *matrix*. The meaning of active/inactive and phase type is explained in the next examples.

ENTER_PHASE_IN_REGION

<ACTIVE OR INACTIVE>

<NAME OF REGION>

<PHASE TYPE IN REGION>

<PHASE NAME>

```
enter_phase_in_region
active
austenite
matrix
fcc_a1
```

In this example only one phase participates, the `fcc_a1` phase, and it must therefore be `active` and of type `matrix`.

The initial composition profile must be specified for all phases that take part in a simulation. Since there are only two elements, Fe and Ni, in the present simulation the initial *composition profile* must only be given for one of them.

ENTER_COMPOSITIONS

<REGION NAME>

<PHASE NAME>

<DEPENDENT COMPONENT>

<COMPOSITION TYPE>

<COMPONENT NAME>

<TYPE OF COMPOSITION PROFILE>

<COMPOSITION PROFILE DEPENDENT INPUT>

```
enter_compositions
austenite
fcc_a1
fe
weight_percent
ni
linear
10
50
```

In the above entries, `Fe` is chosen as the dependent component and the initial profile for Ni is a `linear` variation going from `10` mass-% on the lower/left hand side of the system to `50` mass-% on the upper/right hand side of the system. The composition type can be chosen among a number of different types, e.g. `weight percent` or mole fraction. There are also many different ways of specifying the composition profile, e.g. an arbitrary position dependent function or reading it for each grid point from file. Here the simplest possible type is used a `linear` function.

Now you set the simulation time. If not specified the initial time is set to zero.

SET_SIMULATION_TIME

<SIMULATION END TIME>

<AUTOMATIC TIMESTEP CONTROL Y/N>

<MAXIMUM TIMESTEP>

<INITIAL SIZE OF TIMESTEP>

<SMALLEST ALLOWED TIMESTEP>

```
set_simulation_time
1E5
y
1E4
1E-7
1E-7
```

Here the simulation time is set to 10^5 [s] (`1E5`), the maximum timestep size to 10^4 (`1E4`) and the initial and smallest acceptable to 10^{-7} (both `1E-7`). The *automatic timestep control* should normally always be turned on, which it is by default (you answer `Y` above).

Now you save the workspace:

SAVE_WORKSPACES <FILENAME> <OVERWITE EXISTING FILE Y/N>

```
save_workspaces simplest_dictra y
```

The command name SAVE_WORKSPACES can be misleading. The meaning of this command is roughly set result file. The set-up is saved immediately, but all results during the simulation are also saved to the selected file.

Running and Plotting the Simulation

The SIMULATE_REACTION command starts the simulation.

```
simulate_reaction
```

In order to plot results it is necessary to enter the POST_PROCESSOR sub-module (note that the GOTO_MODULE command is not used).

```
post_processor
```

In most cases, either a specific position in the domain or one or more specific times must be specified with the SET_PLOT_CONDITION command, depending on whether time or spatial position is chosen as independent (x-axis) variable.

SET_PLOT_CONDITION <CONDITION WITH ARGUMENTS>

```
set_plot_condition time 0,1e5
```

Here, the composition profile of Ni at the initial and final time is plotted and thus `time` is chosen as plot condition.

In other cases distance can be given relative to, for example, a phase interface, hence the global specification.

SET_DIAGRAM_AXIS <X OR Y> <AXIS QUANTITY>

```
set_diagram_axis x distance global
```

In this example the only meaningful measure of distance is relative to the domain as a whole, i.e. the leftmost position is zero and the rightmost position corresponds to the width of the region (10^{-4} m).

The dependent property to be plotted is mass-% Ni.

```
set_diagram_axis y weight_percent ni
```

Then plot the diagram:

PLOT_DIAGRAM

```
plot_diagram
```

In the **Console Results** plot window, graphs of the initial and final Ni profile display. Finally, the SET_INTERACTIVE_MODE command is executed to return control to the user. If the command is absent in a macro the program terminates when the end of the macro file is reached.

SET_INTERACTIVE_MODE

```
set_interactive_mode
```

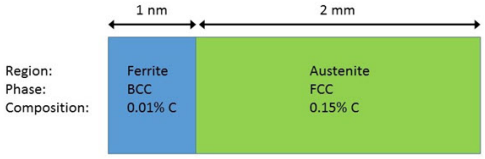
Moving Phase - Specifying the Thermodynamic System *2488*

Setting Up the Moving Phase Boundary Simulation *2489*

Running and Plotting the Moving Phase Simulation *2492*

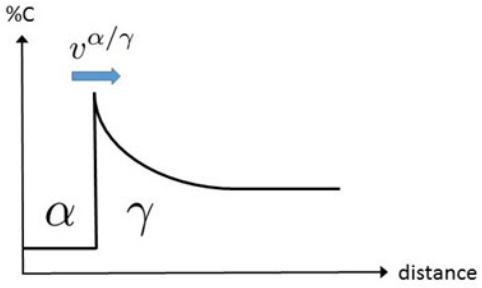
About the Moving Phase Boundary Simulation

The growth of ferrite (bcc) into austenite (fcc) is simulated in this example. The austenite is assumed to be initially homogeneous with the composition Fe - 0.15 mass-% C and the transformation temperature is 1050 K. The initial thickness of the austenite is 2 mm and an initially very thin ferrite (1 nm) is also present at the start of the simulation. The initial state is as below.



The set-up of the Moving Boundary example. There are two regions, Ferrite and Austenite, consisting of bcc and fcc, respectively.

A schematic graph of the carbon profile during the transformation is shown in the image below. Crusius et al. [1992Cru-1] is recommended as further reading.



Schematic view of the carbon profile during the transformation from austenite (γ) to ferrite (α) in the Moving Boundary example.

Theory for the Moving Phase Boundary Simulation

It is assumed that local equilibrium holds at the phase interface, i.e. the chemical potentials of all elements are continuous across the boundary, but the chemical potential gradients are in general discontinuous.

In order to maintain mass balance a set of flux balance equations must be satisfied at the phase interface:

$$v^{\alpha/\gamma}(c_k^\alpha - c_k^\gamma) = J_k^\alpha - J_k^\gamma \qquad k = 1, \ldots, n-1$$

where v is the interfacial velocity. The concentrations and the fluxes c and J are those at the interface on the α and γ sides, respectively.

In the present case there are no degrees of freedom at the interface and the concentrations can be taken directly from a phase diagram. There is only one flux balance equation and the interface velocity can be evaluated once the fluxes at the interface are known. However, for ternary and higher systems the state at the interface must be found by some iterative procedure.

For more information on moving phase boundary problems, see, for example, [1982Ågr], [1992Cru-2], and [1997Hög].

Run the Macro File and Learn the Commands

If the single phase example has just been run, then either restart the software program or open another Console window by clicking the green button with the plus sign.

At the `SYS` prompt, type `macro` (short for the MACRO_FILE_OPEN command) and press <Enter>. Locate and select the macro file called `simple_moving_boundary.dcm` as described in Opening the Module and Macro Files. The commands in the macro file set up, run and plot the simulation in the Console Results window.

In the macro file some abbreviations of the commands are used. You can shorten command names in an arbitrary manner as long as the abbreviations are unambiguous.

In the macro file most commands are first given as comments with the full name and then abbreviated. Commands that were not used in the single-phase simulation, or are used differently, are explained in more detail.

Comments in the macro file can be entered after two `@@` symbols. In most cases the arguments of a command can be entered on the same line as the command itself.

Single-Phase Command Details

Moving Phase - Specifying the Thermodynamic System

This set of commands is the same as in the single-phase simulation example. Thermodynamic and kinetic data is read for Fe and C and the bcc and fcc phases.

Specifying the Multiphase Thermodynamic System *2497*

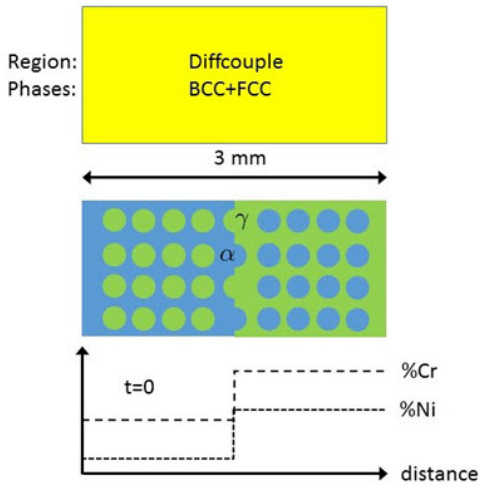
Setting Up the Multiphase Simulation *2497*

Running and Plotting the Multiphase Simulation Results *2500*

About the Multiphase Simulation

This example simulates the evolution of an Fe-Cr-Ni diffusion couple during a 100 hour heat treatment at 1100° C (1373.15 K). Both end members of the diffusion couple are duplex ferrite plus austenite, but the majority phase is ferrite on the left-hand side and austenite on the right.

With this type of simulation it is assumed that the material is fully equilibrated at each grid point, i.e. the local phase fractions, phase compositions and so forth are obtained from an equilibrium calculation with the local overall composition as a condition.



Schematic view of the initial state of the Multiphase example. Two ternary Fe-Cr-Ni alloys form a diffusion couple. There is a single region (diffcouple) where both the bcc and fcc phases are entered. Both alloys are duplex bcc+fcc, but the majority phase is bcc (α) in the left-hand side alloy and fcc (γ) in the right.

Theory for the Multiphase Simulation

More details about the homogenization model for multiphase simulations can be found in Larsson and Engström [2006Lar] and Larsson and Höglund [2009Lar]. As mentioned in the description of this simulation, it is assumed that the material is locally fully equilibrated and that the local phase fractions, phase compositions and so forth are obtained from an equilibrium calculation with the local overall composition as a condition. From a numerical point of view the homogenization model treats the multiphase material as a single phase having the “average”, or “effective”, properties of the local phase mixture.

When estimating the effective kinetics of a multiphase mixture the product of solubility and mobility in each phase is considered. It is therefore convenient to define

$$\Gamma_k^\phi = M_k^\phi c_k^\phi$$

for each phase ϕ. The effective kinetics of the multiphase mixture is denoted and in this example it was evaluated using the lower Hashin-Shtrikman bound. The default method is a simple rule of mixtures

$$\Gamma^\star = \sum_\phi f^\phi \Gamma_k^\phi$$

where f^ϕ is the volume fraction of ϕ. The flux is obtained as

$$J_k = -\Gamma_k^\star \frac{\partial \mu_k}{\partial z}$$

which replaces the single-phase equation

$$J_k = L_{kk} \frac{\partial \mu_k}{\partial z} = M_k c_k \frac{\partial \mu_k}{\partial z}$$

for multiphase simulations.

Run the Macro File and Learn the Commands

At the `SYS` prompt, type `macro` and pres <Enter>. Locate and select the macro file called `multiphase_example.dcm` as described in Opening the Module and Macro Files. The commands in the macro file should set up the simulation, run it and then produce a graph in the Console Results window.

Most of the set-up is the same as the single phase and moving phase boundary examples. Detailed comments are only given for the new commands for this simulation.

Single-Phase Command Details

Specifying the Multiphase Thermodynamic System

Data for Fe, Cr, and Ni and the fcc and bcc phases are read from the *fedemo* (thermodynamics) and *mfedemo* (mobility/kinetic) databases.

```
go da
sw fedemo
def-sys fe cr ni
rej ph *
rest ph bcc,fcc
get
app mfedemo
def-sys fe cr ni
rej ph *
rest ph bcc,fcc
get
```

Setting Up the Multiphase Simulation

Set the temperature `T` during the simulation to 1100° C (`1373.15` K) and enter a region `diffcouple`.

```
go dictra-monitor
set-cond glob T 0 1373.15; * N
ent-reg diffcouple
ent-grid
diffcouple
3e-3
```

```
auto
set-auto-grid-option
fine
```

The automatic (`auto`) grid point distribution is used as with the other examples. One more command SET-AUTO-GRID-OPTION is used and `fine` is chosen to set the number of equidistant points in a region (e.g. maximum distance between two adjacent grid points is the size of the region divided by this number) and the maximum factor that is allowed in the geometric series defining the initial grid.

As always, a region must contain exactly one `active` phase that is of type `matrix`. In this example it is arbitrary whether it is the bcc or the fcc phase that is entered as matrix.

```
enter-phase
active
diffcouple
matrix
fcc
```

The bcc phase is entered in the same manner as the fcc phase, except that the type is set as `spheroid`.

```
enter-phase
active
diffcouple
spheroid
bcc
```

The initial composition profile of the fcc phase is entered as a `function` of distance.

```
enter-composition
diffcouple
fcc
fe
m-f
cr
function
2.57e-1+(4.23e-1-2.57e-1)*hs(x-1.5e-3);
ni
function
6.47e-2+(2.75e-1-6.47e-2)*hs(x-1.5e-3);
```

In the above entries, the `hs` denotes the Heaviside step function that has the following properties:

$$hs(x) = \begin{cases} 0, & x < 0 \\ 1, & x \geq 0 \end{cases}$$

The resulting Cr profile is thus `0.257` on the left half of the domain and `0.423` on the right with a sharp step at the center.

As shown in About the Multiphase Simulation.

The initial composition of the fcc phase is actually the initial overall composition. This is due to the choice of initial composition of the spheroid bcc phase.

ENTER_COMPOSITIONS

<REGION NAME>

<PHASE NAME>

<USE EQUILIBRIUM VALUE Y/N>

```
enter-comp
diffcouple
bcc
y
```

When entering the composition for a type spheroid phase it is possible to either, as here, let the composition of the matrix phase be the overall composition or manually enter a start composition and volume fraction.

The local kinetics of the multiphase mixture must be estimated by means of some function that may depend on the local phase fractions, phase compositions and the mobilities of the individual phases. The command for choosing the function to use is ENTER_HOMOGENIZATION_FUNCTION. There are many such homogenization functions to choose from. In this particular example the so-called lower Hashin–Shtrikman bound [1962Has] is a good choice.

ENTER_HOMOGENIZATION_FUNCTION

<ENTER FUNCTION NUMBER>

```
enter-homo-fun
1
```

Finally, set simulation time (100 h) and select the name of the result file:

```
set-sim-time
3.6e5
```

```
yes
3.6e4
1e-7
1e-7
save multiphase_example y
```

Reference

[1962Has] Z. Hashin, S. Shtrikman, A Variational Approach to the Theory of the Effective Magnetic Permeability of Multiphase Materials. J. Appl. Phys. 33, 3125–3131 (1962).

Running and Plotting the Multiphase Simulation Results

Run the simulation.

```
simulate
```

Go to the post processor.

```
post
```

Plot the mole fraction fcc phase as a function of distance at the end of the heat treatment.

```
set-plot-condition time last
set-diagram-axis x distance global
set-diagram-axis y npm(fcc)
```

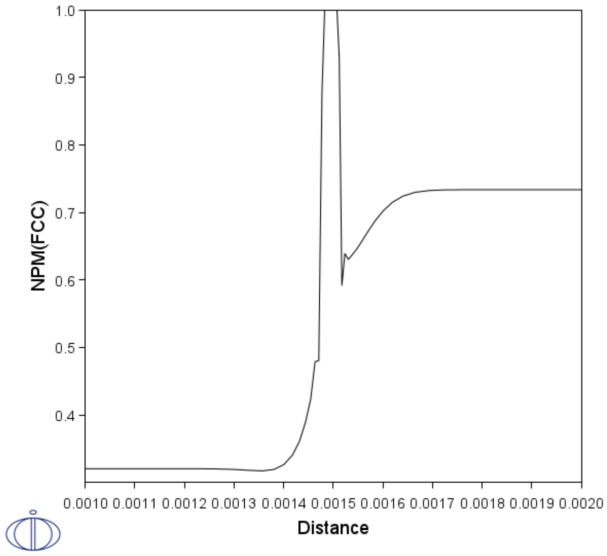
Instead of explicitly entering the final time it is possible to use the keyword `last`. The `np` of npm stands for *number of moles* of the phase argument and the `m` is the normalizing quantity (moles). The limits of an axis can be set with the SET_SCALING_STATUS command. You manually set the scaling of the axis and then restore automatic scaling:

```
SET_SCALING_STATUS
<X OR Y AXIS>
<USE AUTOMATIC SCALING Y/N>
<IF MANUAL SCALING, ENTER LIMITS>
set-scaling-status x n 1e-3 2e-3
```

Plot the diagram.

```
plot
```

The plot below shows that a single phase fcc zone has formed and this was also observed experimentally, see [1995Eng].



Output from the multiphase_example showing the mole fraction fcc phase as a function of distance at the end of the heat treatment.

Next Steps

You have been working within the classic Console Mode. It is recommended to learn how to use Graphical Mode instead. Details can be found as follows.

- Browse the locally installed Help (press F1) or go the web version via the website that matches the most recently released version of Thermo-Calc.
- Open the *Thermo-Calc Software Documentation Set* PDF included with your installation (**Help → Manuals Folder**).
- You can also go to the Thermo-Calc website to see if there are other options suited to you, such as a course or video tutorials. To go to the web page, in the **Project** window, click the top **My Project** node and then click **Video Tutorials**. Or from the main menu, select **Help → Video Tutorials**.

There are several resources available on our website to help you learn how to use Thermo-Calc and other Add-on Modules. Go to the Getting Started Guides page and choose one of the guides that provides new users an introduction to setting up simple calculations in Graphical Mode. The information there is also in this help documentation.

The Role of Diffusion in Materials: A Tutorial is available for download on our website. It is intended for engineers interested in using the Diffusion Module (DICTRA), as well as students learning about the role of diffusion in materials. It is designed to be useful at many levels, from undergraduate studies to someone with a PhD and experience in a related field.

Precipitation Module (TC-PRISMA)

The Precipitation Module (TC-PRISMA) is an Add-on Module that treats concurrent nucleation, growth/dissolution, and coarsening under arbitrary heat treatment conditions in multicomponent and multi-phase systems using Langer-Schwartz theory and the Kampmann-Wagner numerical approach. The Module extends the functionality available in Thermo-Calc by allowing you to make calculations related to the precipitation of your materials. It is available in Graphical Mode.

About the Precipitation Module (TC-PRISMA)

The Precipitation Module, or TC-PRISMA, is an Add-on Module to Thermo-Calc and it is available in Graphical Mode as the *Precipitation Calculator*.

The Module treats concurrent nucleation, growth/dissolution and coarsening under arbitrary heat treatment conditions in multi-component and multi-phase systems using Langer-Schwartz theory and the Kampmann-Wagner numerical approach. It is a general computational tool for simulating kinetics of diffusion controlled multi-particle precipitation processes in multicomponent and multiphase alloy systems.

You can use the Precipitation Module for:

- Concurrent nucleation, growth/dissolution and coarsening of precipitates
- Normal grain growth and Zener pinning
- Temporal evolution of particle size distribution
- Average particle radius and number density
- Volume fraction and composition of precipitate
- Nucleation rate and coarsening rate
- Time-Temperature-Precipitation (TTP) diagrams
- Continuous-Cooling-Transformation (CCT) diagrams
- Estimation of multi-component interfacial energy
- Estimation of yield stress using the Yield Strength Property Model

The configuration of the **Yield Strength** Property Model is completed on the **Property Model Calculator** and then accessed as a variable with the Plot Renderer or Table Renderer.

Performing Simulations in the Module

In order to perform a simulation in the Precipitation Module, both a thermodynamic database and a kinetic database is needed. The thermodynamic database is a normal Thermo-Calc database, whereas the kinetic database contains information about the atomic mobility of individual elements in various phases.

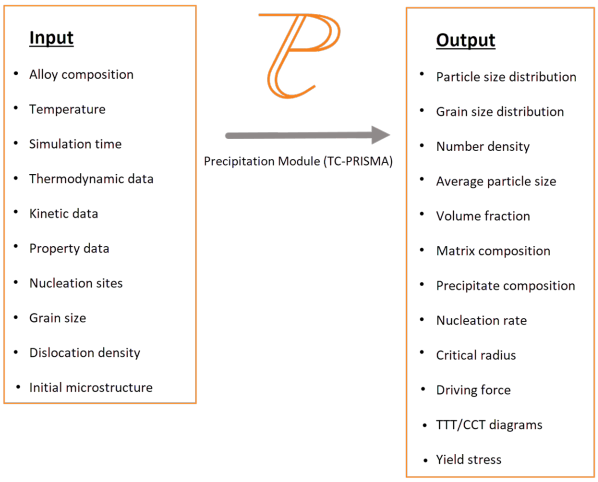
Precipitation, formation of particles of a second phase, or second phases from a supersaturated solid solution matrix phase, is a solid state phase transformation process that has been exploited to improve the strength and toughness of various structural alloys for many years. This process is thermochemically driven and fully governed by system (bulk and interface) thermodynamics and kinetics.

Typically, a precipitation process has three distinctive stages: nucleation, growth, and coarsening. However, under certain conditions, these can also happen at the same time. With the Precipitation Module, the kinetics of concurrent nucleation, growth, and coarsening can be simulated by calculating the evolution of the probability distribution of the particle number densities, usually called particle size distribution (PSD). The simulation results can be used to understand and guide how to obtain desirable precipitates with certain PSD or to avoid undesirable precipitations during heat treatments of alloys such as aging and tempering.

Inputs and Outputs of the Module

A summary for the input and output of the Precipitation Module is shown.

Input and Output of the Precipitation Module



The CALPHAD Method

The Precipitation Module relies on CALPHAD-based software tools and databases to provide the necessary bulk thermodynamic and kinetic data for phases in multicomponent systems. The CALPHAD approach has been developed for more than 50 years and is routinely applied to design new alloys and optimize existing materials within various metal industries, such as

steels and alloys of nickel, titanium, aluminum and magnesium.

The power of this approach is due to the adopted methodology where free energy and atomic mobility of each phase in a multicomponent system can be modeled hierarchically from lower order systems, and model parameters are evaluated in a consistent way by considering both experimental data and ab-initio calculation results. The Precipitation Module is directly integrated into Thermo-Calc, a CALPHAD-based computer program for calculating phase equilibrium. Another Add-on Module, the Diffusion Module (DICTRA) is available for diffusion controlled phase transformation in multicomponent systems.

The CALPHAD Method and the Thermo-Calc Databases

What Calculations Can I Do?

With Thermo-Calc and the accompanying thermodynamic and mobility databases, almost all fundamental phase equilibrium and phase transformation information can be calculated without unnecessary and inaccurate approximations. For example you can calculate:

- Driving forces for nucleation and growth
- Operating tie-lines under local equilibrium conditions
- Deviations from local equilibrium at interfaces due to interface friction
- Atomic mobilities or diffusivities in the matrix phase

In addition to bulk thermodynamic and kinetic data, a few other physical properties, such as interfacial energy and volume, are needed in precipitation models. These additional physical parameters can be obtained by experiments or other estimation models or first principles calculations. Volume data are available in most of our thermodynamic databases . The Precipitation Module has an estimation model available for interfacial energy.

It is recommended that you use the Help, which you can access in Thermo-Calc by pressing F1 or from the main menu choose **Help** → **Online help**.

Available Options

The Precipitation Module, also referred to as TC-PRISMA, is an Add-on Module to the core Thermo-Calc software.

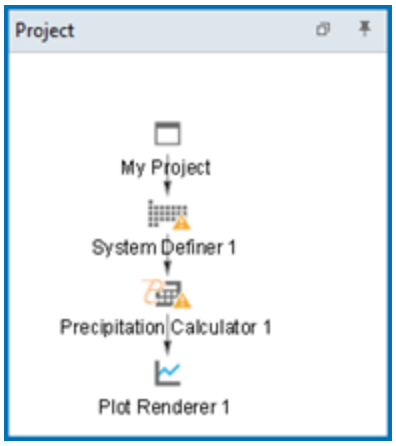
A separate license is required to perform calculations for more than three elements. Without it you are able to use the module in *Demo Mode*.

Precipitation Template

A **Precipitation** template under **Non-Equilibrium Calculations** is available to all Thermo-Calc users when in Graphical Mode. If you are in DEMO mode then this is indicated by the addition of **DEMO** text.

Using the Template

After opening Thermo-Calc in Graphical Mode, in the templates section under **Non-Equilibrium**, click the **Precipitation** button to add a *System Definer*, *Precipitation Calculator*, and *Plot Renderer* to the **Project** tree.



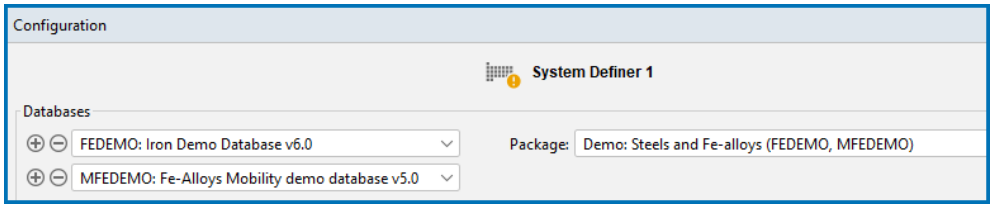
Creating a Project from a Template

Precipitation Calculator

A Precipitation Calculator allows you to set the conditions for, and perform, a precipitation calculation. Details about this activity are described in Precipitation Calculator.

Demo Database Packages for the Examples Collection

Both a thermodynamic and mobility database are required to run the Precipitation Module simulation. If you have a Precipitation Module (TC-PRISMA) license you can run all the examples as the demonstration database packages are included with your installation. Select the database packages from the **System Definer** → **Configuration** window to run a simulation.



Demonstration (Demo) Mode

The Precipitation Module, and some examples, are available to all Thermo-Calc users but only for simulations of alloys with up to three elements. If you do not have a license for the Precipitation Module then you are in *Demonstration Mode* when using the Precipitation Calculator or Precipitation Simulation template.

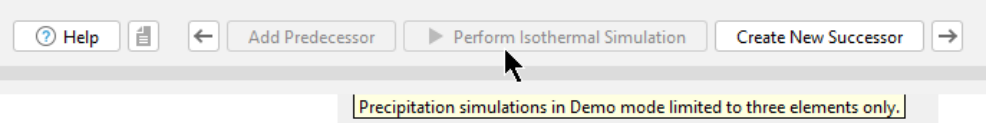
Network License Restrictions

A **Precipitation** template under **Non-Equilibrium Calculations** is available to all Thermo-Calc users when in Graphical Mode. If you are in DEMO mode then this is indicated by the addition of **DEMO** text.

Precipitation Calculator

If you are experimenting with the Precipitation Calculator in Demo Mode, you may have access to a variety of databases based on your license. However, you can only define up to three elements for a demo simulation.

If you define more than three elements on the System Definer, when you go to the Precipitation Calculator, the **Perform** button is unavailable and the tooltip explains why. In this case one of the chosen elements needs to be removed and then the Perform button is made available.



Even if you have more than three elements, the Plot Renderer or Table Renderer **Perform** button is still available. However, if you click the button and try to run the simulation the Event Log displays an error message.

Additive Manufacturing (AM) Module

There is connectivity between the Diffusion Module (DICTRA) or the Precipitation Module (TC-PRISMA) and the Additive Manufacturing (AM) Module when you have full licenses available for all relevant Add-on Modules and databases.

You can add a Diffusion Calculator or Precipitation Calculator as a successor to the AM Calculator and then when probes are included with the AM Calculator this data can be further used with the thermal profile.

Details are in the AM Module documentation. See AM Calculator: Working with Probe Data.

Network License Restrictions

The Precipitation Module (TC-PRISMA) requires a separate license. If you are using a network client installation of Thermo-Calc, then you may not be able to use it even if you have access to a license server with a valid network license file. The reason for this is because other clients who are part of your network installation may have checked out all instances of the network license allowed to run simultaneously.

For users with a network license, you must exit Thermo-Calc to release the license for other users. The license is checked out as soon as you add a Precipitation Calculator and remains unavailable to other users until you exit the program.

With a network license, and if as per above you temporarily do not have access to a license, you are automatically put into *Demo Mode*. Then the Precipitation Calculator is available with three elements.

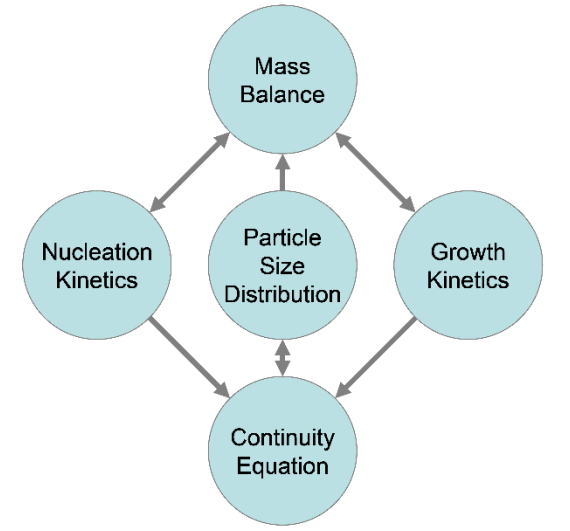
Theory Overview

Based on the theory from Langer-Schwartz [1980Lan] the Precipitation Module (TC-PRISMA) adopts Kampmann-Wagner numerical (KWN) [2013Wag] method to simulate the concomitant nucleation, growth, and coarsening of precipitates in multicomponent and multiphase alloy systems. The KWN method is an extension of the original Langer-Schwartz (LS) approach and its modified (MLS) form, where the temporal evolution of the mean radius and particle density over the whole course of precipitation are predicted by solving a set of rate equations derived with certain assumptions for the rates of nucleation and growth, as well as the function of particle size distribution (PSD). The MLS approach differs from the LS with respect to the Gibbs-Thomson equations used for calculating equilibrium solubilities of small particles. The former applies the exact exponential form, whereas the latter takes the convenient linearized version. Instead of assuming a PSD function *a priori* and working with rate equations for determining only mean radius and particle density, the KWN method extends the LS and MLS approaches by discretizing the PSD and solving the continuity equation of the PSD directly. Therefore, the time evolution of the PSD and its n^{th} moment (*0*: number density; 1^{st}: mean radius; 3^{rd}: volume fraction) can be obtained altogether during the simulation. The key elements of the KWN method are the models for nucleation and growth under the mean field mass balance condition and the numerical algorithm for solving the continuity equation of the PSD. Coarsening comes out naturally without any *ad hoc* treatment.

The key elements of the KWN method and their relationship as implemented in the Precipitation Module (TC-PRISMA).



Integration of the Precipitation Module into Thermo-Calc

Precipitation Module (TC-PRISMA) is integrated with Thermo-Calc in order to directly get all necessary thermodynamic and kinetic information required in the KWN method. For industry relevant multicomponent alloys, thermodynamic and kinetic databases and calculation tools have to be used in order to obtain various quantities in the multicomponent models for nucleation and growth, such as the driving forces for the formation of embryos and their compositions, the atomic mobilities or diffusivities in the matrix, the operating interface compositions under local equilibrium conditions, the Gibbs-Thomson effect, and the deviation from local equilibrium due to interface friction etc. With Thermo-Calc and the Diffusion Module (DICTRA) as well as the accompanying databases, all these properties and effects can be calculated without unnecessary and inaccurate approximations.

In the following topics, various models and numerical methods implemented in Precipitation Module (TC-PRISMA) are introduced. Unless specified, spherical particles are assumed in the discussion.

Nucleation Theory

Precipitation starts from the nucleation of clusters that can be considered as embryos of new phases with distinctive structures or compositions. In a perfect single crystal, nucleation happens homogeneously. In an imperfect crystal or polycrystalline materials, nucleation tends to occur heterogeneously due to the presence of dislocations, grain boundaries, grain edges, and grain corners. These imperfections or defects reduce the nucleation barrier and facilitate nucleation. However, if supersaturation or driving force is very large homogeneous nucleation is also possible since all sites including those inside a grain can be activated.

The following sections further elaborate on this theory.

- Homogeneous Nucleation
- Heterogeneous Nucleation
- Nucleation During a Non-isothermal Process

Homogeneous Nucleation

This section discusses the homogenous nucleation theory.

Background Theory

The classic nucleation theory (CNT) [2000, Kashchiev; 1980, Russell] has been extended for the purpose of modeling nucleation in multicomponent alloy systems. The time-dependent nucleation rate $J(t)$ is given by

[*Eq. 1*] $$J(t) = J_s exp\left(\frac{-\tau}{t}\right)$$

where

- J_s is the steady state nucleation rate,
- τ is the incubation time for establishing steady state nucleation conditions, and
- t is the time.

The steady state nucleation rate J_s is expressed by

[*Eq. 2*] $$J_s = Z\beta^* N exp\left(\frac{-\Delta G^*}{kT}\right)$$

where

- Z is the Zeldovich factor,
- β^* is the rate at which atoms or molecules are attached to the critical nucleus,
- N is the number of available nucleation sites (of a particular type) per unit volume. In the case of homogeneous nucleation, initially, each atom in the whole volume of the mother phase is a potential nucleation site. As precipitation proceeds, the number of available nucleation sites decreases due to the occupancy of part of the matrix volume by formed secondary phase particles. In the case of heterogeneous nucleation, the initial number can also be estimated, given the grain size or dislocation density in the matrix phase. It decreases also with time but at different rates.
- ΔG^* is the Gibbs energy of formation of a critical nucleus,
- k is Boltzmann's constant,
- T is absolute temperature.

The Gibbs energy of formation of a critical nucleus is expressed as

$$\Delta G^{*} = \frac{16\pi\sigma^{3}}{3\left(\Delta G_{m}^{\alpha\rightarrow\beta}/V_{m}^{\beta}\right)^{2}} \quad \text{[Eq. 3]}$$

where

- σ is the interfacial energy,
- $\Delta G_{m}^{\alpha\rightarrow\beta}$ is the molar Gibbs energy change for the formation of the β precipitate of the critical composition X_{i}^{β} from the α matrix, i.e. the maximum driving force for the $\alpha \rightarrow \beta$ phase transformation
- V_{m}^{β} is the molar volume of the β precipitate phase.

If elastic strain energy is excluded, $\Delta G_{m}^{\alpha\rightarrow\beta}$ is the chemical driving force for nucleation. There are two ways to calculate the nucleation driving force $\Delta G_{m}^{\alpha\rightarrow\beta}$ and the critical composition X_{i}^{β}, as shown in Figure 1 for a prototype binary system. The standard calculation in Figure 1 is to obtain the maximum driving force by finding the parallel tangent lines or surfaces passing through the alloy composition of the matrix, which is a routine calculation in the Thermo-Calc software. The approximate calculation in Figure 1 is performed by using the Gibbs energy difference corresponding to the equilibrium composition in the precipitate phase. It can be used when the standard calculation fails, mostly within a miscibility gap. Additionally, the standard calculation is also used for driving force under paraequilibrium conditions, while the approximate calculation is used for driving force under NPLE (Non-Partitioning Local Equilibrium) conditions.

Growth

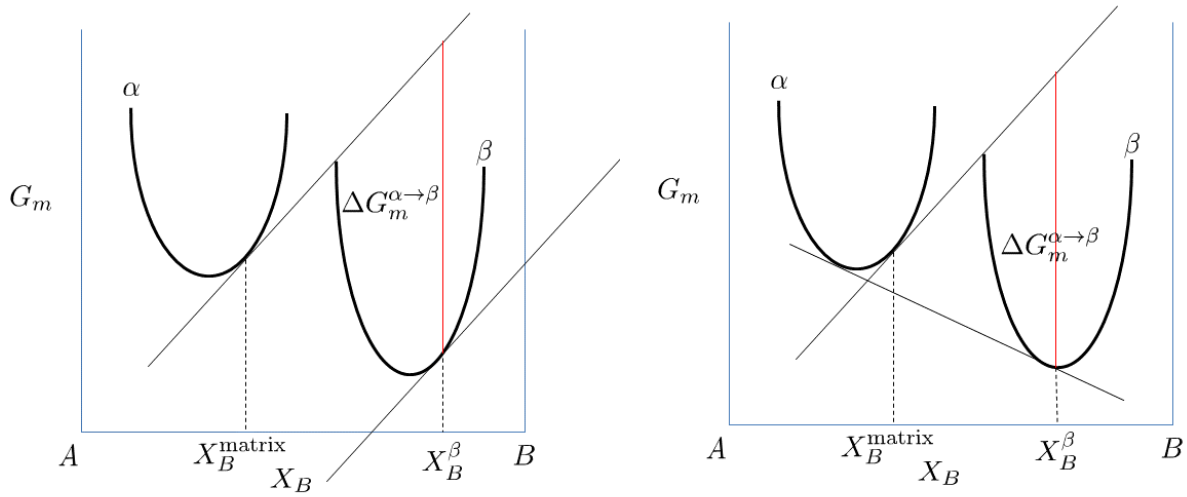

Figure 1: Methods to calculate the nucleation driving force $\Delta G_m^{\alpha\to\beta}$ and the critical composition X_i^{β}. The standard calculation (left) and an approximate calculation (right).

Nucleation is a stochastic process and can be considered formally as a diffusion process or Brownian movement in the particle size space. Supercritical nuclei with radius slightly larger than the critical radius have a probability of passing back across the free energy barrier and dissolve in the matrix. The Zeldovich factor (Z) is a measure of such probability and is related solely to the thermodynamics of the nucleation process in

[*Eq. 4*] $$Z = \frac{V_m^{\beta}}{2\pi N_A r^{*2}}\sqrt{\frac{\sigma}{kT}}$$

where N_A is the Avogadro number and r^*, the critical radius, is given by

[*Eq. 5*] $$r^* = -\frac{2\sigma V_m^{\beta}}{\Delta G_m^{\alpha\to\beta}}$$

The atomic or molecular attachment rate β^* reflects the kinetics of mass transport in the nucleation process and is given by Svoboda et al. [2004Svo].

[*Eq. 6*] $$\beta^* = \frac{4\pi r^{*2}}{a^4}\left[\sum_{i=1}^{k}\frac{\left(X_i^{\beta/\alpha} - X_i^{\alpha/\beta}\right)^2}{X_i^{\alpha/\beta} D_i}\right]^{-1}$$

where

- a is the lattice parameter,
- $X_i^{\beta/\alpha}$ and $X_i^{\alpha/\beta}$ are the mole fractions of element *i* at the interface in the precipitate and matrix, respectively.
- D_i is the corresponding diffusion coefficient in the matrix.

The incubation time τ for an isothermal reaction is

[*Eq. 7*] $$\tau = \frac{1}{\theta Z^2 \beta^*}$$

where θ differs from one derivation to another. The value 2 from Feder et al. [1966Fed] is adopted.

Elastic Strain Energy

Elastic strain energy, E_{el}, reduces the nucleation driving force, $\Delta G_m^{\alpha\rightarrow\beta}$ in Eq. 3, hence affecting nucleation rate and nuclei size. It also changes the shape of the particle by competing with interfacial energy.

Cuboid Particle

Precipitation Morphology

The numerical simulations by Onaka et al. [2003Ona] indicate that the elastic strain energy is reduced almost linearly with increasing cubic factor η. Since the numerical simulations are computationally expensive, we assume that the elastic strain energy follows the linear relationship with η, and the elastic strain energy for spherical ($\eta = 1$) and cubic ($\eta = \sqrt{2}$) are calculated based on Khachaturyan's approximation [1983/2008Kha].

[*Eq. 8*] $$E_{el} = \frac{1}{2}(c_{11} + 2c_{12})\epsilon_0^2 V[A_1 + A_2]$$

where

- ϵ_0 is the lattice misfit strain,
- c_{11}, c_{12}, c_{44} are elastic constants in a cubic system,
- V is particle volume,
- A_1 and A_2 are expressed as

$$A_1 = 2\frac{c_{11}-c_{12}}{c_{11}} - 12\frac{c_{11}+2c_{12}}{c_{11}}\frac{c_{11}-c_{12}-2c_{44}}{c_{11}+c_{12}+2c_{44}}I_1$$

$$A_2 = -54\frac{c_{11}+2c_{12}}{c_{11}}\frac{(c_{11}-c_{12}-2c_{44})^2}{(c_{11}+c_{12}+2c_{44})(c_{11}+2c_{12}+4c_{44})}I_2$$

with

Sphere

$$I_1 = \frac{1}{15} \qquad I_2 = \frac{1}{105}$$

Cubic

$$I_1 = 0.006931 \qquad I_2 = 0.000959$$

Ellipsoidal Particle (Plate and Needle)

Precipitation Morphology

Since they are ellipsoidal shape, it is convenient to use Eshelby's theory [1957/1959Esh] with a reasonable computational cost. The Eshelby's tensor can be calculated by simply performing a surface integral over a unit sphere

[*Eq. 9*] $$D_{ijkl} = -\frac{abc}{4\pi}\int_0^{\pi}\int_0^{2\pi}\Omega_{ij}n_k n_l\frac{\sin\theta}{\beta^3}d\phi d\theta$$

where

- a, b, c are ellipsoid axes,
- $n_i (i = 1, 2, 3)$ are unit directional vector normal to the spherical surface and

  $$\beta = \sqrt{(a^2\cos^2\phi + b^2\sin^2\phi)\sin^2\theta + c^2\cos^2\theta}$$

For matrix phase with cubic crystal symmetry, we have for $\Omega_{ij}(i, j = 1, 2, 3)$. See [1983Kha].

$$\Omega_{ii}(\vec{n}) = \frac{c_{44}+(c_{11}-c_{44})(n_j^2+n_k^2)+\xi(c_{11}+c_{12})n_j^2n_k^2}{c_{44}D(\vec{n})}$$

$$\Omega_{ij}(\vec{n}) = -\frac{(c_{12}+c_{44})(1+\xi n_k^2)}{c_{44}D(\vec{n})}n_i n_j$$

where

$$\xi = \frac{c_{11}-c_{12}-2c_{44}}{c_{44}}$$

$$D(\vec{n}) = c_{11} + \xi(c_{11}+c_{12})(n_1^2n_2^2 + n_1^2n_3^2 + n_2^2n_3^2) + \xi^2(c_{11}+2c_{12}+c_{44})n_1^2n_2^2n_3^2$$

The Eshelby S tensor can then be calculated as

[Eq. 10] $$S_{ijmn} = -\frac{1}{2} C_{lkmn} \left(D_{iklj} + D_{jkli} \right)$$

The total strain ϵ_{ij} at each location inside the particle is related to its transformation strain (eigenstrain) ϵ^*_{ij} as

[Eq. 11] $$\epsilon_{ij} = S_{ijkl} \epsilon^*_{kl}$$

Combined with elastic stress calculated as

$$\sigma_{ij} = C_{ijkl} \left(\epsilon_{kl} - \epsilon^*_{kl} \right)$$

The elastic strain energy can be then obtained

[Eq. 12] $$E^{el} = -\frac{1}{2} \sigma_{ij} \epsilon^*_{ij} V$$

with V the particle volume.

Spherical Approximation for Nuclei

In the Precipitation Module, the user-input or calculated interfacial energy is assumed to be the coherent interfacial energy that applies to the habit plane, $\sigma^{\text{sph}}_{\text{coh}}$, consistent with the approximation made by the embedded interfacial energy model. When calculating the critical nuclei, the interfacial energy in Eq. 3 is assumed to be that of a spherical particle with constant specific interfacial energy $\sigma^{\text{sph}}_{\text{coh}}$. This is consistent with the fact that the nuclei tend to be spherical due to dominant interfacial energy. Interfacial energy penalty assuming a nucleus with pre-defined, and most likely large, aspect ratio is thus over-estimated, and has been found to shut down nucleation event abnormally.

Under spherical approximation, the elastic strain energy is calculated using spherical expression in Eq. 8 for spherical and cuboidal particles, or by setting $a = b = c$ in Eq. 9 for ellipsoidal particles.

Heterogeneous Nucleation

All equations remain the same for the calculation of heterogeneous nucleation rate within the framework of classic nucleation theory (CNT), but the nucleation energy and available nucleation site are different.

To a first approximation, the nucleation energy may be calculated by assuming an effective interfacial energy for each heterogeneous nucleation site.

For a rigorous treatment of heterogeneous nucleation the effect of wetting angles need to be considered.

Non-Spherical Particles and the Effect of Wetting Angle

Precipitation Module (TC-PRISMA) Bibliograpy

Non-spherical particles have been considered for grain boundary (GB) precipitation. Three morphologies are implemented for grain boundary, grain edge and grain corner precipitation, respectively, as shown in Figure 2. The parameter that defines the deviation from spherical shape is wetting angle (or dihedral angle), θ, as described in Figure 3 and taken from Clemm and Fisher [1955Cle].

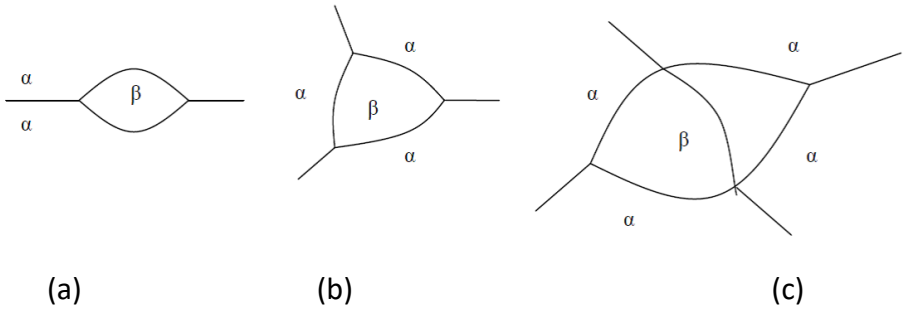

Figure 2: Non-spherical particles (β) that precipitate at grain boundaries of matrix phase(α) (a) grain boundary (two-grain junction) (b) grain edge (three-grain junction) (c) grain corners (four-grain junction). Images from [2004Zan].

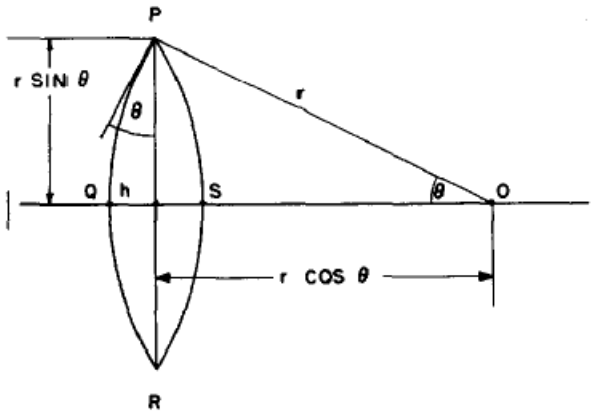

Figure 3: The nucleus at the grain boundary. Image from [1955Clem].

Some physical parameters, mainly in nucleation models, have to be modified for the effect of the wetting angle. The following discussions contribute to this effect.

Shape Factors

Following Clemm and Fisher, the eliminated grain boundary area between $\alpha - \alpha$ grains due to the formation of nucleus of a new phase β is:

[*Eq. 1*] $$A_{\alpha\alpha} = ar^2$$

Where r is the radius of curvature of the nucleus. The surface area of the nucleus is:

[*Eq. 2*] $$A_{\alpha\beta} = br^2$$

and the volume of the nucleus is

[*Eq. 3*] $$V = cr^3$$

The expression of a, b, c in Eq. 1 and Eq. 3 for grain boundary (two-grain junction), grain edge (three-grain junction) and grain corner (four-grain junction) can be found in the paper by Clemm and Fisher [1955Cle].

Critical Radius and Activation Energy

The energy change due to the formation of the new particle is thus

[*Eq. 4*] $$\Delta F = \frac{\Delta G_m^{\alpha\to\beta}}{V_m}\cdot cr^3 + br^2\sigma_{\alpha\beta} - ar^2\sigma_{\alpha\alpha}$$

where $\sigma_{\alpha\beta}$ and $\sigma_{\alpha\alpha}$ are the interfacial energy and grain boundary energy, respectively.

Then the critical radius should be

[*Eq. 5*] $$r^* = -\frac{2\left(b\sigma_{\alpha\beta} - a\sigma_{\alpha\alpha}\right)V_m}{3c\Delta G_m^{\alpha\to\beta}}$$

And the activation energy barrier for nucleation is

[*Eq. 6*] $$W = \frac{4}{27}\frac{\left(b\sigma_{\alpha\beta} - a\sigma_{\alpha\alpha}\right)^3 V_m^2}{c^2\left(\Delta G_m^{\alpha\to\beta}\right)^2}$$

The interfacial energy, grain boundary energy and wetting angle can be related as

[*Eq. 7*] $$k = \cos\theta = \frac{\sigma_{\alpha\alpha}}{2\sigma_{\alpha\beta}}$$

i.e.

[*Eq. 8*] $$\sigma_{\alpha\alpha} = 2k\sigma_{\alpha\beta}$$

which can be replaced into Eq. 5 and Eq. 6.

[*Eq. 9*] $$r^* = -\frac{2\left(b - 2ak\right)\sigma_{\alpha\beta}V_m}{3c\Delta G_m^{\alpha\to\beta}}$$

[*Eq. 10*] $$W = \frac{4}{27}\frac{\sigma_{\alpha\beta}^3 V_m^2}{\left(\Delta G_m^{\alpha\to\beta}\right)^2}\frac{\left(b - 2ak\right)^3}{c^2}$$

The bulk, spherical precipitation equation is recovered by:

[*Eq. 11*] $$a = 0, \quad b = 4\pi, \quad c = \frac{4\pi}{3}$$

so that

[*Eq. 12*] $$r^* = -\frac{2\sigma_{\alpha\beta}V_m}{\Delta G_m^{\alpha\to\beta}}$$

[*Eq. 13*] $$W = \frac{16\pi}{3}\frac{\sigma_{\alpha\beta}^3 V_m^2}{\left(\Delta G_m^{\alpha\to\beta}\right)^2}$$

And also the grain boundary precipitation with spherical shape (with weighting angle $90°$) follows Eq. 12 and Eq. 13 by $k = \cos\theta = 0$.

Precipitation upon Precipitates

Precipitates may act as a nucleation site for other precipitates. The precipitate phase acting as a nucleation site is known as an inoculant phase. They may be incoherent with the matrix, with the dislocations forming their interface with the matrix providing sources of nucleation sites. A coherent inoculant phase may distort the matrix significantly, with the heavily distorted matrix acting as a nucleation site. The inoculant particle may also be rich in solutes needed to nucleate the new phase.

Thermo-Calc uses a wetting angle as described by Fletcher [1958Fle] to describe the interaction between the nucleating precipitate and the inoculant particle, as shown in Figure 4.

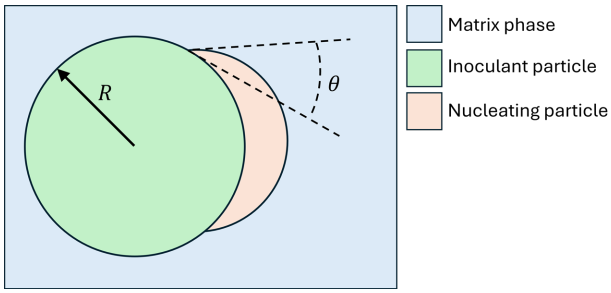

Figure 4: The wetting angle θ for a precipitate nucleating on an inoculant particle with radius R.

The impact of the wetting angle is shown below. A wetting angle of 180° results in no direct interaction between the inoculant and nucleating particle, descriptive of when the nucleation site occurs within the distorted lattice surrounding the inoculant particle. Angles smaller than 180° result in contact between the inoculant and nucleating particle resulting in a reduction in the energy barrier for nucleation.

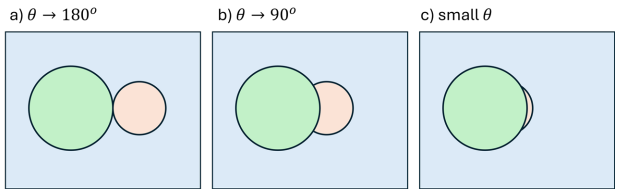

Figure 5: a) Non-interacting particles with a $\theta \rightarrow 180^{\circ}$, b) a wetting angle of ~90° and c) an example of a very large wetting angle.

Fletcher [1958Fle] provides the following relationship for the wetting angle as a function of the interfacial energies of the different interfaces:

[*Eq. 14*] $$m = cos\theta = \frac{\sigma_{12}-\sigma_{23}}{\sigma_{12}}$$

where the first index is the matrix, the second is the new particle, and the third is the inoculant particle, so that

- σ_{13}: The interfacial energy between the matrix and inoculant particle
- σ_{23}: The interfacial energy between the new particle phase and the inoculant particle
- σ_{12}: The interfacial energy between the matrix and new particle phase.

Fletcher [1958Fle] calculated a shape factor for the energy barrier that is a function of the wetting angle and the relative size between the inoculant particle and the critical nucleation radius of the new phase:

[*Eq. 15*] $$W_{co}^{*} = \frac{8\pi\sigma_{12}^{3}}{3(\Delta G_{v})^{2}} f(m,x) = W_{sphere}\frac{1}{2}f(m,x)$$

Where $x = R_j/R_n^*$ describing the mean radius of the inoculant particles, and R_n is the nucleation radius of the new phase. The shape factor is given in Eq. 16.

[*Eq. 16*] $$f(m,x) = 1 + \left(\frac{1-mx}{g}\right)^3 + x^3\left[2 - 3\left(\frac{x-m}{g}\right) + \left(\frac{x-m}{g}\right)^3\right] + 3mx^2\left(\frac{x-m}{g} - 1\right)$$

where $g = \sqrt{1 + x^2 - 2mx}$.

Figure 6 shows the impact of the shape factor, varying the wetting angle and the relative size between the inoculant mean particle radius and the critical radius of the new phase.

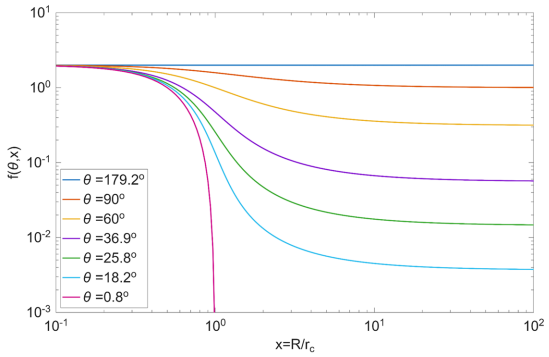

Figure 6: The shape function f(x,m) for varying x and θ.

The nucleation rate is now calculated using a size dependent energy barrier and nucleation site density

[*Eq. 17*] $$J_s = Z\beta^* \int_0^\infty N_j(R_j) exp\left(\frac{-W_{co}^*(R_j)}{kT}\right) dR_j$$

Where N_j is the concentration density of inoculating particles with a radius varying between R_j and $R_j + dR_j$.

There is a significant reduction in the energy barrier for nucleation. This helps describe kinetics for precipitates which have a high interfacial energy and can only nucleate due to the favorable conditions when nucleating upon the inoculant particle.

The phase transition from a GP zone to a more stable precipitate can be approximated by modeling the GP zone as an inoculant phase. This captures the correlation between the number of nucleation sites of GP zones and the amount of particles that can transform to the new phase.

Zeldovich Factor

The Zeldovich factor is modified as

[*Eq. 18*] $$Z = Z_b\sqrt{f}$$

with Z_b the original value, and f the volume factor that is the ratio of the c in Eq. 3 to the spherical shape factor $4\pi/3$.

[*Eq. 19*] $$f = \frac{3c}{4\pi}$$

Impingement Rate

The surface area factor in impingement rate calculation is changed from $4\pi(r^*)^2$ to $b(r^*)^2$.

Nucleation Site Density

In each time step, the occupied grain boundary area

[*Eq. 20*] $$A_{\text{red}} = a \cdot nr^2$$

is deducted when calculating available nucleation site density.

Growth Rate

The radius r defined in previous equations is the curvature of the precipitate surface (the Big radius) as shown in Figure 3. It is exactly the definition in the growth rate whose coarsening consideration relates to the curvature effect. Therefore, the growth rate equation can be directly used with r being defined here. Again, for bulk, spherical precipitation it automatically corresponds to the particle radius.

Output

The volume of the precipitate should be calculated appropriately as cr^3 with r being the curvature of the particle surface as defined above. For output of the particle size (mean radius, critical radius and particle size distribution) in the user interface, it seems better to use the radius of the eliminated grain boundary area, i.e.

[*Eq. 21*] $$r' = \sqrt{\frac{a}{\pi}} \cdot r$$

With a defined in Eq. 1.

For example, the size of the precipitate at grain boundary (two-grain junction) is the radius of the lens shown in Figure 3.

$$r' = r \sin\theta = r\sqrt{1-k^2}$$

The Number of Available Heterogeneous Nucleation Sites

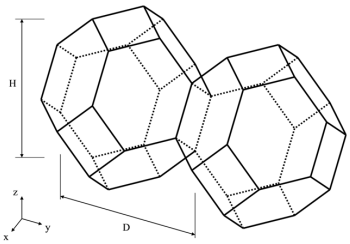

Figure 7: An example of tetrakaidecahedron approximation of grains.

The number of different nucleation sites is dependent on the shape and size of grains in the matrix. Assuming all grains are equally large tetrakaidecahedra with the distance between one pair of square faces as H, and that between the other two pairs as D we obtain the densities ρ_2, ρ_1, and ρ_0 for the grain boundary area, edge length, and grain corner number, respectively in

[*Eq. 22*] $$\rho_2 = \frac{6\sqrt{1+2A^2}+1+2A}{4A} D^{-1}$$

[*Eq. 23*] $$\rho_1 = 2\frac{\sqrt{2}+2\sqrt{1+A^2}}{A} D^{-2}$$

[*Eq. 24*] $$\rho_0 = \frac{12}{A} D^{-3}$$

where $A = H/D$ is the aspect ratio, defining the degree of elongation of the grains.

By default, the aspect ratio is set to 1 and the densities are then the same as obtained by Cahn [1956Cah]. Once the densities are known, if taking boundary thickness as one atomic layer, the available nucleation sites can be calculated by

[*Eq. 25*] $$N_i = \rho_i \left(\frac{N_A}{V_m^\alpha} \right)^{i/3} \quad i = 2, 1, 0$$

where V_m^α is the molar volume of the matrix phase and N_A is the Avogadro number.

For a crystalline material, given a dislocation density ρ_d, the number of nucleation sites at the dislocations N_d can be calculated with the same form as in

[*Eq. 26*] $$N_d = \rho_d \left(\frac{N_A}{V_m^\alpha} \right)^{1/3}$$

Nucleation During a Non-isothermal Process

Under non-isothermal conditions, temperature dependency of key parameters such as nucleation driving force, solute diffusivities and solute concentrations, etc., have been taken into account, and are updated automatically during a simulation.

Background Theory

Another important parameter that depends on thermal history is the incubation time, defined by

[*Eq. 1*] $$\tau = \frac{1}{\theta Z^2 \beta^*}$$

for an isothermal condition. In a non-isothermal process, the exact calculation of the incubation time requires a solution to the Fokker-Planck equation. In the Precipitation Module, an approximation approach has been employed to deal with the transient nucleation, which gives the incubation time as an integral form of past thermal history [2004Jou] as in

[*Eq. 2*] $$\int_o^\tau \beta^*(t')dt' = \frac{1}{\theta Z^2(\tau)}$$

where

τ is the incubation time, β^* is the impingement rate for solute atoms to the critical cluster as defined in

[*Eq. 3*] $$\beta^* = \frac{4\pi r^{*2}}{a^4}\left[\sum_{i=1}^{k}\frac{\left(X_i^{\beta/\alpha} - X_i^{\alpha/\beta}\right)^2}{X_i^{\alpha/\beta} D_i}\right]^{-1}$$

and Z is the Zeldovich factor, previously defined in

[*Eq. 4*] $$Z = \frac{V_m^\beta}{2\pi N_A r^{*2}}\sqrt{\frac{\sigma}{kT}}$$

but now as a function of τ derived from temperature change.

The starting point of the integral $t' = 0$ is either the starting time if there is an initial nucleation driving force, or the latest time when the nucleation driving force is vanished.

Growth

This section discussed the growth theory for spherical and non-spherical particles.

The growth rate models implemented in the Precipitation Module are called **Advanced**, **Simplified**, **General**, **Para-eq**, **NPLE**, and **PE Automatic**. All models treat a spherical particle (precipitate) of stoichiometric composition or with negligible atomic diffusivity.

Learn More

All models treat a particle (precipitate) of stoichiometric composition or with negligible atomic diffusivity. Except for the **PE Automatic** model, local equilibrium or paraequilibrium at the precipitate-matrix interface is assumed. The **PE Automatic** model enables smooth transition from paraequilibrium to local equilibrium.

A reference for the non-spherical particles sections is in [2018Wu].

In the documentation and on the GUI, the abbreviations *Para-eq* and *PE* are both used for paraequilibrium. There is also the use of OE as an abbreviation for *ortho-equilibrium* and LE for *local equilibrium*.

Advanced Growth Rate Model (Spherical Particles)

The *Advanced* model is proposed by Chen, Jeppsson, and Ågren (CJA) [2008Che]. In this model, the velocity of a moving phase interface and the operating tie-line are solved together from flux-balance equations. This model can treat both high supersaturation and cross diffusion rigorously. It can also capture the transition between NPLE (non-partitioning local equilibrium) and PLE (partitioning local equilibrium) without any *ad hoc* treatment.

According to the CJA model, the interface velocity v can be obtained together with interface concentrations by numerically solving $2n-1$ equations, comprising of the flux balance equations for $n-1$ independent components and the local equilibrium conditions for all n components as in

[*Eq. 1*] $$v(c_i^{\beta/\alpha}-c_i^{\alpha/\beta})=c_i^{\alpha/\beta}M_i\frac{\mu_i^{\alpha}-\mu_i^{\alpha/\beta}}{\xi_i r}$$

[*Eq. 2*] $$\mu_i^{\alpha/\beta}=\mu_i^{\beta/\alpha}+\frac{2\sigma V_m^{\beta}}{r}$$

where

- $c_i^{\beta/\alpha}$ and $c_i^{\alpha/\beta}$ are the volume concentrations of component i at the interface in the precipitate and matrix, respectively,
- M_i is the corresponding atomic mobility in the matrix,
- μ_i^{α} and $\mu_i^{\alpha/\beta}$ are the chemical potentials in the matrix of the mean-field concentration and at the interface, respectively.
- $\mu_i^{\beta/\alpha}$ is the chemical potential at the interface in the precipitate.

In the above local equilibrium condition, the multicomponent Gibbs-Thomson effect has been taken into account by adding a curvature induced pressure term to the Gibbs energy of the precipitate phase.

The introduced effective diffusion distance factor, ξ_i, for each independent component is given by

[*Eq. 3*] $$\xi_i=\frac{\Omega_i}{2\lambda_i^2}$$

where

$$\Omega_i=\frac{c_i^{\alpha}-c_i^{\alpha/\beta}}{c_i^{\beta/\alpha}-c_i^{\alpha/\beta}}$$

is the so-called dimensionless supersaturation for an individual component, and λ_i is obtained via

[*Eq. 4*] $$2\lambda_i^2-2\lambda_i^3\sqrt{\pi}\exp(\lambda_i^2)\mathrm{erfc}(\lambda_i)=\Omega_i$$

Simplified Growth Rate Model (Spherical Particles)

In some cases, the **Advanced** model fails to find the solution to flux-balance equations. Even when it does, the calculation can be time consuming. Therefore, a simple and efficient, albeit less rigorous, model is preferred in many applications. The **Simplified** model [2022Ågr], in a pseudo-steady state approximation, is developed by solving Laplace equation along radial direction, and is expressed as

[*Eq. 5*] $$v = \frac{K}{r}\left[\Delta G_m - \frac{2\sigma V_m^\beta}{r}\right] = \frac{2\sigma V_m^\beta K}{r}\left[\frac{1}{r^*} - \frac{1}{r}\right]$$

where ΔG_m is the nucleation driving force and r^* is the radius of critical nuclei. K is the kinetic parameter that is related to solute composition and mobility. Neglecting cross diffusion, it is expressed as

[*Eq. 6*] $$K = K_{\text{sphere}}^{\text{simplified}} = \left[\sum_i \frac{\left(X_i^{\beta/\alpha}(r) - X_i^{\alpha/\beta}(r)\right)^2 \xi_i}{X_i^{\alpha/\beta}(r) M_i}\right]^{-1}$$

The interface compositions (mole fractions) $X_i^{\beta/\alpha}(r)$ and $X_i^{\alpha/\beta}(r)$ for precipitate and matrix phase, respectively, are tie-line compositions across the matrix composition. To avoid time-consuming equilibrium calculations and also realizing that precipitate composition $X_i^{\beta/\alpha}(r)$ only appears in the difference term

$$\left(X_i^{\beta/\alpha}(r) - X_i^{\alpha/\beta}(r)\right)$$

Equation 6 is further simplified by replacing $X_i^{\beta/\alpha}(r)$ with nuclei composition from nucleation driving force calculation, and $X_i^{\alpha/\beta}(r)$ with matrix composition.

The K constant defined here relates growth rate to driving force in $v = \frac{K}{r}\left[\Delta G_m - \frac{2\sigma V_m^\beta}{r}\right]$, which is not to be confused with coarsening rate constant relating mean particle radius cubed to time.

For the *Precipitation Calculator* → *Precipitate Phase* settings, **Phase energy addition** G_m^a and **Phase boundary mobility** M^B shifts the Gibbs energy of the precipitate β phase by

$G_m^a + vV_m^\beta/M^B$. As a result, the driving force ΔG_m is reduced by $G_m^a + vV_m^\beta/M^B$, and the equilibrium compositions $c_i^{\beta e}$ and $c_i^{\alpha e}$ are shifted.

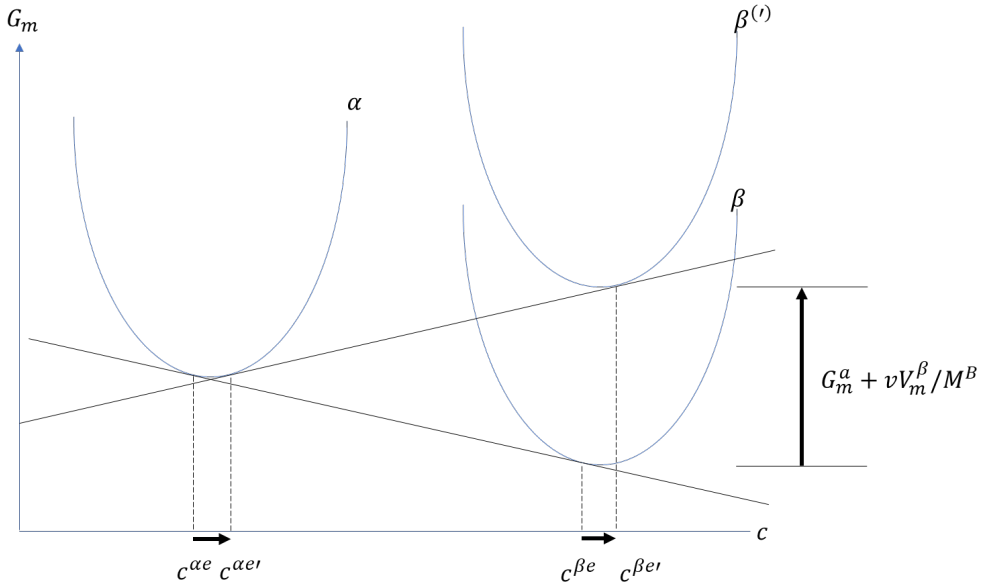

Figure 8: Effects of "Phase energy addition" G_m^a and "Phase boundary mobility" M^B.

General Growth Rate Model (Spherical Particles)

The **General** model is based on the existing coarsening models [1993Uma; 1994Mor; 1995Mor], which follows the same quasi-steady state approximation as the **Simplified** model, but improves by taking into account the cross diffusion. The growth rate equation has thus the same format as that in the Simplified model, i.e., Eq. 5, with the kinetic parameter K defined as

[*Eq. 7*] $$K = K_{\text{sphere}}^{\text{general}} = \frac{1}{(\Delta X^{\alpha\beta}][\ddot{G}][D]^{-1}[\Delta X^{\alpha\beta})}$$

where $(\Delta X^{\alpha\beta}]$ and $[\Delta X^{\alpha\beta})$ are $n-1$ row and column vector, respectively, whose *i*th element is the composition difference $\left(X_i^{\beta/\alpha}(r) - X_i^{\alpha/\beta}(r)\right)$ as described in Eq. 6. $[\ddot{G}]$, a $(n-1)\times(n-1)$ matrix, is based on thermodynamic factor matrix $[G^\alpha]$ with a correction factor

[Eq. 8] $[\ddot{G}] = f[G^{\alpha}]$

where thermodynamic factor matrix is defined as the secondary derivative of free energy with respect to composition in the matrix phase

$$[G^{\alpha}]_{ij} = \frac{\partial^2 G_m^{\alpha}}{\partial X_i^{\alpha} \partial X_j^{\alpha}}$$

$[G^{\alpha}]$ is evaluated at the far-field matrix composition to consider the multicomponent Gibbs-Thomson effect [1995Mor]. For a particle with critical nuclei size r^*, the Gibbs-Thomson equation is

[Eq. 9] $(\Delta X^{\alpha\beta})\,[G^{\alpha}]\,[\Delta X^{\alpha}) \approx \frac{2\sigma V_m}{r^*} = \Delta G_m$

where $[\Delta X^{\alpha})$ is a $n-1$ column vector representing the difference between the far-field matrix composition $[X^{\alpha})$ and the equilibrium (tie-line) composition of the matrix phase $[X^{\alpha/\beta})$. It has been found that Eq. 9 is not numerically accurate and sometimes the deviation can be quite significant. Therefore, a correction factor is introduced as

$$f = \frac{\Delta G_m}{(\Delta X^{\alpha\beta}][G^{\alpha}][\Delta X^{\alpha})}$$

which then appears in Eq. 8.

$[D]^{-1}$ in Eq. 7 is the inverse of the chemical diffusivity matrix $[D]$. In some alloy systems, diffusivity is strongly composition dependent, so that an effective diffusivity is necessary. A series of numerical simulations in comparison with DICTRA calculations indicates that a good approximation can be achieved if $[D]$ is the arithmetic mean of the diffusivity with far-field matrix composition and diffusivity with equilibrium (tie-line) composition

$$[D] = \frac{1}{2}\left\{[D]_{(X^{\alpha})} + [D]_{(X^{\alpha/\beta})}\right\}$$

Paraequilibrium Growth Rate Model (Spherical Particles)

The paraequilbrium (**Para-eq**) growth rate model is only available for alloy systems where Fe is the major element and C is the only interstitial element, which also partitions into the precipitate phase.

The intersitial elements, e.g. C, N, etc., usually have remarkably faster diffusion rate than the substitutional elements. Meanwhile, they are assumed to have negligible volume contribution, and as a result the composition variables in Eq. 6 to Eq. 9 are replaced by *u*-fractions when interstitial elements are included in the system. The paraequilbrium growth rate model is designed specifically to address the fast diffusion of C in Fe alloys. Based on the *Simplified* growth rate model, it holds a paraequilbrium condition [1953Hil] at the migrating interface, in that, instead of assuming that all alloying elements are in equilibrium at the interface as the regular ortho-equilibrium condition states, only C assumes equilibrium state, while the substitutional elements are immobile and thus have the same compositions (*u*-fractions) across the interface. Therefore, only composition of C and its mobility appear in Eq. 6.

PE Automatic Growth Rate Model (Spherical Particles)

The tempering of martensite in steels induces the precipitation of cementite particles. The growth kinetics initially follows the paraequilbrium (abbreviated here as PE) condition due to the fast diffusion of interstitial C, and gradually transforms to regular Local Equilibrium (LE), i.e. Ortho-equilibrium (OE), condition so that substitutional elements can reach equilibrium partitioning at the migrating interface. The **PE Automatic** model enables the smooth transition from *Paraequilibrium growth rate model* to *Simplified growth rate model*. The rate of transition process is dependent on the relative differences in diffusion between C and substitutional elements, as well as the differences in driving force between PE and OE.

NPLE Growth Rate Model (Spherical Particles)

The Non-Partitioning Local Equilibrium (NPLE) growth rate model is only available for alloy systems where Fe is the major element and at least one interstitial element partitions into the precipitate phase.

The **NPLE** growth model is designed specially to deal with the fast diffusion of interstitial element (C, N, etc.) in Fe alloys. Based on the *Simplified* growth model, it still holds a local equilibrium condition at the migrating interface, but chooses a tie-line under NPLE condition [1958Kir] that the *u*-fractions of all substitutional elements and minor interstitial elements in the precipitate phase are the same as those in the far-field matrix phase (i.e. the overall instantaneous matrix composition).

Model Selections (Spherical Particles)

The most efficient model is the **Simplified** model, which is the default and applicable to most alloy systems under conditions that either the supersaturation is small, or the alloying elements have comparable diffusivity. If all alloying elements are substitutional but they have remarkable diffusivity difference, e.g. in Al-Zr system, or the diffusivity is strongly composition dependent, the **General** model is preferred. If the supersaturation is high, and meanwhile there are fast-diffusing interstitial elements such as C, the **Advanced** model is more appropriate to capture the NPLE mechanism.

In some cases with the **General** model, you may need to switch to another model if the matrix composition passes through a spinodal composition space where the thermodynamic factor becomes negative, thus leading to an abnormal growth rate. When this happens, Thermo-Calc alerts you that the *Matrix Composition in Spinodal Zone*. It is then recommended to switch to other models.

Non-Zero Volume Correction (Spherical Particles)

The non-zero volume correction to the velocity according to Chen and Voorhees [1993Che] is taken into account and it follows as

[*Eq. 10*] $$v' = v\left(1 + r\sqrt{4\pi N_V \langle r \rangle}\right)$$

where

- v' is the corrected velocity
- $\langle r \rangle$ is the mean radius
- N_V is the number density

Particle Shape Determination (Non-Spherical Particles)

The shape of the cuboid particles, the cubic factor, is determined by the minimization of combined interfacial energy and elastic strain energy. If you choose **Calculated from molar volume** for the **Transformation strain** as the *Precipitation Calculator* → *Precipitate Phase* settings, the lattice misfit is then calculated from difference in molar volume between matrix and precipitate phase, and the elastic strain energy is calculated accordingly. If you disregard

the transformation strain, the elastic strain energy is neglected and hence the particles remain spherical in shape.

If you select the **Calculated aspect ratio from elastic energy** checkbox for either a plate or needle **Morphology** on the *Precipitation Calculator* → *Precipitate Phase* settings, the particle shape is determined by the minimization of combined interfacial energy and elastic strain energy. Otherwise, if you enter a value for aspect ratio, the particle shape is fixed except for nucleation calculation in which a spherical particle is always assumed.

Homogeneous Nucleation

Interfacial Energy Anisotropy (Non-Spherical Particles)

Precipitation Morphology

Isotropic interfacial energy is always assumed for spherical and cuboidal particles. For plate and needle, when the aspect ratio becomes larger than 1, the interfacial energy anisotropy occurs, so that the interfacial energy at the edge is larger than that at the broad face (habit plane). This increases the overall interfacial energy which is given as follows for each morphology.

Plate

$$E_{\text{int}} = 4\pi\sqrt[3]{\alpha^2}\sigma_0^{\text{sph}} r^2$$

Needle

$$E_{\text{int}} = 4\pi\sqrt[3]{\alpha}\sigma_0^{\text{sph}} r^2$$

Where

- α is the aspect ratio
- σ_0^{sph} is the interfacial energy of the habit plane, i.e., the plane normal to the shorter axis
- r is the radius of a sphere with equivalent volume

Growth Rate Adjustment (Non-Spherical Particles)

Precipitation Morphology

For non-spherical particles, the growth rate equations for spherical particles are still applicable, but adjustment parameters are introduced to take into account the shape effect. The cuboid particles arise from "symmetry preserving" transformation, e.g., FCC_A1 to $L1_2$, and are thus highly isotropic and assumed growth rate equal to that of spherical particles. The plate and needle particles, on the other hand, arise from "symmetry breaking" transformations, e.g., cubic to tetragonal transformation, and are thus anisotropic leading to a significant increase of growth rate.

We define r as the radius of a sphere with equivalent volume of the non-spherical particle, so that the format of Eq. 5 keeps unchanged. In our current model, two effects are considered contributing to the growth rate for plate and needle particles, from interfacial energy anisotropy and particle shape effect. The kinetic parameter K defined in Eq. 5 is thus given as

[*Eq. 11*] $$K = K_\sigma \cdot K_{\text{shp}} \cdot K_{\text{sphere}}$$

with K_{sphere} defined in Eq. 6 and Eq. 7. The interfacial energy σ in Eq. 5 is that of habit plane, i.e., the plane that is normal to the shorter axis of the particle. K_σ is the parameter that takes into account the Gibbs-Thomson effect due to interfacial energy anisotropy, based on Johnson [1965Joh].

Plate

$$K_\sigma = \sqrt[3]{\alpha^2}$$

Needle

$$K_\sigma = \sqrt[3]{\alpha}$$

where α is the aspect ratio of the ellipsoidal particle. K_{shp} is the parameter that takes into account the non-spherical concentration field around the particle. Assuming a shape-conserving concentration field and thus following the derivation by Ham [1958 and 1959], it is given as

Plate

$$K_{\text{shp}} = \frac{e\sqrt[3]{\alpha}}{\arccos(0) - \arccos(e)}$$

Needle

$$K_{\text{shp}} = \frac{2\sqrt[3]{\alpha^2}e}{\ln(1+e) - \ln(1-e)}$$

where e is the eccentricity of the ellipsoidal particle.

$$e = \sqrt{1 - \frac{1}{\alpha^2}}$$

Coarsening

Physically speaking, coarsening or Ostwald ripening where big particles grow and small particles shrink is a process driven by lowering the total surface energy of the system. From a thermodynamic point of view, the Gibbs-Thomson effect leads to inhomogeneous chemical potentials in the system if the particle sizes are not uniform. Solutes at the interface in the matrix near a particle of a radius smaller than critical radius have a higher chemical potential than that corresponding to the mean concentration of the matrix. As a result, the solutes diffuse from the precipitate/matrix interface to the inside of the matrix and cause dissolution of the particle. Conversely, particles with a radius larger than the critical size have lower interface potentials, and the solutes diffuse to the interface and cause growth of the particles.

Since it is not possible to find a closed form analytic solution for the problem of diffusion-controlled spherical particle dissolution [1970Aar], we simply apply the Growth equations 1 to 5 with the absolute value of Ω_i to calculate the interface velocity for particles of all sizes.

As can be easily seen, if $r < r^*$, then the Gibbs-Thomson Equation 1 gives $\mu_i^{\alpha/\beta} > \mu_i^{\alpha}$, and a negative velocity results from Equation 2 for particles having $r < r^*$, which means that they shrink.

Results for particles having $r > r^*$ are obtained vice versa. In all situations, when the absolute values of Ω_i are very small, the steady-state solution for either growth or dissolution are recovered. In conclusion, the dissolution is treated as the reverse of growth (1970Aar, Ibid.), and the coarsening comes out naturally either together with nucleation and growth or as a dominant process finally in the course of the evolution of the PSD.

Continuity Equation

Let $f(r)$ be the PSD of a precipitate phase, N the number of particles per unit volume, $\langle r \rangle$ the mean radius and ϕ the particle volume fraction, is expressed as

[*Eq. 1*] $$N = \int_0^\infty f(x)dr$$

[*Eq. 2*] $$\langle r \rangle = \int_0^\infty r f(r)dr$$

[*Eq. 3*] $$\phi = \int_0^\infty (\tfrac{4\pi}{3}) r^3 f(r)dr$$

The time evolution of $f(r)$ follows the continuity as in Langer and Schwartz [1980Lan].

[*Eq. 4*] $$\frac{\partial f}{\partial t} = -\frac{\partial}{\partial r}[v(r)f(r)] + j(r)$$

Where $v(r)$ is the growth rate of a particle of size r, and $j(r)$ is the distributed nucleation rate, which is defined by

[*Eq. 5*] $$J = \int_{r*}^\infty j(r)dr$$

where J is the nucleation rate.

Mass Conservation

The matrix concentration is updated at each time step according to the law of mass conservation. If the alloy concentration, i.e. initial mole fraction of component i in the matrix phase is X_i^0, the new concentration X_i can be obtained from the following mass balance shown in

$$X_i^0 = \left(1 - \sum_p \int_0^\infty \frac{4\pi r_p^3 f(r_p)}{3V_m^p} dr_p\right) X_i + \sum_p \int_0^\infty \int_0^{t_j} \frac{4\pi r_p^2 f(r_p,t) v(r_p,t)}{V_m^p} X_i^p(r_p,t) dt dr_p$$

where

- $X_i^p(r_p,t)$ is the mole fraction of element i at the interface in the precipitate phase p of particle size r_p at time t. $f(r_p,t)$, $v(r_p,t)$ and V_m^p are the PSD function, growth rate, and molar volume of the precipitate phase p, respectively.
- t_j is the time at time step j.

Apparently, the new matrix concentration, and thus the updated supersaturation, nucleation rate, and interface velocity are all functions of the PSD function. This inevitably leads to the complex non-linear behavior of and great difficulty in solving the continuity equation.

Numerical Method

Since it is impossible to have a general close form solution, the complex non-linear continuity equation (see Continuity Equation) of the particle size distribution (PSD) function has to be solved numerically. Different numerical methods can be found in the literature to solve this equation, such as finite difference and method of characteristics. In all approaches, the continuous PSD is discretized into a sufficiently large number of size classes, and then integrated discretely in the time space. The Precipitation Module utilizes the method of characteristics, where the number of particles in each size class is kept constant unless particles of the same size have been nucleated.

An adaptive geometric grid allocation method has been used for particle size discretization since from nucleation to coarsening the particle size can span several orders of magnitude. In this approach, the new size grids are allocated evenly in a logarithmic scale and the number of grid points over one order of magnitude is kept almost constant during the whole process by class merging and splitting. The time step is controlled by several adjustable numerical parameters based on mechanistic quantities.

Summarized below are all numerical parameters used in this approach to control either the size grid distribution or time steps.

Maximum Time Step Fraction

P_{dt}^{max}

Maximum time step allowed for time integration as fraction of the simulation time.

Number of Grid Points Over One Order of Magnitude in r

P_{Nr}

Default number of grid points for every order of magnitude in size space. The number determines a default ratio between two adjacent grid points. When there is a need to create new grid points, such as nucleating at a new radius not covered by the current range of PSD, this default ratio is used to add these new radius grid points. A larger value of this parameter enforces a finer grid to allow better numerical accuracy. However, this also comes with performance penalty, since finer grid in the size space often requires smaller time step to resolve the calculations.

Maximum Number of Grid Points Over One Order of Magnitude in r

P_{Nr}^{max}

The maximum allowed number of grid points in size space. This parameter determines a lower bound limitation for the ratio of every two next nearest grid points in order to maintain adequate computational efficiency. When a ratio of two next nearest grid points is less than this limit, the middle grid point is removed and the corresponding size class merged with the two neighboring ones.

Minimum Number of Grid Points Over One Order of Magnitude in r

P_{Nr}^{min}

The minimum allowed number of grid points in size space. This parameter determines an upper bound limitation for the ratio of every two adjacent grid points in order to maintain proper numerical accuracy. When a ratio of two adjacent grid points exceeds this limit, a new grid point is then inserted between the two adjacent grids to keep the required resolution.

Maximum Relative Radius Change

P_r

The maximum value allowed for relative radius change in one time step. This parameter limits the time step according to the following relation, which is controlled by the particle growth:

$$\Delta t \leq P_r \times r/(|dr/dt|) \text{ for } r > r_{dt}$$

where r_{dt} is a cut-off subcritical size defined by the next parameter. The growth rates of supercritical particles (with $r > r_c$) are always bounded, and there is a size class and the corresponding growth rate that controls the time step. The subcritical particles (with $r < r_c$), however, has a mathematical singularity (negative infinity) in growth rate as rr approaches 0. This means that the time step can become extremely small if applying the above criterion to very small subcritical particles. In open literature, several researchers have tried mathematical transformation to avoid this singularity. Unfortunately, the transformation also complicates the formulation of the models. The Precipitation Module implementation uses a simple approach to deal with this issue by defining a cut-off size r_{dt}. All the particles with $r < r_{dt}$ may disappear within one time step. is determined by the next input parameter.

Maximum Relative Volume Fraction of Subcritical Particles Allowed to Dissolve in One Time Step

P_{rdt}

This parameter represents the portion of the volume fraction that can be ignored when determining the time step. It is used to calculate the cut-off subcritical size, r_{dt}, for the above time step control that allows a maximum relative radius changes for all particles:

$(\int_0^{rdt} fr^3 dr)/(\int_0^{\infty} fr^3 dr) = P_{rdt}$

Relative Radius Change for Avoiding Class Collision

P_{cc}

For the supercritical particles, the growth rate is non-linear – usually, it first increases with r and then decreases after a certain size. In the region(s) with growth rate decreasing with r, it is possible that the smaller size grid point can catch up with the larger size grid, if the time step is not controlled. To prevent this from happening, an additional parameter, P_{cc}, can be used to set a limit on time step according to the following relation:

$\Delta t \leq P_{cc} \times (r_{i+1} - r_i)/(dr_i/dt - dr_{i+1}/dt)$

for

$r_{i+1} > r_{i+1}$

and

$dr_{i+1}/dt < dr_i/dt$

Maximum Overall Volume Change

P_v

This parameter defines the maximum absolute (not ratio) change of the volume fraction allowed during one time step. This parameter is also used in controlling allowable variation in volume fraction due to the newly created particles within one time step. That is

$\Delta t \leq P_V/10/(4\pi r_{eff}^3 J/3)$

where r_{eff} and J are effective radius and nucleation rate, respectively.

Maximum Relative Change of Nucleation Rate in Logarithmic Scale

P_{logJ}

This parameter ensures accuracy for the evolution of effective nucleation rate. It sets a limit on time step so that the relative change of nucleation rate does not exceed the specified value, based on the information of previous step. That is

$$\Delta t \leq P_{logJ} \times \Delta t_{previous} / (|log(J_1/J_2)|)$$

where nucleation rate J_1 and J_2 occurs at the beginning and end of $\Delta t_{previous}$.

Maximum Relative Change of Critical Radius

P_{rc}

During the nucleation under high supersaturation, the critical radius can vary dramatically. Hence, this parameter can be used to place a constraint on how fast the critical radium can vary, and thus put a limit on time step:

$$\Delta t \leq P_{rc} \times \Delta t_{previous} / (|r_{c1} - r_{c2}/r_{rc1}|)$$

Minimum Radius for a Nucleus to be Considered as a Particle

P_{rmin}

The cut-off lower limit of precipitate radius. Particles with radius smaller than the value specified for this parameter are discarded. In reality, the particle cannot be smaller than an atom; hence, there is no reason to keep track of particles of unphysical sizes.

Maximum Time Step During Heating Stages

P_{htmax}

The upper limit of the time step that has been enforced in the heating stages. The current algorithm may over-estimate the subsequent time increment when temperature is increased. It is thus required to reduce this value when the calculation terminates unexpectedly during or after a heating stage.

Numerical Control Parameters Default Values

Default value for numerical parameters that controls the size grid distribution and time step.

Parameter	*Default value*
P_{dt}^{max}	0.1
P_{Nr}	200
P_{Nr}^{max}	300
P_{Nr}^{min}	100
P_{r}	0.01
P_{rdt}	0.01
P_{cc}	0.5
P_{ν}	0.001
P_{logJ}	0.5
P_{rc}	0.1
P_{rmin}	5e-10m
P_{htmax}	1.0s

Estimation of Coherent Interfacial Energy

Learn about some of the background theory about interfacial energy.

Background Theory

Interfacial energy is an important parameter used in precipitation simulations to calculate the rates of nucleation, growth/dissolution, and coarsening. The value of interfacial energy can vary dramatically (usually between 0.01 to 2.0 J/m^2).

The extended Becker's model functions to estimate coherent interfacial energy by using thermodynamic data from existing CALPHAD thermodynamic databases:

$$\sigma_c = \frac{n_s z_s}{N_A z_l} \Delta E_s$$

where σ_c is the coherent interfacial energy, n_s is the number of atoms per unit area at the interface, z_s is the number of cross bonds per atom at the interface, z_l is the coordination number of an atom within the bulk crystal lattice, and ΔE_s is the energy of solution in a multicomponent system involving the two phases being considered [1938Bec].

Interfacial Energy Anisotropy (Non-Spherical Particles)

Precipitation Morphology

As the spherical particle is the default morphology, for precipitations within the grain, three non-spherical shapes are considered: *cuboid*, *plate* and *needle*.

Also see Growth, Homogeneous Nucleation, and Precipitate Phase Settings.

Cuboid

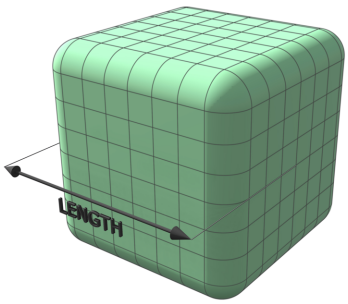

Figure 9: Cuboids have six faces, which form a convex polyhedron.

The cuboid shape is described by a supersphere

$$x_1^p + x_2^p + x_3^p = R^p \qquad (p \geq 2)$$

with p=2 being spherical shape. The larger the *p*, the more cubic the shape. Sometimes it is useful to define the cubical character as

$$\eta = \sqrt{2} \cdot 2^{-1/p}$$

Which gives a spherical shape when $\eta = 1$, and a cubic shape when $\eta = \sqrt{2}$.

Plate

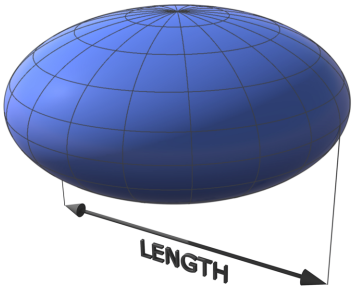

Figure 10: Oblate spheroids have rotational symmetry around an axis from pole to pole.

The plate is described as oblate spheroid

$$\frac{x_1^2}{l^2} + \frac{x_2^2}{l^2} + \frac{x_3^2}{r^2} \leq 1 \qquad l > r$$

with aspect ratio

$$\alpha = \frac{l}{r} > 1$$

Needle

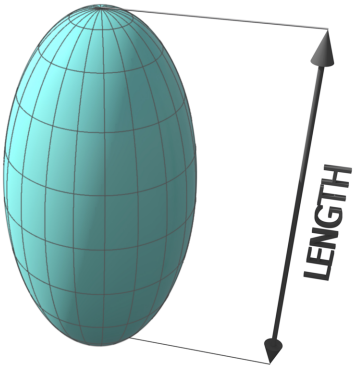

Figure 11: A prolate spheroid is a surface of revolution obtained by rotating an ellipse about its major axis.

The needle shape is described as prolate spheroid

$$\frac{x_1^2}{r^2} + \frac{x_2^2}{r^2} + \frac{x_3^2}{l^2} \leq 1 \qquad l > r$$

with aspect ratio

$$\alpha = \frac{l}{r} > 1$$

Precipitations at a Grain Boundary, Edge, or Corner

For precipitations at a grain boundary, grain edge, or grain corner, non-spherical particles are considered based on wetting angle.

Heterogeneous Nucleation and Matrix Phase Settings

About Matrix Phase Switching

The matrix switch functionality enables an on-the-fly change of the matrix phase between two predefined phases. This capability is useful for material systems in which the parent phase undergoes a structural transformation during heat treatment, such as martensitic transformation. Precipitation of secondary phases, such as carbides, proceeds continuously through the matrix switch; however, the precipitation kinetics may change because the relevant matrix properties are updated after transformation. Therefore, the properties of both matrix phases must be defined independently.

The matrix switch represents the transformation as an instantaneous and complete phase change once the specified temperature or thermodynamic driving force criterion is satisfied. The phase compositions are assumed to remain unchanged at the moment of switching. As a result, neither chemical redistribution nor transformation kinetics is explicitly modeled. Two criteria are available to activate the transition. The first criterion is based on transition temperature. Separate transition temperatures can be specified for cooling and heating, allowing the transformation from the high-temperature phase to the low-temperature phase during cooling or quenching to be modeled with an adjustable undercooling. The same framework can also be used to model the reverse transformation during heating. The second criterion is based on driving force, defined as the Gibbs free-energy difference between the two phases at the same composition. When the calculated Gibbs free energy of the dormant phase is lower than that of the active phase by more than the specified threshold, the matrix switch is activated.

The **Allow for matrix switch** checkbox is found on the **Precipitation Calculator Configuration** window and the settings are described in Matrix Phase Settings

Normal Grain Growth

The normal grain growth model in the Precipitation Module (TC-PRISMA) uses a similar approach to its precipitation counterpart (see Theory Overview) in that it calculates the temporal evolution of grain size distribution (GSD). The grains are assumed of spherical morphology when modeling the growth rates. Nucleation is not considered, thus an initial GSD is necessary to start the simulation.

Background Theory

The boundary motion of a grain with radius R_i without considering pinning forces from precipitate particles, is driven by curvature and can be modeled as [1957Fel; 1965Hil]

[*Eq. 1*] $$\frac{dR_i}{dt} = \alpha M \gamma \left(\frac{1}{R_{cr}} - \frac{1}{R_i} \right)$$

where

- M is grain boundary mobility (m^4/Js)
- γ is the grain boundary energy (J/m^2)
- α is a dimensionless constant

If it should be satisfied that $k = M\gamma$, which is the parabolic growth rate of average grain size at steady-state

[*Eq. 2*] $$\bar{R}^2 - \bar{R}_0{}^2 = kt$$

It was found that $\alpha \approx 2$ [1965Hil].

R_{cr} in Eq. 1 is the critical grain size, which, not necessarily the average grain size, is determined by volume conservation [2008Jep]

[*Eq. 3*] $$\frac{dV}{dt} = 4\pi \sum_i \frac{R_i^2 dR_i}{dt} = 0$$

where the index i covers all the grains at each time step. Substituting Eq. 1 into Eq. 3, R_{cr} is obtained at each time step.

Grain Boundary Mobility Values

The grain boundary mobility M can be calculated as:

[Eq. 4] $$M = M_0 exp(-\frac{Q}{RT})$$

where

- M_0 is the prefactor (m^4/Js)
- Q is the activation energy (J/mol)

The recommended values of M_0 and Q in high purity metals such as ferritic iron, austenitic iron, nickel, and aluminum are shown in the table below.

Since grain growth is significantly affected by grain boundary segregation, precipitation, and grain boundary complexion, the accuracy of the mobility data used for the recommended values is not guaranteed.

If the grain size is in nanoscale, these parameters may not be applicable since the effects of grain boundary junction and complexion cannot be ignored in nanocrystals. For some alloys, such as Al, the parameters can also be sensitive to temperature. The temperature range in the table is the suggested best fit.

Recommended grain growth parameters for mobility prefactor M_0 and activation energy Q.

	Matrix Phase	Temperature Range (K)	Prefactor M_0 (m^4/Js)	Activation Energy Q (J/mol)	Reference

Zener Pinning

Zener [1948Smi] proposed a pinning force due to second-phase particles, so that the normal grain growth would be completely inhibited when the grain size reached a critical maximum grain size R_z.

Background Theory

In general form, it can be expressed as [1998Man]

[*Eq. 1*] $$R_z = K\frac{r}{f^m}$$

Where

- r is the radius of the pinning particles
- f the volume fraction of the particles
- K is a dimensionless constant
- m an exponential index for f

The original Zener pinning theory gives

$$K = 4/3, m = 1$$

which has been found to be inconsistent with the experimental information and thus needs refinement.

For simplicity, the average particle radius $\bar{r}_j$ of a precipitate phase j has been used to calculate the pinning force arising from all the particles of this phase. The pinning force, z_j, can be evaluated as the inverse of $R_{z,j}$

$$z_j = \frac{1}{R_{z,j}} = \frac{1}{K_j}\frac{f_j^{m_j}}{\bar{r}_j}$$

When there are multiple precipitate phases, the overall pinning effect is the sum of that from all precipitate particles,

$$z_j = \sum_j z_j = \sum_j \frac{1}{K_j}\frac{f_j^{m_j}}{\bar{r}_j}$$

The retarding force due to Zener pinning, RF_z, is therefore [1965Hil]

$$RF_z = \sigma \cdot z = \frac{\sigma}{R_z}$$

where σ is the grain boundary energy.

Realizing that the drag force resists the grain boundary motion, no matter in the growing (positive velocity) or shrinking (negative velocity) direction, the overall growth rate is expressed as [1965Hil]

$$\frac{dR_i}{dt} = \alpha M \sigma \left[\left(\frac{1}{R_{cr}} - \frac{1}{R_i} \right) \pm \frac{1}{R_z} \right]$$

The negative sign holds when

$$\left(\frac{1}{R_{cr}} - \frac{1}{R_i} \right) - \frac{1}{R_z} > 0$$

while positive sign holds when

$$\left(\frac{1}{R_{cr}} - \frac{1}{R_i} \right) + \frac{1}{R_z} < 0$$

And $\frac{dR_i}{dt} = 0$ when R_i lies between these two limits.

In the Precipitation Module (TC-PRISMA), you can input parameters K_j and m_j for each precipitate phase. An additional parameter, *cutoff radius* (unit= m), can be used so that precipitates with a smaller size than this value are excluded from the calculation of pinning force. This adjustment avoids an unreasonably large pinning force calculated from very small precipitates (e.g. nuclei).

Stereology

Stereology is the science of assessing the three-dimensional (3D) geometry and morphology of objects utilizing data descriptive of a cross-section of the material. It is common to characterize a precipitate dispersion utilizing quantitative image analysis of micrographs obtained from light or scanning electron microscopy. In these cases, the data describes the precipitates found in a cross-section taken through the sample.

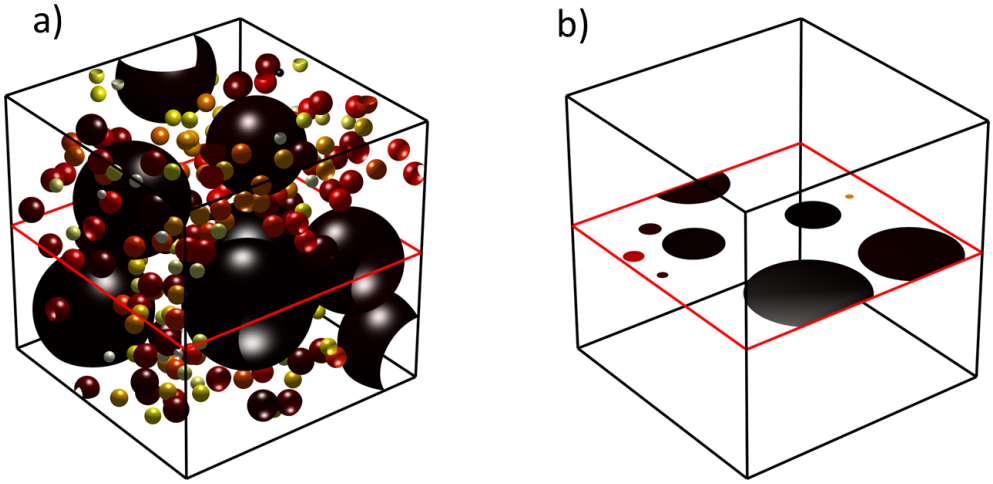

Figure 12: a) A 3D dispersion of non-penetrating polydisperse particles. b) A cross-section taken through the dispersion.

Background Theory

Stereological considerations are important when seeking greater quantitative accuracy comparing model calculations and experimental data. The two-dimensional (2D) size distribution is of interest for the calculation of mechanical properties as it represents the size distribution of obstacles encountered by a dislocation on a slip system.

The size of the precipitates can be expressed as the equivalent radius of a circle with the same cross-sectional area as measured from the micrograph. Figure 13, Figure 14, and Figure 15 compare the 3D and 2D size distributions of a spherical dispersion considering a left skewed, a normal, and a right-skewed distribution. Observe the changes in shape of the distribution in addition to the smaller 2D mean radius compared to the true 3D size.

The 3D to 2D conversion implementation considers spherical particles. Although the precipitates may be approximated as spherical for the approximation of the 2D size distribution, there may be a large error for geometries that differ largely from spheres.

The **3D → 2D** checkbox that is available to use this feature requires (1) that the *Precipitate Phase***Morphology** is set to **Sphere** on the Precipitation Calculator, and then (2) one of these axis variables is selected on either the Plot or Table Renderer: **Mean radius**, **Size distribution**, **Number density distribution**, or **Normalized number density distribution**.

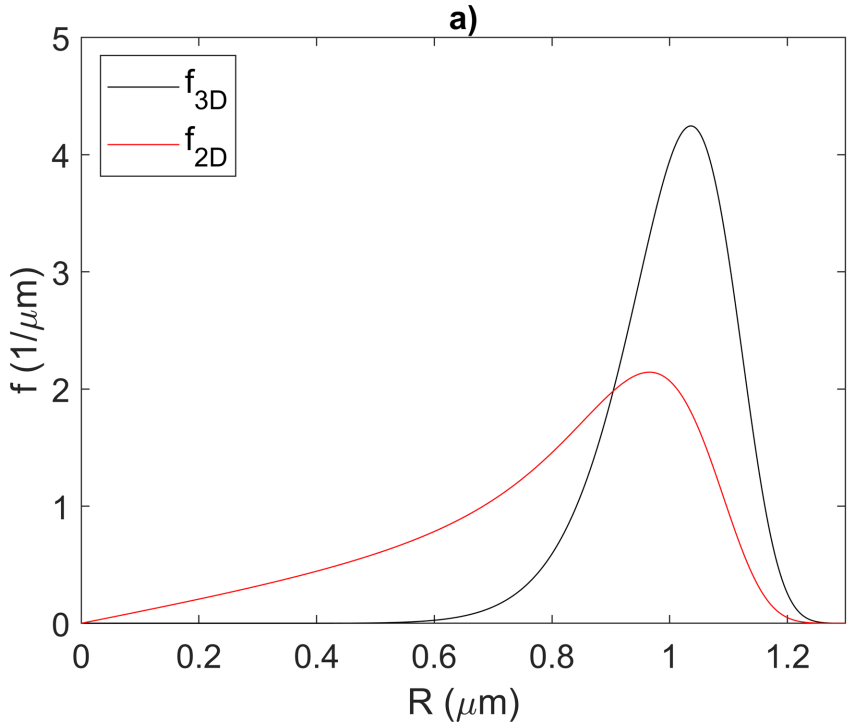

Figure 13: A comparison of the 3D and 2D particle size distributions considering a left-hand skewed Weibull distribution.

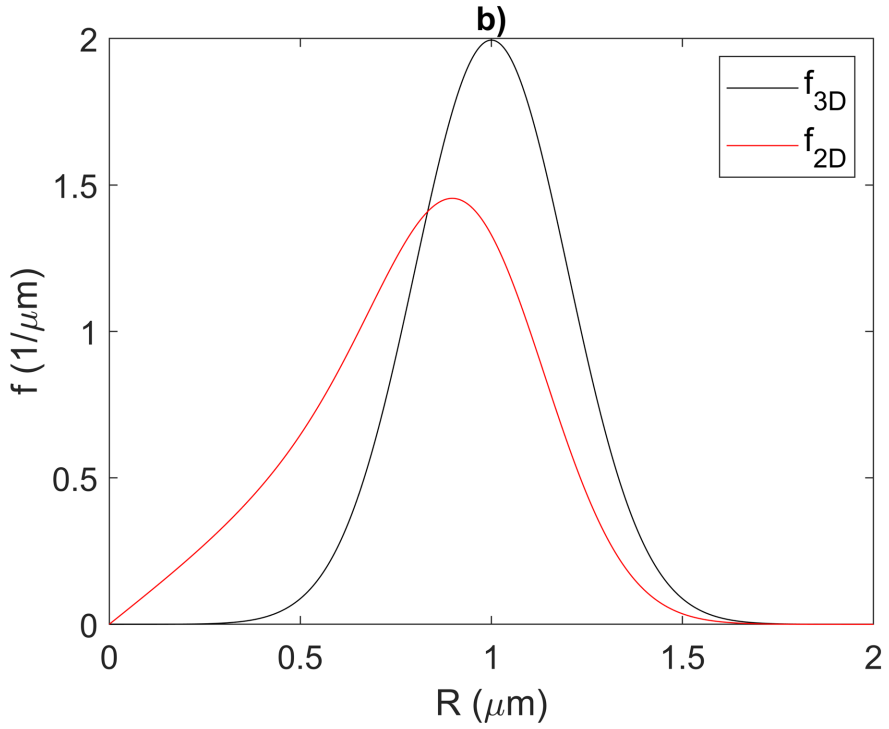

Figure 14: A comparison of the 3D and 2D particle size distributions considering a normal distribution

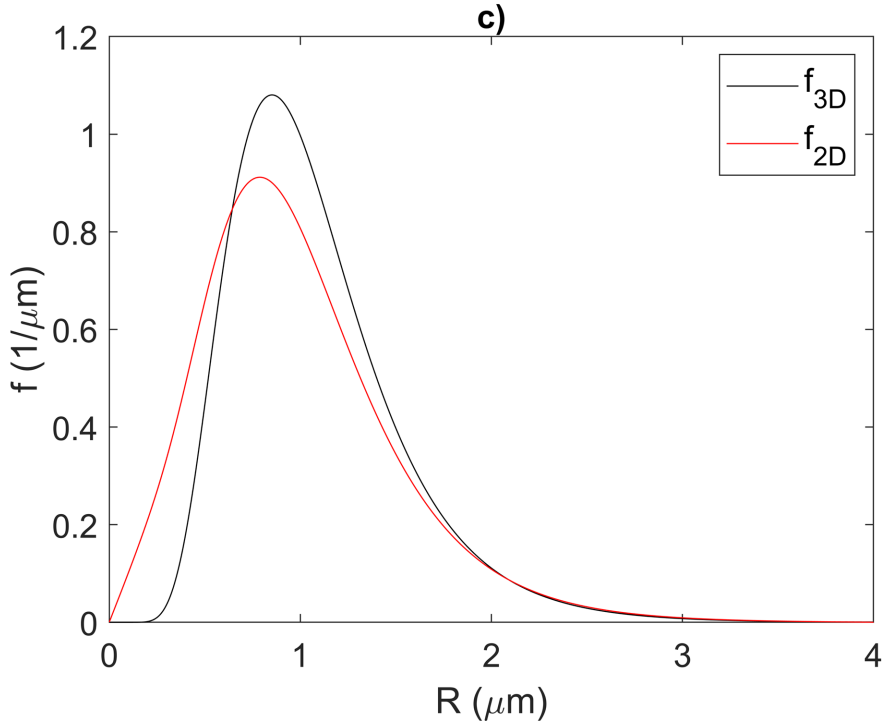

Figure 15: A comparison of the 3D and 2D particle size distributions considering a right-hand skewed log-normal distribution.

Analytical solutions exist for the determination of the 2D size distribution of impenetrable polydisperse spheres [1958Sal; 1925Wic]. Thermo-Calc has implemented the Jeppsson-Mannesson-Borgenstam-Agren (JMBA) [2011Jep] Saltykov conversion method to calculate the 2D size distribution.

Let $F_{3D}(r)dr$ describe the number of particles with radius varying between r and $r+dr$ within a unit volume. The corresponding 2D size distribution is given by $F_{2D}(r)dr$, describing the number of particle cross-sections with a radius varying between r and $r+dr$ within a unit area. Following the Saltykov method, the 2D size distribution is obtained from the following matrix calculation:

$$\underline{F_{2D}} = \underline{\underline{\alpha}}\,\underline{F_{3D}}$$

where $\underline{\underline{\alpha}}$ is a matrix of probabilities for the conversion and $\alpha_{i,j}$ describe the likelihood of obtaining a 2D cross-section of radius r_i from 3D grains of radius r_j . The JMBA model derived these probabilities as:

$$\alpha_{i,j} = \begin{cases} 2r_i \frac{\Delta rb_i}{\Delta rb_j} \frac{\sqrt{r_i^2 - b_{j-1}^2} - \sqrt{r_j^2 - b_j^2}}{r_i} & i < j \\ \frac{\Delta b_j 4\pi r_j^3/3 - \sum_{i=1}^{j-1}\left(\pi r_j^2 b_i \Delta b_{i-1} \alpha_{i,j}\right)}{\Delta b_j \pi r_j^2} & i = j \\ 0 & i > j \end{cases}$$

Where b_i and b_{i+1} describe the lower and upper boundaries to the particle radii class r_i. Δr_i and Δb_i are the spacing between radii midpoints and class boundaries, respectively. For a linear discretization, $\Delta b_i = \Delta r_i$.

It is assumed that the 2D cross-section is a perfect cut through the material however there may be some error in this approximation. Figure 16 presents the idealized case with a 3D and 2D size distribution with a mean radius of 1.5 µm. In Figure 17, it is assumed that the minimum size of particles that can be quantified in the micrograph is 0.25 µm. This crops off the left-hand tail of the 2D distribution. Etching away the matrix reveals sub-surface particles. Figure 18 shows the impact of etching a depth of 30 nm, further exposing particles that have a center below the cross-section of the cut.

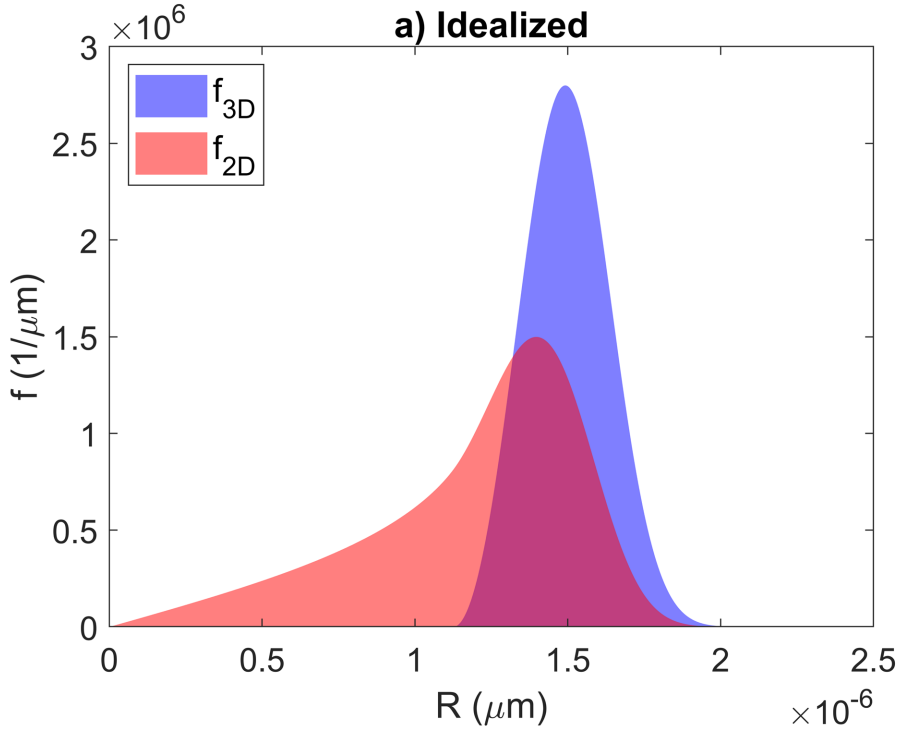

Figure 16: Potential causes of error in micrographs showing the idealized 2D size distribution.

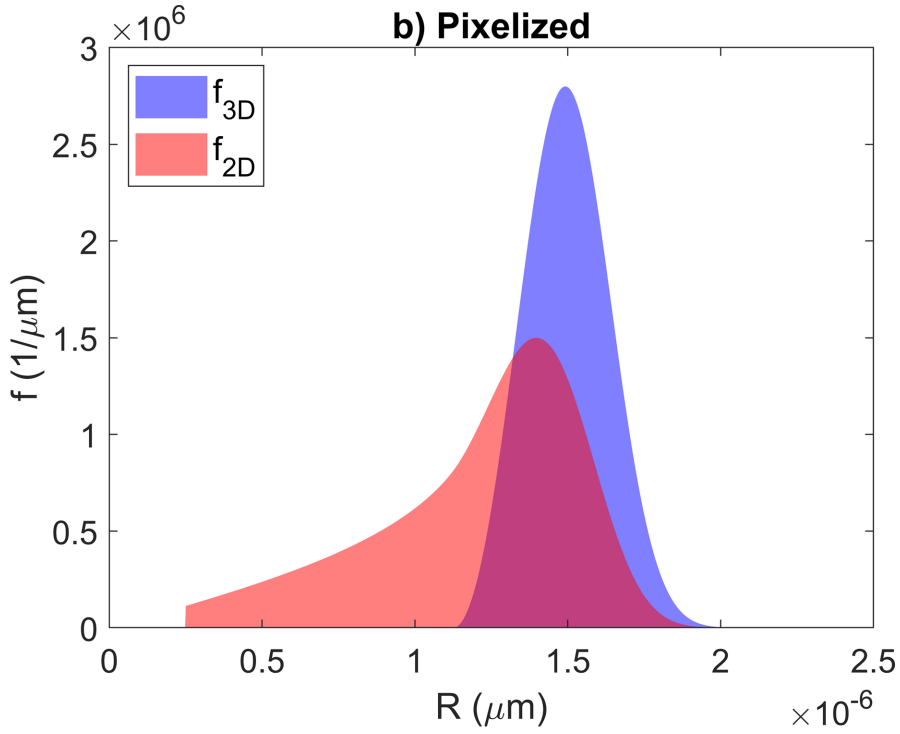

Figure 17: Potential causes of error in micrographs showing the cropped left-hand tail caused by a limiting size that can be measured from the micrograph.

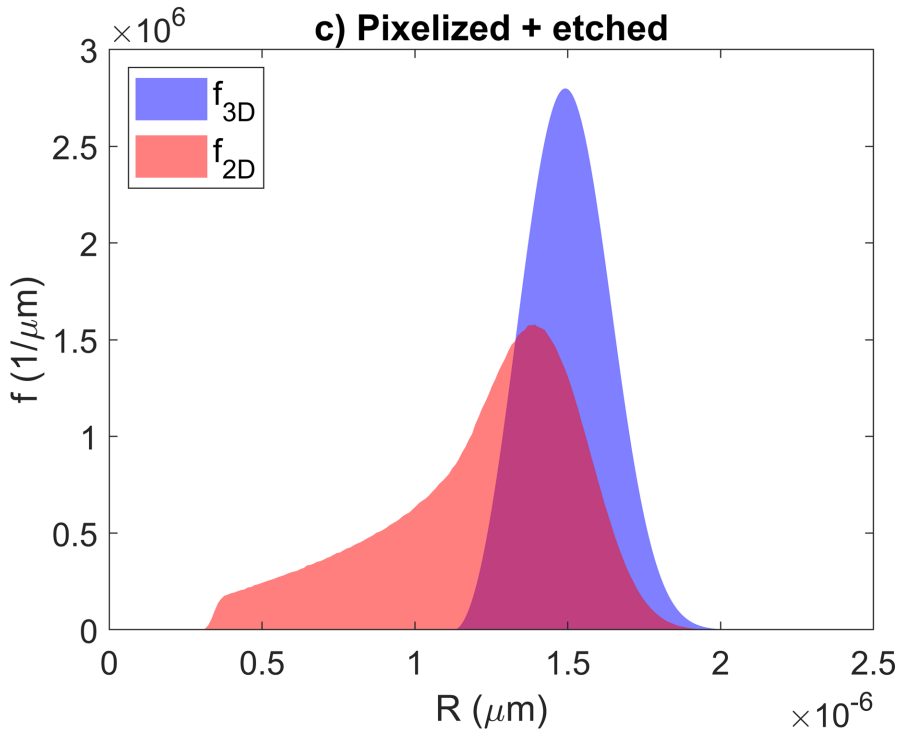

Figure 18: Potential causes of error in micrographs showing how the left-hand tail can be blurred due to etching.

Microstructure Descriptions

Precipitation kinetics and grain coarsening is modeled by the evolution of size distributions. Distribution functions describe the matrix grain size, and a size distribution for each precipitate phase specific to an individual nucleation site. Let the number concentration of precipitates or grains within the size interval of r and $r + dr$ be defined by fdr. The mean radius (r), number concentration N, and volume fraction ϕ of the precipitates or matrix grains are obtained from moments taken from the distribution function. The key statistics are obtained from the first set of equations (Eq. 1), where η is the volumetric shape factor. For spherical particles, $\eta = 4\pi/3$.

[*Eq. 1*]
$$\langle r \rangle = \frac{\int_0^\infty fr\,dr}{\int_0^\infty f\,dr}$$

$$N_v = \int_0^\infty f\,dr$$

$$\phi = \eta \int_0^\infty fr^3\,dr$$

The default output mean radius in the Precipitation Module (TC-PRISMA) uses a cubic mean radius. This value is less sensitive to numerical noise in the solution, and provide a better approximation of the three-dimensional size of the precipitates.

The cubic mean radius are given as follows:

[*Eq. 2*]
$$\langle r \rangle = \left(\frac{\int_0^\infty fr^3\,dr}{\int_0^\infty f\,dr} \right)^{1/3}$$

For sectioned spherical particles, a quadratic mean radius is used.

[*Eq. 3*]
$$\langle r \rangle = \left(\frac{\int_0^\infty fr^2\,dr}{\int_0^\infty f\,dr} \right)^{1/2}$$

The conventional mean radius as defined in the first set of equations (Eq. 1) is available as an output from calculations for precipitates and grains. The result can be split into individual populations, and sectioned to approximate the 2D size distribution.

Define the Precipitation Calculator

This topic lists the basic steps to define a **Precipitation Calculator**.

Working with these simulations is an advanced topic. It is recommended you review the documentation and videos available or search for a specific topic.

1. Add a **Precipitation Calculator** node to the System Definer. If you used the **Precipitation** template (on the **My Projects Configuration** window under **Non-Equilibrium**), click the node to display the **Configuration** settings window.
2. In the Precipitation Calculator **Configuration** window, enter the settings on the **Conditions** and **Options** tabs. These are described separately:
   - Matrix Phase
   - Precipitate Phase
   - Calculation Type and Precipitation Calculator Thermal Profile
   - Options Tab Advanced Settings
3. Once you have finished defining the Precipitation Calculator, you also choose settings on the **Plot Renderer**. Some additional settings are specific to the Precipitation Calculator Plot Renderer.

Learn More

When you also have licenses either for the Diffusion Module (DICTRA) and/or the Precipitation Module (TC-PRISMA), for transient simulations you can additionally include probe data from the AM Calculator in the set up of the thermal profile for diffusion and precipitation calculations, respectively.

There is a **Precipitation** template available under **Non-Equilibrium** that you can use to quickly set up a simulation. See Getting Started Links, Templates, and the Property Navigator.

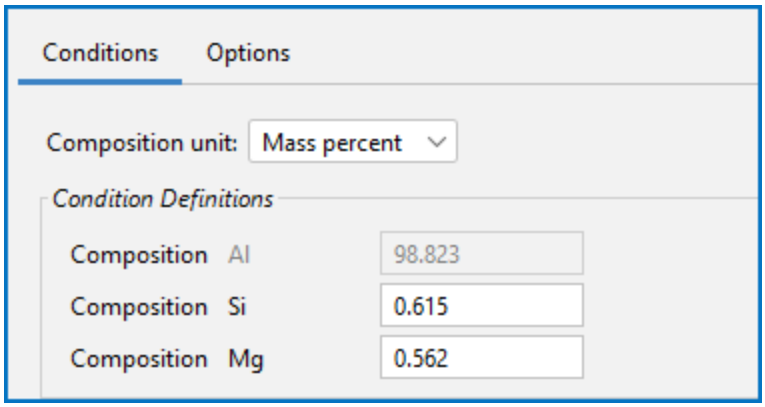
Available Options

Precipitation Module (TC-PRISMA) Examples Collection

Precipitation Calculator

A **Precipitation Calculator** allows you to set the conditions for, and perform, a precipitation calculation. You can add the calculator to the System Definer directly (right-click and select it from the **Create New Successor** menu)

Once you have added a Precipitation Calculator, the **Configuration** window has **Conditions** and **Options** settings tabs where there are many available conditions to set and then continue the settings with the specialized **Plot Renderer**.



The Conditions and Options tabs for a Precipitation Calculator.

Conditions

Set the conditions for your calculation that define the *Matrix phase* and *Precipitate phase*. Choose the *Calculation Type*.

- Matrix Phase Settings
- Precipitate Phase Settings
- Calculation Type Settings

Options

Modify *Numerical Parameters* that determine how the conditions are calculated.

- Options Tab

Plot Renderer

There are also unique settings available for this calculator once you add a Precipitation Calculator Plot Renderer.

Learn More

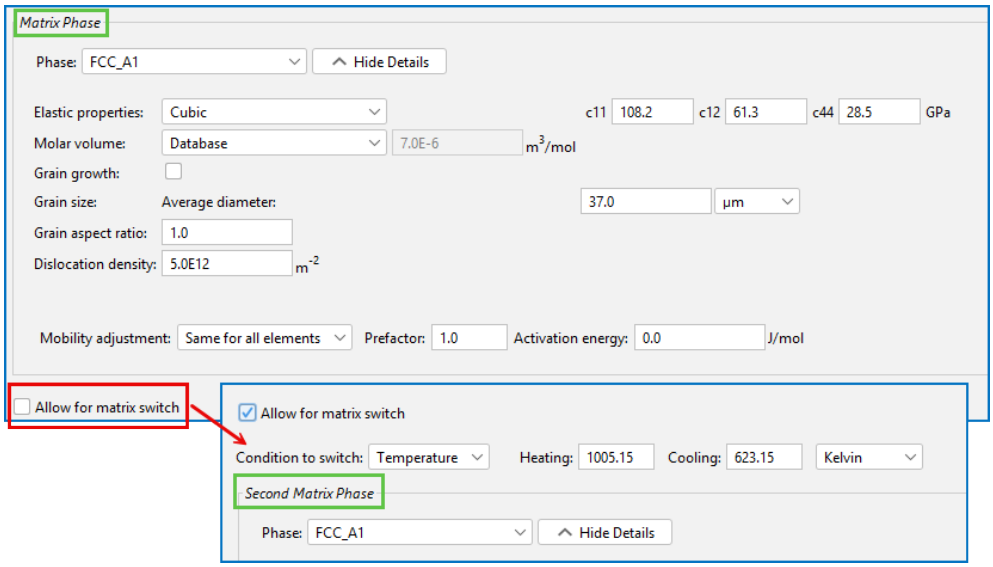
The Precipitation Calculator is available with three elements if you do not have the additional Precipitation Module (TC-PRISMA) license. With the Add-on Module you can use all available elements. See Available Options for details about this and other options available with additional licenses.

There is a **Precipitation** template available under **Non-Equilibrium** that you can use to quickly set up a simulation. See Getting Started Links, Templates, and the Property Navigator.

Matrix Phase Settings

Below are details about the settings available for the *Composition* and *Matrix Phase*, which is selected from the **Conditions** tab on the calculator **Configuration** window.

When the **Allow for matrix switch** checkbox is also selected, there are more settings for the *Second Matrix Phase*. See Matrix Phase Switch for details.



An example of the Matrix Phase settings area on the Configuration window where Show Details is expanded. At the bottom of this section is an Allow for matrix switch checkbox. When the checkbox is selected, the area expands further with additional settings where you define the Second Matrix Phase.

Show or Hide Details

Click **Show Details** to view some of the additional settings listed below. You can also set the default to display in **Phase view mode** on the **Options** window then click the **Graphical Mode** tab and the **Precipitation** node in the tree. Click **Hide Details** to hide the information.

Global Options

You can change these settings locally for a specific Calculator or globally for some defaults in the **Options** *window* (a different location than the tab).

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Graphical Mode** tab and the **Precipitation** node in the tree.

Composition Settings

Composition Unit

Select the **Composition unit**: **Mass percent**, **Mole percent**, **Mass fraction**, or **Mole fraction**.

Matrix Phase Settings

Selecting the Disordered Phase as a Matrix Phase

Phase

Only phases with kinetic data can be selected as the matrix phase. If the list is empty, go to the System Definer to confirm that both thermodynamic and kinetic databases are selected and defined.

System Definer

Choose a **Phase** from the list. The list is based on the settings for the System Definer. When setting up a system, choose a matrix phase with kinetic data available in the database.

Elastic Properties

See Homogeneous Nucleation for theory.

Choose **Disregard** to ignore the elastic properties.

Default elastic constants for **Isotropic** or **Cubic** are based on the major element of the alloy system. The elastic properties can affect nucleation rate, nuclei size, and particle shape.

- For **Isotropic**, enter values for **Shear modulus** (in GPa) and **Poisson's ratio** as required.
- For **Cubic**, enter values for **c11**, **c12**, and **c44** as required. c_{11}, c_{12}, c_{44} are the elastic constants.

Molar Volume

Use the **Database** value (if the molar volume for the phase is defined in the thermodynamic database) or select **User-defined** to enter another value in m^3/mol.

If you select the **Grain growth** checkbox, see the separate Grain Growth Settings section for details.

Grain Size

If the **Grain growth** checkbox is NOT selected then this version of the **Grain size** section is available in order for the **Average diameter** of the grain size to be entered.

Grain size is the "diameter" of a grain. The **Grain size** value changes the available nucleation sites when **Grain boundaries**, **Grain edges**, or **Grain corners** is selected along with **Calculate from matrix settings** in the *Precipitate Phase*. Enter a numerical value and choose a unit from the list. The default is `1.0E-4` m.

See Precipitation Morphology and The Number of Available Heterogeneous Nucleation Sites for theory.

Grain Aspect Ratio

For an elongated grain with a minor axis and a major axis, one may use the minor axis as grain size and the major/minor ratio as the grain aspect ratio to characterize the grain. The **Grain aspect ratio** value also changes the available nucleation sites when **Grain boundaries**, **Grain edges**, or **Grain corners** is selected along with **Calculate from matrix settings** in the *Precipitate Phase*. Enter a numerical value. The default is 1.0.

If the **Grain growth** checkbox is selected, the aspect ratio is fixed at 1.0 and can not be changed. See Grain Growth Settings.

See Precipitation Morphology and The Number of Available Heterogeneous Nucleation Sites for theory.

Dislocation Density

The **Dislocation density** value changes the available nucleation sites when **Dislocations** is selected along with **Calculate from matrix settings** in the *Precipitate Phase*. Enter a numerical value. The default is 5.0E12 m^{-2}.

See Precipitation Morphology and The Number of Available Heterogeneous Nucleation Sites for theory.

Mobility Adjustment

The **Mobility adjustment** parameters modify the atomic mobility data from a database.

Choose **Same for all elements**, which applies the adjustment to all elements, or **Per element** to adjust to each individual element. Then for the following settings, enter one set of values for **Same for all elements**, or individually for **Per element**.

- **Prefactor** (unitless) is a parameter that multiplies to the mobility data from a database. This value scales the mobility by a constant amount.

  For the Precipitation Calculator, this can be useful, for example, when the material has a higher than normal vacancy concentration at the start of the precipitation simulation. (e.g. from a prior solutionizing and quenching treatment).

- The **Activation energy** (J/mol) is a value that adds to the activation energy of mobility data from a database. This value scales the mobility by a temperature-dependent amount. Similar usage as the **Mobility adjustment >Prefactor** setting.

Grain Growth Settings

The **Grain growth** checkbox is not available when the **Allow for matrix switch** checkbox is selected.

Grain Growth

Select the **Grain growth** checkbox to use this to calculate the temporal evolution of grain size distribution (GSD). The grains are assumed of spherical morphology when modeling the growth rates. Nucleation is not considered, thus an initial GSD is necessary to start the simulation.

After selecting the checkbox, there are additional settings made available as described in this section.

This checkbox is not available when a **TTT diagram** or **CCT diagram***Calculation Type* is selected.

See Normal Grain Growth and Zener Pinning for theory.

Grain Size >> Grain Size Distribution

When the **Grain growth** checkbox is selected, then this version of the **Grain size** settings section is available. This is where you access the grain *Size distribution* settings.

Click **Edit grain size distribution** to open the *Size distribution* settings window. In this window, you can edit the parameters and generate a graph comparing the radius and number density for initial grains.

Select a **Length unit**: **Meter**, **Micrometer**, **Nanometer**, or **Ångström**.

Select a **Distribution**: **Normal**, **Log normal**, or **From file**.

- If **Normal** or **Log normal** is selected, enter values for **Mean radius** and **Std** (standard deviation). The default Std is different for each choice.
- If **Hillert** is selected, enter a value for the **Mean radius**.
- If **From file** is selected, click **Import** and navigate to the file containing the required information and click **Open**. This file can be in .xls, .xlsx, .csv or .txt formats. The file should consist of two columns with values where the first column contains **radius** data and the second contains **number density** data.

A similar setup can also be found in the Particle Size Distribution (PSD).

Once the size distribution is defined, click **Generate** to view or update the graph comparing the radius and number density for initial grains.

Grain Boundary Energy

This setting is available when the **Grain growth** checkbox is selected.

Enter a value for the **Grain boundary energy**. The default is 0.5 J/m^2.

See Normal Grain Growth for theory.

Grain Boundary Mobility

This setting is available when the **Grain growth** checkbox is selected.

The **Prefactor** (m^4/Js) is a parameter that represents the magnitude of the grain boundary motion.

The **Activation energy** (J/mol) is a parameter that describes the temperature dependence of the grain boundary mobility.

See Grain Boundary Mobility Values for theory and recommended values.

Zener Pinning

This setting is available when the **Grain growth** checkbox is selected.

Select the **Zenner pinning** checkbox to consider the effect of precipitates on inhibiting normal grain growth. When this checkbox is selected, there are additional settings available in the **Precipitate Phase** section.

See Zener Pinning for theory.

P_14: Grain Growth and the Zener Pinning Effect

Matrix Phase Switch

Select the **Allow for matrix switch** checkbox to enable switching of the matrix phase between two defined phases.

See About Matrix Phase Switching for background information.

Grain growth is not available when the **Allow for matrix switch** checkbox is selected.

From the **Condition to switch** list, select **Temperature** or **Driving force**.

- If **Temperature** is selected, enter the **Heating** and **Cooling** transition temperatures, and select the appropriate temperature unit, **Kelvin**, **Celsius**, or **Fahrenheit**
- If **Driving force** is selected, enter the driving force value in J/mol. The driving force is treated as a non-negative value. If a negative value is entered, its absolute value is used.

Then enter the properties of the *Second Matrix Phase*. These properties have the same definitions as those specified for the first matrix phase. What you enter for the First and Second Matrix Phases also depends on whether you chose **Temperature** or **Driving force** as the condition to switch.

- When **Temperature** is selected as the transition condition, the first matrix phase must be the high-temperature phase, and the second matrix phase must be the low-temperature phase.
- When **Driving force** is selected as the transition condition, it is recommended, though not mandatory, to follow the same phase sequence: first matrix phase as the high-temperature phase and second matrix phase as the low-temperature phase.

Learn More

There are additional **Conditions** tab settings described for the Precipitate Phase and Calculation Type.

Selecting the Disordered Phase as a Matrix Phase

The following information is about using disordered FCC as a matrix phase with the following thermodynamic and mobility database packages:

- TCCU and MOBCU (Cu-based alloys)
- TCNI and MOBNI (Ni-based alloys)

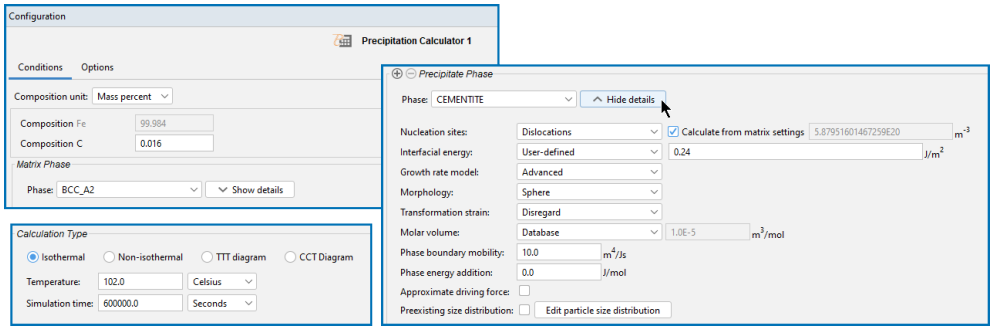
In the TCNI/MOBNI and TCCU/MOBCU packages, the well-known order/disorder two-sublattice model is used to describe the Gibbs energy of both FCC_A1 and FCC_L12. With this treatment, FCC_L12 is becoming FCC_A1 if the site fractions of each element on both sublattices are identical, which means that FCC_A1 is only a special case of FCC_L12. Therefore, FCC_A1 is not shown in the phase list on the *Phases and Phase Constitution* tab on the System Definer activity and in subsequent equilibrium calculation results. Instead it is shown only as FCC_L12. The real ordered FCC_L12 is shown as FCC_L12#2.

In precipitation simulations, the matrix phase is quite often the disordered FCC phase. You can directly select FCC_L12 as the matrix phase and run a simulation. However, the speed is not optimal due to the sophisticated model used for both Gibbs energy and atomic mobilities. A better and more convenient way is to deselect FCC_L12 and FCC_L12#2 from the phase list on the *Phases and Phase Constitution* tab on the **System Definer** if the ordered phase is irrelevant in the alloy under investigation, such as in most Cu alloys. Once these are unchecked (i.e. not selected), the FCC_A1 phase is available and can later be selected as the matrix phase.

For Ni-based superalloys using the TCNI/MOBNI package, the ordered FCC_L12#2 (gamma prime) has to be included as the precipitate phase in most of calculations. In this case, you can select DIS_FCC_A1 from the phase list on the *Phases and Phase Constitution* tab and then select it as the matrix phase in the **Precipitation Calculator**.

Precipitate Phase Settings

Below are details about the settings for the *Precipitate Phase*, which is selected from the **Conditions** tab on the Precipitation Calculator **Configuration** window.



There are three distinct settings areas for the Configuration window for example P_04_ Precipitation_Fe-C_Cemetite. In this case, Show Details is expanded to show the Precipitate Phase settings.

Show or Hide Details

Click **Show Details** to view some of the additional settings listed below. You can also set the default to display in **Phase view mode** on the **Options** window then click the **Graphical Mode** tab and the **Precipitation** node in the tree. Click **Hide Details** to hide the information.

Global Options

You can change these settings locally for a specific Calculator or globally for some defaults in the **Options** *window* (a different location than the tab).

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Graphical Mode** tab and the **Precipitation** node in the tree.

Allow for Matrix Switch

Unless specified otherwise, if the **Allow for matrix switch** checkbox is selected, each setting applies to precipitations in either matrix phase.

Phase

The phases available to choose have thermodynamic data. If the list is empty, or a desired phase is absent, go to the System Definer to confirm that the thermodynamic database is selected and defined, and the desired phase is selected.

See System Definer for setting details.

Choose a **Phase** from the list. The list is based on the System Definer settings.

Nucleation Sites

See Homogeneous Nucleation and Heterogeneous Nucleation for theory.

The number of different nucleation sites is dependent on the shape and size of grains in the matrix. Grain size is the "diameter" of a grain. Choose one of the following from the list.

- **Bulk**, **Grain boundaries**, **Grain edges**, **Grain corners**, or **Dislocations**. If more than one *Precipitate Phase* is added, **Precipitate** is also available.
- For **Grain boundaries**, **Grain edges**, and **Grain corners**, enter the **Wetting angle (0-90)** in addition to the matrix settings. **Wetting angle** defines the deviation from spherical shape (or dihedral angle).
- When **Precipitate** is selected, you can choose other precipitates to nucleate on and enter a **Number of sites per precipitate** there should be. For precipitation upon Precipitates, the nucleation site which acts as the inoculant phase must be selected. The number of nucleation sites per inoculant phase can be defined, and has a default value of one. The wetting angle for precipitation upon precipitates describes the impact of the phase boundary between the precipitate and inoculant particle. A wetting angle of 180 degrees means that there is no contact between the inoculant particle and nucleating particle. This is the case if nucleation site exists within the

distorted matrix surrounding the inoculant particle. As the wetting angle reduces, there is greater contact between the inoculant phase and the nucleating particle, lowering the energy barrier for nucleation.

Click to select the **Calculate from matrix settings** checkbox to calculate the initial number density of sites from the matrix grain size or dislocation density.

To enter a specific value for the number of **Nucleation sites**, click to clear the checkbox.

If the **Allow for matrix switch** checkbox is selected, the entered value only applies to precipitation in the first matrix phase. Nucleation sites in the second matrix phase are always calculated from settings of second matrix phase.

Interfacial Energy

See Estimation of Coherent Interfacial Energy and Interfacial Energy Anisotropy (Non-Spherical Particles) for theory.

Choose **Calculated** to use the estimated value. To adjust the estimate, enter a different **prefactor** or choose **User-defined** to enter a value in J/m^2. For the User-defined option, you can also enter it as a function of radius (r) and temperature (T).

If the **Allow for matrix switch** checkbox is selected, then **Calculated** uses the thermodynamic properties of precipitate and activated matrix phase to estimate the interfacial energy, whereas selecting **User-defined** applies the entered value regardless of which matrix phase is activated.

Growth Rate Model

Select **Simplified**, **General**, **Advanced**, **Para-eq**, **NPLE**, or **PE Automatic** (where Para-eq and PE are both abbreviations for *paraequilibrium*).

All models treat a particle (precipitate) of stoichiometric composition or with negligible atomic diffusivity. Except for the **PE Automatic** model, local equilibrium or paraequilibrium at the precipitate-matrix interface is assumed. The **PE Automatic** model enables smooth transition from paraequilibrium to local equilibrium.

In the documentation and on the GUI, the abbreviations *Para-eq* and *PE* are both used for paraequilibrium. There is also the use of OE as an abbreviation for *ortho-equilibrium* and LE for *local equilibrium*.

See Growth.

Morphology

See Precipitation Morphology for theory.

Choose the particle shape: **Sphere** (default), **Cuboid**, **Plate**, or **Needle**. Options are based on the **Elastic properties** selected for the **Matrix** phase:

- For a **Cubic** elastic property, **Sphere**, **Plate**, **Needle**, and **Cuboid** are available.
- For an **Isotropic** elastic property, **Sphere**, **Plate** and **Needle** are available.

If **Sphere** is selected, there is an option to use a **3D → 2D** conversion on the Plot or Table Renderer for certain variables. See Stereology for theory details.

For **Plate** or **Needle**, select the **Calculate aspect ratio from elastic energy** checkbox or enter a numerical value in the **Aspect ratio** field to provide a constant aspect ratio.

See Particle Shape Determination (Non-Spherical Particles) for theory.

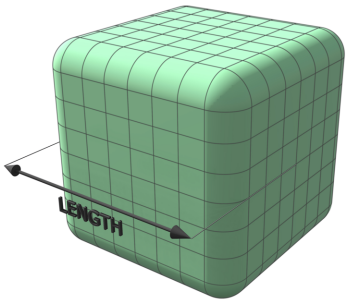


Figure 19: The cuboid shape is described by a supersphere. Cuboids have six faces, which form a convex polyhedron.

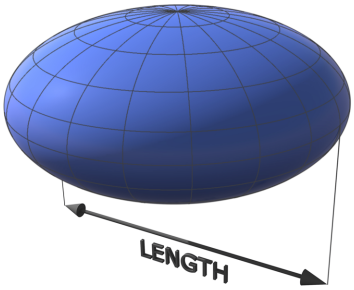

Figure 20: The plate is described as oblate spheroid. Oblate spheroids have rotational symmetry around an axis from pole to pole.

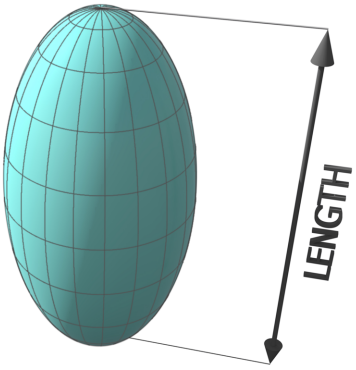

Figure 21: The needle shape is described as prolate spheroid. A prolate spheroid is a surface of revolution obtained by rotating an ellipse about its major axis.

Transformation Strain

Choose **Disregard** to ignore the transformation strain. When **Isotropic** or **Cubic** is chosen in **Elastic properties** in Matrix Phase, you can also choose **Calculated from molar volume** to obtain a purely dilatational strain. If **Plate** or **Needle** is selected as the **Morphology**, you can alternatively choose **User-defined** and enter the properties for **ε11**, **ε12**, **ε13**, **ε22**, **ε23**, and **ε33**.

See Particle Shape Determination (Non-Spherical Particles) for theory.

Molar Volume

Use the **Database** value (if the phase molar volume is defined in the thermodynamic database) or select **User-defined** to enter another value.

Zener Pinning Parameters

These parameters are available when the **Zener pinning** checkbox is selected under the **Matrix Phase** settings. These settings are to consider the effect of precipitates on inhibiting normal grain growth.

- **Cutoff size**: Precipitates with radius smaller than this value are neglected in pinning force calculation. Default value : 7×10^{-7} m.
- **Kinetic prefactor**: Dimensionless kinetic coefficient in Zener equation. Default value: 0.5.
- **Exponent**: Exponent of precipitate volume fraction in Zener equation. Default value: 0.93.

See Zener Pinning for theory.

P_14: Grain Growth and the Zener Pinning Effect

Phase Boundary Mobility

A parameter that accounts for interface-controlled growth. Only effective if a very small, positive value is used. Use with caution due to a tentative treatment.

See Simplified Growth Rate Model (Spherical Particles) for theory.

Trans-Interface Mobility Adjustment

This setting is available when the **Growth rate model** is **PE Automatic** .

The **Trans-Interface mobility adjustment** parameters modify the atomic mobility data from a database.

Choose **Same for all elements**, which applies the adjustment to all elements, or **Per element** to adjust to each individual element.

The transition kinetics from Para-Equilibrium (PE) to Ortho-Equilibrium (OE) is controlled by the ratio of atomic mobility of substitutional elements to that of interstitial elements. This implies that the option of **Same for all elements**—while useful to the case that the atomic mobility data for all elements are needed to be scaled with the same factor to match experimental trans-interface mobility data—does not change the PE-OE transition kinetics. Therefore, the change of transition kinetics separately requires adjustment of individual elements, which is when the **Per element** setting is useful.

Then for the following settings, enter one set of values for **Same for all elements**, or individually for **Per element**:

- **Prefactor** (unitless) is a parameter that multiplies to the mobility data from a database. This value scales the mobility by a constant amount. This results in the trans-interface mobility that controls the kinetics of Para-Equilibrium (PE) to Ortho-Equilibrium (OE) transition.
- The **Activation energy** (J/mol) is a value that adds to the activation energy of mobility data from a database. This value scales the mobility by a temperature-dependent amount. Similar usage as the **Trans-Interface mobility adjustment >Prefactor** setting.

Phase Energy Addition

An energy value that adds to the Gibbs free energy of the precipitate phase from a database. Enter a value in the field and choose a unit **J/mol formula unit** or **J/mol substitutional atom**.

See Simplified Growth Rate Model (Spherical Particles) for theory.

Approximate Driving Force

Select the checkbox to include this if simulations with several compositions sets of the same phase create problems.

See Nucleation Theory.

Preexisting Size Distribution

Select the checkbox to include this. Click **Edit particle size distribution** to open the **Preexisting Particle Size Distribution** window where you can edit the parameters and view a graph comparing the radius and number density for the selected component.

See Particle Size Distribution (PSD) for detailed instructions.

Learn More

There are additional **Conditions** tab settings described for the Matrix Phase and Calculation Type.

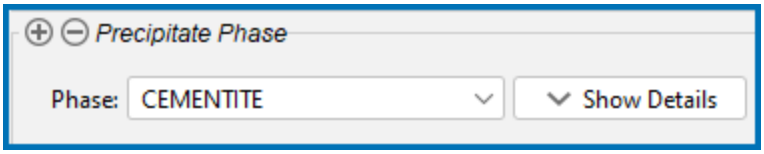
Particle Size Distribution (PSD)

On the **Precipitation Calculator** you can set the pre-exisiting particle size distribution (PSD) parameters in the **Show Details** section. The size distribution can be generated from a probability distribution function, by importing a file, calibrating a probability distribution function to experimental data, or by manually entering information into a table. Uni-modal distributions can be created within the Graphical Mode interface. Pre-existing multimodal distributions can be loaded from a file.

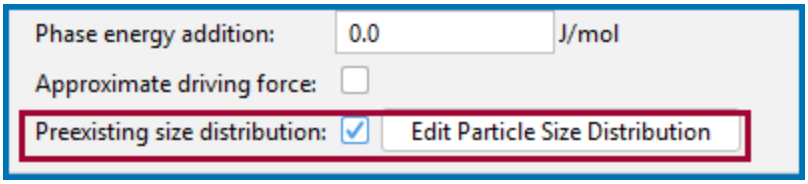
P_10: Initial Particle Size Distribution of Fe-Cr-C

Accessing the 'Preexisting Size Distribution' Settings

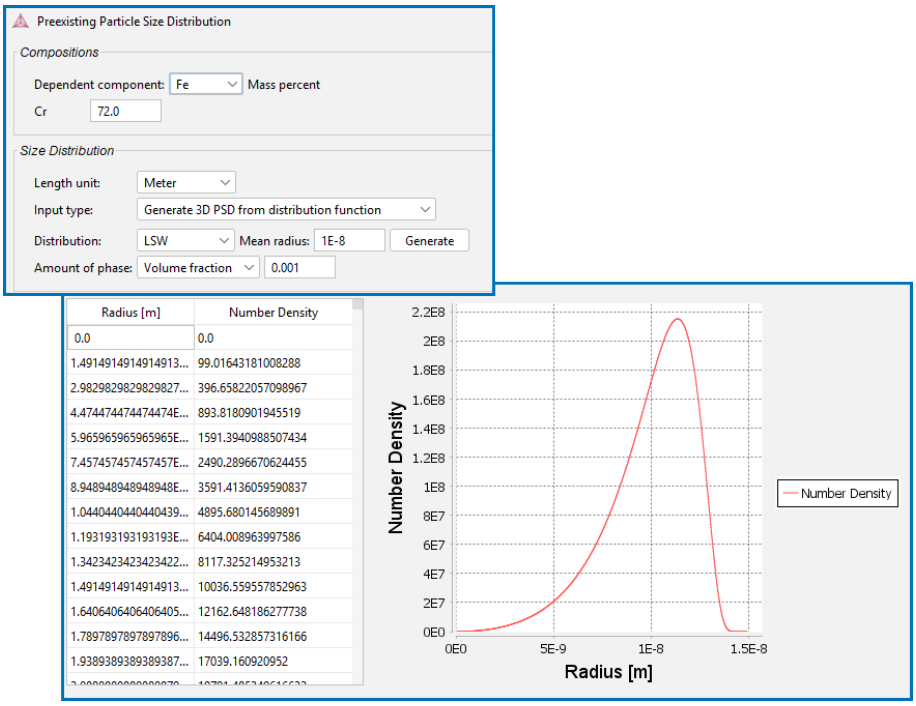
1. To the right of the *Precipitate Phase* settings fields, click **Show Details**.



2. At the bottom of the *Precipitate Phase* section, click to select the **Preexisting size distribution** checkbox. Then click **Edit Particle Size Distribution**.



3. The **Preexisting Particle Size Distribution** window opens as shown for example P_10 CEMENTITE phase.



General Settings

Compositions

Choose a **Dependent component** from the list and enter the composition for the other component.

Length Unit

Choose a **Length unit**: **Meter**, **Micrometer**, **Nanometer**, or **Ångström**.

Amount of Phase

For all options, choose an **Amount of phase**: **Volume percent** or **Volume fraction** and then enter a number in the field.

Input Type

Choose an **Input type**: **Generate 3D PSD from distribution function**, **From File**, or **Approximate the 3D PSD from experimental data**. See the following sections for the details about each setting.

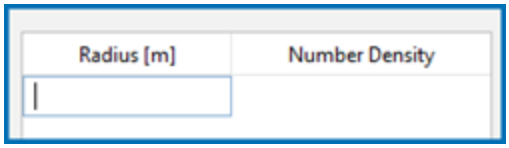
Generate 3D PSD from Distribution Function

This option allows the generation of the size distribution from a list of probability distribution functions. The **Distribution** types include **LSW**, **Normal**, **Log normal**, and **Weibull**.

- **Mean radius** The mean particle radius.
- **Sigma** The standard deviation for the chosen length unit.
- **Alpha** A dimensionless shape factor that should vary between 1.5 and 10.
- **Fraction offset** The fraction offset applied to the mean radius to shift the start of the distribution. This must be greater than or equal to zero, and less than 0.95.

Once the **Distribution** is defined, click **Generate** to create the size distribution.

You can also click in the table to manually enter numbers into the cells rather than use one of the provided probability distribution functions. The radius values must monotonically increase in size.



From File

This option lets you load the initial size distribution from a file. Click **Import** and navigate to the file containing the required information and click **Open**. This file can be in .xls, .xlsx, .csv, or .txt formats. The file should consist of two columns with values where the first column contains **radius** data and the second contains **number density** data.

The example `P_10` (available from the **Example files** → **Precipitation Module - TC-PRISMA** folder) shows this for the precipitate phase M23C6. There is also a file in this folder called `P_10_Precipitation_Initial_PSD_FeCrC_psd_3D_M23C6.csv` that is an example of a correctly formatted text file.

The imported size distribution is normalized into a probability distribution function by ensuring that the zeroth moment is unity. If you wish to import a histogram that has un-even bin spacing, it is necessary to convert the Y-axis counts of the histogram to a count density first to avoid changes to the shape of the distribution. The count density is obtained simply by dividing the count of a bin by the bin's width.

Approximate the 3D PSD from Experimental Data

The **Approximate the 3D PSD from experimental data Input type** allows you to calibrate a continuous probability distribution function to an experimentally measured size distribution, and account for stereological considerations. There are additional settings related to this.

The **Dimensionality of exp. data** setting must be defined.

- For precipitate radius measurements that are a good approximation of the 3D size of the particles, select **3D**. Measurements from quantitative image analysis of Transmission Electron Micrographs (TEM) provide **3D** size data, however the precipitates can still be truncated within the TEM sample foil thickness.
- **2D** data is obtained from a cross section taken through the microstructure. Examples include micrographs taken from Scanning Electron Microscopy (SEM), and Optical Microscopy (OM). The radius measurements are obtained from calculating the equivalent radius of a circle from the areas of identified objects from quantitative image analysis of the micrographs. It is possible that the samples of interest are over-etched, revealing the full size of the precipitates. In this case the data may be more descriptive of the **3D** size, however smaller particles are removed by the etching, distorting the obtained size distribution.
- **1D** data is obtained from applying the linear intercept method to micrographs descriptive of a cross section through the dispersion. A half-linear intercept is used in this calculation, which is analogous to the radius of the particle, opposed to the diameter.

Click **Import exp. data** to import the experimental data. Navigate to the file containing the required information and click **Open**. This file can be in .xls, .xlsx, .csv, or .txt formats. The file should consist of two columns with values where the first column contains **radius** data and the second contains **number density** data.

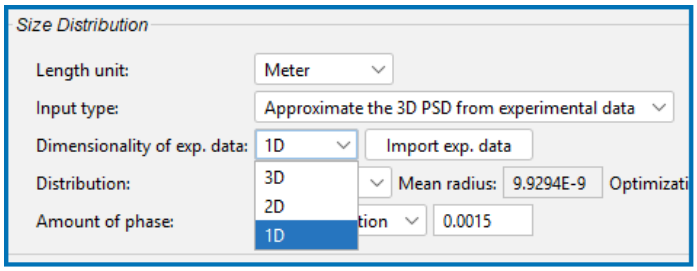
The example `P_10` (available from the **Example files** → **Precipitation Module - TC-PRISMA** folder) shows this for the precipitate phase M7C3. There is also a file in this folder called `P_10_Precipitation_Initial_PSD_FeCrC_psd_1D_M7C3.csv` that is an example of a correctly formatted text file.

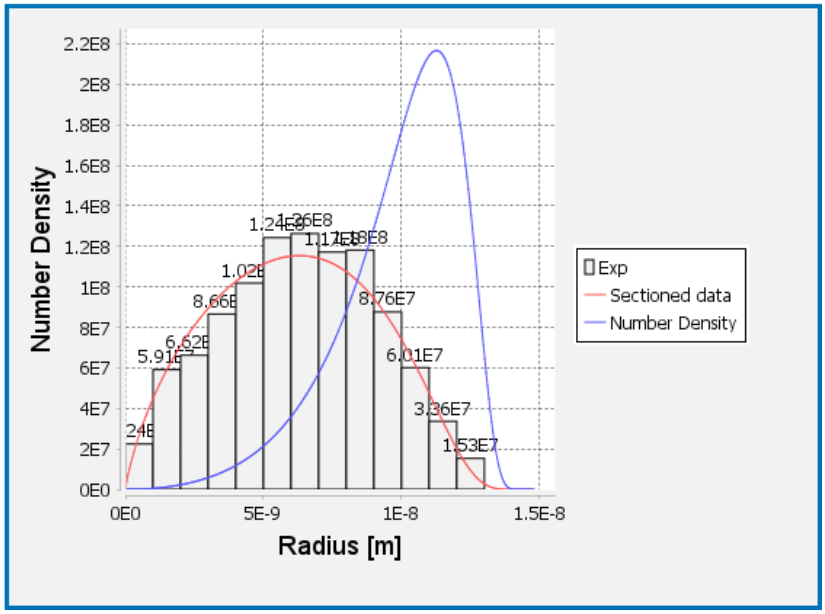
Distribution

Choose a **Distribution**: **LSW** (Lifshitz-Slyozov-Wagner), **Normal**, **Log normal**, or **Weibull**.

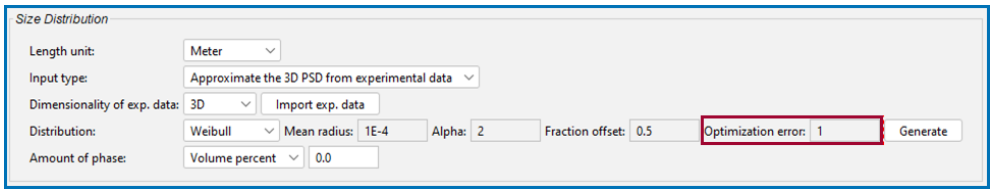
Click **Generate** to calibrate the chosen **Distribution** to capture the **Import exp. data** accounting for the chosen stereological **Dimensionality of exp. data**.

For 3D data, there are two datasets shown in the preview; the experimental data and the 3D model data. For 2D and 1D data, the sectioned model data is also shown and compared with the experimental data





The Optimization error is output into the text-field highlighted below. This can be used to determine the best distribution type to use for a given dataset.



Calculation Type Settings

Below are details about the settings for the *Calculation Type*, which is selected from the **Conditions** tab on the Precipitation Calculator **Configuration** window.

Settings

Isothermal

Use an **Isothermal** calculation type to do a simulation at constant temperature.

These settings are described in the section for the Precipitation Calculator Thermal Profile.

Non-isothermal

Nucleation During a Non-isothermal Process

Use a **Non-isothermal** calculation type to do a simulation with a user-defined temperature profile. You can enter information directly or import a data file.

These settings are described for the Precipitation Calculator Thermal Profile including information about importing data files.

When you also have a license for the Additive Manufacturing (AM) Module you can include probe data from the AM Calculator in the set up of the thermal profile.

TTT Diagram

Use a **TTT-diagram** to calculate the time-temperature-transformation (TTT) curve for the formation of the precipitate phase.

- **Temperature**: Enter **Min**, **Max**, and **Step** numerical values and choose a temperature **Unit**.
- **Max annealing time**: Enter a numerical value and choose a time **Unit**.
- **Stop criteria**: Choose **Volume fraction of phase** or **% of equilibrium fraction** and then enter a numerical value. For each temperature, the simulation stops when the stop criteria is fulfilled or if the maximum annealing time is reached, whichever happens first.

See example P_03: Stable and Metastable Carbides - TTT Diagram

CCT Diagram

Use a **CCT-diagram** to calculate the continuous-cooling-transformation (CCT) curve for precipitation.

- **Temperature**: Enter **Min** and **Max** numerical values and choose a temperature **Unit**.
- **Cooling rate(s)**: Enter a range of values in the field, e.g. `.01 .1 1 10 100`. These values are equal to **K/s**, **°C/s** or **°F/s** per second based on the temperature **Unit** selected.
- **Stop criteria**: Enter a numerical value for the **Volume fraction of phase**. For each temperature, the simulation stops when the stop criteria is fulfilled.

See example P_07: Continuous Cooling Transformation (CCT) Diagram of Ni-Al-Cr γ-γ'.

Learn More

There are additional **Conditions** tab settings described for the Matrix Phase and Precipitate Phase.

Options Tab

The Precipitation Calculator settings including the sections *Numerical Parameters*, *Save Options*, *Preprocessing Operations*, and *Interpolation Scheme* are located on the **Configuration** window → **Options** tab.

For equations and details about these settings, see Numerical Method.

You can change these settings locally for a specific Precipitation Calculator or globally for some defaults in the **Options** window settings.

Numerical Parameters

- **Max Time Step Fraction**: The maximum time step allowed for time integration as fraction of the simulation time. The default is 0.1.
- **No. of Grid Points Over One Order of Magnitude in Radius**: The default number of grid points for every order of magnitude in size space. The default is 150.0.
- **Max No. of Grid Points Over One Order of Magnitude in Radius**: The maximum allowed number of grid points in size space. The default is 200.0.
- **Min No. of Grid Points Over One Order of Magnitude in Radius**: The minimum allowed number of grid points in size space. The default is 100.0.
- **Max Relative Volume Fraction of Subcritical Particles Allowed to Dissolve in One Time Step**: The portion of the volume fraction that can be ignored when determining the time step. The default is 0.01.
- **Max Relative Radius Change**: The maximum value allowed for relative radius change in one time step. The default is 0.01.
- **Relative Radius Change for Avoiding Class Collision**: Set a limit on the time step. The default is 0.5.
- **Max Overall Volume Change**: This defines the maximum absolute (not ratio) change of the volume fraction allowed during one time step. The default is 0.001.
- **Max Relative Change of Nucleation Rate in Logarithmic Scale**: This parameter ensures accuracy for the evolution of effective nucleation rate. The default is 0.5.
- **Max Relative Change of Critical Radius**: Used to place a constraint on how fast the critical radium can vary, and thus put a limit on time step. The default is 0.1.

- **Min Radius for a Nucleus to be Considered as a Particle**: The cut-off lower limit of precipitate radius. The default is 5.0E-10 m.
- **Max Time Step During Heating Stages**: The upper limit of the time step that has been enforced in the heating stages. The default is 1.0 s.
- **Maximum Relative Solute Composition Change at Each Time Step**: Set a limit on the time step by controlling solute depletion or saturation, especially at the isothermal stage. The default is 0.01.

Save Options

From the **Save frequency** list, select an option that can reduce file size and speed up post-processing: **Medium** (the default), **High**, **Low**, or **Last result**. There is also an option to use **Original** settings and in some cases this is automatically selected.

When using the **High**, **Medium**, or **Low** save frequency settings, the particle size distribution (PSD) information is interpolated from the closest saved results. This is the most accurate when using the **High** setting as it reduces the error from the interpolation.

- **High** aims to capture all behavior, but may save more data than needed, with larger file sizes. This is a good option for scenarios where multimodal precipitate dispersions form, or you are interested in the change in the particle size distribution during the simulation.
- **Low** aims to only save when a dispersion changes. It may miss behavior but keeps the file size small.
- A **Medium** setting is a compromise between the High and Low settings, and is the default.
- The **Last result** option only saves information about the precipitates for the last time-step. This can be of interest to keep a small file size during high throughput calculations.

If you are modeling grain growth or doing CCT or TTT simulations, then **High**, **Medium**, **Low**, and **Last result** are not available. In these cases, **Original** is automatically selected by the software and then the same save logic as used as in Thermo-Calc versions 2025b and older.

Preprocessing Operations

Preprocess Equilibrium Data

These settings are not available when the **Allow for matrix switch** checkbox is selected on the **Conditions** tab under *Matrix Phase*.

Select the **Preprocess equilibrium data** checkbox to calculate the required phase equilibrium properties as a function of temperature for stable and metastable conditions. This speeds up the computation time of non-isothermal simulations or isothermal simulations where there is difficulty with losing precipitate phases during the calculation.

When the checkbox is selected, the stable and meta-stable property diagram data for all simulated precipitate phases is preprocessed. This preprocessing avoids repeating global equilibrium calculations, and speeds up computational time. It also allows for an improved description of precipitate kinetics under severe dissolution conditions. This can occur when temperatures are too high, where the phase is no longer detected in equilibrium calculations, or if the matrix is depleted of precipitate forming species, and the precipitate phase is lost when calculating the driving force.

This feature is used primarily for non-isothermal simulations. For isothermal simulations it can be used when there is difficulty losing precipitate phases during the calculation. In this case, it alters the predicted dissolution kinetics in certain conditions where the precipitation phase is lost and then it also speeds up these calculations.

Include Incipient Melting

> To use the **Include incipient melting** checkbox requires that the thermodynamic database (i.e. TCFE, TCNI, and so on) includes the liquid phase. If the liquid phase is not included, then the **Perform** button is not available (it is grayed out with a message explaining why) until either a liquid phase is included or this checkbox is deselected.

This is available when the **Preprocess equilibrium data** checkbox is selected.

Select the **Include incipient melting** checkbox to approximate the melting temperature of precipitate phases. The precipitates are removed upon exceeding this temperature.

Incipient melting is a phenomenon where, due to rapid heating rates, a solid-state precipitate is in solution at temperatures where it would normally dissolve. It liquidates rather than dissolves into the matrix. Being able to include (or exclude) the incipient melting is relevant to simulations involving welding and AM. Including incipient melting in AM calculations is useful to avoid excessive computation time modeling the dissolution of precipitates which would melt. The precipitates are assumed to melt instantaneously upon reaching their incipient melting temperature.

Interpolation Scheme

> These settings are not available when the **Allow for matrix switch** checkbox is selected on the **Conditions** tab under *Matrix Phase*.

Use Interpolation Scheme

Select the **Use interpolation scheme** checkbox to turn on an interpolation scheme for thermodynamic and mobility calculations. This can accelerate the computation time.

The advantage of using interpolation is mainly with CCT calculations, where the same matrix compositions are revisited repeatedly as several precipitation simulations are executed in sequence under different cooling rates.

Many precipitate simulations, however, do not reduce simulation times when using interpolation. For example, in isothermal precipitation, the matrix composition gradually changes from the initial oversaturated to the equilibrium composition during the simulation. By default, interpolation is therefore turned off.

The interpolation scheme is not compatible with the advanced growth-rate and is turned off automatically if this option is used in a simulation. It is also not recommended for use with the para growth-rate.

Largest improvements to computation time are seen with the simplified growth rate. In some cases, decent performance improvements have been obtained with the general and NPLE descriptions. Minor improvements are obtained for PE Automatic. Simulation times with the interpolation scheme are slower with the para-equilibrium growth-rate.

The interpolation scheme does not take advantage of pre-processed data, making it liable to issues where the precipitate phase is lost in equilibrium calculations, incurring error. This can happen at high super-solvus temperatures, or when the matrix is highly depleted from precipitate forming elements.

Discretization Method

The **discretization** can be either **Linear** or **Logarithmic** (the default). Logarithmic discretization is best when modeling interstitial elements where the composition can vary by orders of magnitude. Linear discretization works well when modeling only substitutional elements.

Number of Steps

Enter what is essentially the number of **steps in each dimension** in composition-temperature space for each equilibrium condition. In the limit where an infinite number of steps are used, exactly the same solution is obtained as without the interpolation scheme. However, excellent results can be obtained with a reasonable discretization.

Memory to Use

You can define the upper limit to how much **Memory to use** to store previous results for interpolation. The limit can be set in either **Megabyte** or a **Fraction of free** physical memory available at the start of the simulation.

Precipitation Calculator Plot Renderer

The following is information about the settings available for a when it is a successor to a **Precipitation Calculator**.

Add an Axis and Remove this Axis Button

Use the ⊕ **Add an axis** and ⊖ **Remove this axis** buttons to add additional *X*- and/or *Y*-axes to a plot or to merge plots (to overlay one plot with another in the same diagram). When merging plots, you define this variable as the *Z*-axis.

Available Axis Variables

Quantities Groups Available for Plots and Tables for a general list of quantities. However, for the **Precipitation Calculator Plot Renderer** there are no defined groups to choose from.

In alphabetical order:

- **Active matrix phase**: Name of the matrix phase that is activated during the precipitation process, a useful identification if **Allow for matrix switch** checkbox is selected.
- **Conventional mean radius**: Is available for precipitates and grains. The result can be split into individual populations, and sectioned to approximate the 2D size distribution. See Microstructure Descriptions.
- **Critical radius**: Spherical radius of critical nuclei for a specific phase and nucleation type. If the matrix phase is selected, it outputs critical grain radius.
- **Matrix composition**: Instantaneous compositions of the matrix phase.
- **Mean cubic factor**: Average cubic factor of cuboid particles. Available only when cuboid is selected as the **Morphology**.
- **Mean radius**: Spherical radius of average volume of all particles for a specific phase and nucleation type, regardless of their actual shapes. If the matrix phase is selected, it outputs the average grain radius.

- **Normalized driving force**: Instantaneous nucleation driving force per unit mole of elements for a specific phase and nucleation type. It is normalized with RT and therefore, dimensionless.
- **Normalized Number density distribution**: Retrieve the number density (number of particles per unit volume) of precipitates, or grains if the matrix phase is selected, normalized by total number of particles or grains per unit volume, distributed in different particle sizes normalized by average size.
- **Nucleation rate**: Instantaneous number of nuclei per unit volume per unit time for a specific phase and nucleation type.
- **Number density**: Instantaneous number of particles per unit volume for a specific phase and nucleation type. If the matrix phase is selected, it outputs instantaneous number of grains per unit volume.
- **Number density distribution**: Retrieve the number density (number of particles per unit volume) of precipitates, or grains if the matrix phase is selected, distributed in different particle sizes.
- **Precipitate composition**: To track the instantaneous composition of precipitate particles. In particular, it is useful to distinguish different composition sets of the same phase (for example, FCC_A1#2 and FCC_A1#3). Further choose **Solutes** or **All**.
- **Size distribution**: Number of particles, or grains if the matrix phase is selected, varying with their sizes per unit volume per unit length, for a specific phase and nucleation type, at a specific time.
- **Temperature**
- **Volume fraction**: Instantaneous volume fraction for a specific phase and nucleation type.
- **Yield strength**: To use the Yield Strength Property Model to calculate yield stress. For more information see About the Yield Strength Property Model.

The following settings area available as indicated when **Needle**, **Plate**, or **Cuboid** are selected as the **Morphology** in the *Precipitate Phase* section on the Precipitation Calculator.

- **Cubic factor distribution**: Variation of cubic factor with particle size at a specific time. Available with a cuboid morphology.
- **Mean aspect ratio**: Average aspect ratio of non-spherical particles. Available with a needle or plate morphology. Note that this is always larger than 1, where 1 = a sphere.
- **Mean particle length**: Diameter of non-spherical particles along the longer axis. Available with a needle or plate morphology.
- **Aspect ratio distribution**: Variation of aspect ratio with particle size at a specific time. Available with a needle or plate morphology.

General Configuration Settings

Legend Option

Select whether the diagram's legend displays **On** or **Off**.

Axis Type

Select the type of axis scale: **Linear**, **Logarithmic**, **Logarithmic 10**, or **Inverse**.

Unit (Time X-axis)

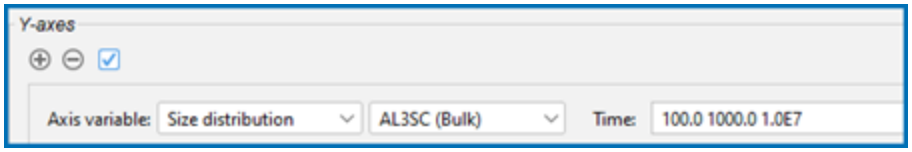
Choose a **Unit**: **Seconds**, **Hours**, or **Days**.

Time (y-axes)

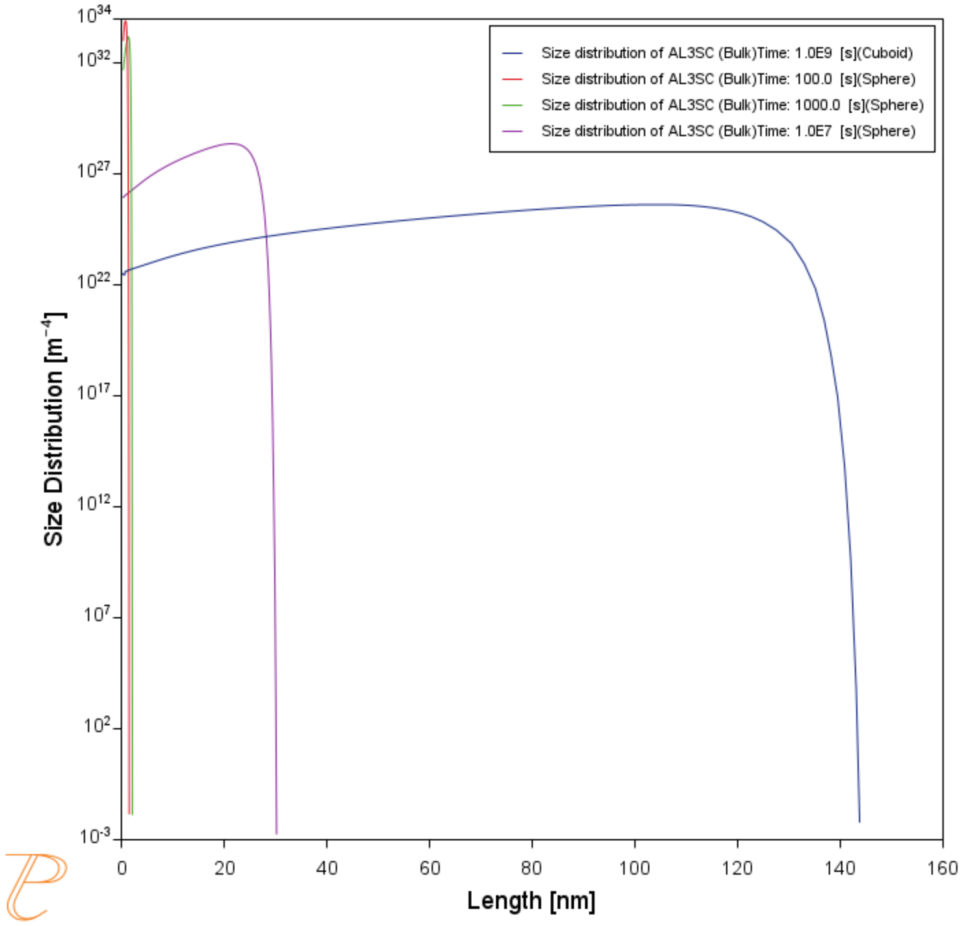
This field is available when **Size distribution** or **Number density distribution** is selected as the Y-axes variable. Enter one or a series of numbers in the field, separated by a space.

P_09: Precipitation of Al-Sc AL3SC with Assumption of Sphere and Cuboid Morphologies

If you open the example P_09, then change the **Time** settings on the **PSD** Plot Renderer to be `100.0 1000.0 1.0E7`:



When you click **Perform** the series of times are plotted:



Limits

Specify the range along the axis to show in the plot. In the fields, enter the minimum and maximum values of the axis variable. You can also determine the **step** size between the tick marks along each axis.

Select the **Automatic scaling** checkbox to allow the program to set the limits.

Y- and X-axes Variables

Set the state variable you want plotted along the X-axis and the Y-axis. The available variables in the list are based on how your system is set up.

Below are additional details related to the axis variable chosen.

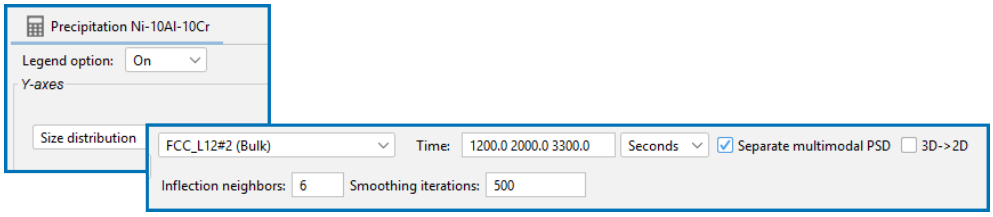
- **Separate Multimodal PSD:** If you select **Mean radius**, **Number density**, **Volume fraction**, **Size distribution**, **Number density distribution**, or **Normalized number density distribution** then the **Separate multimodal PSD** checkbox is available. For variables with time for the X-axis, the number of **Points** used to sample the results can be modified. The **Inflection neighbors** and **Smoothing iterations** are used to identify individual particle populations. See Separate Multimodal PSD below for more detail.
- **3D → 2D:** For a spherical morphology, and if you select **Mean radius**, **Number density**, **Volume fraction**, **Size distribution**, **Number density distribution**, or **Normalized number density distribution** as an axis variable, you can also select the **3D → 2D** checkbox to convert the 3D property to the corresponding 2D property considering the resulting 2D size distribution obtained from sectioning a 3D spherical dispersion. See 3D to 2D Conversion below for more detail.
- **Yield Strength**: If you select this as an axis variable there are additional settings. See Yield Strength Additional Settings below for more detail.

Separate Multimodal PSD

The **Separate Multimodal PSD setting** is available if you select **Mean radius**, **Number density**, **Volume fraction**, or **Size distribution** as the *Axis Variable*.

When the **Separate multimodal PSD** checkbox is selected on a **Plot Renderer** activity for the **Precipitation Calculator**, the size distribution is evaluated at the given time steps and results for individual particle populations are identified and presented. These are separated and used to calculate the specified property.

P_06: Precipitation of γ' in Ni Superalloys - Non-isothermal



Points

This field is available when the **Separate multimodal PSD** checkbox is selected. It is not available with the **Size distribution** variable.

Since the evaluation of multimodality at each time step is costly, you can specify how many evaluation **Points** to use. The points are geometrically distributed over the time scale where nucleated particles are found. The default is 40 points.

Inflection Neighbors

This field is available when the **Separate multimodal PSD** checkbox is selected.

Enter the **Inflection neighbors**, which are the number of neighboring points with consistent gradient direction to identify inflection points. The default is 6. As a guide, too low a number is sensitive to noise and too high a number can fail to detect particle populations.

Smoothing Iterations

This field is available when the **Separate multimodal PSD** checkbox is selected.

Enter the number of **Smoothing iterations** performed to reveal significant particle populations. The default is 500. As a guide, too small a number can fail to remove noise, and too high a number can remove the particle populations of interest.

3D to 2D Conversion

When the *Precipitate Phase* **Morphology** is set to **Sphere** on the Precipitation Calculator, the following options are available when certain axis variables are also selected.

Select the **3D → 2D** checkbox if you want to make a direct comparison between the predicted three-dimensional (3D) radius of the precipitates and the two-dimensional (2D) data obtained from a cross-section taken through the dispersion.

The stereological conversion is described in the theory for spherical particles. See Stereology.

These variables can be converted to 2D:

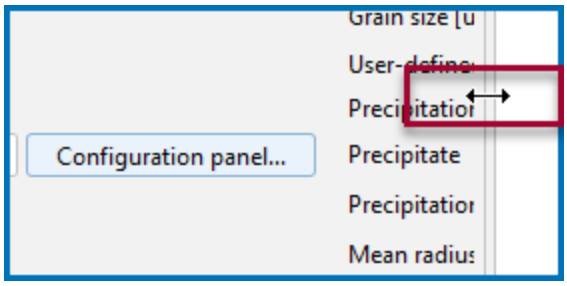
- **Mean radius**: The average circular radius of cross sections of particles obtained by taking a section through the dispersion, assuming spherical precipitates.
- **Number density** The number concentration of precipitates found on a 1 m^2 cross-section through the microstructure.
- **Volume fraction** The area fraction of precipitates found on a cross-section taken through the microstructure.
- **Size distribution**: The number density of particle cross sections that have a radius varying within a given size class in a unit area.
- **Number density distribution**: The number of particle cross sections that have a radius varying within a given size class in a unit area.
- **Normalized number density distribution**: The probability of finding particle cross sections with a cross sectional radius varying within the size class. The radius is normalized by the volumetric mean of the dispersion.

Yield Strength Additional Settings

If you choose **Yield strength** as an *Axis variable*, you can further define the model. Click to expand the drop down list to the right of the *Axis variable*, then select any or all of the checkboxes listed below to plot the respective contributing elements to the yield strength.

Click **Configuration Panel** toggle between the settings options and to further fine-tune the model. These options are described for the Yield Strength: Simplified Mode Settings and Yield Strength: Advanced Mode Settings. The greyed out sections (e.g. the **Matrix**, **Precipitate** phases, and **Grain size**) are defined on the **Precipitation Calculator** and cannot be changed.

To see these settings after clicking **Configuration Panel**, you need to expand the **Plot Renderer Configuration** window to the right. Either detach the window to resize, or hover with the mouse until you see the double arrow, then click and drag to expand the window.



- Total yield strength
- Intrinsic strength
- Solid solution strengthening
- Solid solution strengthening FCC
- Solid solution strengthening BCC
- Solid solution strengthening HCP
- Grain boundary strengthening
- Total precipitation strengthening
- Precipitation strengthening per phase
- Constant strength addition

The **P_01: Isothermal Precipitation of Al3Sc** example demonstrates the use of this Yield Strength Model.

Precipitation Calculator Thermal Profile

The **Thermal Profile** is set up on the **Configuration** window for a . The isothermal or non-isothermal profile is viewed in the **Visualizations** window. Choose **Isothermal** to do a simulation at constant temperature. Choose **Non-isothermal** to enter or import data for a user-defined temperature profile.

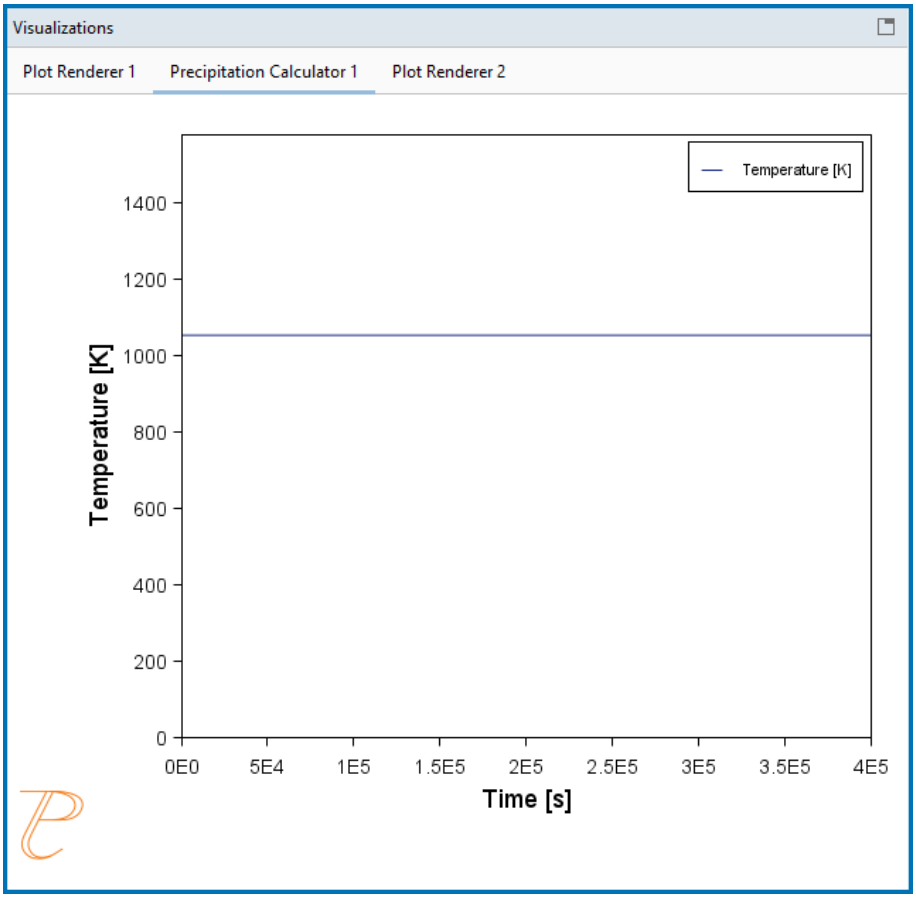
When connected to an **AM Calculator** (see Including Probe Data from an AM Calculator) the **Isothermal** and **Non-isothermal** options are not visible as it is not relevant to that view.

Isothermal Calculations

Many of the Graphical Mode examples for this Add-on Module are isothermal calculations, e.g. *P_02_Precipitation_Fe-C-Cr_Cementite-M7C3-M23C6*.

1. On the Precipitation Calculator **Configuration** window, first enter the required *Matrix Phase* and *Precipitate Phase* settings.
2. Under **Calculation Type**, click to choose **Isothermal** to do a simulation at constant temperature.
3. Enter a **Temperature** and choose a unit (**Kelvin**, **Celsius**, or **Fahrenheit**).
4. Enter an **End time** and choose a unit: **Seconds**, **Minutes**, **Hours**, or **Days**. The *Simulation time* is displayed as text.

   The profile is displayed on the **Precipitation Calculator** tab in the **Visualizations** window showing the constant temperature entered.



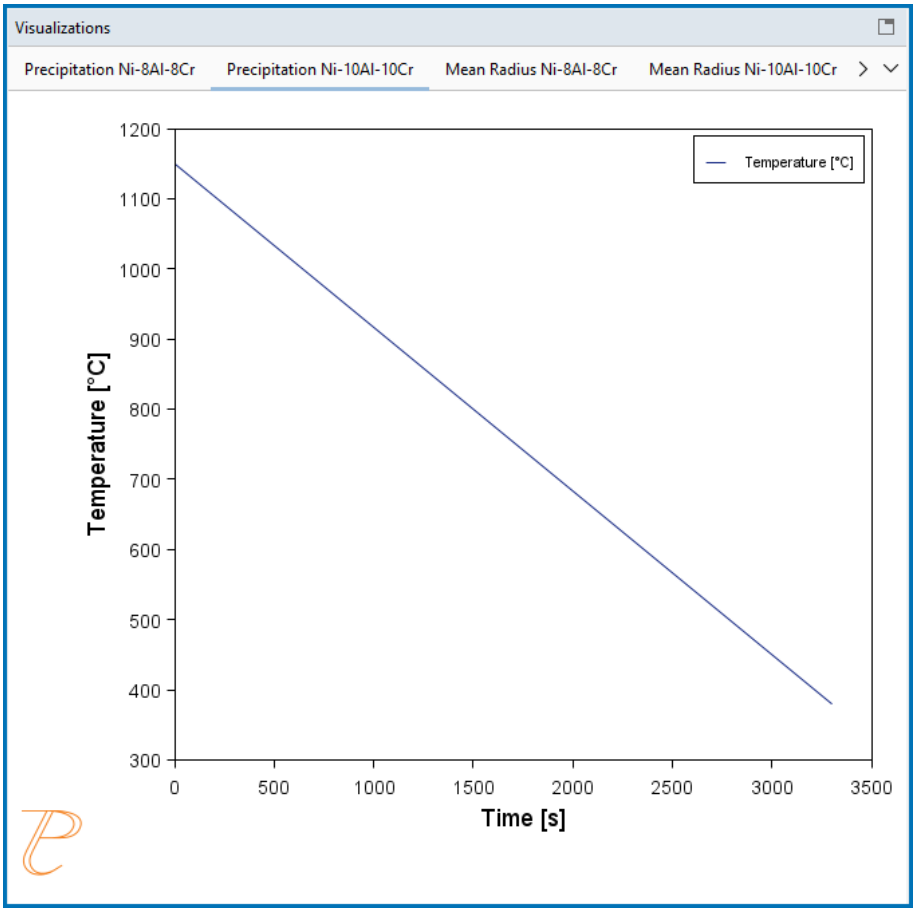
5. For this calculation type this completes the settings you need to enter for the Thermal Profile.

Non-isothermal Calculations

1. On the Precipitation Calculator **Configuration** window, first enter the required *Matrix Phase* and *Precipitate Phase* settings.
2. Under **Calculation Type**, click to choose **Non-isothermal** to enter or import data for a user-defined temperature profile.
3. Select a **Temperature unit**: **Kelvin**, **Celsius**, or **Fahrenheit**.
4. Enter an **End time** and choose a unit: **Seconds**, **Minutes**, **Hours**, or **Days**. The *Simulation time* is displayed as text.

   You can next either directly enter **Time** and **Temperature** coordinates into the table or import the information from a file. A minimum of two points is required.

5. To enter directly into the table:
    a. Click in each cell under the applicable columns, **Time** and **Temperature** then directly enter the values in the table.
    b. Press <Enter> to add rows and use the scroll bars to navigate the table.
6. To import a data file:
    a. Although it is a simple set of data, prepare the data file as in Guidelines for Importing Data Files to Thermal Profiles.
    b. When the data file is ready, to the right of the **Import from file** field, click the file button.
    c. Navigate to a data file such as an MS Excel spreadsheet (with ***.xls** or ***.xlsx** extensions) or a ***.csv** file. You can also use other programs (e.g. Google Sheets) to enter data and export to a CSV format that can be read by the software. Click **Open** to import the data to the **Configuration** window table.
    d. If there are issues with the above import, experiment with choosing the delimiter type that corresponds to the data in the file: **Comma** (,), **Colon** (:), **Equals sign** (=), **Semicolon** (;), or **Tab**. Click the **Reload** button. The data is imported to the **Configuration** window table.
7. For this calculation type this completes the settings you need to enter for the profile, which is displayed on the **Precipitation Calculator** tab in the **Visualizations** window. Make adjustments to the settings as needed and watch it dynamically change in the window.



This is from the non-isothermal calculation example, *P_06_Precipitation_Ni-Al-Cr_Non-isothermal_Gamma-Gamma_prime*.

Including Probe Data from an AM Calculator

When you also have a license for the Additive Manufacturing (AM) Module you can include probe data from the AM Calculator in the set up of the thermal profile.

There is connectivity between the Diffusion Module (DICTRA) or the Precipitation Module (TC-PRISMA) and the Additive Manufacturing (AM) Module when you have full licenses available for all relevant Add-on Modules and databases.

You can add a Diffusion Calculator or Precipitation Calculator as a successor to the AM Calculator and then when probes are included with the AM Calculator this data can be further used with the thermal profile.

Details are in the AM Module documentation. See AM Calculator: Working with Probe Data.

Guidelines for Importing Data Files to Thermal Profiles

The **Thermal Profile** settings are done on the **Configuration** window for a Precipitation Calculator. The profile is then previewed in the **Visualizations** window.

You can import data from a file. There are specific guidelines needed to correctly prepare the data in this file to ensure it imports without errors.

Data File Requirements

For a Thermal Profile you can either directly enter **Time** and **Temperature** coordinates into the table on the **Configuration** window, or import the data from a file. A minimum of two points is required.

Although there are only two columns to define, it is still important to ensure the file is set up correctly. In order for the data to be included in the calculation, the column and row definitions in the file must adhere to certain rules of entry.

General Rules

- No abbreviations are allowed in the header.
- A header is not actually required in this file but in order to know which column is which, it is recommended to include it.
- All header text must be in English, i.e. no translations into other languages will be read correctly by the data file.

Only the columns described here are read / used in the calculation. It is important to enter the information exactly as described. It is recommended that the data file is cleaned up before importing / loading it and performing calculations.

	A	B
1	Time	Temperature
2	0	1173
3	773	1050
4	1000	1075
5	1500	2000

Figure 22: This is an example of data entered into an Excel spreadsheet (which is then converted to csv format). Columns A and B show the data entered to create the Thermal Profile.

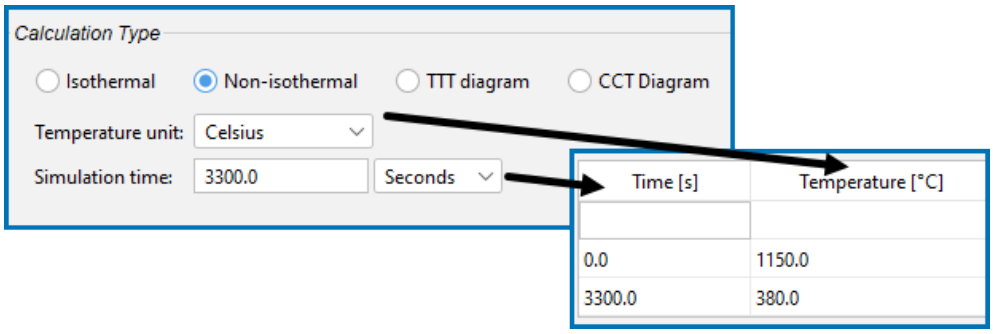


Figure 23: The units shown on the Configuration window for the Time and Temperature correspond to settings that can ONLY be selected on the Configuration window. The data file does not contain any information about the units.

Column and Row Requirements

Column Heading Requirements and Options	*Row Cell Requirements and Options*
Time This is column A as in Figure 22 Enter the text `Time`. No abbreviations allowed but it is not case sensitive. It is also not required but recommended to include so you know which column of data it applies to.	Valid format and entries for each row in this column: • Any numerical input for the time that corresponds to the unit selected on the Configuration window e.g. `0.0`, `773`, `1000`, `1500`, are times in seconds, which is the unit chosen in the example shown in Figure 23.
Temperature This is column B as in Figure 22 Enter the text `Temperature`. No abbreviations allowed but it is not case sensitive. It is also not required but recommended to include so you know which column of data it applies to.	Valid format and entries for each row in these columns: • Any numerical input for the temperature that corresponds to the unit selected on the Configuration window e.g. `1173`, `1050`, `1075`, are temperatures in Celsius, which is the unit chosen in the example shown in Figure 23

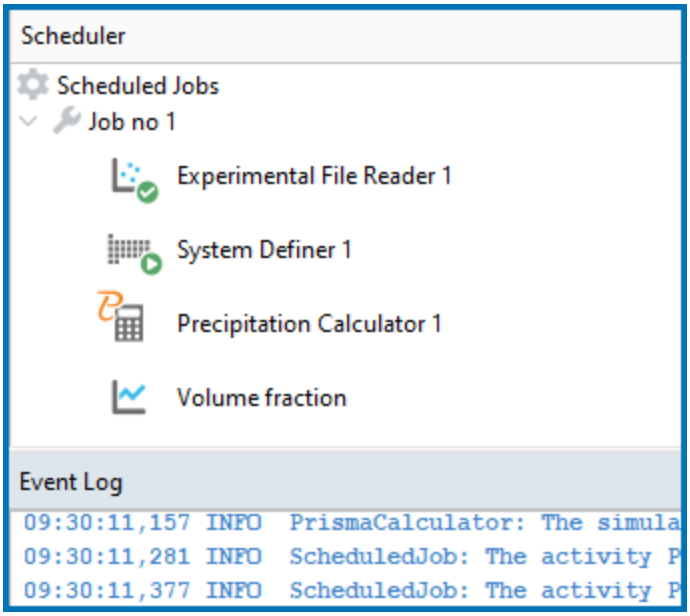
Pause, Resume, and Cancel Precipitation Calculations

Precipitation calculations are often complex simulations that take some time to complete. Sometimes you may want or need to pause or resume a calculation, or make adjustments to your compositions and start again. You pause and resume from the Precipitation Calculator **Configuration** window.

This is also available for the **Diffusion Calculator** (but not any other calculators). See Pause, Resume, and Cancel Diffusion Calculations.

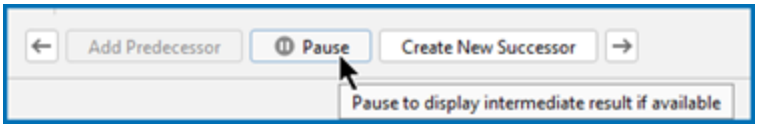
Pausing and Resuming a Job

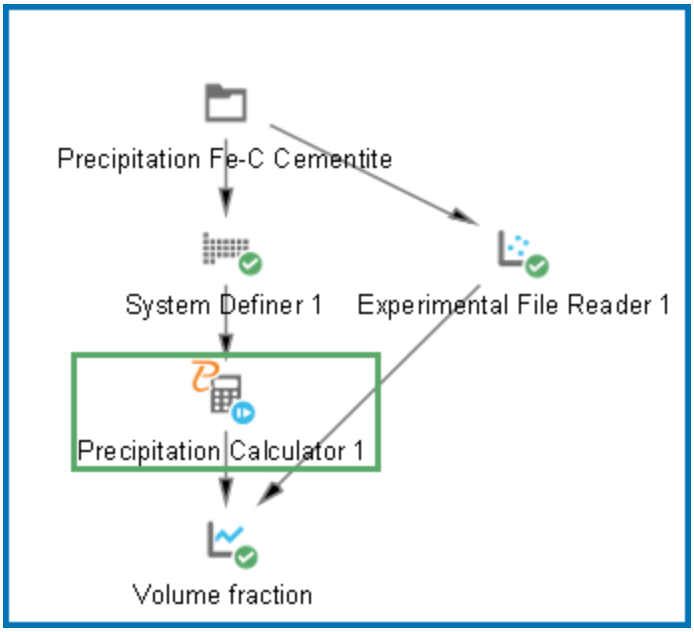
1. Run the job (i.e. click **Perform Tree**). In the **Scheduler**, you can see the job listed and in the **Event Log** you can follow the progress of the calculation.



2. In the **Project** window, click the **Precipitation Calculator** node.

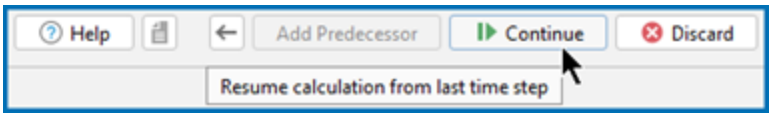
3. In the **Configuration** window at the bottom, click **Pause**. Observe that the **Precipitation Calculator** in the **Project** window has a pause indicator. If there are intermediate results available these will be listed in the **Event Log**.





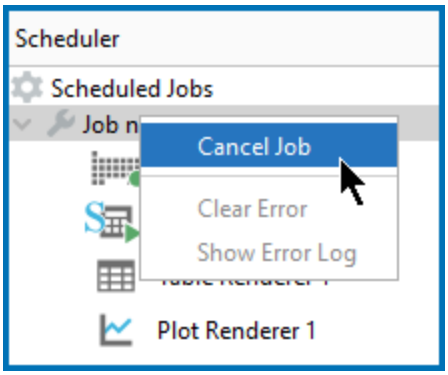
4. When pausing the calculation, you can make changes to a variety of settings under the *Matrix Phase* or *Precipitate Phase* sections (click **Show Details**), plus the **Interfacial energy**, **Temperature** (for non-isothermal calculations), and **Simulation time**. The rest of the **Configuration** window settings are grayed out and no other editing can be done while paused.

5. When ready, click **Continue** to resume your calculations from the last time step or click **Discard** to discard the calculation (then click **Yes** or **No** on the window that opens).



Cancelling a Job

- In the **Scheduler** window, right-click the job you want to cancel and select **Cancel Job**.



Precipitation Module (TC-PRISMA) Examples Collection

Examples that use up to three elements are available to all users. Other examples require a Precipitation Module (TC-PRISMA) license to calculate and plot results.

When an example uses a demonstration (demo) database package, this is included with your installation.

Unless specified in tables for each example, all the numerical parameters are assumed default values.

P_01: Isothermal Precipitation of Al_3Sc

This example simulates the kinetics of precipitation of Al_3Sc from an FCC_A1 solution phase. The simulation results can be compared with experimental data collected from Marquis and Seidman [2001Mar] and Novotny and Ardell [2001Nov].

This example also includes a plot using the **Yield strength** Property Model. This demonstrates how you can use the results from a Precipitation Module (TC-PRISMA) simulation as input to the Yield Strength Model, i.e. the calculated precipitate radius/radii for each time step is used to calculate the precipitation strengthening, and similarly, the matrix composition for each time step is used to calculate the solid solution strengthening when this is selected in the **Configuration** on the Plot Renderer. The experimental data for the Yield Strength Model is from Seidman et al. [2002Sei]. In this example, the *Precipitation strengthening model* used is **Seidman model (Al-base)**. This is selected on the Plot Renderer configuration panel that is connected to the Property Model.

Project File and Step-By Step Instructions

- Folder: **Precipitation Module - TC-PRISMA**
- File name: `P_01_Precipitation_Al-Sc_AL3SC.tcus`

Example Settings

System (System Definer)	
Database package	Demo: Aluminum-based alloys (ALDEMO, MALDEMO)
Elements	Al, Sc
Conditions (Precipitation Calculator)	
Composition	Al-0.18Sc Mole percent
Matrix phase	FCC_A1

Precipitate phase	AL3SC
Precipitate Phase Data Parameters (Precipitation Calculator)	
Nucleation sites	Bulk
Interfacial energy	Calculated
Calculation Type (Precipitation Calculator)	
Calculation type	Isothermal
Temperature	350° C
Simulation time	1.0E7 seconds
Experimental File Reader 1 and 2	
There are two Experimental File Reader nodes used. One for the mean radius plot and one to demonstrate the *Yield Strength Property Model*.	

Visualizations

This example is included as a Precipitation Module (TC-PRISMA) tutorial on our website and as part of the playlist on our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Thermal Profile**: When setting up a calculator on a **Configuration** window for **Isothermal** or **Non-isothermal** *Calculation Types*, you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.

For **TTT Diagram** and **CCT Diagram** calculations there is nothing shown for the Precipitation Calculator tab in the **Visualizations** window as there is no Thermal Profile to be defined.

- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

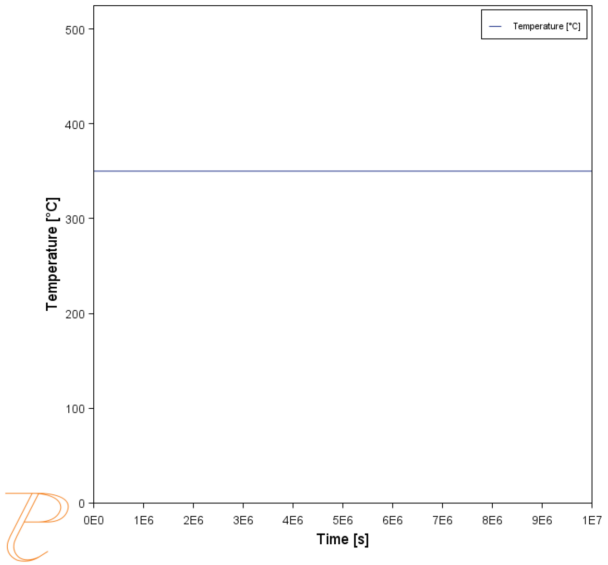

Figure 1: During set up of the calculation, preview the Thermal Profile. Click the tab in the Visualizations window to preview it. For an Isothermal Thermal Profile this shows the constant temperature as entered.

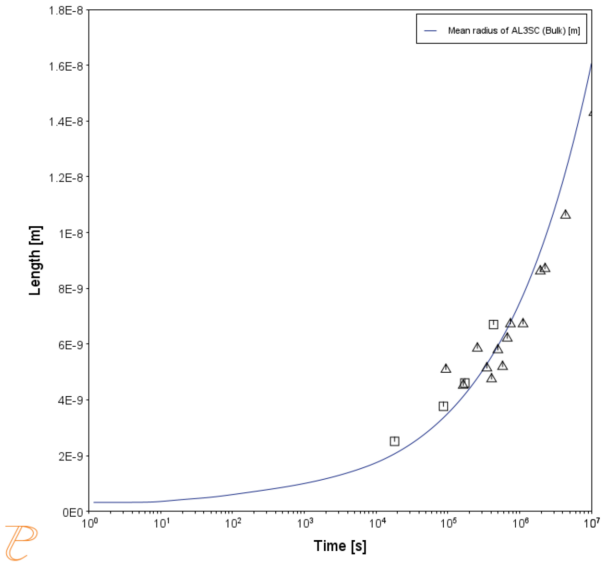

Figure 2: After performing the calculation, you can view the result on the applicable tab. This plot shows the mean radius of the AL3SC precipitate as a function of time.

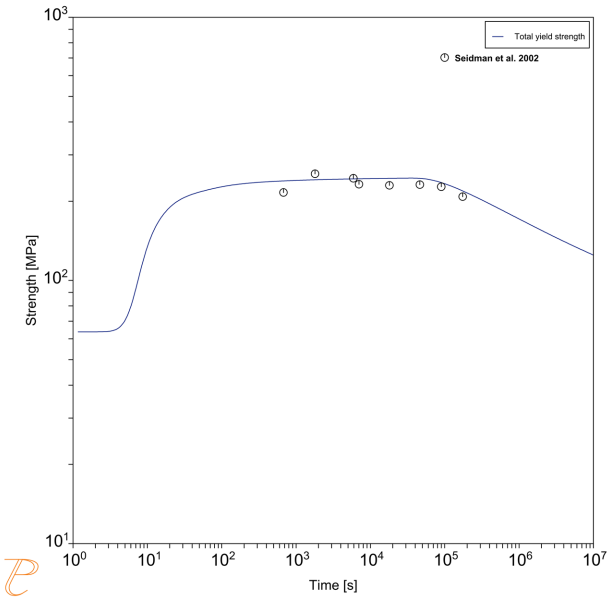

Figure 3: After performing the calculation, you can view the result on the applicable tab. This plot shows the total yield strength of the AL3SC precipitate as a function of time compared to experimental data from Siedmen et al. [2002Sei]. The model captures the over-tempering behavior from excessive coarsening of the strengthening precipitates.

About the Yield Strength Property Model

P_02: Stable and Metastable Carbides - Isothermal

This example simulates the kinetics of precipitation of both stable and metastable carbides from ferrite phase. It demonstrates that metastable carbides (cementite, M7C3) may first emerge and then disappear and the stable phase (M23C6) prevails.

This example uses the Equilibrium Calculator and a one axis calculation to determine how the phases change with temperature. We are interested in the carbide precipitation at 1053 K where only the carbide M23C6 is stable according to the equilibrium calculation. The Precipitation Calculator is used to do an isothermal calculation of the three phases (cementite, M23C6, and M7C3) where cementite and M7C3 are metastable phases.

Project File Information

- Folder: **Precipitation Module - TC-PRISMA**
- File name: `P_02_Precipitation_Fe-C-Cr_Cementite-M7C3-M23C6.tcu`

Example Settings

System (System Definer)	
Database package	Demo: Steels and Fe-alloys (FEDEMO and MFEDEMO)
Elements	Fe, C, Cr
Conditions (Precipitation Calculator)	
Composition	Fe-0.1C-12Cr Mass percent
Matrix phase	BCC_A2
Precipitate phases	Cementite, M23C6 and M7C3
Matrix Phase Data Parameters (Precipitation Calculator)	
Grain size (click **Show Details** to display this setting)	1.0E-4 m
Precipitate Phase Data Parameters (Precipitation Calculator)	
Nucleation sites	Grain boundaries

Interfacial energy	Cementite 0.167 J/m^2, M23C6 0.252 J/m^2, M7C3 0.282 J/m^2
Calculation Type (Precipitation Calculator)	
Calculation type	Isothermal
Temperature	1053 K
Simulation time	400 000 seconds

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Thermal Profile**: When setting up a calculator on a **Configuration** window for **Isothermal** or **Non-isothermal** *Calculation Types*, you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.

For **TTT Diagram** and **CCT Diagram** calculations there is nothing shown for the Precipitation Calculator tab in the **Visualizations** window as there is no Thermal Profile to be defined.

- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

For this **Isothermal** example, its **Thermal Profile** is also displayed in the **Visualizations** window showing the constant temperature entered for this calculation type. The tab names match the node names in the **Project** window.

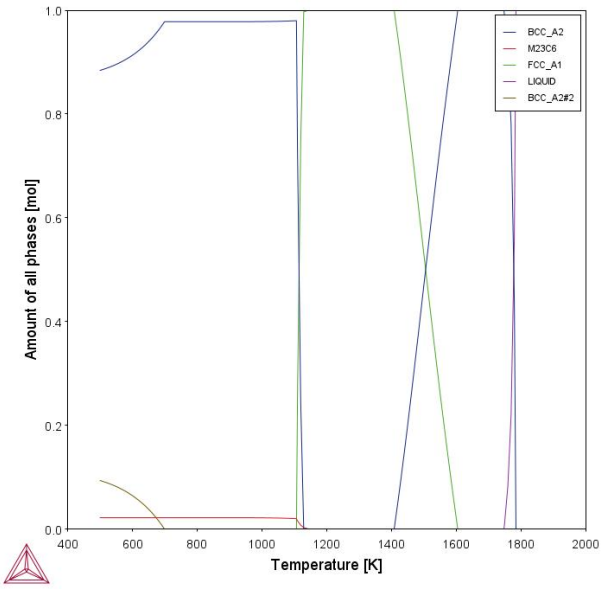

Figure 4: After performing the calculation, you can view the result on the applicable tab. This shows the equilibrium property diagram for the Fe-C-Cr alloy, highlighting what phases are predicted to be at equilibrium for a range of temperatures. The calculation shows that at 1053 K, M23C6 is the stable carbide.

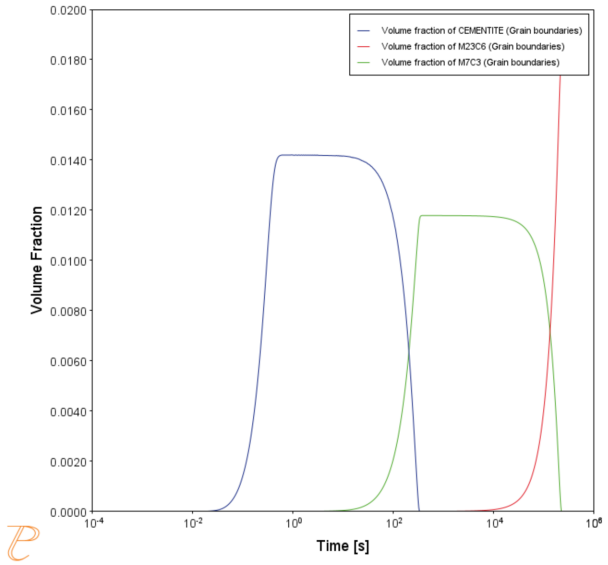

Figure 5: After performing the calculation, you can view the result on the applicable tab. This shows the evolution of the volume fraction of cementite, M7C3, and M23C6 during an isothermal heat treatment of an Fe-C-Cr alloy at 1073 K. The cementite and M7C3 are metastable at this temperature, however their nucleation kinetics are faster than the stable phase, allowing them to form and then dissolve when the next more thermodynamically stable phase nucleates.

P_03: Stable and Metastable Carbides - TTT Diagram

In this example, the kinetics of precipitation of both stable and metastable carbides is calculated from the ferrite phase. It demonstrates that metastable carbides may first emerge and then disappear and the stable phase prevails.

This example uses the Equilibrium Calculator and a one axis calculation type to determine how the phases change with temperature. Using this result, the Precipitation Calculator is used to do a TTT (Time-Temperature-Transformation) diagram calculation of the three phases (cementite, M23C6 and M7C3) at the grain boundaries.

For a TTT diagram calculation, select **TTT diagram** in **Calculation Type**, then enter **Min**, **Max**, and **Step** of **Temperature**, as well as **Max annealing time**. In **Stop criterion**, choose **Volume fraction of phase** and enter the value.

Example Settings

System (System Definer)	
Database package	Demo: Steels and Fe-alloys (FEDEMO and MFEDEMO)
Elements	Fe, C, Cr
Conditions (Precipitation Calculator)	
Composition	Fe-0.1C-12Cr Mass percent
Matrix phase	BCC_A2

Precipitate phases	Cementite, M23C6 and M7C3
Matrix Phase Data Parameters (Precipitation Calculator)	
Grain size (click **Show Details** to display this setting)	1.0E-4 m
Precipitate Phase Data Parameters	
Nucleation sites	Grain boundaries
Interfacial energy	Cementite 0.167 J/m^2, M23C6 0.252 J/m^2, M7C3 0.282 J/m^2
Calculation Type (Precipitation Calculator)	
Calculation type	TTT diagram
Temperature	500° to 800° C with 25° C steps
Max. annealing time	1.0E8 seconds
Stop criteria	Volume fraction of phase is set to 0.0001
Options > Numerical Parameters	
No. of grid points over one order of magnitude in radius	150
Max no. of grid points over one order of magnitude in radius	200
Min no. of grid points over one order of magnitude in radius	100

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Thermal Profile**: When setting up a calculator on a **Configuration** window for **Isothermal** or **Non-isothermal** *Calculation Types*, you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.

  For **TTT Diagram** and **CCT Diagram** calculations there is nothing shown for the Precipitation Calculator tab in the **Visualizations** window as there is no Thermal Profile to be defined.

- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

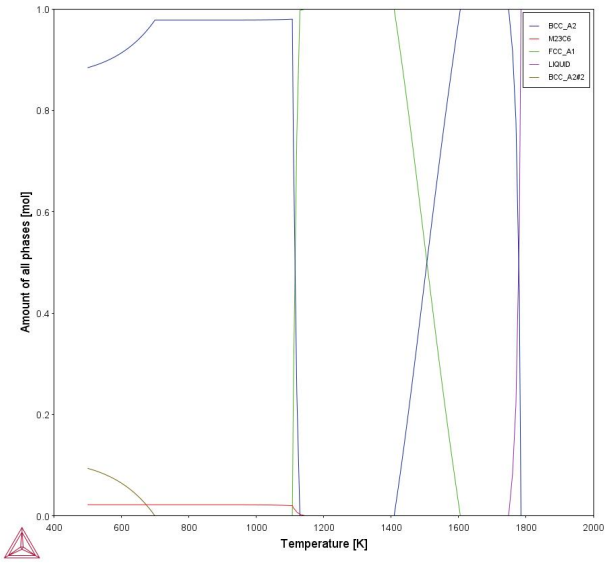

Figure 6: After performing the calculation, you can view the result on the applicable tab. Here the results from the equilibrium calculator are shown, which assesses the stability of phases across the temperature range of interest.

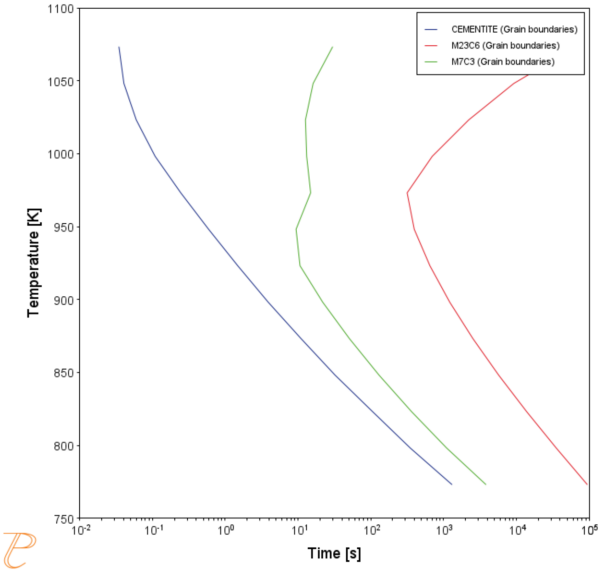

Figure 7: After performing the calculation, you can view the result on the applicable tab. This shows results from a TTT (Temperature-Transformation) simulation using the Precipitation Calculator to examine the sequence of phase transitions considering the formation of cementite, M7C3, and M23C6 carbide phases. The previous Equilibrium Calculator reveals the temperatures where the cementite and M7C3 are metastable.

P_04: Precipitation of Iron Carbon Cementite

This example is based on [1949Wer] and simulates the kinetics of precipitation of carbides from a BCC Fe solution phase. This isothermal calculation example uses the Precipitation Calculator plus two Experimental File Reader activities to plot the volume fraction of the cementite phase.

Project File Information

P_05: Precipitation of γ' in Ni Superalloys - Isothermal

This example simulates the kinetics of precipitation of gamma prime (γ') phase from gamma (γ) phase. The simulation results can be compared with experimental data collected from Sudbrack et al. [2008Sud].

This example uses three Experimental File Reader activities with the Precipitation Calculator. It does an isothermal calculation to plot the volume fraction, mean radius, and number density of the cementite phase.

DIS_FCC_A1 needs to be selected on the System Definer. See Selecting the Disordered Phase as a Matrix Phase for details.

P_07: Continuous Cooling Transformation (CCT) Diagram of Ni-Al-Cr γ-γ'

This example shows you how to simulate a CCT (Continuous Cooling Transformation) diagram for gamma prime (γ') precipitation in a Ni-Cr-Al alloy using the Precipitation Calculator. A CCT calculation maintains the same cooling rate the entire time.

The system is a Ni-10Al-10Cr γ - γ' alloy and it is calculated and plotted with superimposition of the cooling rate values.

3851.40185	1161.48826

Figure 18: An example of the table shown in the Visualizations window, which shows the same information as in the plot - for each cooling rate the temperature and the time it takes for γ' to transform according to the stop criteria, which is a volume fraction of 1e-4.

P_08: Precipitation of Cu-Ti CU4TI with Assumptions of Sphere and Needle Morphologies

In this isothermal calculation example, the precipitation of Cu4Ti phase in a Cu-Ti binary alloy is calculated. To make a comparison, two separate simulations are performed, one assuming spherical morphology without elastic strain energy, and the other assuming needle morphology whose shape, determined by competition between interfacial energy and elastic strain energy, is changed during the simulation. The transformation strain is obtained from Borchers [1999Bor]. The results are compared with experiment results from Kampmann et al. [1987Kam].

P_09: Precipitation of Al-Sc AL3SC with Assumption of Sphere and Cuboid Morphologies

In this isothermal calculation example, the precipitation of Al_3Sc phase from FCC_A1 matrix phase in an Al-Sc binary alloy is simulated. To make a comparison, two separate calculations are performed, one assuming spherical morphology without elastic strain energy, and the other assuming cuboid morphology whose shape is determined by competition between interfacial energy and elastic strain energy. The simulation results are compared with experimental data collected from Marquis and Seidman [2001Mar] and Novotny and Ardell [2001Nov]. In addition, mean cubic factor and cubic factor distribution are also plotted for cuboid shape to illustrate the spherical-cuboidal transition during precipitation.

Project File and Step-By Step Instructions

- Folder: **Precipitation Module - TC-PRISMA**
- File name: `P_09_Precipitation_Al-Sc_AL3SC_Sphere_Cuboid.tcu`

Example Settings

To ensure that the settings are done on the correct Precipitation Calculators, the **Sphere** and **Cuboid** nodes are renamed from **Precipitation Calculator** to match their morphology. The morphology is set in the **Precipitate Phase** section when you click **Show Details**. See P_08 for an example of this.

System (System Definer)	
Database package	Demo: Aluminum-based alloys (ALDEMO and MALDEMO)

P_10: Initial Particle Size Distribution of Fe-Cr-C

This example demonstrates the effect of initial particle size distribution (PSD) of the precipitate phases on the overall precipitation kinetics. It uses two Precipitation Calculators to simulate and compare carbide precipitations from a ferritic BCC_A2 matrix in a Fe-0.1C-12Cr alloy. Three carbides, CEMENTITE, M23C7, and M7C3 are included in the calculations simulating a complex precipitation sequence with stable and meta-stable precipitate phases. The results show a large difference in predicted behaviour, with meta-stable precipitates dissolving earlier as a result of the stable precipitates existing in the initial condition.

This example also shows the different ways to create the initial size distribution.

- **Generate 3D PSD from distribution function**: CEMENTITE's PSD is approximated from an LSW distribution.
- **From File**: M23C6's PSD is loaded from a file.
- **Approximate the 3D PSD from experimental data**: M7C3's PSD is approximated from 1D experimental data descriptive of halved linear intercepts.

Project File Information

- Folder: **Precipitation Module - TC-PRISMA**
- File name: `P_10_Precipitation_Initial_PSD_FeCrC.tcu`

There are also two *.csv files available for you to use as a template for when you are importing data from a file.

- Input data for M23C6: `P_10_Precipitation_Initial_PSD_FeCrC_psd_3D_M23C6.csv`
- Input data for M7C3: `P_10_Precipitation_Initial_PSD_FeCrC_psd_1D_M7C3.csv`

Preexisting Particle Size Distribution

The **Preexisting Particle Size Distribution** window shown in Figure 27 is a graphical representation of the radius versus corresponding number densities, with fields available to enter the initial precipitate composition and volume fraction. An editable table is also provided for the particle size distribution.

Particle Size Distribution (PSD)

Cementite

The amount of Fe and Cr must be defined for Cementite for this alloy. Fe is set to the dependent component, and 72 mass percent of Cr is set. The option **Generate 3D PSD from distribution function** is chosen to create the PSD for Cementite. The initial volume fraction of 0.001 % is assumed. An LSW distribution is selected with a mean radius of 1E-8m.

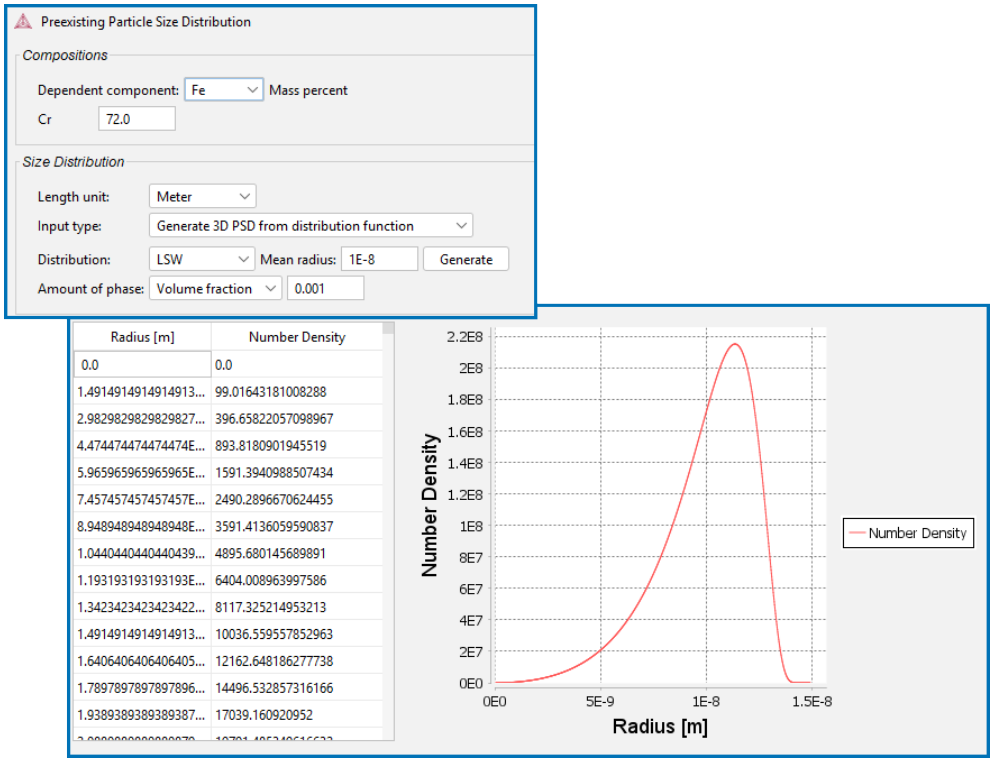

Figure 27: An LSW distribution with a mean radius of 1E-8m is used.

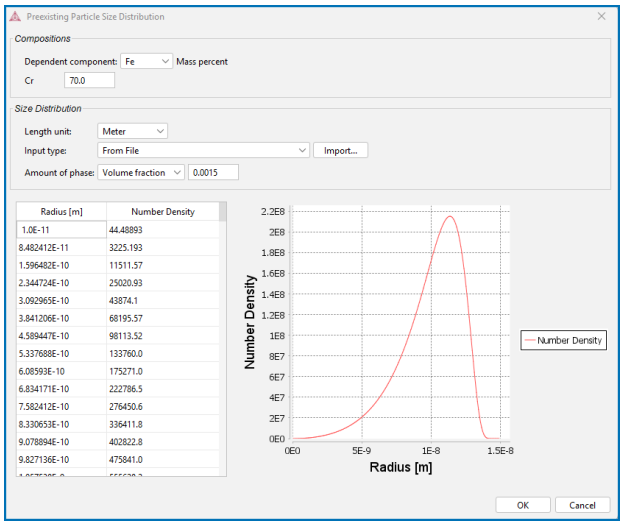
M23C6

The amount of Fe and Cr must be defined for M23C6 for this alloy. Fe is set to the dependent component, and 70 mass percent of Cr is set. The **From File** option is used to create the PSD.

The file loaded for M23C6 is available from the **Example files → Precipitation Module - TC-PRISMA** folder and is named `P_10_Precipitation_Initial_PSD_FeCrC_psd_3D_M23C6.csv`.

You can import data from a spreadsheet or text file (.xls, .xlsx, .csv, or .txt formats are acceptable). The initial volume fraction of 0.15 % is assumed.



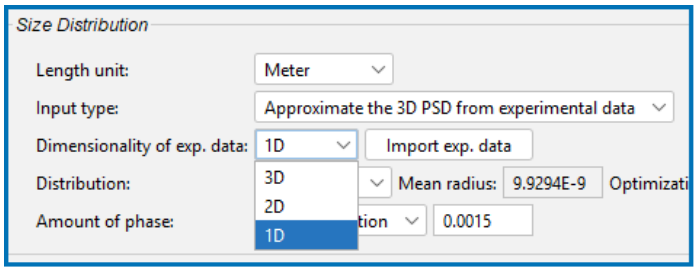
M7C3

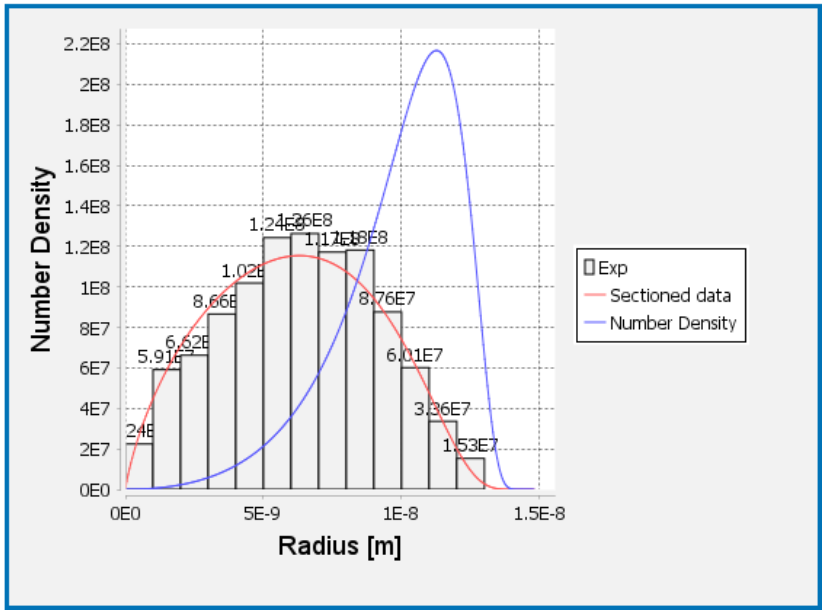
The amount of Fe and Cr must be defined for M7C3 for this alloy. Fe is set to the dependent component, and 83 mass percent of Cr is set. The Approximate the 3D PSD from experimental data option is used to create the PSD.

In this example, the linear intercept method is used to measure the size distribution of M7C3 from micrographs descriptive of sectioning the dispersion. A size distribution of halved linear intercepts is created and is available as a file you can use as a template.

The file loaded for M7C3 is available from the **Example files → Precipitation Module - TC-PRISMA** folder and is named `P_10_Precipitation_Initial_PSD_FeCrC_psd_1D_M7C3.csv`.

The **Dimensionality of the exp. data** is set to 1D. The experimental data is loaded by importing the above named *.csv file. An **LSW Distribution** is used. When you click **Generate**, it calibrates the chosen distribution and stereology description to the experimental data. The initial volume fraction of 0.15 % is assumed.





Example Settings

System (System Definer)	
Database package	Demo: Steels and Fe-alloys (FEDEMO and MFEDEMO)
Elements	Fe, C, Cr
Conditions (Precipitation Calculator)	
Composition	Fe-0.1C-12Cr Mass percent
Matrix phase	BCC_A2 All other defaults are kept.

Precipitate phases	CEMENTITE, M23C6 and M7C3
Precipitate Phase Data Parameters (Precipitation Calculator)	
Nucleation sites	Grain boundaries (all calculations): Calculated from the matrix settings with a wetting angle of 90°
Interfacial energy	User-defined function f(r,T) (all calculations): • CEMENTITE: 0.167 J/m^2 • M23C6 0.252 J/m^2 • M7C3 0.282 J/m^2
Preexisting size distribution (click **Show Details** to display this setting)	For the Precipitation Calculator including particle size distribution (PSD), and for all precipitate phases, this checkbox is selected. For each precipitate phase (CEMENTITE, M23C6 and M7C3), click **Edit Particle Size Distribution** to make changes to the parameters. A window opens with a graphical representation of the radius vs number density. **Input type** • Generate 3D PSD from distribution function - CEMENTITE uses this option in the example • From File - M23C6 uses this option in the example • Approximate the 3D PSD from experimental data - M7C3 uses this option in the example.
Calculation Type (Precipitation Calculator)	
Calculation type	Isothermal
Temperature	1053 K
Simulation time	400 000 seconds

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Thermal Profile**: When setting up a calculator on a **Configuration** window for **Isothermal** or **Non-isothermal** *Calculation Types*, you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.

  For **TTT Diagram** and **CCT Diagram** calculations there is nothing shown for the Precipitation Calculator tab in the **Visualizations** window as there is no Thermal Profile to be defined.

- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

For this **Isothermal** example, its **Thermal Profile** is also displayed in the **Visualizations** window showing the constant temperature entered for this calculation type. The tab names match the node names in the **Project** window.

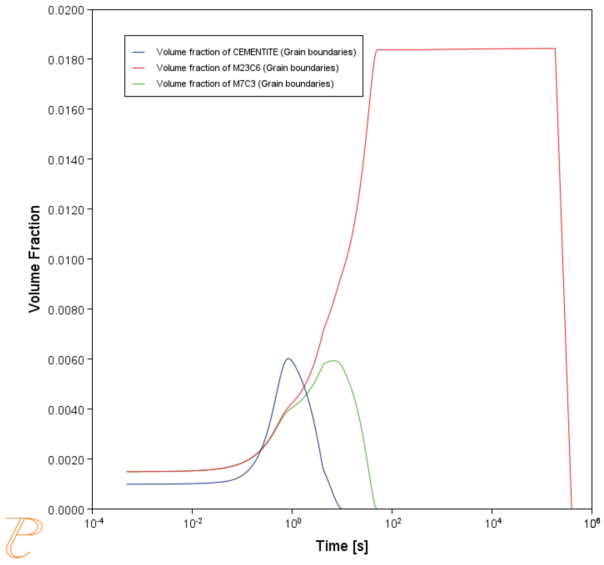


Figure 28: These results show the predicted volume fraction of cementite, M23C6, and M7C3 during an isothermal aging with an initial particle size distribution of each precipitate phase. The predicted kinetics are sensitive to the initial size, volume fraction, and composition of these precipitates.

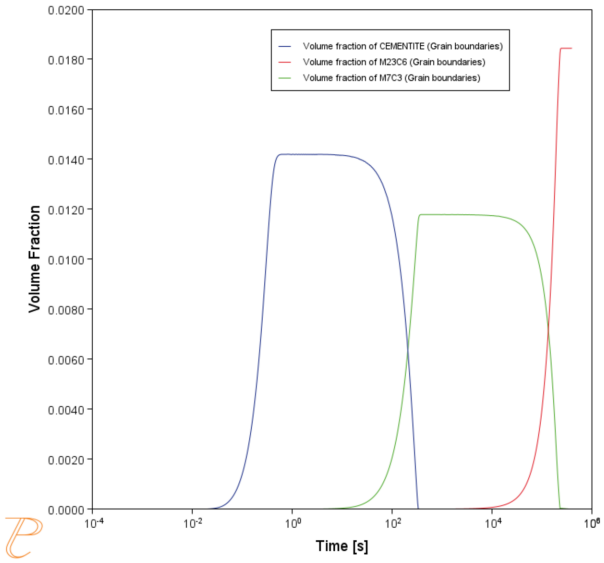

Figure 29: The predicted volume fraction of cementite, M23C6, and M7C3 during an isothermal aging with no precipitates in solution in the initial condition.

P_11: Interfacial Energy Function

In some cases, interfacial energy may be a function of temperature and/or particle radius. This example uses four Precipitation Calculators at four temperature points in 30 K increments: 673 K, 703 K, 733 K, and 763 K. It is an isothermal calculation to examine the mean radius of an Al-0.12Sc system. It uses an FCC_A1 matrix phase and AL3SC precipitate phase with bulk nucleation sites and user-defined interfacial energy function. The user defined interfacial energy function uses an error function to set a smooth transition of the interfacial energy from 0.065 J/m^2 to 0.085 J/m^2 for particle radii below and above $1e^{-8}$m and $5e^{-8}$m, respectively.

A dataset based on Iwamura and Miura [2004Iwa] data is compared with the calculated results.

Interfacial Energy Anisotropy (Non-Spherical Particles)

P_12: Comparing Growth Rate Models for an Al-Zr System

This example compares the **Simplified**, **General**, and **Advanced** growth rate models for an Al-Zr system. The resulting plot compares the mean radius of the spheres for each AL3ZR_D023 precipitate phase calculated for each type of growth rate model.

Background

All models treat a spherical particle (precipitate) of stoichiometric composition or with negligible atomic diffusivity. Local equilibrium at the precipitate-matrix interface is assumed.

When you use the *Advanced* model, the velocity of a moving phase interface and the operating tie-line are solved together from flux-balance equations. This model can treat both high supersaturation and cross diffusion rigorously. It can also capture the transition between NPLE (non-partitioning local equilibrium) and PLE (partitioning local equilibrium) without any *ad hoc* treatment.

The *Simplified* model is based on the quasi-steady state diffusion approximation, and estimates solute partitioning with matrix composition and nuclei composition instead of time-consuming stepwise tie-line calculations. It also neglects cross diffusion for simplicity.

The *General* model can be considered the same theoretical approximation as, but an improvement over, the *Simplified* model, with cross-diffusion terms taken into account, as well as adjustment of Gibbs-Thomson effect and effective diffusivity implemented. A dataset based on Knipling et al. [2008Kni] data is compared with the calculated results.

P_13: Paraequilibrium Precipitation of Cementite Fe-C-Cr

In this example, the precipitation of cementite during tempering of a Fe-Cr-C steel is simulated considering two interface conditions: one is the usual ortho-equilibrium condition; the other is the para-equilibrium condition. The simulation results are compared with the experimental data from Sakuma et al. [1980Sak].

This example demonstrates that the early stage of the cementite precipitation can only be accounted for by a simulation applying the para-equilibrium condition, under which the precipitation kinetics are controlled by the diffusion of C. The comparison also shows a later stage gradual transition from the para-equilibrium condition to the ortho-equilibrium condition, and if the tempering time is long enough the diffusion of Cr has a dominating effect on the coarsening of cementite.

P_15: Smooth Transition from Paraequilibrium to Ortho-equilibrium

In this example, the precipitation of cementite during tempering of an Fe-Mn-C steel is simulated considering three interface conditions: the usual ortho-equilibrium (OE) condition; paraequilibrium (PE) condition; and a smooth transition from paraequilibrium to ortho-equilibrium condition (PE-OE). The simulation results are compared with the experimental data from Miyamoto et al. [2007Miy].

Overview

The Precipitation Calculator nodes are renamed in the example to match the abbreviations for the three interface conditions considered: OE, PE, and PE-OE. Also see the video to learn how to create this example.

This example demonstrates that the early stage of the cementite precipitation follows a PE condition, under which the precipitation kinetics is controlled by the diffusion of C. At a later stage, gradual transition from PE condition to OE condition occurs, and if the tempering time is long enough the diffusion of Mn has a dominating effect on the coarsening of cementite. While a *Simplified* model follows the OE condition and a *Para-eq* model follows PE condition, the *PE Automatic* model enables the smooth transition from PE condition at early stage to OE condition at a late stage.

The example uses the demonstration steel databases, FEDEMO and MFEDEMO. These databases are available to all users (i.e. you do not need a license for the Precipitation Module (TC-PRISMA)) and contain the necessary thermodynamic and kinetic data needed for the calculation.

For this **Isothermal** example, its **Thermal Profile** is also displayed in the **Visualizations** window showing the constant temperature entered for this calculation type. The tab names match the node names in the **Project** window.

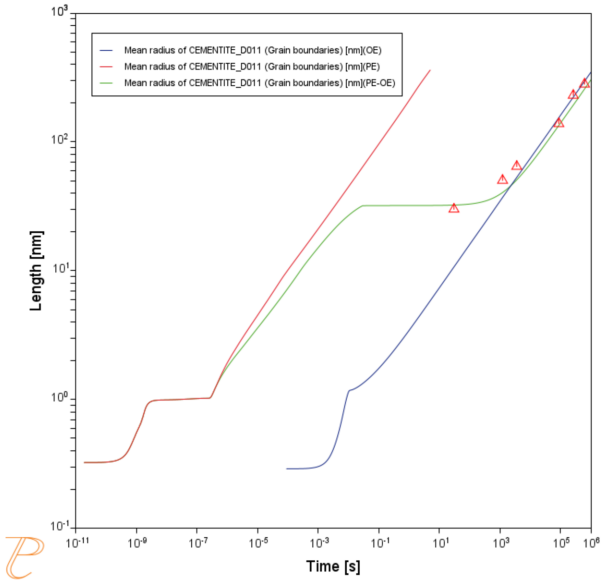

Figure 35: A comparison between the measurements of mean cementite radius from [2007Miy] with the simplified (OE), para-eq (PE), and PE Automatic (PE-OE) growth models. The PE-OE model is needed to capture the nucleation, growth, and coarsening behavior of cementite.

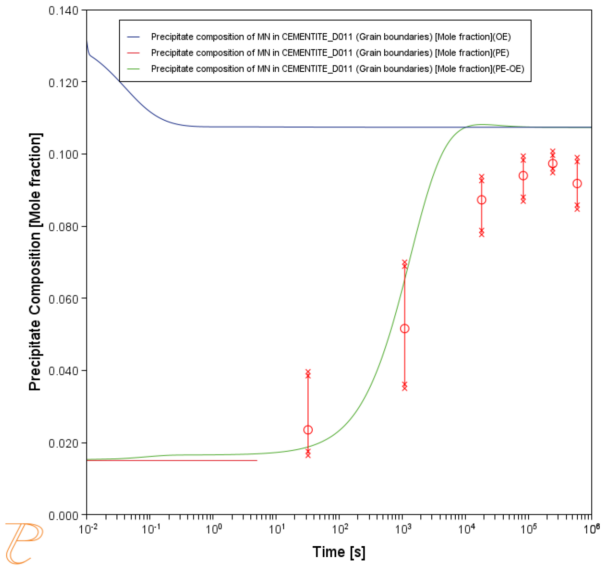

Figure 36: A comparison of the evolution of the cementite Mn composition during isothermal aging at 923.15 K between the experimental data from [2007Miy] with model predictions obtained from the simplified (OE) growth model, the para-eq (PE) growth model, and the PE Automatic (PE-OE) growth model. The PE-OE model captures the behavior shown in the experimental data, where the Mn composition transitions from the initial ferrite composition towards the equilibrium cementite composition.

P_16 Isothermal Coarsening and a 3D to 2D Stereological Conversion

This example demonstrates the use of the **3D → 2D** stereological conversion functionality to compare Precipitation Module (TC-PRISMA) predictions with experimental data obtained from Scanning Electron Micrographs (SEM).

The **3D → 2D** setting is available on a **Plot** or **Table Renderer** that is a successor to the **Precipitation Calculator**, and when certain axis variables are selected for a spherical morphology.

The isothermal coarsening kinetics of γ' precipitates in a Ni-Al-Cr alloy is modeled. The experimental data is from [2008Sud], which investigates isothermal coarsening kinetics at a temperature of 873 K for up to 264 h.

It is assumed that there are no precipitates in solution at the beginning of the isothermal heat treatment.

Project File Information

- Folder: **Precipitation Module - TC-PRISMA**
- File name: `P_16_Precipitation_Ni-Al-Cr_Stereology.tcu`

Example Settings

The example also includes an Equilibrium Calculator and Table Renderer to first confirm the stability of the precipitate phase for this system (FCC_L12#2), then determine particle composition at 1073 K, and this information is used with the Precipitation Calculator set up.

System (System Definer)	
Database package	Demo: Nickel-based superalloys (NIDEMO and MNIDEMO)

Elements	Ni, Al, Cr
Conditions (Precipitation Calculator)	
Composition	Ni-10l-8.5Cr Mole percent
Matrix Phase	DIS_FCC_A1 • Click **Show Details** and for the **Mobility adjustment** enter `0.5` for the **Prefactor**. • All other defaults are kept.
Precipitate Phase	FCC_L12#2 Click **Show Details** and adjust the default settings as indicated: • **Interfacial energy**: Select **User-defined** and enter `0.01` J/m^2.
Calculation Type (Precipitation Calculator)	
Calculation Type	Isothermal
Temperature	1073 Kelvin
Simulation time	300 h
Datasets (Experimental File Reader)	
[2008Sud]	Data sets are included with this example and are imported using the Experimental File Reader activity. There are 2D size distributions comparing results after a total of 16 h aging, 64 h aging, and 264 h of aging, and a comparison of the experimental and predicted 2D mean radius versus time.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

There is a variety of information shown in the **Visualizations** window that can be viewed during configuration and after performing the calculation.

- **Thermal Profile**: When setting up a calculator on a **Configuration** window for **Isothermal** or **Non-isothermal** *Calculation Types*, you can preview the profile and adjust settings as needed. When you click a calculator node in the **Project** window, the matching name of the node is on the tab(s) displayed in the **Visualizations** window.

  For **TTT Diagram** and **CCT Diagram** calculations there is nothing shown for the Precipitation Calculator tab in the **Visualizations** window as there is no Thermal Profile to be defined.

- **Plot** or **Table** results: After completing the set up and performing the calculation, to view the matching name of the node on tab(s) in the **Visualizations** window, either click a **Plot Renderer** or **Table Renderer** node in the **Project** window or click the tabs individually in the **Visualizations** window.

For this **Isothermal** example, its **Thermal Profile** is also displayed in the **Visualizations** window showing the constant temperature entered for this calculation type. The tab names match the node names in the **Project** window.

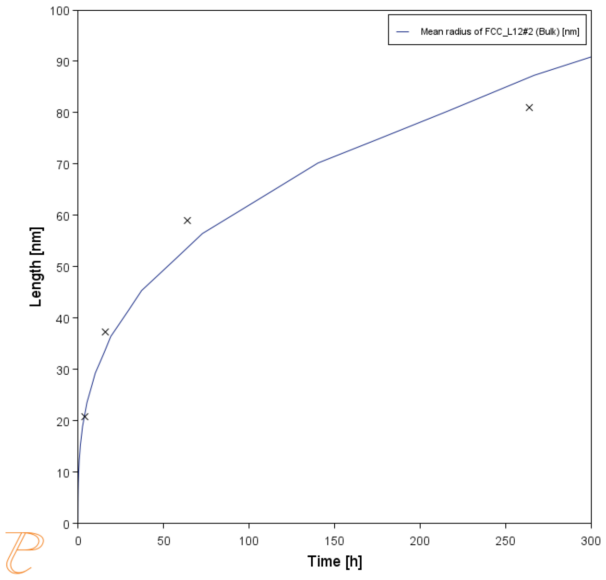

Figure 37: A comparison of the evolution of the mean 2D precipitate radius measurements of [2008Sud] with model predictions.

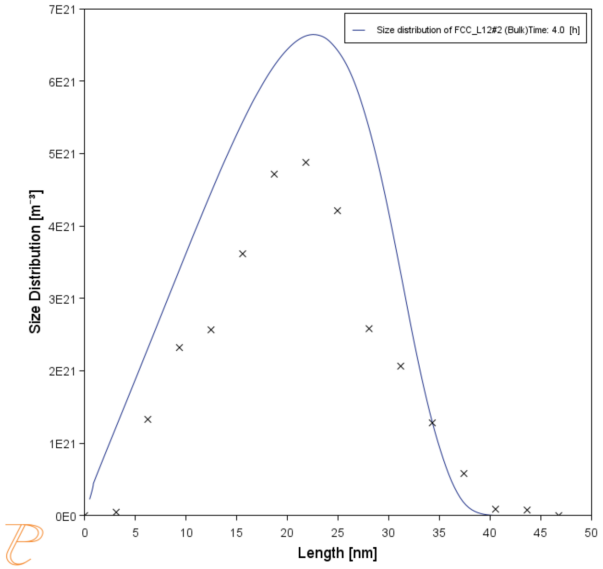

Figure 38: A comparison of the predicted and measured 2D size distribution after 4 h of aging.

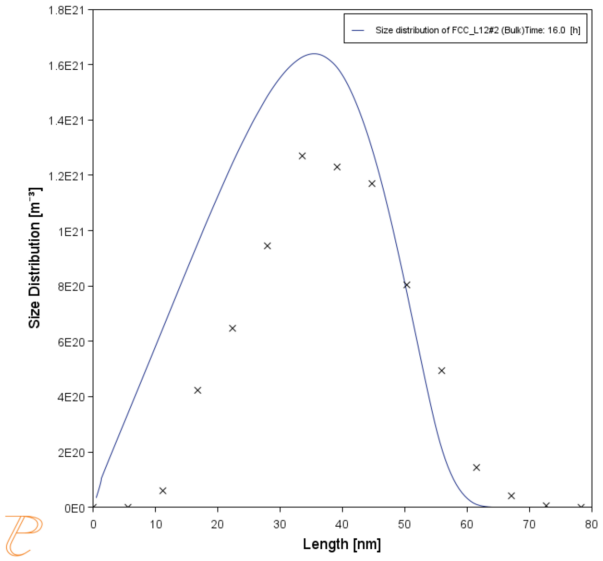

Figure 39: A comparison of the predicted and measured 2D size distribution after 16 h of aging.

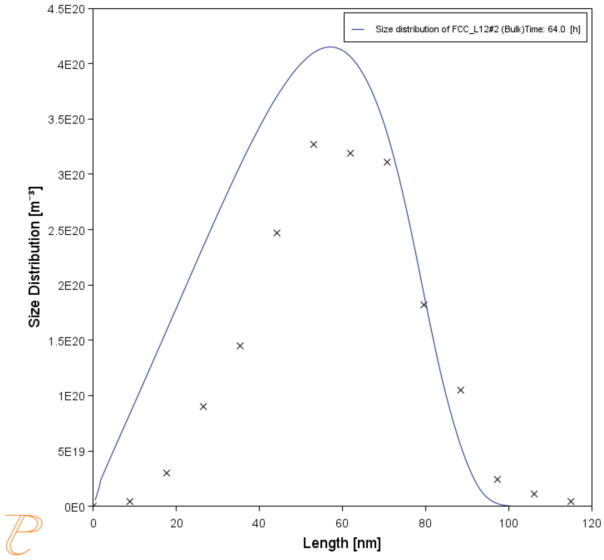

Figure 40: A comparison of the predicted and measured 2D size distribution after 64 h of aging.

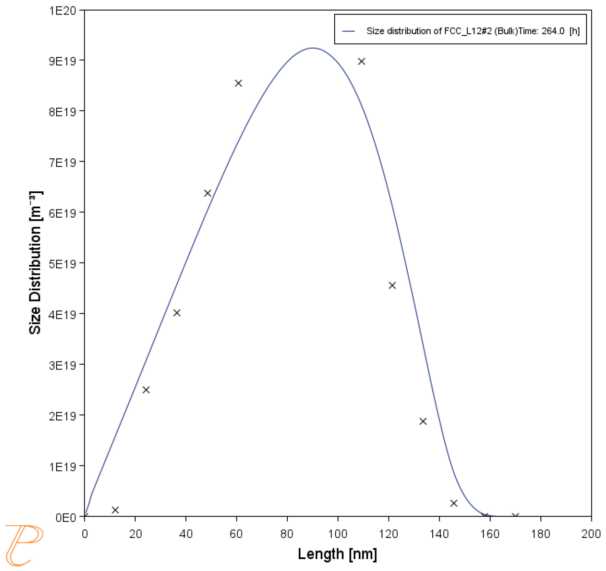

Figure 41: A comparison of the predicted and measured 2D size distribution after 264 h of aging.

P_17 Precipitate Upon Precipitate and Nucleation Sites

This example demonstrates the ability to model precipitate phases acting as a nucleation site. A particle phase acting as a nucleation site is referred to as an *inoculant*. The example simulates the nucleation of β'' (BETA_DPRIME), and its transition into β' (BETA_PRIME) in an Al-Mg-Si alloy, comparing results to the experimental data of Myhr et al. [2001Myh].

The heat treatment is isothermal at 185 °C for 300 hours. The β'' phase is assumed to be spherical, and the β' phase is approximated as needles.

Project File Information

- Folder: **Precipitation Module - TC-PRISMA**
- File name: `P_17_Precipitation_Upon_Precipitate.tcu`

To run the example requires licenses to both the thermodynamic and mobility databases: TCS Al-based Alloys Database (TCAL) and TCS Al-alloys Mobility Database (MOBAL).

Example Settings

System (System Definer)	
Database package	TCS Al-based Alloys thermodynamic and mobility databases (TCAL10 and MOBAL8)
Elements	Al, Mg, Si
Conditions (Precipitation Calculator)	
Composition	Al-0.615Si-0.562Mg Mass percent
Matrix Phase	FCC_A1 Click **Show Details** and then: • For **Elastic properties**, **Cubic** is selected with `108.2`, `61.3`, and `28.5` GPa entered for **c11**, **c12**, and **c44**, respectively. • A **Grain size** is set at `37` µm.

	• All other defaults are kept.
Precipitate Phase 1	BETA_DPRIME • The **Nucleation sites** are set to **Bulk**. • A **User-defined Interfacial energy** of `0.115` J/m^2 is entered. • Click **Show Details** and then **General** is selected as the **Growth rate model**. • All other defaults are kept.
Precipitate Phase 2	BETA_PRIME • The **Nucleation sites** are set to **Precipitate**, with the **BETA_DPRIME (Bulk)** particles selected. The **Wetting angle** is `90` degrees, with the Number of sites per precipitate (i.e. the nucleation site per inoculant particle) set to `1.0`. • A **User-defined Interfacial energy** of `0.19` J/m^2 is entered. Click **Show Details** and then: • **General** is selected as the **Growth rate model**. • A **Needle Morphology** is chosen with an **Aspect ratio** of `4.0`. • A **User-defined Transformation strain** is chosen, with non-zero values entered for **ε11**, **ε22**, and **ε33** with magnitudes of `0.015`, `0.015`, and `0.005`, respectively. • All other defaults are kept.
Calculation Type (Precipitation Calculator)	
Calculation Type	Isothermal
Temperature	185 °C
Simulation time	300 h
Datasets (Experimental File Reader)	
[2001Myh]	Data sets are included with this example and are imported using the Experimental File Reader activity. This includes measured particle concentrations and sizes for different times during the aging heat treatment.

P_18: Matrix Switch During Heat Treatment of a Low-Alloyed Tool Steel

This example shows the use of the matrix switching settings including the use of the **Active matrix phase** variable.

In this example, carbide precipitation during the heat treatment of a low-alloy martensitic tool steel is simulated. The simulation begins at the austenitization stage with an austenitic matrix, FCC_A1, which transforms to martensite, BCC_A2, during oil quenching. The martensitic transformation is assumed to occur at an Ms temperature of 350 °C. The quenched material is then subjected to subsequent heating and tempering. The simulation results are compared with the experimental data reported by Claesson et al. [2022Cla].

The example shows that appreciable amounts of cementite (CEMENTITE_D011), MC carbide (FCC_A1#2), and M2C carbide (HCP_A3#2) precipitate during the heat treatment process. Among these phases, MC carbide initially forms from austenite and subsequently continues to precipitate from martensite, whereas cementite and M2C carbide form mainly from martensite.

Project File Information

- Folder: **Precipitation Module - TC-PRISMA**
- File name: `P_18_Tool_Steel_Matrix_Switch.tcu`

To run the example requires licenses to both the thermodynamic and mobility databases: TCS Steel and Fe-alloys Database (TCFE) and TCS Steels/Fe-Alloys Mobility Database (MOBFE).

When you run (Perform) this example, it takes at least 30 minutes for the calculations to complete.

Example Settings

System (System Definer)	
Database package	TCS Steel and Fe-alloys thermodynamic and mobility databases (TCFE15/MOBFE9)
Elements	Fe, C, Mn, Cr, Ni, Mo, Si, and V
Conditions (Precipitation Calculator)	
Composition	Fe-0.3C-0.81Mn-1.5Cr-1.4Ni-1.1Mo-1.1Si-0.13V Mass percent
Matrix Phase 1	FCC_A1 • **Allow for matrix switch** checkbox is selected. • Click **Show Details** and then set **Grain size** to `1.0e-5` m • All other defaults are kept.
Matrix Phase 2	BCC_A2 Click **Show Details** and then: • **Grain size > Average diameter**: `2.0E-7` m • **Grain aspect ratio**: 20.0 • **Dislocation density**: `1.0E15` m^{-2} • All other defaults are kept.
Precipitate Phase 1	FCC_A1#2 • **Nucleation sites**: **Grain boundaries** • **Interfacial energy**: **User-defined** `0.04` J/m^2 • Click **Show Details** and then select the **Approximate driving force** checkbox. • All other defaults are kept.
Precipitate Phase 2	CEMENTITE_D011 • **Nucleation sites**: **Bulk** • **Interfacial energy**: **User-defined** `0.14` J/m^2 Click **Show Details** and then set: • **Growth rate model**: **PE Automatic**

	• **Trans-interface mobility adjustment**: **Per element**. Then enter a **Prefactor for C** of `0.002` • All other defaults are kept.
Precipitate Phase 3	HCP_A3#2 • **Nucleation sites**: **Dislocations** • **Interfacial energy**: **User-defined** `0.12` J/m^2 • All other defaults are kept.
Precipitate Phase 4	M23C6_D84 • **Nucleation sites**: **Grain boundaries** • **Interfacial energy**: **User-defined** `0.252` J/m^2
Precipitate Phase 5	M7C3_D101 • **Nucleation sites**: **Grain boundaries** • **Interfacial energy**: **User-defined** `0.282` J/m^2 • All other defaults are kept.
Calculation Type (Precipitation Calculator)	
Calculation Type	Non-isothermal
Temperature and Times	Time [s] / Temperature [°C] 0.0 / 850.0 1800.0 / 850.0 1860.0 / 300.0 3660.0 / 600.0 90060.0 / 600.0

Process Metallurgy Module

The Process Metallurgy Module is an Add-on Module within Thermo-Calc that makes it easy to set up calculations for steel and slag. The Module also includes a kinetic model that allows the simulation of the evolution of the steel and slag composition and also the inclusion amount and composition as a function of time based on the actual steelmaking process, including alloy or slag additions, blowing of gases into the steel, heating by electric arc, and so on.

The Module is primarily designed for application to steelmaking and steel refining processes including converters, such as basic oxygen furnaces, electric arc furnaces, ladle furnace metallurgy, and more. The Module can also be applied to other metallurgical processes. It is available in Graphical Mode.

About the Process Metallurgy Module

The Process Metallurgy Module is an Add-on Module to Thermo-Calc and it is available in Graphical Mode as the *Process Metallurgy Calculator*. The Add-on Module is designed to model reactions that occur in metallurgical processes. Although primarily used in steelmaking and steel refining processes—such as basic oxygen furnaces, electric arc furnaces, ladle furnace metallurgy, and so forth—applications are not limited to steelmaking.

There are two main branches of calculations possible: **Equilibrium** and **Process simulation**. Equilibrium calculations do not consider any kinetics, the process simulation includes reaction kinetics.

In general, for both types, the main difference compared to using a standard Equilibrium Calculator is that it is easy to handle the different materials present in a metallurgical process. The materials used in the process can be pre-defined, saved and used for the equilibrium calculations. Metallic materials can be defined in element weight percent, oxide materials in weight percent of oxide components, the gas phase in volume percent of gas components and its amount can be defined in normal cubic meters, and so forth. In principle this can be done in a standard Equilibrium Calculator. However, it is much easier when using the Process Metallurgy Calculator as this is designed for this specific purpose.

When using the **Equilibrium** branch of calculations, both isothermal and adiabatic calculations are possible. Adiabatic calculations assume no heat and mass exchange with the environment during the equilibrium reaction, meaning that the temperature changes as a result of exothermal or endothermal reactions taking place.

For a **Process simulation** branch of calculation, the reaction kinetics of the process are considered. This is done by dividing the system into zones. Typically one would have one steel zone containing liquid metal and a slag zone containing liquid oxide (slag). The kinetic model assumes that only a fraction of the steel zone reacts with a fraction of the slag zone per time step. This reacting fraction of the whole system is termed the reaction zone (in literature it has become known as Effective Equilibrium Reaction Zone or EERZ).

You can use the Process Metallurgy Module to calculate the following:

- The equilibrium between custom-defined steels, slags, and gasses.
- The equilibrium between other metallic and non-metallic phases.
- Desulfurization, dephosphorization, and decarburization.
- Any partition coefficient, for example the partitioning of sulfur between the liquid steel and slag phase.
- Slag characteristics, such as slag basicity or sulfur capacity.
- The fraction of liquid and solid in the slag.

- The temperature change in an adiabatic process.
- Kinetics of the reaction between phases. Typically this is the reaction between a liquid metal and slag phase, but it could also be the reaction between a solid oxide and slag (simulation of refractory wear) or between a solid metal and liquid metal (simulation of dissolution of alloy), etc.

Learn More

The Process Metallurgy Module requires both a valid Maintenance and Support Subscription (M&SS) and a license for the TCS Metal Oxide Solutions Database (TCOX8 or newer).

All users can test the Process Metallurgy Module with the included OXDEMO database, which is limited to these elements: Al, C, Ca, Fe, O, S, and Si. For more information about this and other products visit our website.

Read more on our website about applications for Sustainability. The webpage highlights several examples demonstrating how Thermo-Calc has been applied to address key sustainability challenges.

Available Options with the Process Metallurgy Module

The Process Metallurgy Module is an Add-on Module to the core Thermo-Calc software.

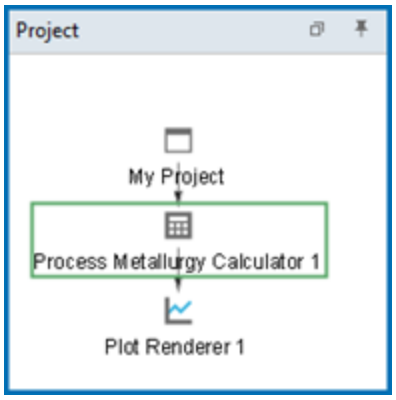
A separate license is required to perform calculations for more than three elements. Without it you are able to use the module in *Demo Mode*.

Process Metallurgy Template

A **Process Metallurgy** template under **Applications** is available to all Thermo-Calc users when in Graphical Mode. If you are in DEMO mode then this is indicated by the addition of **DEMO** text.

Using the Template

After opening Thermo-Calc in Graphical Mode, in the templates section under **Applications** click **Process Metallurgy** to add a *System Definer*, *Process Metallurgy Calculator*, and *Plot Renderer* to the **Project** tree.



Creating a Project from a Template

Process Metallurgy Calculator

A Process Metallurgy Calculator allows you to set the conditions for, and perform, a process metallurgy calculation. Details about this activity are described in Process Metallurgy Calculator.

Demonstration (Demo) Mode

The Process Metallurgy Module, and some examples, are available to all Thermo-Calc users but only for simulations of alloys with up to three elements. If you do not have a license for the Process Metallurgy Module then you are in *Demonstration Mode* when using the Process Metallurgy Calculator or its template.

Network License Restrictions

Process Metallurgy Template

A **Process Metallurgy** template under **Applications** is available to all Thermo-Calc users when in Graphical Mode. If you are in DEMO mode then this is indicated by the addition of **DEMO** text.

Process Metallurgy Calculator

If you are experimenting with the Process Metallurgy Calculator in Demo Mode, you may have access to a variety of databases based on your license. However, you can only define up to three elements for a demo simulation.

If you define more than three elements and try to run the simulation the **Event Log** displays an error message.

Network License Restrictions

The Process Metallurgy Module requires a separate license. If you are using a network client installation of Thermo-Calc, then you may not be able to use it even if you have access to a license server with a valid network license file. The reason for this is because other clients who are part of your network installation may have checked out all instances of the network license allowed to run simultaneously.

For users with a network license, you must exit Thermo-Calc to release the license for other users. The license is checked out as soon as you add a Process Metallurgy Calculator and remains unavailable to other users until you exit the program.

With a network license, and if as per above you temporarily do not have access to a license, you are automatically put into *Demo Mode*. Then the Process Metallurgy Calculator is available with three elements.

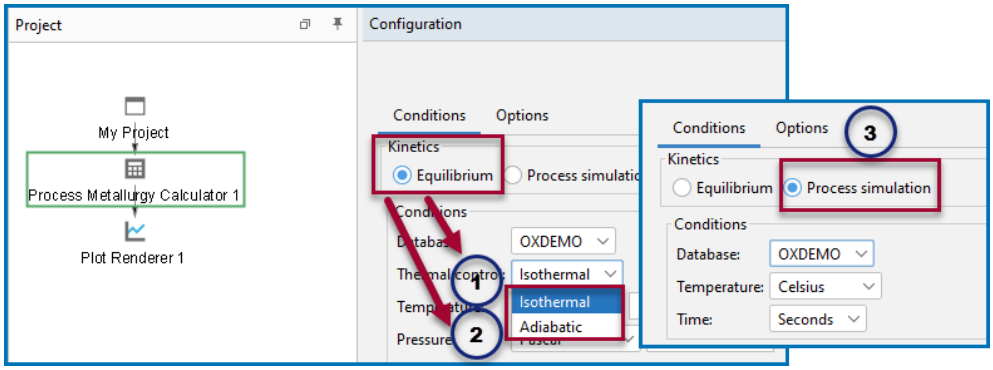
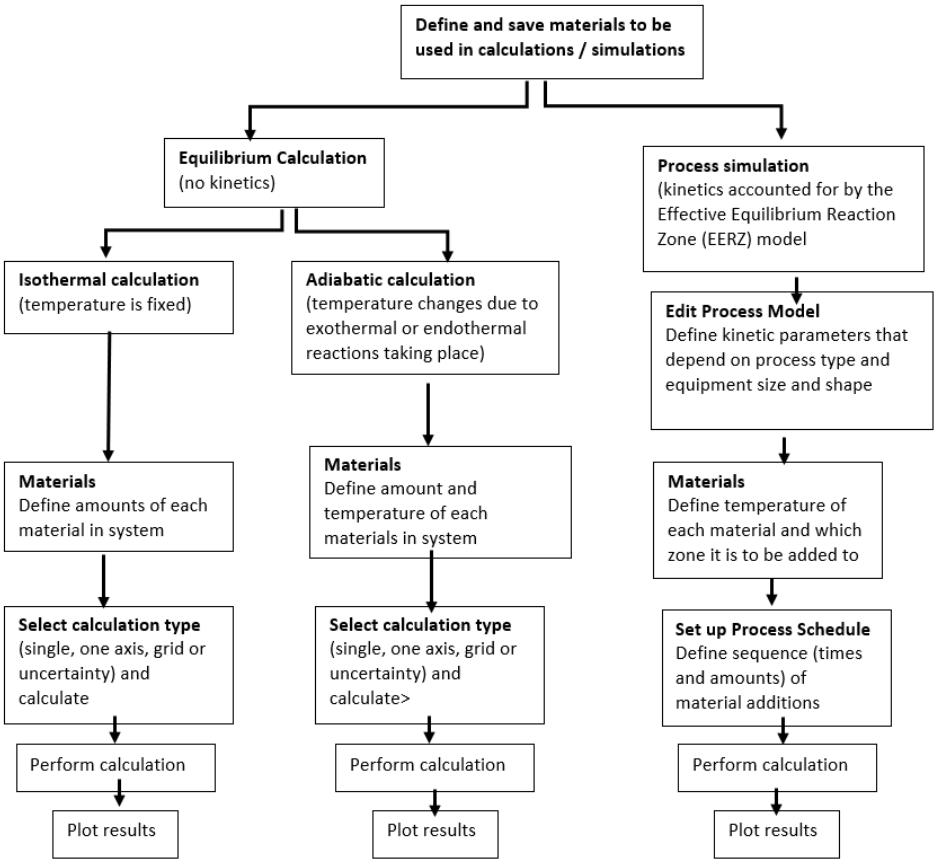
Setting Up a Process Metallurgy Simulation

The following basic steps need to be carried out to set up calculations in the Process Metallurgy Calculator. There are three branches of simulation to choose from on the **Configuration** window when setting up the simulation an isothermal equilibrium calculation, an adiabatic equilibrium calculation, and a process simulation.



Process Simulation Options

This is a useful flowchart to outline the isothermal and adiabatic equilibrium calculation options in the Process Metallurgy Module.



The three branches of simulations available for the Process Metallurgy Calculator (1) an isothermal equilibrium calculation, (2) an adiabatic equilibrium calculation, and (3) a process simulation.

Equilibrium Simulations

Two **Equilibrium** simulation types are available: **Isothermal** and **Adiabatic**. In general for the equilibrium simulation, the three most common material groups—*Steel*, *Slag*, and *Gas*—are automatically included with the default composition input types that are relevant to each material group. You can add materials and save your material compositions directly from the Process Metallurgy Calculator and quickly access these for other simulations. For example, you might want to predefine compositions of steels, ferro-alloys, slags, and slag additions. The overall composition of the steel and slag is then obtained by adding amounts of these predefined materials.

Each group of materials is automatically added to the similar group where it is defined. You can manage these groups using the *Material Manager* (see Working with the Material Manager).

For adiabatic calculations, the selection of material type (steel, slag, gas) has an influence on the calculation. For isothermal calculations, the results are identical.

The reason the selection of materials for adiabatic calculations has an influence is because there are different strategies to calculate the enthalpy of the materials at the temperature at which these are added. Therefore, defining FeO as a *steel* containing 50 at% Fe and 50 at% O or as a *slag* with 50 at% Fe and 50 at% O or as *slag* with 100% FeO, all result in different enthalpies assigned to the component FeO, which in turn results in different equilibrium temperatures.

Defining the Equilibrium Simulation and Equilibrium Simulation: Conditions Tab

Adiabatic Calculations: Material Enthalpy

Process Simulations

When you choose to do a **Process simulation** it includes the reaction kinetics. Using the EERZ (Effective Equilibrium Reaction Zone) model, you can first define your materials as you do with an **Equilibrium** simulation. You also need to define the **Process model** where you define the kinetic parameters of the simulation by setting up reaction zones, reaction rates, heat transfer coefficients, and so forth. You also need to define the **Process schedule** where the sequence and amounts of added materials are defined.

Defining the Process Simulation and Process Simulation: Conditions Tab

Calculation Types

The calculations available for an **Equilibrium** simulation, for both isothermic and adiabatic calculations, are *Single* equilibrium, *One Axis*, *Grid*, and *Uncertainty*. After adding a Plot Renderer or Table Renderer, you can choose a variety of quantities, including slag properties such as Bells ratio and B2, to output results that provide useful visual representations of the steelmaking systems being analyzed.

Process Metallurgy Calculator and Defining the Equilibrium Simulation

Learn More

Examples of using the Process Metallurgy Calculator for Basic Oxygen Furnace (BOF) (with and without kinetics), a Ladle Furnace (LF) simulation, an Argon Oxygen Decarbarization (AOD), and a Vacuum Oxygen Decarborization (VOD) simulation are included with your installation. See Process Metallurgy Module Examples Collection for links.

You can find several learning resources on the Process Metallurgy page of our website (or in Thermo-Calc, go to **Help → Thermo-Calc website**). You can also subscribe to the Thermo-Calc newsletter to be kept up-to-date about upcoming releases, training, examples, videos and much more.

Process Metallurgy Template

Use a *Process Metallurgy* template to add the Process Metallurgy Calculator and a **Plot Renderer** to the **Project** window. The Process Metallurgy Calculator has several preconfigured settings making is easier to setup the different groups and materials needed to define a system for slag, metal and gas used in steelmaking.

Adding a Process Metallurgy Template to a Project

1. In the **Project** window click the **My Project** node to display the templates in the **Configuration** window.
2. Under **Applications**, click **Process Metallurgy**.

A **System Definer**, **Process Metallurgy Calculator**, and a **Plot Renderer** are added to the **Project** window.

You can also add templates by right-clicking the **My Project** node and choosing an option from the **Create New Activity → Use Template** menu.

Working with the Process Metallurgy Module

Working with the Process Metallurgy Calculator allows you to easily define complex metallurgical reactions. The calculator streamlines how you set up these steel and slag systems but there are details about various inputs and outputs that are different from other calculators. This topic is a general collection of information related to the Process Metallurgy Module and is intended to help you better understand how to interpret and make choices when you are setting up your steelmaking simulation.

- Database Dependency
- Material Manager
- Working with Material Groups (Steel, Slag, and Gas)

- Calculation of Component Compositions
- Definition of Partial Pressure of Oxygen
- Activities of Slag Components
- Process Schedule
- Dynamic Time Stepping
- Pressure-Dependent Calculations

Database Dependency

It is not possible to use custom user databases with the Process Metallurgy Module. This is because several internal calculations, such as determining the component compositions of ionic phases, are dependent on the database. Therefore, only TCS Metal Oxide Solutions Database (TCOX) versions 8 and newer, and to a limited extent, OXDEMO, can be used with this Module.

Material Manager

For information about saving and deleting materials used with the Process Metallurgy Calculator, see Working with the Material Manager. Also see the next section.

Working with Material Groups (Steel, Slag, and Gas)

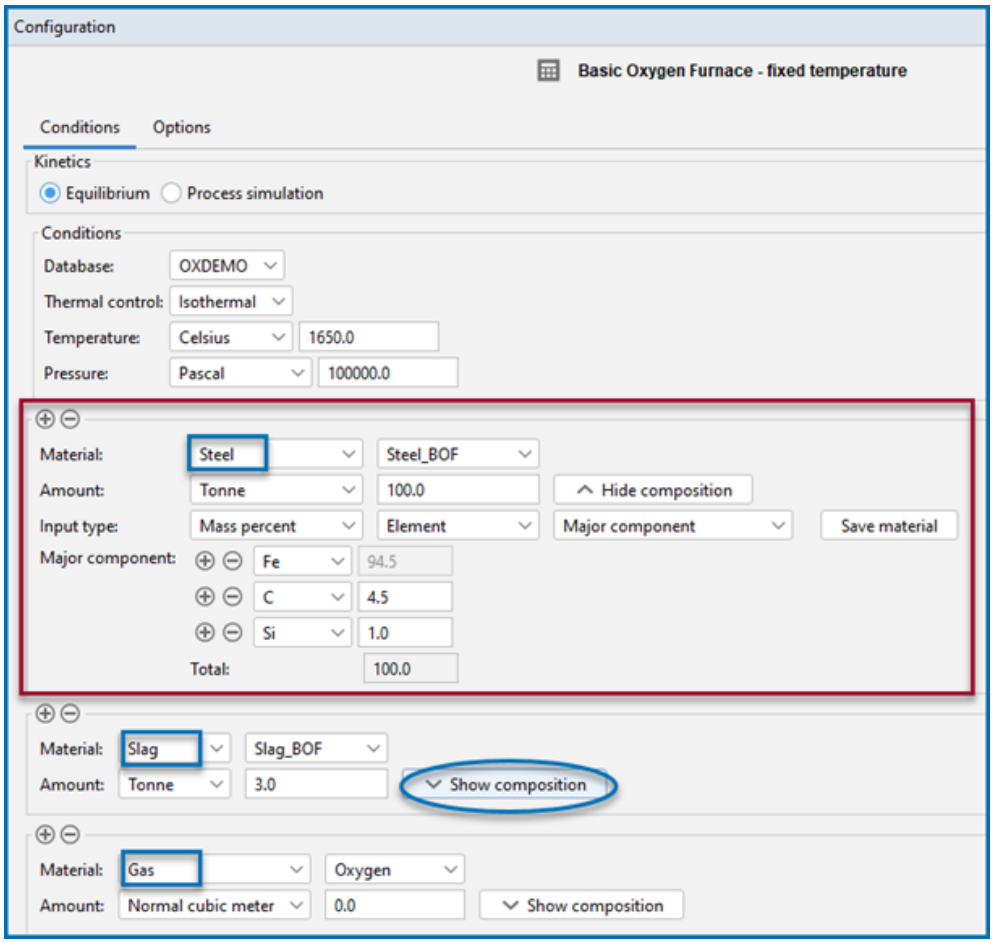
For more details about these fields, see Defining the Equilibrium Simulation. For information about saving and deleting materials, see Working with the Material Manager.

There are three groups to define: **Steel** (or another user-defined **Metal** group), **Slag**, and **Gas**.

It is recommended you open the PMET_01: Basic Oxygen Furnace (BOF) example to follow along with the descriptions. Version b is used in the screenshots.

Open the example project file(s) from Thermo-Calc **Help** → **Example Files** → **Process Metallurgy** → **PMET_01_Basic_Oxygen_Furnace.tcu**. Choose a, b, or c versions of the example based on whether you have a license for the TCOX database.

In the image below, the red-highlighted area is where the Steel material group is defined. The drop-down menu that displays *Steel_BOF* shows a user-defined material. This can be defined and then saved to the material library.

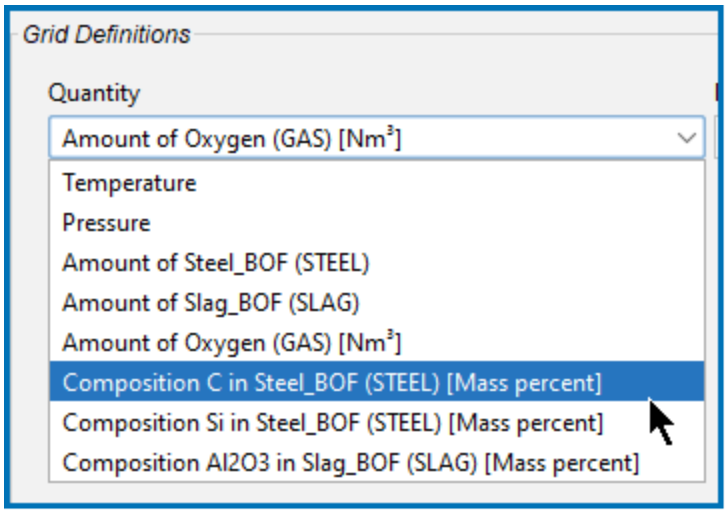


The three material group areas on the Process Metallurgy Calculator where you can define components and save materials. You can create your own material groups using the Material Manager.

When you click **Show composition** next to any material group, additional fields display to give composition and input type where you can further define each material group. You can remove materials and add and remove material groups using the *Material Manager* (available on the **Configuration** window → **Options** tab).

In the example, click **Show composition** next to the **Slag** and **Gas** groups to see how the *Slag_BOF* and *Oxygen* materials are defined.

From this composition area you can click the **Save material** button to add the new material to the group's list. The newly named material composition is then available for use with that material group. In this example, the *Steel_BOF* material was defined first and then named at the end. It is now available in the lists wherever you select the **Steel** material or need to choose quantities to plot.



After defining and saving a material composition, the named material is available for selection in a variety of places such as when choosing quantities on the calculator and defining axis variables on the Plot Renderer.

To add one or more material groups click the add ⊕ button. Click the minus ⊖ button to remove a material group. The new material inherits the default settings of that group.

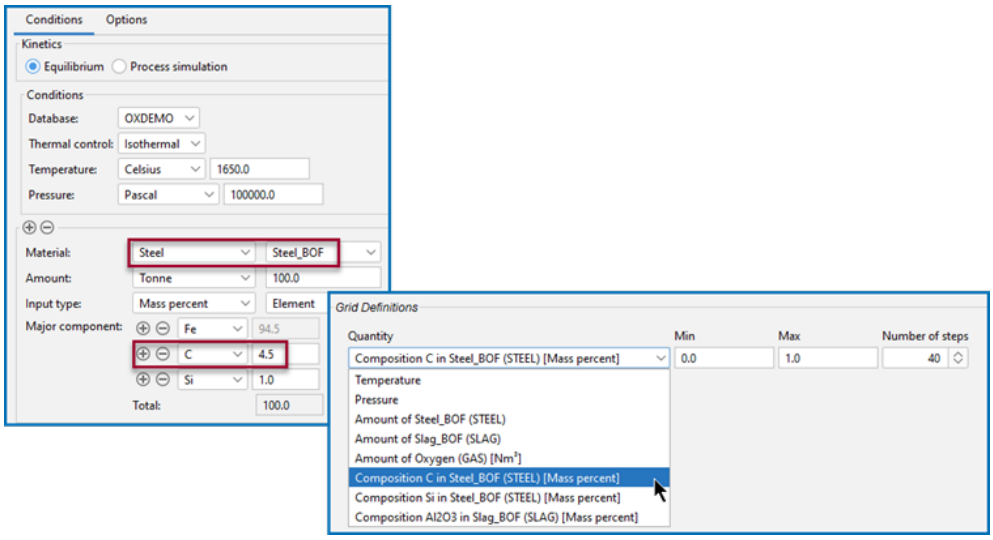
How Grid Definitions Quantities are Related to Composition

This section helps you understand the Grid Definitions Quantities and how these relate to the composition.

When you choose a **One Axis** or **Grid** *Calculation Type*, you also choose a **Quantity** under the *Grid Definitions*. The relationship between these quantities and how the material group composition is defined as follows.

The following uses **Composition of C in Steel_LF (STEEL)** as an example quantity for a **One Axis** calculation.

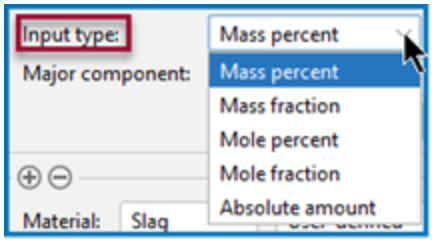
Under *Grid Definitions*, the availability of the **Quantity** in the list is based on the material (**Steel_BOF**) that is defined and saved for the **Steel** group (or any user-defined metal, slag, or gas group).

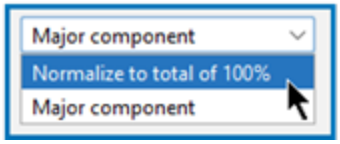


Defining the Material Composition

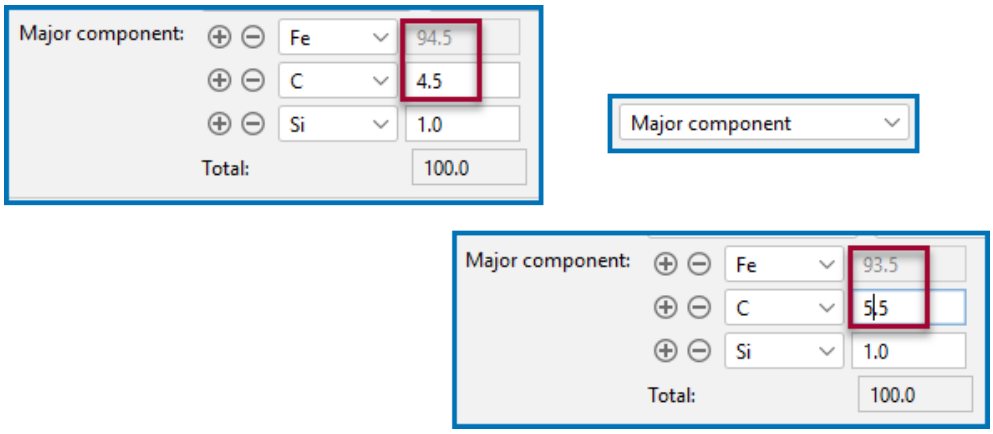
Click **Show composition** so that when you choose the **Input type** for a steel the composition of the elements can be set up using a combination of settings starting with **Mass**- or **Mole percent**, **Mass**- or **Mole fraction**, or for Equilibrium calculations, **Absolute amount**. Then you further choose to define the composition using either the **Major component** or **Normalize to total of 100%** options.

The *Amount of X in Y* quantities you can choose from the various drop-down lists (such as under *Grid Definitions*) are defined as Min-Max variation of the component X in Y. If a dependent element is present that is adapted as usual.

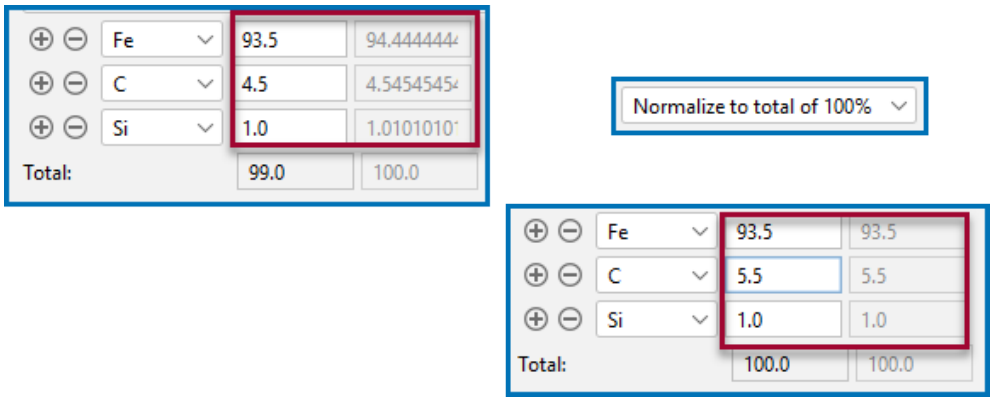




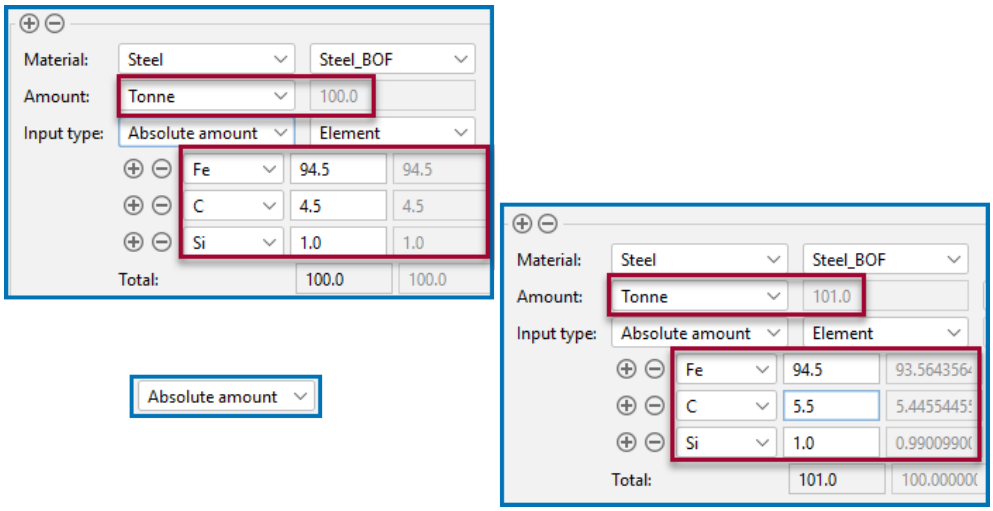
When you use **Major component**, as you add other components or adjust the composition, the major one is adjusted to be the rest of the composition.



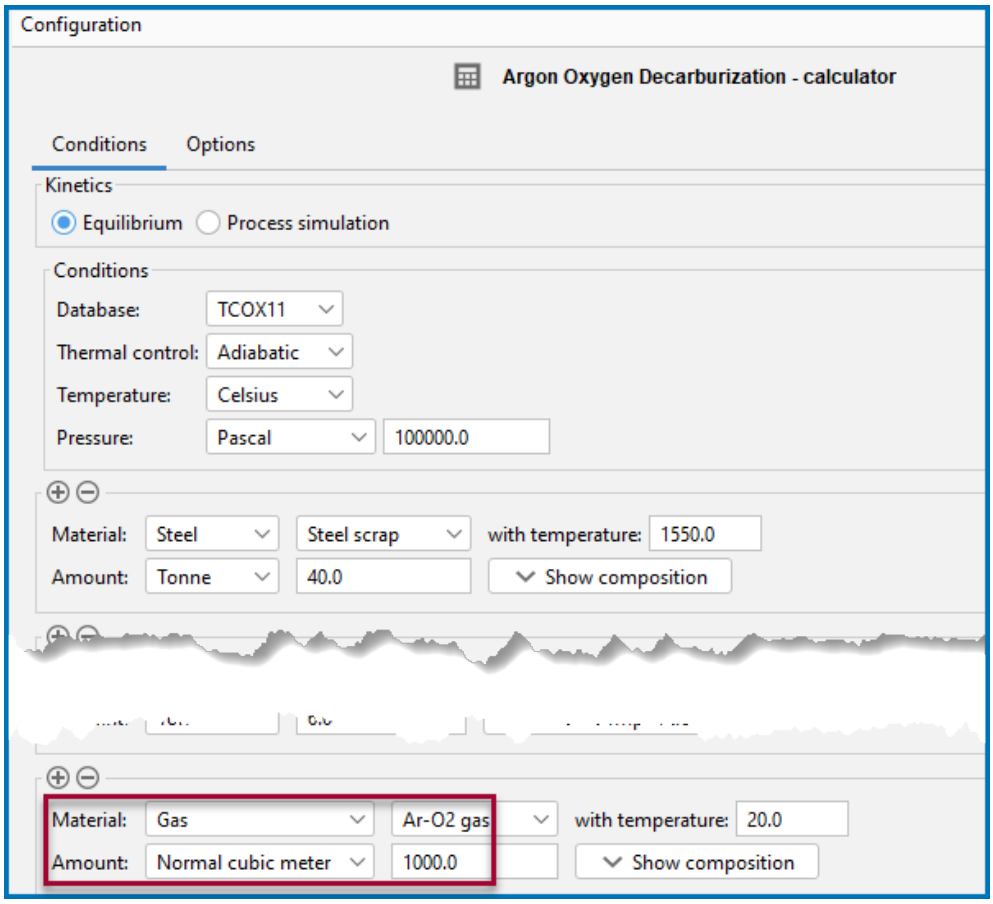
When you use **Normalize to total of 100%**, the sum is adapted to 100%. This is useful if you need to work with a given composition that does not sum up to 100%.



Sometimes its preferable to use input of amount of each component **Amount** by weight (**Tonne**, **Kilogram**, **Gram**, or **Pound**), it can useful to choose **Absolute amount** as the **Input type**. In this case, the total amount of material automatically adjusts the total.



For the **Gas** component, if you choose **Normal cubic meter** as the **Amount**, then beside regular mass units, the amount of gas can also be provided in Nm^3.

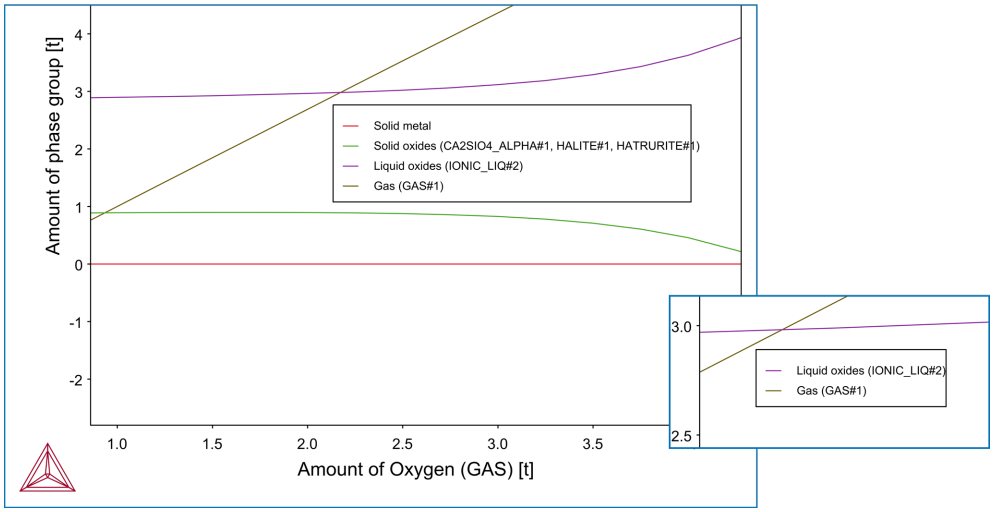


Phase Groups

The phases that are plotted after you run a simulation are grouped together on the plot to make the interpretation of the results easier.

Phases of similar type are bundled together in the groups *liquid metal*, *solid metal*, *solid oxides*, *liquid oxides*, and *gas*. Except for the gas phase, all the groups can have more than one phase. This grouping is particularly useful for liquid metal and liquid oxide because they are both described by the same phase, IONIQ_LIQUID, and because there is typically two or more compositions sets of IONIQ_LIQUID. This is also useful for solid oxides, because a large number of phases can be stable, making the interpretation of results difficult without this grouping.

The term *oxides* in the Process Metallurgy Module can also mean carbides, sulfides, and fluorides.



Example of the plot labels with the phases grouped together. As you zoom in, only the phases that you can see are listed in the label, making it easier to examine the results.

Slag Property Quantities

The slag properties describe the capability of a slag to take up sulfur from the metal melt. The Process Metallurgy Module defines so-called phase groups. These contain all phases of a certain kind, for example all solid slag or all slag phases. The component composition of such a phase group is calculated by weighting the component composition of each phase with their fraction in the group.

This allows to calculate slag properties for the phase groups, for example for the overall slag.

On the Plot Renderer (for axis quantities) and Table Renderer there is an option to choose or define the **Slag property**. The associated quantity that you select has these options: **All**, **B2**, **B3**, **B4**, **Bas2**, **Bells ratio**, **Ls**, or **Log10 (Sulphur capacity)**.

Details, including references and equations, are described in Process Metallurgy Slag Properties.

Adiabatic Calculations

When setting up the Process Metallurgy Calculator under the **Equilibrium Kinetics** branch, you choose the thermal control to be either **Isothermal** or **Adiabatic**. Adiabatic calculations assume no heat and mass exchange with the environment during the equilibrium reaction. The adiabatic process is implemented by an isenthalpic process with constant pressure (i.e. H=CONST), which is equivalent.

Adiabatic Calculations: Material Enthalpy

Gas Volume Units

Beside regular mass units, the amount of gas can also be provided in **Normal cubic meter** (Nm^3). The applied reference conditions are 1013.25 hPa and 15.0 °C (according to ISO 2533).

There are slightly deviating definitions present in the industry, which need to be converted for precise results. For most applications of the Process Metallurgy Module this difference has a minor influence.

Calculation of Component Compositions

The composition of all ionic phases is provided as elemental as well as component composition (i.e. Fe_2O_3, FeO, CaO, …). In order to provide a representation similar to that usually used in the industry, the content of S is provided as elemental content and the content of P is given as component content of P_2O_5. This is a simplification because P and S can also be present as sulphates and phosphates in the slag and can bind to different metal cations. This can cause deviations in the overall component composition if the content of S and P is high in the phases. In doubt, the elemental composition can be used, it will always be exactly correct.

For non-ionic phases such as ALABANDITE, always the elemental composition will be shown only. This is also true if the IONIC_LIQ composition cannot be described by components only due to constraints of the overall composition (for example if the material has been oxidized completely and forces a certain composition of the ionic liquid slag).

Definition of Partial Pressure of Oxygen

The oxygen partial pressure in the gas phase is calculated with the following formula:

$$p_{O_2} = p \cdot AC(O_2, GAS)$$

In the formula, *p* describes the total system pressure and *AC* the activity of oxygen in the gas phase.

Activities of Slag Components

The chemical activity of each component *AC(COMPONENT, REFERENCE_PHASE)* is available either with reference to the liquid or the solid slag phase. It can only be calculated for components being present in the thermodynamic database.

Process Schedule

When you are working with the **Process simulation** branch you set up a process schedule. There are some useful details about this described in Working with the Process Schedule.

Dynamic Time Stepping

The nature of a **Process simulation** requires a dynamic choice of the time step lengths. To understand this better, see About Dynamic Time Stepping. These settings are done on the Options Tab.

Pressure-Dependent Calculations

It is possible to apply variable pressure during process metallurgical calculations, which is relevant in various processes such as Vacuum Oxygen Decarburization (VOD) or Ruhrstahl-Heraeus (RH). See About Pressure-Dependent Calculations.

Working with the Material Manager

Use the *Material Manager*, available only with the Process Metallurgy Module, to create and delete groups of materials and delete materials you have saved directly from the Process Metallurgy Calculator. It is useful for frequently used materials.

Material groups created in the Material Manager display in all of the Process Metallurgy Calculator drop down lists, and these are also globally removed. Deleted group data directories are moved to the computer's trash bin.

A material saved in any of the material configuration panels is directly accessible globally in the Process Metallurgy Calculator Configuration window. When a material is removed in the Material Manager panel it is globally removed from the Process Metallurgy Calculator.

The settings are available on the **Configuration** window Options Tab.

- Saving a Material
- Deleting a Material
- Creating a Material Group
- Deleting a Material Group

Saving a Material

This is done directly from the **Process Metallurgy Calculator** → **Configuration** window.

1. Add the Process Metallurgy Calculator to **My Project** directly (right-click and select it from the **Create New Activity** menu) or use the available Process Metallurgy template on the **My Projects Configuration** window under **Applications**.
2. On the **Configuration** window, next to the **Material** group you want to define, for example **Steel** (or another user-defined metal group), **Slag**, or **Gas**. Click **Show composition**.
3. Enter the composition and the **Major component** of the material you want to save for future use. You can alternatively select **Normalize to total of 100%** and enter the percentages for each element.
4. Click **Save material**.
5. In the window that opens, enter a **Material name**. Click **OK**.

   When you go to the *Material Manager*, you can select this saved material from the applicable list if you need to delete it.

It is not possible to rename a saved material—you need to recreate/redefine the material and save it again with the new name.

Deleting a Material

This is done with the *Material Manager*, located on the **Configuration** window, **Options** tab.

1. After Saving a Material, go to the *Material Manager*.
2. Select the **Material** group associated to the material saved previously, for example, **Steel** (or another user-defined metal group), **Slag**, or **Gas**.
3. From the **Material** list, select the material you want to delete and click **Delete material**.
4. In the window that opens, click **Yes** to delete the material and **No** to cancel.

Creating a Material Group

This is done with the *Material Manager*, located on the **Configuration** window, **Options** tab.

1. Go to the *Material Manager*.
2. Click **Create group**.
3. In the window that opens, select the **Material group type** (**Metal**, **Slag**, or **Gas**) you want to create.
4. Enter a **Material group name**. The new group is now available to select from the **Material group** list.

Deleting a Material Group

This is done with the *Material Manager*, located on the **Configuration** window, **Options** tab.

1. Go to the *Material Manager*.
2. From the **Material group** list, select the group you want to delete and click **Delete group**.
3. In the window that opens, click **Yes** or **No**.

Process Metallurgy Slag Properties

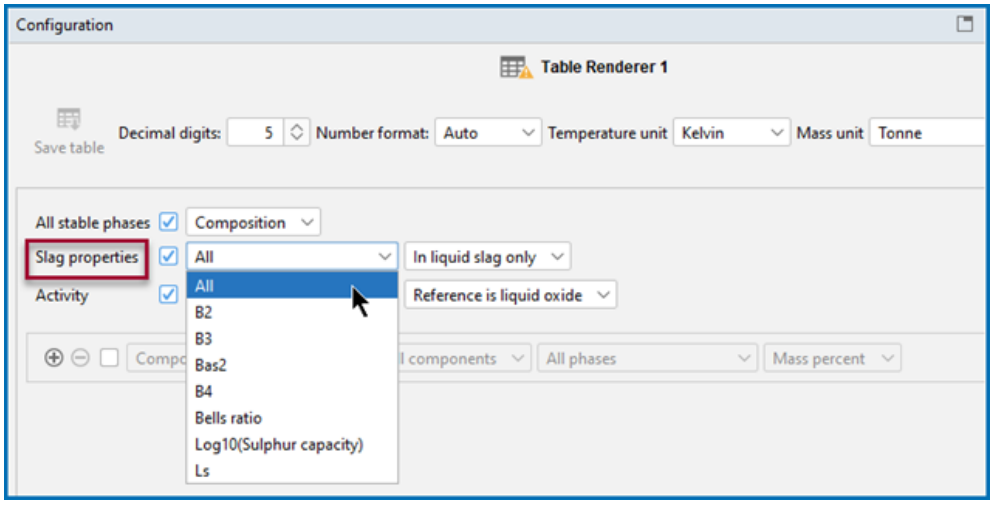
The slag properties describe the capability of a slag to take up sulfur from the metal melt. The Process Metallurgy Module defines so-called phase groups. These contain all phases of a certain kind, for example all solid slag or all slag phases. The component composition of such a phase group is calculated by weighting the component composition of each phase with their fraction in the group.

This allows to calculate slag properties for the phase groups, for example for the overall slag.

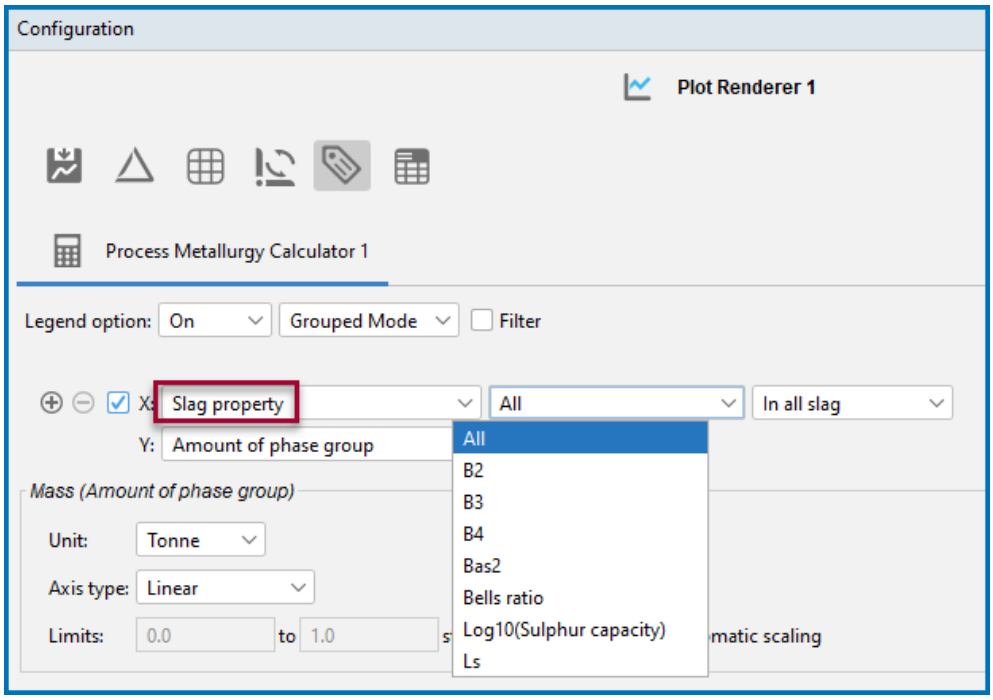
Including Slag Properties in Results

Various predefined slag properties such as different definitions of slag basicity, sulfur capacity and so forth are available for plotting or tabulating. On the Process Metallurgy Calculator when selecting axis variables on the Plot Renderer or choosing the properties to list with the Table Renderer, there is an option to include these slag properties.

The associated quantity selected from the next drop-down list has these options: **All**, **B2**, **B3**, **B4**, **Bas2**, **Bells ratio**, **Ls**, or **Log10(Sulphur capacity)**. Also choose **In liquid slag only**, **In solid slag only**, or **In all slag**. Depending on this setting, the composition averaged over liquid, solid, or all slag is applied as a basis for the slag property calculation. Example PMET_01c is used for the figures below, where a table was added to one of the calculators.



Slag properties for a Table Renderer.



Slag properties for a Plot Renderer.

Equations

The equations and references for the slag properties are defined below. Composition can be given in mass (% or fraction).

The formulas are given in Thermo-Calc console-like syntax (B: mass, W: weight fraction, AC: activity). A slag property is available if all of its components are present in the phase group. Steel and slag are the actual phase groups chosen depending on the user request, i.e. the slag property can be calculated for the liquid slag only or for the overall slag (liquid and solid).

Basicity is defined as:

$$\mathbf{B2} = \frac{B(CaO)}{B(SiO_2)}$$

$$\mathbf{B3} = \frac{B(CaO)+B(MgO)}{B(SiO_2)}$$

$$\mathbf{B4} = \frac{B(CaO)+B(MgO)}{B(SiO_2)+B(Al_2O_3)}$$

$$\mathbf{Bas2} = \frac{B(CaO)+B(MgO)}{B(SiO_2)+B(Al_2O_3)+B(TiO_2)}$$

$$\mathbf{Bells\ ratio} = \frac{B(CaO)+0.7\cdot B(MgO)}{0.94\cdot B(SiO_2)+0.18\cdot B(Al_2O_3)}$$

Sulfur capacity is defined as:

$$\mathbf{Ls} = \frac{W_{(slag)}(S)}{W_{(steel)}(S)}$$

$$\mathbf{Log10}(C_s) = log10(W_{(slag)}(S)\cdot 100\cdot(\frac{AC(O_2,GAS)}{AC(S_2,GAS)})^{(0.5)})$$

Adiabatic Calculations: Material Enthalpy

An adiabatic calculation requires the enthalpy of the input materials as an initial condition. The Process Metallurgy Module uses different approaches for the different material types **metal**, **gas**, and **slag**. Any mechanical mixture is only applied for 1 bar / 1013 hPa.

Metal

Frozen-in global equilibrium calculation at T = 700 °C, taking the resulting enthalpy at the actual initial material temperature. This corresponds to a frozen-in microstructure. At initial material temperatures above 700 °C the equilibrium is instead calculated directly.

Gas

Mechanical mixture between the enthalpy of the gas components. This is no limitation because all gas components in the databases are assumed to be ideal gas.

Slag

- **Mechanical mixture**: If the temperature is below T=1000 °C and every single material component (such as MgO, CaO, …) is fully solid at the requested material temperature, mechanical mixture is assumed. This means that the enthalpy of every component is calculated separately and summed up (weighted by mass fraction). This corresponds to the assumption that different separate components have been added to the slag (such as burnt lime and magnesite). If any component forms gas or liquid at the initial material temperature, this mode is not used. Note that mechanical mixture is also applied if pure elements are added to the slag material, i.e. it is not the same in respect to the material enthalpy to define CaO and Ca + O.
- **Equilibrium**: If no mechanical mixture of the material components is possible or if the temperature is above T=1000 °C. This corresponds to the assumption of a fully homogenized slag material.

Working with the Process Schedule

Materials and heat can be added at any time in any amount. They can be either added to a:

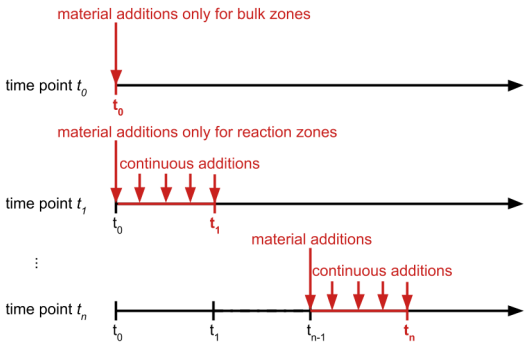
- bulk zone (such as steel, slag, etc.), or
- reaction zone (interface between two bulk zones).

These types of materials are used in the process schedule set up:

- Material addition (in tonne, kilogram, etc.)
- Continuous material addition (in kilogram per minute, etc.)
- Thermal / electrical power (i.e. a continuous heat addition in MW)

A material addition is typically used to model some event like emptying a bucket into the melt. A continuous material addition is instead used to model a continuous material feeding into the melt, such as wire feeding. Finally, heat can be added or removed during a time step and this is defined as power.

Process Schedule Additions Scheme



Modeling the Time Points

Generally the addition of materials and heat is modeled in the process simulations for any time point t_n as follows:

- Material additions happen immediately after the previous time point t_{n-1}, i.e. at the beginning of the time step.
- Continuous material and heat additions (power) are conceptually happening during the complete time step between t_{n-1} and t_n.

The data presented in the results is always referring to the time point, i.e. to the end of the time step. This means that reactions and heat transfer have happened between adding materials and heat at the beginning of the time step and the end of the time step. If for example a strongly cooling material is added, a possibly quite large heating of the zone might have happened until the end of the time step.

The first two time points are different:

- The first time point t_0 at *t=0* does not represent a time step, instead only a mixing and equilibrium reaction of the material additions in each bulk zone is taking place. There are no reaction zones existing at this time point.
- The second time point t_1 represents the first time step in the simulation where the different bulk zones react between each other via the reaction zones. Nevertheless it is conceptually identical to any other time point.

Learn More

Also see these related sections:

- Defining the Process Simulation
- Process Simulation: Process Schedule Tab
- About Dynamic Time Stepping

About Dynamic Time Stepping

The nature of a process simulation requires a dynamic choice of the time step lengths. On the one hand the simulation needs to capture very fast changes of temperature and composition, for example after addition of cold material. On the other hand it should calculate processes that take several hours in reality within an appropriate calculation time.

The time step control algorithm is primarily controlling the change of the temperature in each zone (including the reaction zones) such that it stays below a specified limit but is always as large as possible.

The dynamic time stepping can be switched off by choosing a very large maximum allowed temperature change per step (such as 1.0e6 K). In this case the maximum time step is always used, however this is only recommended in special situations.

If a temperature change is too large, the algorithm reverts the time step and returns to the previous time point in order to try a smaller time step. Therefore you can see in the Event Log output that the time points can jump back. Except for larger additions this is a rare event.

The parameters of the time-step control algorithm are:

- initial time step a *t=0*,
- smallest allowed time step,
- largest allowed time step, and
- maximum allowed temperature change of a zone within a time step.

The initial time step as well as the largest allowed time step are defined in percent of the total duration of the process while the smallest allowed time step is given in seconds. This allows that these parameters normally need no change even if switching between processes with very short and very long duration.

Making the largest allowed time step bigger can reduce the number of steps and consequently the calculation time, but only if the time step is not limited by the maximum temperature change per time step. This means that both parameters need to be considered together.

Taking a too large smallest allowed time step can cause numerical difficulties, especially if large cold material additions are part of the process schedule.

The initial time step is usually of limited relevance for the overall calculation time, but should usually not be larger than the default value of 1.0%.

As different processes show very different temperature changes, it is probably most common to adapt the maximum temperature change per time step in order to have a good balance between accuracy of the results and calculation time. Usually it should be possible to change this parameter without adapting the other algorithm parameters.

The effects of the dynamic time step algorithm can be inspected by activating the data points in the plots.

To show the data points, in the **Visualizations** window in Thermo-Calc, right-click in the plot area and choose **Properties**, then click **Show data points**.

About Pressure-Dependent Calculations

It is possible to apply variable pressure during process metallurgical calculations, which is relevant in various processes such as Vacuum Oxygen Decarburization (VOD) or Ruhrstahl-Heraeus (RH).

The implementation includes all relevant features for a realistic modeling of the pressure-dependency:

- the set pressure at a time-step is valid for all bulk and reaction zones of the system
- the exhaust gas zone has always atmospheric pressure
- the added material (only relevant for gas) has initially always atmospheric pressure
- the material transferred to and from the zones (i.e. the added material and the exhaust gas from the zones) is undergoing an adiabatic expansion / compression because it is moved between different pressures

Generally there is no effect of pressure change on anything else than gas (due to physics and the implementation of the database).

Process Metallurgy Calculator

Use a **Process Metallurgy Calculator** to set up calculations for steel and slag used in steelmaking. Define the composition of a steel (or other metal) and slag system using material groups: one each for steel, slag, and gas. You can save your material compositions directly from the calculator and quickly access and manage the materials and groups—it collects groups of saved materials according to type, thus making it easy to retrieve them.

You can add the calculator to **My Project** directly (right-click and select it from the **Create New Activity** menu) or use the Process Metallurgy Template.

Kinetics - Equilibrium or Process Simulation

Once you have added a Process Metallurgy Calculator, the **Configuration** window is further branched based on the **Kinetics** option you choose, **Equilibrium**, where kinetics are not considered, or **Process simulation**, where kinetics are considered using the Effective Equilibrium Reaction Zone (EERZ) model.

All settings, no matter what kinetics branch, are defined on the **Configuration** window **Conditions** and **Options** tabs.

Conditions Tab

Equilibrium

For information about the individual settings on this tab, see Equilibrium Simulation: Conditions Tab.

Set the conditions for your calculation that define the slag, metal, and gas. The topic, Defining the Equilibrium Simulation, has instructions that walk you through the steps that represent a simplified steelmaking process.

Process Simulation

For information about the individual settings on this tab, see Process Simulation: Conditions Tab.

Set the conditions for your calculation that best describes the process you want to simulate. The topic, Defining the Process Simulation, has instructions that walk you through the steps. Also the description of the kinetics examples are useful to help you better understand the settings.

Options Tab

For information about the individual settings, see Options Tab.

Use the **Material Manager** to create and delete groups of materials and delete materials you have saved directly from the Process Metallurgy Calculator. It is useful for frequently used materials. Also see Working with the Material Manager.

The settings in **Process Material Equilibrium and Grid** define certain numerical settings used by the Thermo-Calc calculation engine for equilibrium calculations such as whether tests for global minimization should always be performed (this significantly slows down the calculations) or never be performed (this speeds up calculations but miscibility gaps might not be found), and so forth.

Calculations of oxide systems are numerically challenging, and they can often fail. The default values are chosen to give the best general performance and reliability and should only be changed by an expert user. Also, a large amount of logic is implemented in the Process Metallurgy Module to improve the convergence and calculation speed of equilibrium calculations. The timestep control is related to how finely the times defined in the **Process schedule** are resolved. See About Dynamic Time Stepping for more information.

Local versus Global Options Settings

The **Options** tab is where you can locally define specific Process Metallurgy Calculator settings. Settings can also be applied globally from the **Options** window.

To open the **Options** window: From the main menu select **Tools → Options → Graphical Mode** and click the **Activities** tab. Then click **Process Metallurgy**. See Global Settings: Process Metallurgy.

Plots and Tables

Right-click the node to add a Plot Renderer or Table Renderer to visualize your results. Although both nodes work the same as with the other calculators in Thermo-Calc, there are additional features and settings unique to the Process Metallurgy Module. Useful information is included throughout the documentation. You can also read more about the unique features in Working with the Process Metallurgy Module.

Learn More

Examples of using the Process Metallurgy Calculator for Basic Oxygen Furnace (BOF) (with and without kinetics), a Ladle Furnace (LF) simulation, an Argon Oxygen Decarbarization (AOD), and a Vacuum Oxygen Decarborization (VOD) simulation are included with your installation. See Process Metallurgy Module Examples Collection for links.

You can find several learning resources on the Process Metallurgy page of our website (or in Thermo-Calc, go to **Help → Thermo-Calc website**). You can also subscribe to the Thermo-Calc newsletter to be kept up-to-date about upcoming releases, training, examples, videos and much more.

Read more on our website about applications for Sustainability. The webpage highlights several examples demonstrating how Thermo-Calc has been applied to address key sustainability challenges.

For information about licenses and availability, see About the Process Metallurgy Module.

Defining the Equilibrium Simulation

After adding a Process Metallurgy Calculator to your project, you can choose to conduct an **Equilibrium** simulation, where you define the steel, slag, and gas groups of materials, or a **Process simulation**, where you set up a process using the EERZ (Effective Equilibrium Reaction Zone) model.

The following steps are for **Equilibrium** simulations. If you choose to do a **Process simulation**, see Defining the Process Simulation.

This is a general overview of the setup based on the PMET_01: Basic Oxygen Furnace (BOF) example, which walks you through the steps that represent a simplified steelmaking process.

1. Add the Calculator and Choose the Simulation Type
2. Select a Database and Enter a Temperature
3. Define the Conditions for the Steel, Slag, and Gas Material Groups
4. Select the Calculation Type and Associated Definitions
5. Add and Define a Plot or Table and Run the Simulation

1: Add the Calculator and Choose the Simulation Type

1. Add a **Process Metallurgy Calculator** node to **My Projects** node. If you used the **Process Metallurgy** template on the **My Projects Configuration** window under **Applications**), click the node to display the **Configuration** settings window.
2. Under **Kinetics**, choose the simulation type, **Equilibrium** or **Process simulation**. For the following steps, choose **Equilibrium**.

2: Select a Database and Enter a Temperature

1. In the **Configuration** window, for the *Database* selection, the program automatically defaults to the highest available version of the TCOX database.

> The Process Metallurgy Module requires both a valid Maintenance and Support Subscription (M&SS) and a license for the TCS Metal Oxide Solutions Database (TCOX8 or newer).

> It is not possible to use custom user databases with the Process Metallurgy Module. This is because several internal calculations, such as determining the component compositions of ionic phases, are dependent on the database. Therefore, only TCS Metal Oxide Solutions Database (TCOX) versions 8 and newer, and to a limited extent, OXDEMO, can be used with this Module.

> All users can test the Process Metallurgy Module with the included OXDEMO database, which is limited to these elements: Al, C, Ca, Fe, O, S, and Si. For more information about this and other products visit our website.

2. Set the **Thermal Control** as being **Isothermal** or **Adiabatic**.
3. Select a **Temperature** unit (**Kelvin**, **Celsius**, or **Fahrenheit**) and enter a numerical value in the field.
4. Select a **Pressure** unit (**Pascal**, **Atmospheres**, or **Bar**) and then enter a numerical value in the field.

3: Define the Conditions for the Steel, Slag, and Gas Material Groups

Next define each material group—**Steel** (or any user-defined **Metal** group), **Slag**, and **Gas**.

See Equilibrium Simulation: Conditions Tab for an overview of the layout of this section. There is also an overview of these material groups in Working with the Process Metallurgy Module.

1. Choose a **Material** to set up first, **Steel** (or any user-defined metal), **Slag**, or **Gas**.
2. Select an **Amount** from the list—**Tonne**, **Kilogram**, **Gram**, or **Pound**. Enter a numerical value in the field.
3. If this is the first time you are defining a material, or at any time when **User-defined** is selected, click **Show composition** to set the composition for the material (steel, slag, or gas or another user-defined metal).

> The composition for each material is hidden by default because the Module allows you to easily save materials and access these from the material menu. Once you save a collection of materials, you will rarely have to click **Show composition**. See Working with the Material Manager for details about saving and deleting materials.

4. To the right of the **Material** list (e.g. for the **Steel** group), choose the material composition you want to use for this simulation. Predefined **Example Steel** and **Example Slag** compositions are included with the installation.
   - If you chose **Adiabatic** as the **Thermal Control**, also enter a **temperature** in the field for each material. This is the initial temperature before the material is added to the process.
5. From the first **Input type** list select **Mass percent**, **Mass fraction**, **Mole percent**, **Mole fraction**, or **Absolute amount**. For **Absolute amount**, you can directly enter values in the fields in the unit selected above for **Amount** (**Tonne**, **Kilogram**, **Gram**, or **Pound**).
6. For the next list, the default is based on which group you are defining. For the Steel (Metal) group it is **Element**, for Slag it is **Component**, and for Gas it is **Gas component**.
7. Choose **Major component** so that as you add other components, the major one is adjusted to be the rest of the composition. Choose **Normalize to total of 100%** so that the sum is adapted to 100%. This is useful if you need to work with a given composition that does not sum up to 100% If you select **Absolute amount**, **Normalize to total of 100%** is not available.
8. Based on which material group you are working with, add the **Element**, **Component**, or **Gas component**.

To add one or more material groups click the add ⊕ button. Click the minus ⊖ button to remove a material group. The new material inherits the default settings of that group.

9. After you have added and defined the element, component, or gas component it is recommended you save and name the material. This makes it easier to work with because the name of the material is automatically updated in the lists (and available as part of your library) instead of being named *User-defined* everywhere.

   The material is automatically saved in the relevant material group, so only steel materials are shown in the steel menu, only slag materials are shown in the slag menu, and only gas in the gas menu. You can also create additional material groups if there are groups you use regularly, such as scrap compositions, ferro-alloys or slag additions. See Working with the Material Manager for more details about creating and deleting material groups and deleting materials.

10. Continue adding and defining the material groups (e.g. Steel, Slag, and Gas). You could, for example, add another Steel group if you wanted to define a composition of a steel scrap to add to a basic oxygen furnace (BOF).

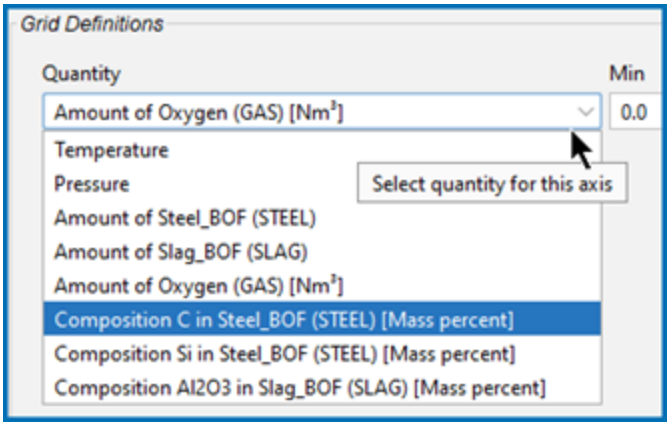
4: Select the Calculation Type and Associated Definitions

These settings are described more in Equilibrium Simulation: Conditions Tab.

1. Under *Calculation Type*, click to choose **Single** (no axes), **One Axis**, **Grid**, or **Uncertainty**.

   For more complex calculations, it is good practice to start with a **Single** equilibrium calculation to make sure the calculation converges. Also see the settings described in Options Tab. These can be useful if your calculation fails.

2. Based on the calculation type, define either the *Grid Definitions* (for **One Axis** or **Grid** calculations) or the *Sampling of Data from Gaussian Distributions* (for **Uncertainty** calculations). The **Quantity** displays all the stepping options set up with the material groups for **Steel**, **Slag**, and **Gas**. The example shows the steel group quantities.



The *Amount of X in Y* quantities you can choose from the various drop-down lists (such as under *Grid Definitions*) are defined as Min-Max variation of the component X in Y. If a dependent element is present that is adapted as usual.

How these quantities relate to the material definition is described in Working with the Process Metallurgy Module.

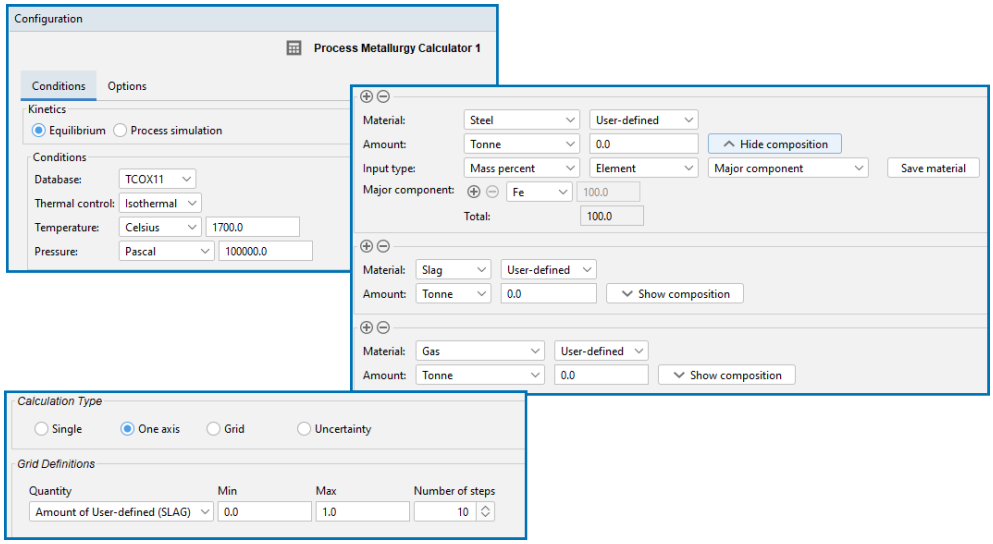
5: Add and Define a Plot or Table and Run the Simulation

Once you have finished defining the Process Metallurgy Calculator, you also define the plot or table settings. To add a Plot Renderer or Table Renderer, right-click the calculator node and select an option from the **Create New Successor** menu.

The settings are generally described for the individual nodes. See Plot Renderer and Table Renderer. Some useful information about the plots is also described in Working with the Process Metallurgy Module.

Equilibrium Simulation: Conditions Tab

The following outlines what you can set on the **Configuration** window **Conditions** tab when working with the Process Metallurgy Calculator and an **Equilibrium** simulation.



An example of the different settings areas for a default Configuration window for a Process Metallurgy Calculator when an Equilibrium simulation type is selected. There are many settings available depending on the parameters.

> Also see Defining the Equilibrium Simulation for instructions that walk you through the steps that represent a simplified steelmaking process. A more complex process is described in Defining the Process Simulation.

Database

The most recent available version of TCS Metal Oxide Solutions Database (TCOX) is selected by default.

The Process Metallurgy Module requires both a valid Maintenance and Support Subscription (M&SS) and a license for the TCS Metal Oxide Solutions Database (TCOX8 or newer).

It is not possible to use custom user databases with the Process Metallurgy Module. This is because several internal calculations, such as determining the component compositions of ionic phases, are dependent on the database. Therefore, only TCS Metal Oxide Solutions Database (TCOX) versions 8 and newer, and to a limited extent, OXDEMO, can be used with this Module.

All users can test the Process Metallurgy Module with the included OXDEMO database, which is limited to these elements: Al, C, Ca, Fe, O, S, and Si. For more information about this and other products visit our website.

General Settings

Thermal Control

Choose **Isothermal** or **Adiabatic**. When **Adiabatic** is selected, no global temperature is defined (as this changes during the process). Instead the initial temperature has to be defined separately for each material. Adiabatic calculations assume no heat and mass exchange with the environment during the equilibrium reaction. Certain types of processes run at almost constant temperatures. For such processes isothermal conditions are acceptable. But in most metallurgical processes the temperature will change sometimes dramatically in function of time due to heating or cooling of the system and due to exothermal or endothermal reactions taking place. For such processes adiabatic conditions are a better choice.

Temperature

Choose a **Temperature** unit (**Kelvin**, **Celsius**, or **Fahrenheit**) and then enter a numerical value in the field.

Pressure

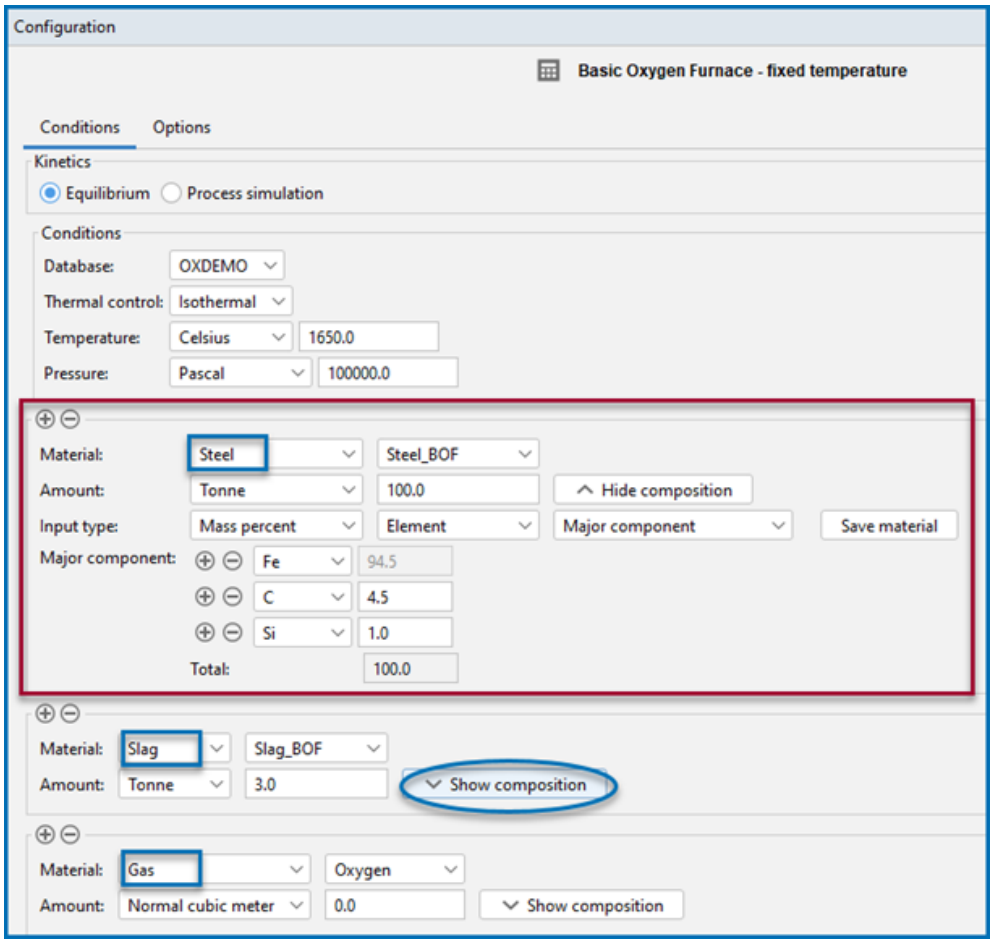
Choose a **Pressure** unit (**Pascal**, **Atmospheres**, or **Bar**) and then enter a numerical value in the field.

Material Groups (Steel, Slag, and Gas)

For more details about these fields, see Defining the Equilibrium Simulation. See also Working with the Material Manager.

There are three groups to define: **Steel** (or another user-defined **Metal** group), **Slag**, and **Gas**.

In the image below, the red-highlighted area is where the **Steel** material group is defined. The drop-down menu that displays *Steel_BOF* is a user-defined material. This can be defined and then saved to the material library.



The three material group areas on the Process Metallurgy Calculator where you can define components and save materials.

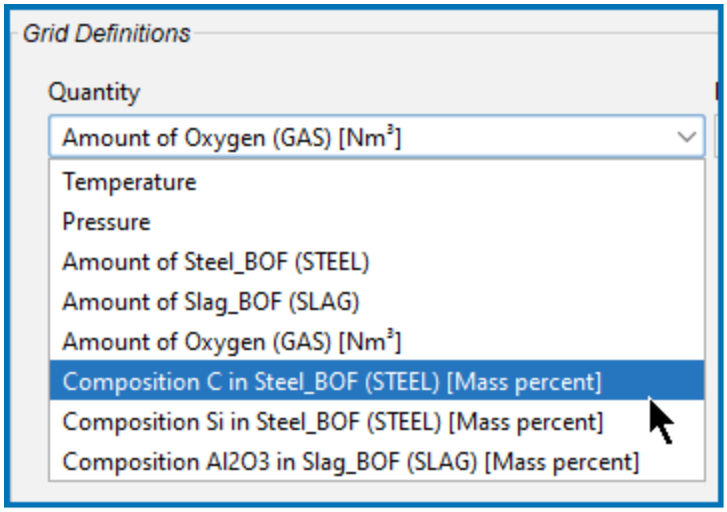
When you click **Show composition** next to any material group, additional fields display (e.g. **Input type**, **Major components**, and so forth) where you can further define each material group. You can add and remove materials using the *Material Manager* (available via the **Configuration** window → **Options** tab).

You can open the example project PMET_01: Basic Oxygen Furnace (BOF) from Thermo-Calc **(Help → Example Files → Process Metallurgy → PMET_01_Basic_Oxygen_Furnace.tcu)**. Then click **Show composition** next to the **Slag** and **Gas** groups to see how the *Slag_BOF* and *Oxygen* materials are defined.

From this composition area you can click the **Save material** button to add the new material to the group's list. The newly named material composition is then available for use with that material group. In this example, the *Steel_BOF* material was defined first and then named at the end. It is now automatically available wherever you select the Steel material or need to choose quantities to plot.

The *Amount of X in Y* quantities you can choose from the various drop-down lists (such as under *Grid Definitions*) are defined as Min-Max variation of the component X in Y. If a dependent element is present that is adapted as usual.

To add one or more material groups click the add ⊕ button. Click the minus ⊖ button to remove a material group. The new material inherits the default settings of that group.



After defining and saving a material composition, the named material is available for selection in a variety of places such as when choosing quantities on the calculator and defining axis variables on the Plot Renderer.

Calculation Type

Click to select a *Calculation Type*.

- **Single**: To calculate a single point. The results from this calculation can be displayed in the **Visualizations** window using a **Table Renderer**.
- **One Axis**: To vary a quantity on the *X*-axis.
- **Grid**: Evaluates two axis variables of the selected quantities in the specified range and number of steps.
- **Uncertainty**: Evaluates calculations where the values of the quantities are sampled from Gaussian distributions. The **Mean** field is as defined under *Condition Definitions* for the respective quantity. The result is visualized as a histogram or normal probability plot by adding a Plot Render activity.

Plot Types

Grid Definitions (One Axis or Grid)

The **Quantity** menu displays all the stepping options set up with the material groups for **Steel** (or any user-defined metal group), **Slag**, and **Gas**.

For **One Axis**, select a **Quantity** to vary along the X-axis, for example, **Temperature** then enter a **Min**, **Max**, and **Number of steps**.

For the **Grid** calculation type, define the two axes variables using the fields and menus: **Quantity**, **Min**, **Max**, and **Number of steps**. The number of steps along with the minimum and maximum values for the axes define a grid. For each grid point the selected equilibrium is evaluated.

Depending on the calculation type selected, there are also a variety of Plot Types to choose from.

Sampling of Data from Gaussian Distributions (Uncertainty)

For the **Uncertainty** calculation type, click to select the applicable checkboxes under **Quantity**. The **Mean** field is for the distribution function as defined under *Condition Definitions* for the respective quantity. The default ΔMin/Max is a 95% confidence interval.

About the Uncertainty Calculations

Sampling Parameters (Uncertainty)

For the **Uncertainty** calculation type, choose a number of **Standard deviations** where you want to **Truncate the distribution**. Choose the **Total number of samples**.

About the Uncertainty Calculations

Defining the Process Simulation

After adding a Process Metallurgy Calculator to your project, you can choose to conduct an **Equilibrium** simulation, where you define the steel, slag and gas groups of materials, or a **Process simulation**, where you set up a process using the EERZ (Effective Equilibrium Reaction Zone) model.

Setting Up a Process Metallurgy Simulation

The following steps are for **Process simulation**. If you choose to do an **Equilibrium**, see Defining the Equilibrium Simulation.

1. Add the Calculator and Choose the Simulation Type
2. Select a Database and Enter a Temperature
3. Define the Process Model
4. Define the Materials
5. Define the Process Schedule
6. Run the Simulation and Add and Define a Plot or Table

1: Add the Calculator and Choose the Simulation Type

1. Add a **Process Metallurgy Calculator** node to **My Projects** node. If you used the **Process Metallurgy** template on the **My Projects Configuration** window under **Applications**), click the node to display the **Configuration** settings window.

2. Under **Kinetics**, choose the simulation type, **Equilibrium** or **Process simulation**. For the following steps, choose **Process simulation**.

   Only adiabatic conditions are available for process simulations as this corresponds best to most practical processes.

2: Select a Database and Enter a Temperature

Process Simulation: Conditions Tab

1. In the **Configuration** window, for the *Database* selection, the program automatically defaults to the highest available version of the TCOX database.

> The Process Metallurgy Module requires both a valid Maintenance and Support Subscription (M&SS) and a license for the TCS Metal Oxide Solutions Database (TCOX8 or newer).

> It is not possible to use custom user databases with the Process Metallurgy Module. This is because several internal calculations, such as determining the component compositions of ionic phases, are dependent on the database. Therefore, only TCS Metal Oxide Solutions Database (TCOX) versions 8 and newer, and to a limited extent, OXDEMO, can be used with this Module.

> All users can test the Process Metallurgy Module with the included OXDEMO database, which is limited to these elements: Al, C, Ca, Fe, O, S, and Si. For more information about this and other products visit our website.

2. Select a **Temperature** unit (**Kelvin**, **Celsius**, or **Fahrenheit**).
3. Select a **Time** unit (**Seconds**, **Minutes**, **Hours**, or **Days**).

3: Define the Process Model

Process Simulation: Process Model Settings

1. Enter a **Name** for the process and the total **Duration** of the process.
2. Choose a **Process model** from the list or click **Edit Process Model** to define a new model or edit an existing one.

3. In the **Process model** the following is defined:

    a. **Pressure**. This is can be either **Constant** throughout the process (enter a constant via the Edit Process Model) or be changed during the process (select **Table input** via the Edit Process Model) and then enter pressure in the **Process schedule** table.

    b. **Zones of the Effective Equilibrium Reaction Zone model**. Only two zones can be defined. The densities need to be given manually. They are used to calculate the volume of the reaction zones, which is in turn used for the calculation of the reaction kinetics. Choose to allow degassing or not.

    c. **Area of the Reaction zone and mass transfer coefficients**. The area is typically the area of the interface between the two zones. The mass transfer coefficients state how fast material is moved into the reaction zone. Large values result in fast kinetics, small numbers in slower kinetics. These values strongly depend on the type of material (mass transfer in slags is slower than in liquid steel due to its higher viscosity) and type of process (the violent reactions in a basic oxygen furnace have higher mass transfer coefficients compared to the gentle stirring performed in a ladle furnace. These parameters are basically fitting parameters that need to be determined based on comparison with experimental data. Typical values can also be found in the literature. Choose to allow degassing or not.

    d. **Transfer of phase group**. This defines how fast “foreign” phases are moved from one zone to the other. Foreign phases could be solid or liquid oxide inclusions in the liquid steel, or metallic droplets in the slag phase. A typical application is the simulation of the flotation of oxide inclusions out of the liquid steel into the slag phase during refining in a ladle furnace.

    e. **The Heat entering or leaving the system and being transferred between the zones.** Constant cooling defines how much heat is lost from the system by radiation and convection. Separate values can be given to each zone if needed. Heat is used when the system is actively heated by an external heat source such as an electric arc or induction heater. Here only the heating efficiency is given, which is the percentage of for example electrical power that is transferred to the system as heat. The times and power are defined in the **Process schedule**. Different amounts of heat and material are added to the zones resulting in the zones having different temperatures. Heat transfer defines how heat flows

from one zone to the other. A high value results in a quick equalization of temperature, a small value results in the zones keeping their different temperatures.

4: Define the Materials

Process Simulation: Materials Tab

The materials can be defined, saved and retrieved in the same way as for an equilibrium simulation. For a process simulation, it must be defined to which zone the material is added. Typically, oxide materials are added to the slag zone and metallic materials are added to the steel zone. Gas or other injected materials (such as carbon or lime powder) are typically added to the reaction zone. But this choice depends on the process to be simulated and must be carefully chosen. By defining the same material twice or even three times, it can be split, so that part of the material is added to one zone and part of it to another zone.

5: Define the Process Schedule

Working with the Process Schedule

Process Simulation: Process Schedule Tab

On the **Process schedule** tab, the sequence and amounts of additions during the duration of the process are defined. All the materials defined in the **Materials** tab automatically are included in the table. If a heat addition is defined in the Process Model this is also included in the table. If the units **Tonne**, **Kilogram**, or **Pound** are selected, then the additions are defined as one-time additions at a certain time. If a rate is chosen as unit of the addition (such as **Kilogram per minute** or **Kilogram per second**, for gas also **Normal cubic meter per minute** or per second can be given) then the rate of addition is entered into the table. The additions are visualized in a plot for clarity.

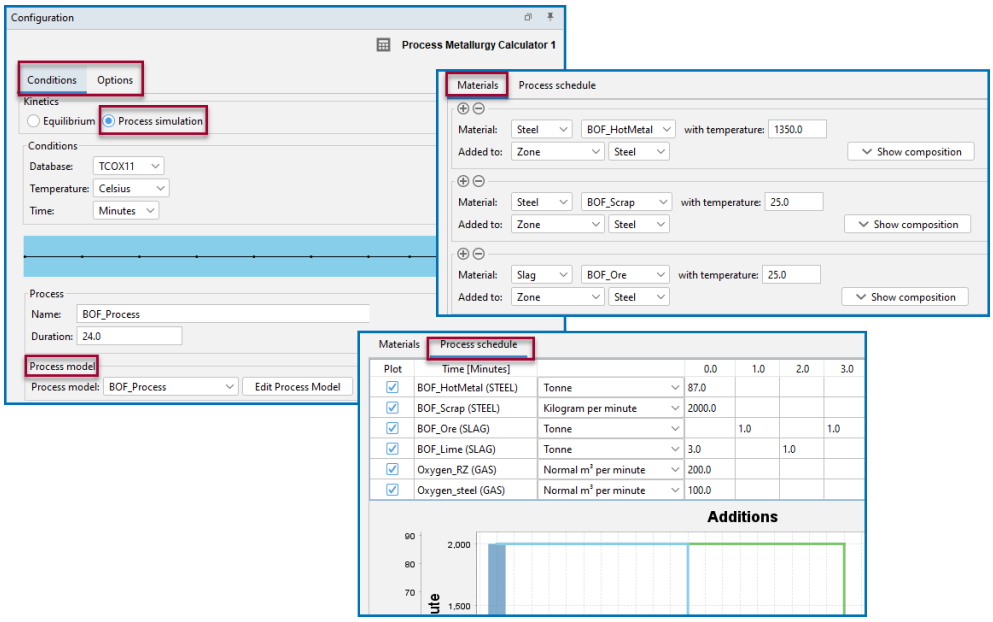
6: Run the Simulation and Add and Define a Plot or Table

When the simulation is set up, click **Perform Tree** to run it. Plots and tables can be added in the same way as for equilibrium calculations.

Process Simulation: Conditions Tab

The following outlines what you can set on the **Configuration** window **Conditions** tab when working with the Process Metallurgy Calculator.

Below is based on selecting a **Process simulation** under **Kinetics**. The settings to complete are for the **Process Model**, the **Materials**, and the **Process Schedule**.



An example of the different sections on the Configuration window for a Process Metallurgy Calculator when a Process simulation type is selected. This screen shot is from the example PMET_04c. There are many settings available depending on the parameters.

Database

The most recent available version of TCS Metal Oxide Solutions Database (TCOX) is selected by default.

The Process Metallurgy Module requires both a valid Maintenance and Support Subscription (M&SS) and a license for the TCS Metal Oxide Solutions Database (TCOX8 or newer).

It is not possible to use custom user databases with the Process Metallurgy Module. This is because several internal calculations, such as determining the component compositions of ionic phases, are dependent on the database. Therefore, only TCS Metal Oxide Solutions Database (TCOX) versions 8 and newer, and to a limited extent, OXDEMO, can be used with this Module.

All users can test the Process Metallurgy Module with the included OXDEMO database, which is limited to these elements: Al, C, Ca, Fe, O, S, and Si. For more information about this and other products visit our website.

Time and Temperature Settings

- **Temperature**: Select a **Temperature** unit (**Kelvin**, **Celsius**, or **Fahrenheit**).
- **Time**: Select a **Time** unit (**Seconds**, **Minutes**, **Hours**, or **Days**).

Additional Settings

The settings sections for all of the **Configuration** window are described in these topics:

- Process Simulation: Process Model Settings
- Process Simulation: Materials Tab
- Process Simulation: Process Schedule Tab

Learn More

See Defining the Equilibrium Simulation for instructions that walk you through the steps that represent a simplified steelmaking process. A more complex process is described in Defining the Process Simulation and where the settings in the following topics are described.

Examples of using the Process Metallurgy Calculator for Basic Oxygen Furnace (BOF) (with and without kinetics), a Ladle Furnace (LF) simulation, an Argon Oxygen Decarbarization (AOD), and a Vacuum Oxygen Decarborization (VOD) simulation are included with your installation. See Process Metallurgy Module Examples Collection for links.

Process Simulation: Process Model Settings

The following outlines what you can set on the **Configuration** window under Process and when you click **Edit Process Model**. The overall steps to set this up are described in Defining the Process Simulation.

General Settings

Process

Under *Process*, enter a **Name** and **Duration**.

> For more complex processes, you could, for example, enter the process reference as its *Name* as is done for the EERZ example PMET_06: Kinetics of Steel Refining in a Ladle Furnace (LF).

Process Model

Choose a *Process model*. Click **Edit Process Model** to enter details as below.

> You can create your own **Process model** and name them so these are available to choose from the list in the future. This is done using the **Edit Process Model** window.

Edit Process Model

To open the **Edit Process Model** window, click **Edit Process Model** to access the following settings.

Pressure

For **Pressure**, this is can be either **Constant** throughout the process or be changed during the process (using **Table input** here and then entering values in the Process Schedule). Choose:

- **Constant** to choose a unit (**Pascal**, **Atmospheres**, or **Bar**) and then enter a numerical value in the field.

  > Only constant pressure throughout the process can be used. Also, the pressure only influences reactions involving the gas phase.

- **Table input** to add or use the values entered in the **Process Schedule** table.

Zones

In this section define the material zone(s), which are added to a **Zone** or **Reaction zone** on the **Materials** tab.

Enter a **Name** and **density** (in kg/m^3) for the zones.

For example, enter `Steel` and `Slag`, which in the next section are available to define for **Zone 1** or **Zone 2** in the Reaction zone.

Select the **Allow degassing** checkbox to be able to simulate vacuum degassing, for example.

Click the ⊕ **Add** button to define additional items and the ⊖ **Remove** button to delete items.

Reactions

In this section you are defining either a **Reaction zone** and/or **Transfer of phase group**.

Select the **Allow degassing** checkbox to be able to simulate vacuum degassing, for example.

Click the ⊕ **Add** button to define additional items and the ⊖ **Remove** button to delete items.

Reaction Zone

If you choose **Reaction zone** from the list then enter an *area* (in m^2).

Next choose from each **Zone 1** and **Zone 2** list the Zone as defined above, for example **Steel** or **Slag**.

For **mass transfer coefficient** choose:

- **Constant** to enter a numeric value in the field in m/s for each.
- **Table input** to add or use the values entered in the **Process Schedule** table.

Reaction zone area and mass transfer coefficient defines the kinetics of the reaction between the two zones. A large area and fast mass transfer results in fast kinetics.

Transfer of Phase Group

If you choose to define a **Transfer of phase group**, then choose the state as **Liquid metal**, **Solid metal**, **All metal**, **Solid oxides**, **Liquid oxides**, **All oxides**, or **Gas**.

Then choose the two zones (e.g. Steel or Slag) to define **from zone** and **to zone**. Then enter a value and choose a time from the list, **Percent per minute** or **Percent per second**.

This parameter defines how fast “foreign” phases are transferred from one zone to another. A typical example is the flotation of oxide inclusions in liquid steel up into the slag phase.

Heat

Choose the type of heat to apply to the process: **Constant cooling**, **Heat transfer**, and/or **Heat**.

Click the **Add** button to define additional items and the **Remove** button to delete items.

Constant Cooling

If you choose **Constant cooling**, enter a **Name**, choose either **Zone** or **Reaction Zone** and enter a numerical value in the field in MW (megawatts).

If you choose **Zone**, you can further choose either Zone defined above (e.g. **Steel** or **Slag**). If you choose **Reaction Zone**, then heat is lost from the EERZ, the size of which is calculated at each timestep depending on the kinetic parameters defined in **Reaction Zone**.

This parameter defines how much heat is lost from a zone (or the reaction zone) by radiation or convection and results in an overall cooling of the system.

Heat Transfer

If you choose **Heat transfer**, select two zones between where heat should flow and enter a **heat transfer coefficient** in Wm^2/K.

As different amounts of material and also different amounts of heat can be added to the different zones, these temperature are different. As the two zones are in contact heat flows from the hotter zone to the cooler zone thus equalizing the temperature. The amount of heat flowing from one zone to the other is defined by the **Heat transfer**. A high heat transfer coefficient leads to fast temperature equalization, a small heat transfer coefficient results in the zones keeping different temperatures.

Heat

If you choose **Heat**, enter a *Name*, then select **Zone** or **Reaction zone**, choose a Zone (e.g. **Steel** or **Slag**) and enter a percentage of **MW efficiency** in the field.

Select **Heat** if the system is actively heated by an external heat source such as an electric arc or induction coil. Here only the efficiency is defined, which is the percentage of power (for example electrical power) that is transformed into heat that enters the system and heats it up. The profile of power versus time is defined in the **Process Schedule**.

Click **Save** when the Process Model is defined and enter a **Process model name**. Each time you save a process model it adds it to the list on the main **Configuration** window, which you can use in future set ups.

Process Simulation: Materials Tab

This section is similar to how you define the materials for the Equilibrium branch. Some information is explained in more detail for Equilibrium Simulation: Conditions Tab and not repeated here.

Settings

The following outlines what you can set on the **Configuration** window **Materials** tab. The overall steps to set this up are described in Defining the Process Simulation.

Material

Materials are grouped into **Steel** (or another user-defined **Metal** group), **Slag** (or another user-defined non-metallic group), and **Gas**.

Some of what you choose from lists in this section depend on what you have entered as the **Process Model** above. For example, the **Zone** or **Reaction zone** options are based on those entries (e.g **Steel** or **Slag**).

To add one or more material groups click the add ⊕ button. Click the minus ⊖ button to remove a material group. The new material inherits the default settings of that group.

After choosing the Material for the section being defined, also enter a value of the *temperature* in the field. Choose what **Zone** or **Reaction zone** it is to be **Added to**.

The times and amounts of additions are defined in the **Process schedule**.

Show Composition

When you click **Show composition** next to any material group, additional fields display where you can further define each material group.

From this composition area you can click the **Save material** button to add the new material to the group's list. The newly named material composition is then available for use with that material group.

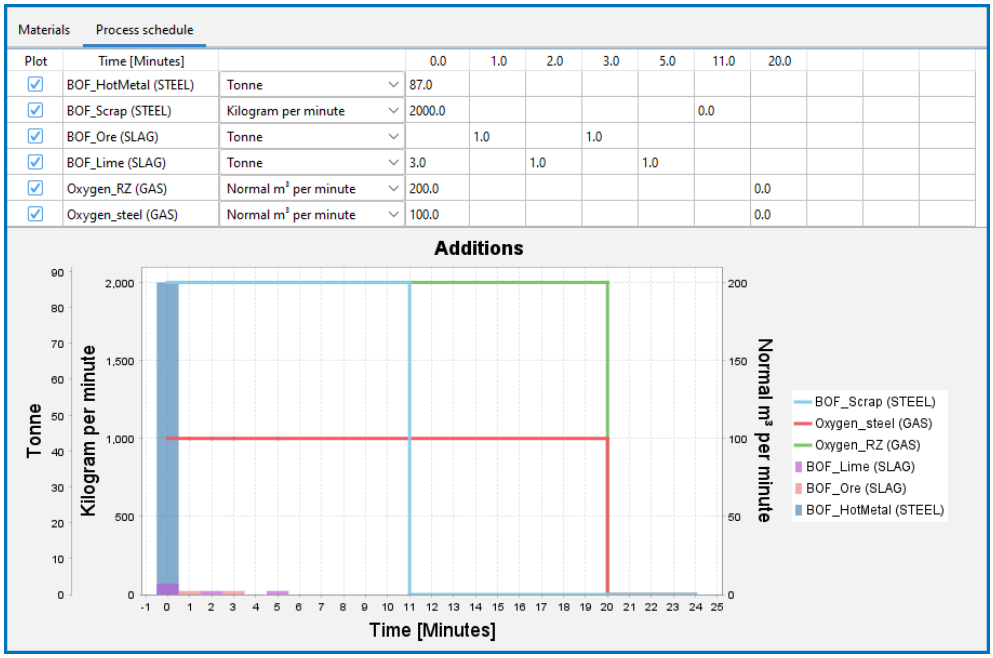
From the first **Input type** list select **Mass percent**, **Mass fraction**, **Mole percent**, or **Mole fraction**.

For the next list, the default is based on which group you are defining. For the Steel (Metal) group it is **Element**, for Slag it is **Component**, and for Gas it is **Gas component**.

Choose **Major component** so that as you add other components, the major one is adjusted to be the rest of the composition. Choose **Normalize to total of 100%** so that the sum is adapted to 100%. This is useful if you need to work with a given composition that does not sum up to 100%.

Process Simulation: Process Schedule Tab

On the **Process schedule** tab, the sequence and amounts of additions during the duration of the process are defined. All the materials defined in the **Materials** tab automatically are included in the table. If a heat addition is defined in the *Process Model* this is also included in the table.



Settings

The following outlines what you can set on the **Configuration** window **Process Schedule** tab. The overall steps to set this up are described in Defining the Process Simulation. Also see Working with the Process Schedule.

Plot

Select the **Plot** checkbox to include or exclude the components in the process schedule plot area, for example, to help you examine the changes in the plot window, after defining the Steel, Scrap, Slag, or Gas rows, see what happens when you remove one or more items from the plot.

Unit

Enter a value and choose a unit **Tonne**, **Kilogram**, **Pound**, **Kilogram per second**, or **Kilogram per minute**. For **Gas** you can also choose **Normal m3 per minute** as the unit.

If a unit **Tonne**, **Kilogram**, or **Pound** is selected, then the additions are defined as one-time additions at a certain time. If a rate is chosen as unit of the addition (such as Kilogram per minute or second, for gas Normal cubic meter per minute or second) then the rate of addition is entered into the table and it stays constant until a different value is entered.

Options Tab

These settings are for the Process Metallurgy Calculator and are located on the **Configuration** window → **Options** tab. Only unique settings are described below.

Equilibrium Simulation: Conditions Tab

Material Manager

Use the **Material group** and **Material** lists to create and delete material groups, as well as delete material compositions that are saved from the Process Metallurgy Calculator. It is useful for frequently used materials.

See Working with the Material Manager for details.

- **Material group**: To create or delete a group, choose it from this list, e.g. **Steel**, **Slag**, or **Gas**. The *Steel* group is simply a generic **Metal** group. You can create other user-defined metal groups and then these are listed. Click **Create group** or **Delete group** as required to manage the list.
- **Material**: To delete a material, choose the group type then select the material composition to delete. For example, select the **Slag** material group, then choose the **Example Slag** material and click **Delete material** to remove it from all lists.

Process Material Equilibrium and Grid

Minimization Strategy

Under *Process Material Equilibrium and Grid*, the default uses the **Global test preferred** option for **Equilibrium** simulations and the **Local minimization preferred** option for **Process simulations**.

The **Minimization Strategy** setting is used to ensure that the most stable minimum under the specified conditions is computed.

With either the *Global test preferred* or *Local minimization preferred* setting, the program cycles through options before it gives up:

- For **Global test preferred** the minimization starts with a global test and if that fails it runs full global minimization.
- For **Local minimization preferred** the minimization starts with a local minimization, in case of failure it tries a global test and finally a full global minimization.

If you choose **Local minimization only** or **Global minimization only**, the program just tries the one setting and gives up if it fails.

For general information about global minimization, see the topic related to the Console Mode command, GLOBAL_MINIMIZATION.

Max No. of Iterations

Under *Process Material Equilibrium and Grid*, the default for the **Max no. of iterations** is that the program tries 2000 iterations before it gives up.

Required Accuracy

The default **Required accuracy** is `1.0E-6`. This is a relative accuracy, and the program requires that the relative difference in each variable must be lower than this value before it has converged. A larger value normally means fewer iterations but less accurate solutions. The value should be at least one order of magnitude larger than the machine precision.

Smallest Fraction

Under *Process Material Equilibrium and Grid*, the default **Smallest fraction** is `1.0E-16`. If this value fails, the program tries other values. This is the value assigned to constituents that are unstable.

The default value is for all phases except for the IDEAL phase with one sublattice site (such as the GAS mixture phase in many databases) where the default value is always as 1E-30.

Max Grid Points (in Global Minimization)

Under *Process Material Equilibrium and Grid*, from the **Max grid points** list choose:

- **Coarse** for 2000 grid points, the default,
- **Medium** for 20,000 grid points,
- **Fine** for 200,000 grid points, or
- **Custom** to set your own number of grid points.

Approximate Driving Force for Metastable Phases

Under *Process Material Equilibrium and Grid*, the **Approximate driving force for metastable phases** checkbox is selected by default, which means the metastable phases are included in all iterations. However, these may not have reached their most favorable composition and thus these driving forces may be only approximate.

Force Positive Definite Phase Hessian

Under *Process Material Equilibrium and Grid*, the **Force positive definite phase Hessian** checkbox is selected by default and this setting determines how to reach the minimum of an equilibrium state.

Control Step Size

Under *Process Material Equilibrium and Grid*, the **Control step size** checkbox is selected by default and this setting determines how to reach the minimum of an equilibrium state.

Timestep Control

This section is used with the **Process simulation** calculations. Read About Dynamic Time Stepping to better understand these settings.

Timestep

Under *Timestep control*, enter numerical values in the fields for the **Timestep**:

- **Initial %**
- **Smallest allowed** in seconds (s)
- **Max % of duration**

Max Temperature Change Per Time Step

Under *Timestep control*, in the field enter the **Max temperature change per time step** in Kelvin (K).

Global Options

You can change these settings locally for a specific Calculator or globally for some defaults in the **Options** *window* (a different location than the tab).

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** <*version*> → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Graphical Mode** tab and the **Process Metallurgy** node in the tree.

Process Metallurgy Module Examples Collection

The Process Metallurgy Module requires both a valid Maintenance and Support Subscription (M&SS) and a license for the TCS Metal Oxide Solutions Database (TCOX8 or newer).

All users can test the Process Metallurgy Module with the included OXDEMO database, which is limited to these elements: Al, C, Ca, Fe, O, S, and Si. For more information about this and other products visit our website.

PMET_01: Basic Oxygen Furnace (BOF)

The example uses the **Process Metallurgy Calculator** to demonstrate a simplified steelmaking process in a Basic Oxygen Furnace (BOF).

This example has some step-by-step instructions available on our website. It shows how you can use equilibrium calculations set up in the Process Metallurgy Module to gain a general understanding of your Basic Oxygen Furnace (BOF) process and help you determine optimal operation conditions and predict and optimize costs of raw materials and recycling.

Two elements that are very important in steelmaking and steel refining are sulfur (S) and phosphorus (P). Both elements are usually undesirable and must be removed from the liquid steel. This is generally done by transferring them to a CaO-rich slag phase. In this example, we show how the Process Metallurgy Module in Thermo-Calc can be used to investigate suitable conditions to remove P from liquid steel using a Basic Oxygen Furnace.

Thermo-Calc Software offers two application examples showing how the Process Metallurgy Module can be used to calculate the Basic Oxygen Furnace Process. This example uses equilibrium calculations to gain a general understanding of your BOF process.

The other set of examples gives instructions on how to simulate the kinetics of the BOF process using the kinetic process simulation (see PMET_04: Kinetic Simulations of the Basic Oxygen Furnace (BOF) Process).

Project File and License Information

- Folder: **Process Metallurgy**
- File name: `PMET_01_Basic_Oxygen_Furnace.tcu`

Choose a, b, or c versions of the example based on your license.

- **PMET_01a_Basic_Oxygen_Furnace** is included in a regular Thermo-Calc installation as well as the free Educational version of Thermo-Calc. This is a highly simplified example and uses the OXDEMO database, and only considers the elements Fe, C, and O.
- **PMET_01b_Basic_Oxygen_Furnace** is also a simplified calculation but uses the

OXDEMO database. It requires a full license of Thermo-Calc 2021b and newer.

- **PMET_01c_Basic_Oxygen_Furnace** requires the TCOX11 database and newer and a full license of Thermo-Calc 2021b and newer.

Resources

This example is included as a Process Metallurgy tutorial on our website and as part of the playlist our YouTube channel.

One way to learn how to work with the Process Metallurgy Calculator is to use the project files as templates to help you set up your own simulation. For example, you can examine the settings available on the **Configuration** window and that are described in Process Simulation: Conditions Tab and the Options Tab.

PMET_02: Desulphurization in a Ladle Furnace (LF)

The example, which has some step-by-step instructions available on our website, uses the **Process Metallurgy Calculator** to demonstrate the use of a Ladle Furnace (LF) with the Process Metallurgy Module.

The ladle furnace (LF) fulfils many purposes in the steelmaking process. Desulphurization, which we will focus on in this example, is merely one of them.

Desulphurization is usually performed by transferring S that is dissolved in the liquid metal to a CaO-rich slag phase. For this process to be successful, two conditions need to be fulfilled:

1. The slag must be fully liquid (liquid fraction > 0.9). This is required for kinetic reasons. The slag phase must be fluid so that it can emulsify with the liquid steel and form a large surface area where the reaction between steel and slag can take place.
2. The slag must take up a large amount of S from the liquid steel (have a "high sulphur capacity") so that a significant amount of sulphur will move from the liquid steel to the slag phase.

The example demonstrates how the Process Metallurgy Module in Thermo-Calc can be used to explore these two conditions for an equilibrium between liquid steel and slag in a ladle furnace, trying to find good slag compositions. We also investigate why excessive slag carry-over from the BOF or EAF is detrimental for desulphurization in the LF and who how slag conditioning with CaC_2 as fluxing agent can recover the desulphurizing ability of the slag.

PMET_03: Argon Oxygen Decarburization (AOD)

The Argon Oxygen Decarburization (AOD) process is a converter process applied in stainless steel making. In this process the oxidation of chromium in the steel melt needs to be prevented while carbon is oxidized. This is achieved by reducing the oxygen partial pressure by having a high Ar-content in the blowing gas. It is a highly exothermic process that requires adiabatic modeling. In this example the conversion of carbon-rich steel scrap is modeled together with additions of Ferronickel and Ferrochrome to a stainless steel. The example uses the **Process Metallurgy Calculator**.

Project File and License Information

- Folder: **Process Metallurgy**
- File name: `PMET_03_Argon_Oxygen_Decarburization.tcu`

This example requires a license to run the simulation. It works with TCS Metal Oxide Solutions Database (TCOX) versions 8 and newer.

Visualizations

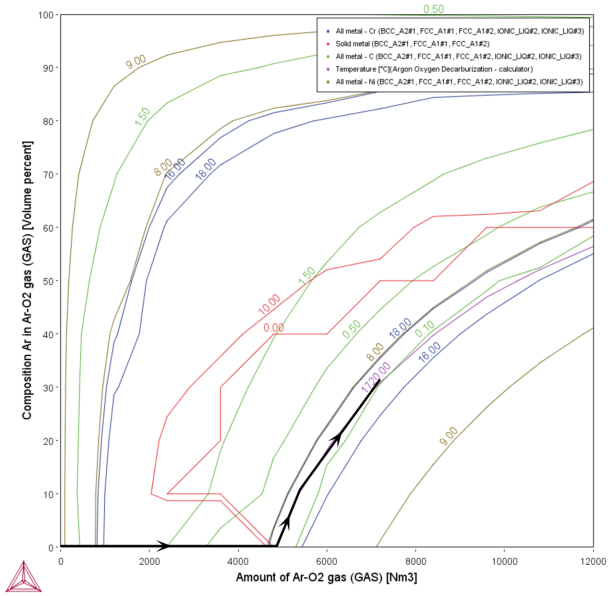
Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

Background Description

The AOD-process is characterized by an initially high O_2-content of the blowing gas, which is gradually replaced by Ar. The maximum temperature of the process is typically around 1720 °C. A grid plot of an adiabatic calculation is well suited to model the required simultaneous change of amount of gas and its composition during this process. The black line in the plot above indicates a possible process control path that finally leads to suitable alloy composition close to a X5CrNi 18-10 stainless steel.



In principle, this plot could be used to control the blowing gas flow in a plant process. However, note that the simulation only considers a global gas phase, i.e. additional gas is added but never removed. This means that the given gas phase composition is an average one and not identical to the composition of the gas flowing in at each point in time. Additionally there is a certain impact on the resulting equilibria from the fact that all gas remains in the system and is not removed.

Slag Basicity

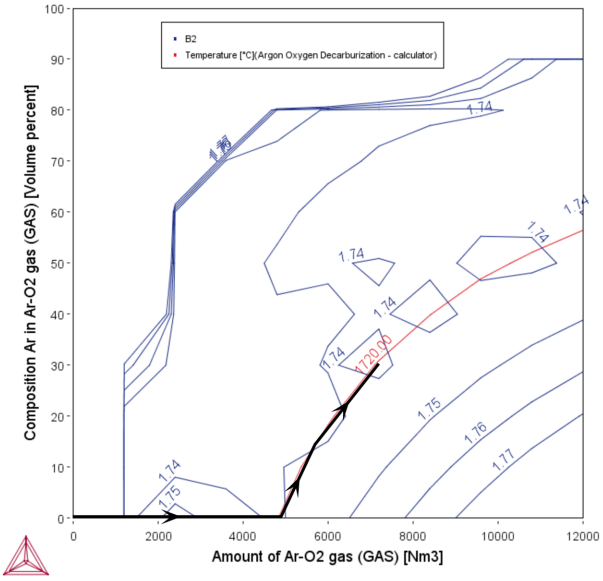


Figure 1: The Slag Basicity plot shows the basicity of the slag (which is a measure for the sulphur capacity of the slag). The process achieves a final basicity of 1.74 which is typical for an AOD-process. The black line in the plot indicates a possible process control path that finally leads to suitable alloy composition close to a X5CrNi 18-10 stainless steel.

S Content in Steel

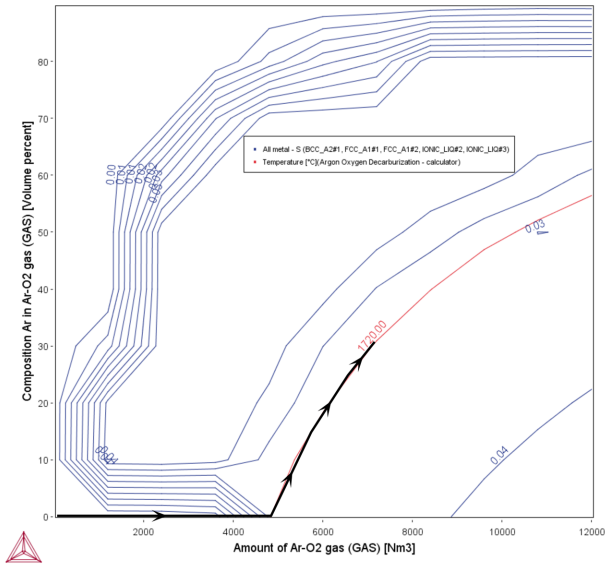

Figure 2: In the S Content in Steel plot, the sulphur content in the steel melt is slightly reduced during the process from 0.056% in the initial steel scrap to finally ca. 0.035%. The black line in the plot indicates a possible process control path that finally leads to suitable alloy composition close to a X5CrNi 18-10 stainless steel.

Cr Content in Slag

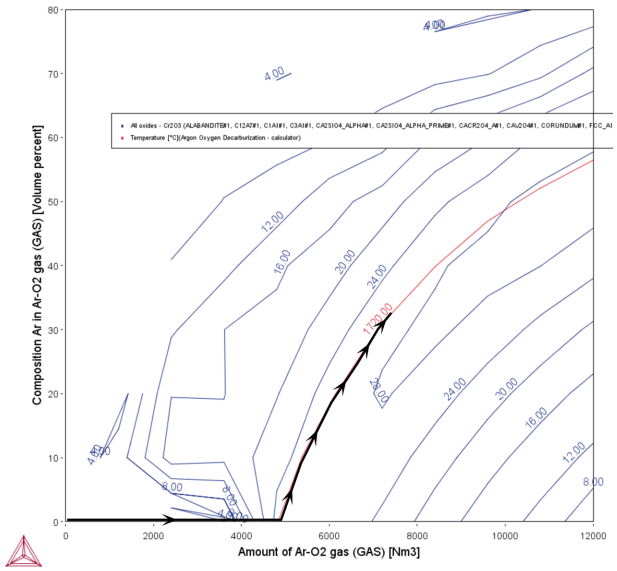

Figure 3: In the Cr Content in Slag plot, the Cr2O3-content in the slag reaches at the end of the process ca. 26 wt-%. This is typical for the AOD-process and requires an additional Cr-recovery step after the conversion to reduce the loss of chromium. The black line in the plot indicates a possible process control path that finally leads to suitable alloy composition close to a X5CrNi 18-10 stainless steel.

Amount of Slag

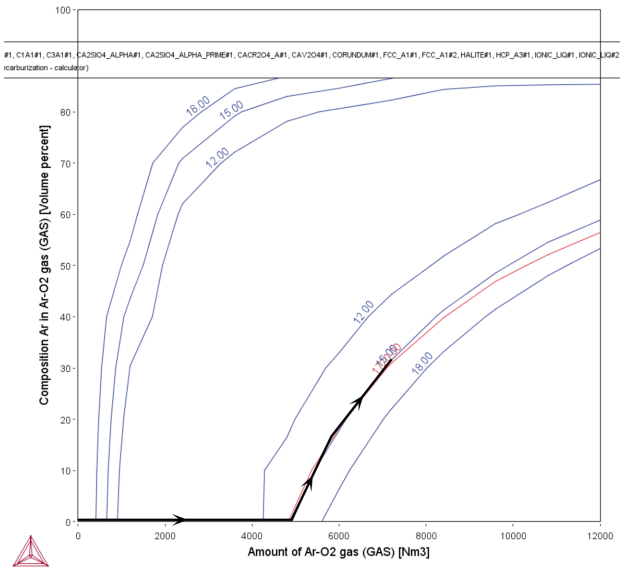

Figure 4: In the Amount of Slag plot, you can see that the process generates about 15 tons of slag in the total. The black line in the plot indicates a possible process control path that finally leads to suitable alloy composition close to a X5CrNi 18-10 stainless steel.

Liquid Slag Fraction

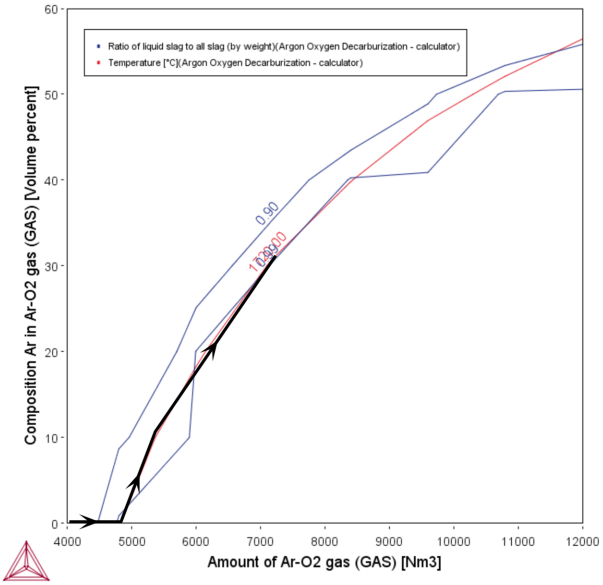

Figure 5: In the Liquid Slag Fraction plot, you can see that towards the end of the process the slag is calculated to be mostly liquid. The black line in the plot indicates a possible process control path that finally leads to suitable alloy composition close to a X5CrNi 18-10 stainless steel.

PMET_04: Kinetic Simulations of the Basic Oxygen Furnace (BOF) Process

The example uses the **Process Metallurgy Calculator** to simulate the kinetics of the Basic Oxygen Furnace (BOF) process. This application example in its various forms has step-by-step instructions available on our website.

Metallurgical processes such as the BOF process rarely reach equilibrium. Therefore, a model description must include kinetics if meaningful results are to be obtained. In recent years, a simple but powerful model termed the Effective Equilibrium Reaction Zone (EERZ) model has been developed and widely applied to simulate various metallurgical processes.

This example shows you how to set up a kinetic simulation of the BOF process in the Process Metallurgy Module and includes a description of the EERZ model.

For information about the equilibrium examples, see PMET_01: Basic Oxygen Furnace (BOF).

Project File Information

- Folder: **Process Metallurgy**

Choose a, b, or c versions of the example based on your license.

- `PMET_04a_Basic_Oxygen_Furnace_Kinetics` is included in a regular Thermo-Calc installation as well as the free Educational version of Thermo-Calc. This only considers the elements Fe, C, and O.
- `PMET_04b_Basic_Oxygen_Furnace_Kinetics` needs a full license of Thermo-Calc 2021b or newer, but uses the free OXDEMO database. It considers the elements Fe, C, O, Ca, Al, Si, and S.
- `PMET_04c_Basic_Oxygen_Furnace_Kinetics` requires both a full license of Thermo-Calc 2021b or newer and a license for the TCOX11 database and newer. This simulation corresponds pretty much to a real BOF process with the elements Fe, Mn, C, O, Ca, Al, Mg, Si, S, and P considered.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

PMET_05: Lab Scale Ladle Furnace (LF) Kinetics

Using the **Process Metallurgy Calculator** and the **Process simulation** branch, this example is based on the publication by Piva et al [2017Piv] where a lab scale sample of pure iron is first deoxidized with Si-Mn and then a synthetic top slag is added to the steel. Generally, by using the project file and the information below, you can get an idea about how to set up a ladle furnace simulation using the Process Metallurgy Module.

Project File and License Information

- Folder: **Process Metallurgy**
- File name: `PMET_05_Lab_Scale_Ladle_Furnace_Kinetics.tcu`

This example is best run with the TCS Metal Oxide Solutions Database (TCOX) version 13 or newer and a full license of Thermo-Calc 2024a or newer. Running the example with earlier versions of the database is possible but the results are not consistent with the referenced paper.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

About the Plot Results

Many different aspects of the reactions taking place in the LF can be plotted and analyzed. After you run the project file and obtain the plots, you can experiment by adjusting the settings on each Plot Renderer to see what happens in each case. There is more analysis about

this and other examples available at the links to our website.

For an example of a more realistic industry scale, see PMET_06: Kinetics of Steel Refining in a Ladle Furnace (LF).

Setting Up the LF Process Simulation

In the paper by Piva et al. [2017], it is experimentally investigated how the steel and inclusion composition changes in function of time as the Si-Mn killed steel reacts with the slag. This experiment can serve as a model for the production of SiMn killed steel with subsequent top-slag deoxidation.

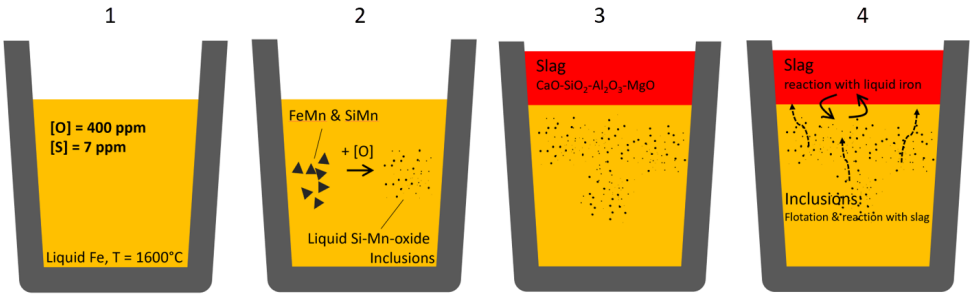

Figure 6: Diagram of the experiment performed by Piva et al. [2017]. The sequence as described in the text is: (1) liquid Fe with dissolved oxygen; (2) FeMn and SiMn added to deoxidize Fe; (3) top slag added after 360s; and (4) gradual reaction between steel, slag and inclusions.

According to the publication the following reaction sequence is expected as shown in the diagram:

1. In the initial state the steel contains 400 ppm of dissolved oxygen.
2. The deoxidizing agents are added. They dissolve and react with the oxygen in the steel forming oxide inclusions, thereby reducing the amount of dissolved oxygen ("killing" the steel). The kinetics are fast, and it can be assumed that the reaction proceeds to thermodynamic equilibrium.
3. On adding the slag (360 s after step 2, killing the steel) the liquid steel starts reacting with the slag.
4. According to the authors the most important reaction that takes place is the dissolution of Al out of the slag and its transferal into the liquid steel, where it reacts with the inclusions and changes their chemistry. Flotation of the inclusions is assumed to be negligible, due to the small size of the crucible and lack of stirring.

In this example only the last reaction is simulated after adding the slag. The kinetic parameters, compositions of all materials and process schedule are all taken from the publication.

Results and Experimental Analysis

The plots below compare the Al content in the liquid steel with the experimentally determined amount. The bottom plot shows how the Al_2O_3 from the slag phase is gradually reduced to metallic Al that dissolves in the liquid steel.

In this example, only part of the Al in the liquid steel is dissolved as metallic Al. With the Process Metallurgy Module, it is possible to plot both dissolved Al and also total Al.

In the steel industry this fraction of Al in the liquid steel is often termed *dissolved Al*. The rest of the Al reacts with the oxygen in the liquid steel and forms oxide inclusions. The amount of dissolved Al plus the Al bound up in oxide inclusions is often termed *total Al*. The difference between total Al minus dissolved Al is an important measure for the steel cleanness.

Total Al is what was measured by Piva et al. [2017] and their experimental data are compared to the calculated values below.

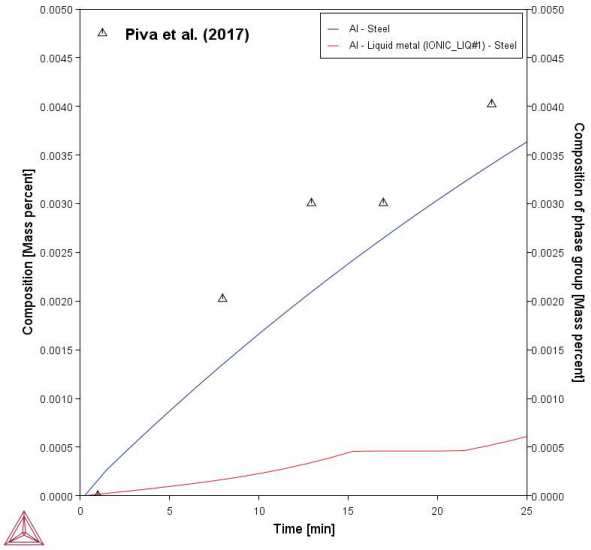

Figure 7: Total Al in the steel compared with experimental data (blue/top curve). Additionally the amount of dissolved Al is plotted (red/bottom curve), this is done by selecting "Composition of phase group" and "Liquid metal". Note that the red/bottom curve is not available with the example.

Immediately after killing the steel with SiMn and FeMn, the liquid steel contains liquid Si-Mn-oxide inclusions only. As the liquid steel picks up Al from the slag phase in function of time, the inclusions get richer and richer in Al. This experimentally verified change in inclusion chemistry is well reproduced by this simulation.

In the experiment, only the average composition of all inclusions could be measured; the type of inclusion (liquid / solid) was not determined.

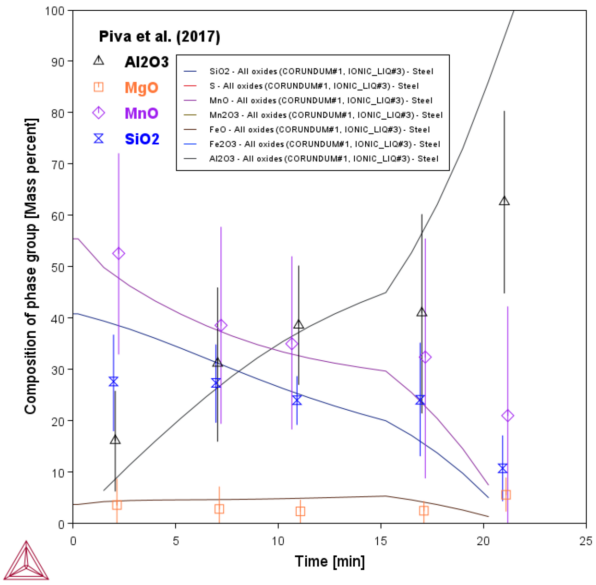

Figure 8: Calculated composition of non-metallic inclusions in function of processing time compared to experimental data [2017Piv].

With this simulation it is also possible to calculate the amount and type of inclusions present in the liquid steel. At the beginning of the process all the inclusions are liquid oxides, that gradually get richer in Al_2O_3 as the steel picks up Al from the slag. After 20 minutes processing time, the first solid corundum (Al_2O_3) inclusions start appearing. After 25 minutes almost no liquid inclusions remain.

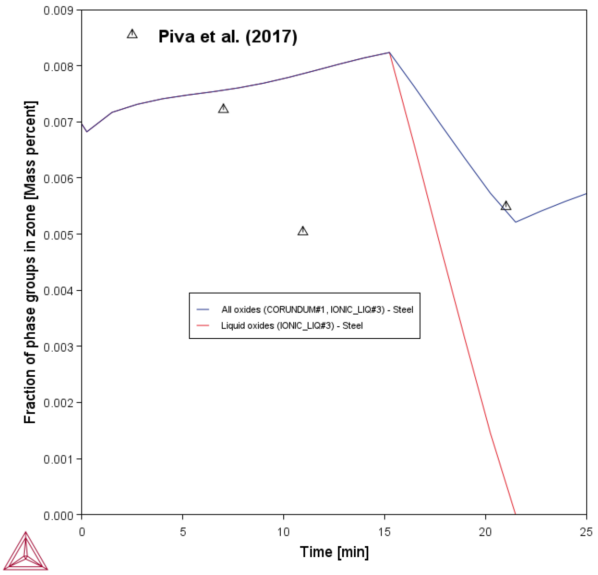

Figure 9: Amount of inclusions in the liquid steel in function of processing time. The total amount of inclusions (red line) and liquid oxide inclusions (blue line) are plotted. Up to about 20 min all inclusions are liquid oxide type, then they are replaced by solid corundum (Al_2O_3) inclusions. Experimental data from [2017Piv].

Setting Up a Process Metallurgy Simulation and Defining the Process Simulation

Visit the Process Metallurgy Module page on our website for more background information and to access resources such as training videos, presentations, publications, webinars, and much more.

PMET_06: Kinetics of Steel Refining in a Ladle Furnace (LF)

This in-depth example, which has some step-by-step instructions available on our website, uses the **Process Metallurgy Calculator** to show how to set up a full kinetic simulation of steel refining in a ladle furnace using the Process Metallurgy Module in Thermo-Calc. The Process Metallurgy Module uses the Effective Equilibrium Reaction Zone model (EERZ) to simulate the kinetics of the process. In this example, a full kinetic simulation of the LF refining process is set up using the Process Metallurgy Module.

For a simpler process that describes a lab-scale ladle furnace process, see PMET_05: Lab Scale Ladle Furnace (LF) Kinetics.

The simulation is based on an LF process described in a publication by K. J. Graham and G.A. Irons [2009Gra]. The results of this simulation are compared to the experimentally determined steel, slag, and inclusion composition as a function of processing time.

Background Overview

After steelmaking, which is mostly performed in a basic oxygen furnace (BOF) or electric arc furnace (EAF), the steel is usually tapped into a ladle where certain additions are made (deoxidation agents, slag formers, certain alloying elements) and then transferred to the ladle furnace (LF). The LF fulfils many purposes in the steel refining process, the most important being:

- Temperature control / heating by an electrical arc.
- Mixing by Ar or N2 bubbling through porous plugs in the bottom of the ladle to achieve homogeneous temperature and composition throughout the ladle.
- Removal of unwanted non-metallic phases / inclusions such as corundum (Al2O3), liquid oxide inclusions, spinel, on so on, by flotation, aided by Ar or N2 bubbling.
- Modification / engineering of non-metallic inclusions so that they are not detrimental for the downstream processing and/or the final product.
- Removal of unwanted volatile elements such as Pb, Zn, Sn, and so on. Due to their high vapor pressure, these elements are enriched in the rising Ar or N2 bubbles. After the gas escapes out of the ladle and cools, they condense, forming copious amounts of dust.
- Removal of unwanted elements such as sulphur by liquid steel / slag reactions.

- Lowering of the dissolved gas content. In the LF this is mainly achieved through chemical reactions. For direct removal of dissolved gas, vacuum degassing (VD) is usually required.
- Alloying and trimming of the steel to achieve the exact alloy composition required by the specification of the steel that is to be produced.

The reactions taking place in a LF are a complex interplay between equilibrium thermodynamics that define the direction of chemical reactions, and kinetics that define how fast the equilibrium state is approached.

Project File and License Information

PMET_07: Vacuum Oxygen Decarburization Kinetics

The vacuum oxygen decarburization (VOD) process is used to lower the carbon content in a stainless steel without compromising on the Cr yield.

This application example, which has some step-by-step instructions available on our website and uses the **Process Metallurgy Calculator**, shows how the Process Metallurgy Module in Thermo-Calc can be used to simulate the Vacuum Oxygen Decarburization (VOD) process for a stainless steel.

In this example, based on data of a real vacuum oxygen decarburization (VOD) process published by Ding et al. [2000Din], we show how to set up the VOD process in Thermo-Calc's Process Metallurgy Module. Use of the following features in the Process Metallurgy Module are highlighted in this example:

- Change of pressure as a function of time during the process
- Change of reaction kinetics as a function of time during the process
- Selection of zone where degassing is allowed

The kinetic simulation excellently reproduces the temperature, the steel chemistry, and the slag chemistry as a function of time. The example can easily be modified and adapted for different chemistries and process parameters.

PMET_08: Steel Deoxidation on Tapping

This application example, which has some step-by-step instructions available on our website and uses the **Process Metallurgy Calculator**, shows a few of the ways the Process Metallurgy Module in Thermo-Calc can be used to investigate steel deoxidation (killing) on tapping.

About Deoxidation or "Killing" of Steel

Deoxidation of steel, also known as killing of steel, occurs toward the end of the steelmaking process, but before desulphurization. After primary steelmaking, for example in a basic oxygen furnace (BOF) or electric arc furnace (EAF), the liquid steel contains a large amount of dissolved oxygen [O] (400 to over 1000 ppm.) (see PMET_04: Kinetic Simulations of the Basic Oxygen Furnace (BOF) Process).

This oxygen must be removed from the liquid steel for several reasons, including:

- Desulphurization is not effective with high oxygen content in the steel
- Continuous casting of un-killed steel is not possible and will result in "boiling" of the steel in the mould and massive porosity.

The two most widely applied methods of deoxidizing or killing the steel are adding Al to the steel (Al-killed steel) and adding Si to the steel (Si-killed steel). In this example we look at how the Process Metallurgy Module in Thermo-Calc can be used to investigate these two widely applied methods of deoxidizing or killing the steel.

The two most widely applied methods of deoxidizing or killing the steel are adding Al (Al-killed steel) to the steel and adding Si (Si-killed steel) to the steel. These elements readily react with oxygen to form oxides that precipitate within the liquid steel. This does not reduce the total amount of oxygen in the liquid steel; it simply transforms the dissolved oxygen into an oxide precipitate. This oxide precipitate then needs to be removed from the steel by flotation during secondary metallurgy in the ladle furnace (LF).

This, however, can result in the formation of damaging inclusions that cause problems during further processing, so we go on to look at two simple and very common processes that are used to transform the solid SiO_2 and Al_2O_3 inclusions into liquid oxides so that they are less damaging.

- File name: `PMET_08_Steel_Deoxidation_on_Tapping.tcu`

Choose a or b versions of the example based on your license.

- `PMET_08a_Steel_Deoxidation_on_Tapping.tcu` is included in a regular Thermo-Calc installation as well as the free Educational version of Thermo-Calc. It is a simplified version that uses the OXDEMO database.
- `PMET_08b_Steel_Deoxidation_on_Tapping.tcu` requires a full license of Thermo-Calc version 2021b or newer and database TCOX11 or newer.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

Nickel Model Library Property Models

The Nickel Model Library is a set of Property Models designed to help experts working with nickel quickly and easily set up calculations using the Property Model Calculator.

About the Nickel Model Library Property Models

These **Nickel Models** are available with the Property Model Calculator and as part of the Nickel Model Library.

As a starting point, the **Property Navigator** can more quickly help guide you to set up the initial simulation. See Creating a Project with the Property Navigator.

Antiphase Boundary Energy - Ni

The **Antiphase Boundary Energy - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates the antiphase boundary energy for the gamma prime (γ') precipitate phase in Ni-base alloys. The model considers a disordered FCC matrix and gamma prime with L12 ordering.

Alloy strength can be assumed to be proportional to the product of the antiphase boundary energy and the square root of the fraction of the strengthening gamma-prime phase.

Equilibrium is calculated with the selected phases and conditions. The antiphase boundary energy is then evaluated for the gamma prime phase given the equilibrium composition.

See About the Antiphase Boundary Energy Property Model and Antiphase Boundary Energy Property Model Settings for background theory and input parameter details.

Coarsening - Ni

The **Coarsening - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates the coarsening rate coefficient *K* of one or several precipitate phases in a matrix phase, assuming spherical geometry of the precipitating phase(s).

This model is based on the **General Models → Coarsening** Property Model, the primary difference is that you are guided to the selection of phases during the set up.

See About the Coarsening Nickel Property Model and Coarsening Nickel Property Model Settings.

Equilibrium with Freeze-in Temperature - Ni

The **Equilibrium with Freeze-in Temperature - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates equilibrium at the freeze-in temperature and evaluates the properties at a different temperature. The assumption is that diffusion and phase transformations are negligible when changing from the freeze-in-temperature and, therefore, that the phase amounts and compositions of phases are kept at the evaluation temperatures. Typically, the freeze-in occurs during cooling where equilibrium can be assumed above the freeze-in temperature.

See About the Equilibrium with Freeze-in Temperature Nickel Property Model and Equilibrium with Freeze-in Temperature Nickel Property Model Settings.

Solvus for Ordered Phase - Ni

The **Solvus for Ordered Phase - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates the solvus of ordered phases such as FCC_L12, BCC_B2, NI3TA_D0A, NI3TI_D024, TCP-phases (Sigma), and so forth. The Model chooses the correct composition set by minimizing the Gibbs energy, which means that the correct composition set is automatically detected by the software.

See About the Solvus for Ordered Phase Property Model and Solvus for Ordered Phase Property Model Settings.

Strain-Age Cracking - Ni

The **Strain-Age Cracking - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, is used in applications related to welding or additively manufactured components, where there are interface strains between γ' (gamma prime) and the matrix. Strain-age cracking may occur at negative values of the misfit parameter in combination with thermal stresses and the risk for cracking is also related to the gamma prime volume fraction. Misfit strain naturally varies with temperature (thermal expansion) and phase composition (molar volume depends on composition and temperature) and therefore an accurate assessment of the strain-age cracking risk must account for these variables. This is managed using either a *Single temperature* or *Temperature interval* mode setting.

See About the Strain-Age Cracking Property Model and Strain-Age Cracking Property Model Settings.

About the Equilibrium with Freeze-in Temperature Nickel Property Model

The **Equilibrium with Freeze-in Temperature - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates equilibrium at the freeze-in temperature and evaluates the properties at a different temperature. The assumption is that diffusion and phase transformations are negligible when changing from the freeze-in-temperature and, therefore, that the phase amounts and compositions of phases are kept at the evaluation temperatures. Typically, the freeze-in occurs during cooling where equilibrium can be assumed above the freeze-in temperature.

The **Equilibrium above freeze-in temperature** checkbox is automatically selected for when the freeze-in occurs during cooling and where equilibrium can be assumed above the freeze-in temperature. Change the default (i.e. click to clear the checkbox) when the frozen structure should be evaluated at a higher temperature than the freeze-in temperature.

The electrical resistivity due to phase interface scattering is evaluated as the scattering constant times sum of the interaction between the volume fraction of all the phases. The default value for the constant is 4.0e-8 Ωm. The contribution to thermal conductivity is assumed to be related to that of electrical resistivity, following the Wiedemann-Franz law.

A selection of homogenization functions is available for the evaluation of thermal- and electric-properties. Thermal and electric properties depend on the microstructure and the geometrical representation of phases in the microstructure can be linked to different homogenization functions. The homogenization function is applied on thermal- and electrical-resistivity. The electric conductivity, thermal conductivity, and thermal diffusivity are evaluated from the resistivities.

Learn More

To run calculations with the **Nickel Models** requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases. About the Solvus for Ordered Phase Property Model

The **Solvus for Ordered Phase - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates the solvus of ordered phases such as FCC_L12, BCC_B2, NI3TA_D0A, NI3TI_D024, TCP-phases (Sigma), and so forth. The Model chooses the correct composition set by minimizing the Gibbs energy, which means that the correct composition set is automatically detected by the software.

The remarkable properties of Ni-base superalloys often rely on the formation of finely dispersed ordered phases. In order to obtain the correct microstructure, and therefore also the properties you want, it is necessary to heat treat the alloy accordingly. One important aspect of the heat treatment is the solvus temperature for the phase or phases that is expected and wanted in the microstructure. An appropriate heat treatment aims to dissolve the ordered phases in the as-cast or as-printed structure, which must be done above the respective phases' solvus temperature.

By combining the **Solvus for Ordered Phase - Ni** model with the latest TCS Ni-based Superalloys Database (TCNI) version, you can predict the solvus temperature for any ordered phase, provided that it is present in the database and that it is stable for the given alloy chemistry. As such, appropriate heat treatments may readily be designed with guidance from thermodynamic calculations, which efficiently cuts down on time spent using trial-and-error approaches.

Learn More

To run calculations with the **Nickel Models** requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Nickel Model Library.

Configuration Settings

The input parameters are entered on the **Configuration** window for the Property Model Calculator. There are also settings on the Plot Renderer where you can choose from the available and relevant axis variables.

See Solvus for Ordered Phase Property Model Settings for details.

Example

For an example, see PM_Ni_03: Critical Temperatures of Alloy 718.

About the Strain-Age Cracking Property Model

The **Strain-Age Cracking - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, is used in applications related to welding or additively manufactured components, where there are interface strains between γ' (gamma prime) and the matrix. Strain-age cracking may occur at negative values of the misfit parameter in combination with thermal stresses and the risk for cracking is also related to the gamma prime volume fraction. Misfit strain naturally varies with temperature (thermal expansion) and phase composition (molar volume depends on composition and temperature) and therefore an accurate assessment of the strain-age cracking risk must account for these variables. This is managed using either a *Single temperature* or *Temperature interval* mode setting.

Background Theory

Strain-age cracking (SAC) may occur in welded or additively manufactured components due to interface strains between γ' (gamma prime) and the matrix. The interface strain may be quantified as a misfit parameter, i.e.

$$\delta = \frac{2(a_{\gamma'} - a_{\gamma})}{(a_{\gamma'} + a_{\gamma})}$$

where a is the lattice parameter of each respective phase (γ matrix or γ') in conjunction with residual thermal stresses from welding or additive manufacturing. Strain-age cracking may occur at negative values of the misfit parameter in combination with thermal stresses and the risk for cracking is also related to the γ' volume fraction.

Single Temperature Mode

When using the **Single temperature** mode, the model evaluates the misfit parameter at the Evaluation temperature and composition specified. By stepping in **Evaluation temperature** or composition (or both), it is possible to get an idea of how the misfit varies. Misfit values calculated using this mode can be compared with experiment but it is necessary to remember that comparisons are only valid if experimental data are taken from fully equilibrated alloys.

Temperature Interval Mode

The **Temperature interval** mode circumvents the issue of having to compare with fully equilibrated alloys. It provides a single parameter to describe the tendency for strain-age cracking. When using this mode, the Model searches for a temperature interval, between the

low limit specified and the high limit (by default the calculated γ' solvus, which can also be changed by using the **Set maximum temperature** checkbox), where the misfit parameter becomes negative.

The misfit value, and the γ' volume fraction is then integrated over the interval where the misfit is negative and the risk value for strain-age cracking is thereafter calculated.

Values of the SAC risk factor close to or below 0 indicate low or no risk for strain-age cracking. Positive values indicate risk for cracking and the more positive the value, the higher the risk. The risk factor, as defined here, also incorporates all thermodynamically related factors for strain-age cracking and makes it possible to differentiate the SAC risk for various alloys using a single number for any given temperature interval.

Learn More

For best results with this Property Model and the features it uses, it is recommended to use TCNI version 12 and newer.

To run calculations with the **Nickel Models** requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Nickel Model Library.

Configuration Settings

The input parameters are entered on the **Configuration** window for the Property Model Calculator. There are also settings on the Plot Renderer where you can choose from the available and relevant axis variables.

See Strain-Age Cracking Property Model Settings for details.

Example

For an example, see PM_Ni_04: Strain Age Cracking (SAC).

Antiphase Boundary Energy Property Model Settings

The **Antiphase Boundary Energy - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates the antiphase boundary energy for the gamma prime (γ') precipitate phase in Ni-base alloys. The model considers a disordered FCC matrix and gamma prime with L12 ordering.

Alloy strength can be assumed to be proportional to the product of the antiphase boundary energy and the square root of the fraction of the strengthening gamma-prime phase.

Equilibrium is calculated with the selected phases and conditions. The antiphase boundary energy is then evaluated for the gamma prime phase given the equilibrium composition.

Configuration Settings

These settings are found on the Property Model Calculator when **Antiphase Boundary Energy - Ni** is selected under **Nickel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Freeze-in Temperature

Enter a **Freeze-in temperature**, which is the temperature at which the freeze-in occurs.

Subset of Phases

The **Subset of phases** setting allows you to select a subset of phases relevant to the material type under investigation. The purpose is to consider only phases relevant to typical commercial Ni-base alloys, for example it excludes the eta and delta phases that are normally

thermodynamically stable at heat treatment temperatures but rarely form in practice due to their slow formation. Select an option to include the specified phases in the calculation:

- **All phases**: To include all phases entered in the current system.
- **Gamma and gamma prime only** (γ and γ' only): Includes the disordered Gamma (γ) (FCC_L12) and ordered Gamma-Prime (γ') (FCC_L12#2) phases.

  For the **Coarsening - Ni** Property Model, you select **Gamma and selected precipitate(s)** instead and it still includes only gamma (γ) (FCC_L12) and gamma-prime (γ') (FCC_L12#2) phases.

  For **Solvus for Ordered Phases - Ni** and **Strain-Age Cracking - Ni**, this option is **Gamma + Gamma Prime**.

- **Typical Ni-base superalloy**: To include phases typically present in Ni-base superalloys,
  - Oxide and metal liquid phases: IONIC_LIQ, IONIC_LIQ#2, LIQUID
  - Gamma (γ) (#1) and Gamma-Prime (γ') (#2): DIC_FCC_A1, FCC_A1, FCC_A1#2, FCC_L12, FCC_L12#2
  - Carbides/Nitrides: FCC_L12#3, HCP_A3#1, HCP_A3#2, M23C6, M6C, M7C3
  - B2 phases: BCC_A2, BCC_A2#2, BCC_B2, BCC_B2#2
  - Gamma Double-Prime (γ"): BCT_D022
  - Additional Phases: PI, NI3B_D011, M2B_TETR, D5A_M3B2, M3B2, MB_B33, MB2_C32, G_PHASE, NI5ZR, NI7ZR2, CR3NI5SI2, CR3NI5SI2, SPINEL, ALPHA_SPINEL, CORUNDUM
- **Typical Ni-base superalloy plus eta and delta**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Delta (δ) phase: NI3TA_D0A
  - Eta (η) phase: NI3TI_D024
- **Typical Ni-base superalloy plus TCP phases**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Topologically close packed (TCP) phases: C14_LAVES, SIGMA, MU_PHASE, R_PHASE, P_PHASE, Z_PHASE, and CR3SI_A15

Equilibrium Minimization Strategy

This setting is not available if **Gamma and gamma-prime only** is selected as the **Subset of phases**.

Select an **Equilibrium minimization strategy**. The default uses the **Global test preferred** option. For this Property Model, and for either Global option, also enter the **Max number of global gridpoints**, where the default is 20000.

The **Minimization Strategy** setting is used to ensure that the most stable minimum under the specified conditions is computed.

With either the *Global test preferred* or *Local minimization preferred* setting, the program cycles through options before it gives up:

- For **Global test preferred** the minimization starts with a global test and if that fails it runs full global minimization.
- For **Local minimization preferred** the minimization starts with a local minimization, in case of failure it tries a global test and finally a full global minimization.

If you choose **Local minimization only** or **Global minimization only**, the program just tries the one setting and gives up if it fails.

For general information about global minimization, see the topic related to the Console Mode command, GLOBAL_MINIMIZATION.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Select from these plot quantities and then choose the unit Joule per m^2 or Millijoule per m^2:

- **APBE average (1/2)**: The average of the antiphase boundary energy for the 100- and 111-plane for the first γ' phase.
- **APBE average (2/2)**: The average of the antiphase boundary energy for the 100- and 111-plane for the first γ' phase in the case more than one FCC_L12 composition set is identified as γ'.
- **APBE for 111 plane (1/2)**: The antiphase boundary energy for the 111-plane for the first γ' phase.
- **APBE for 111 plane (2/2)**: The antiphase boundary energy for the 111-plane for the second γ' phase in the case more than one FCC_L12 composition set is identified as γ'.
- **APBE for 100 plane (1/2)**: The antiphase boundary energy for the 100-plane for the first γ' phase.
- **APBE for 100 plane (2/2)**: The antiphase boundary energy for the 100-plane for the second γ' phase in the case more than one FCC_L12 composition set is identified as γ'.
- **Composition**
- **Delta APBE rel.pure Ni3Al**: w.r.t. Ni3Al - The antiphase boundary energy of the 111-plane for the current γ' relative to 'pure' Ni3Al γ'.
- **Evaluation temperature**
- **Freeze-in temperature**

Learn More

About the Antiphase Boundary Energy Property Model

For an example, see PM_Ni_02: Antiphase Boundary Energy of γ'

Coarsening Nickel Property Model Settings

The **Coarsening - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates the coarsening rate coefficient *K* of one or several precipitate phases in a matrix phase, assuming spherical geometry of the precipitating phase(s).

This model is based on the **General Models → Coarsening** Property Model, the primary difference is that you are guided to the selection of phases during the set up.

Configuration Settings

The settings are found on the Property Model Calculator when **Coarsening - Ni** is selected under **Nickel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Subset of Phases

The **Subset of phases** setting allows you to select a subset of phases relevant to the material type under investigation. The purpose is to consider only phases relevant to typical commercial Ni-base alloys, for example it excludes the eta and delta phases that are normally thermodynamically stable at heat treatment temperatures but rarely form in practice due to their slow formation. Select an option to include the specified phases in the calculation:

- **All phases**: To include all phases entered in the current system.
- **Gamma and gamma prime only** (γ and γ' only): Includes the disordered Gamma (γ) (FCC_L12) and ordered Gamma-Prime (γ') (FCC_L12#2) phases.

> For the **Coarsening - Ni** Property Model, you select **Gamma and selected precipitate(s)** instead and it still includes only gamma (γ) (FCC_L12) and gamma-prime (γ') (FCC_L12#2) phases.

> For **Solvus for Ordered Phases - Ni** and **Strain-Age Cracking - Ni**, this option is **Gamma + Gamma Prime**.

- **Typical Ni-base superalloy**: To include phases typically present in Ni-base superalloys,
  - Oxide and metal liquid phases: IONIC_LIQ, IONIC_LIQ#2, LIQUID
  - Gamma (γ) (#1) and Gamma-Prime (γ') (#2): DIC_FCC_A1, FCC_A1, FCC_A1#2, FCC_L12, FCC_L12#2
  - Carbides/Nitrides: FCC_L12#3, HCP_A3#1, HCP_A3#2, M23C6, M6C, M7C3
  - B2 phases: BCC_A2, BCC_A2#2, BCC_B2, BCC_B2#2
  - Gamma Double-Prime (γ"): BCT_D022
  - Additional Phases: PI, NI3B_D011, M2B_TETR, D5A_M3B2, M3B2, MB_B33, MB2_C32, G_PHASE, NI5ZR, NI7ZR2, CR3NI5SI2, CR3NI5SI2, SPINEL, ALPHA_SPINEL, CORUNDUM
- **Typical Ni-base superalloy plus eta and delta**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Delta (δ) phase: NI3TA_D0A
  - Eta (η) phase: NI3TI_D024
- **Typical Ni-base superalloy plus TCP phases**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Topologically close packed (TCP) phases: C14_LAVES, SIGMA, MU_PHASE, R_PHASE, P_PHASE, Z_PHASE, and CR3SI_A15

Equilibrium Minimization Strategy

This setting is NOT available if **Gamma and selected precipitate(s)** is selected.

Select an **Equilibrium minimization strategy**. The default uses the **Global test preferred** option. For this Property Model, and for either Global option, also enter the **Max number of global gridpoints**, where the default is 20000.

The **Minimization Strategy** setting is used to ensure that the most stable minimum under the specified conditions is computed.

With either the *Global test preferred* or *Local minimization preferred* setting, the program cycles through options before it gives up:

- For **Global test preferred** the minimization starts with a global test and if that fails it runs full global minimization.
- For **Local minimization preferred** the minimization starts with a local minimization, in case of failure it tries a global test and finally a full global minimization.

If you choose **Local minimization only** or **Global minimization only**, the program just tries the one setting and gives up if it fails.

For general information about global minimization, see the topic related to the Console Mode command, GLOBAL_MINIMIZATION.

Matrix Phase

Choose a **Matrix phase**. The default is **Gamma** (γ).

Precipitate Phase

Choose a **Precipitate phase** to calculate its coarsening rate. Click the **Add phase** button to add another Precipitate phase. Click the **Remove phase** button to remove a phase.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Select from these plot quantities:

- **Coarsening rate coefficient Ni [m^3/s]** for the precipitate phase.
- **Evaluation temperature**
- **Interfacial energy Ni [J/m^2]** for it to be between the matrix and precipitate phase.

Learn More

About the Coarsening Nickel Property Model

The **Coarsening - Ni** Property Model specifically requires a kinetic database with mobilities for the matrix phase. As long as you are using version 5 or newer of the TCS Ni-alloys Mobility Database (MOBNI), you can use the model.

Equilibrium with Freeze-in Temperature Nickel Property Model Settings

The **Equilibrium with Freeze-in Temperature - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates equilibrium at the freeze-in temperature and evaluates the properties at a different temperature. The assumption is that diffusion and phase transformations are negligible when changing from the freeze-in-temperature and, therefore, that the phase amounts and compositions of phases are kept at the evaluation temperatures. Typically, the freeze-in occurs during cooling where equilibrium can be assumed above the freeze-in temperature.

Configuration Settings

The settings are found on the Property Model Calculator when the **Equilibrium with Freeze-in Temperature - Ni** Model is selected under **Nickel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Freeze-in Temperature

Enter a **Freeze-in temperature**, which is the temperature at which the freeze-in occurs.

Equilibrium Above Freeze-in Temperature

The **Equilibrium above freeze-in temperature** checkbox is selected by default and it calculates equilibrium above freeze-in temperature. Click to clear the checkbox when evaluating the frozen-in structure at higher temperatures than the freeze-in temperature.

Subset of Phases

The **Subset of phases** setting allows you to select a subset of phases relevant to the material type under investigation. The purpose is to consider only phases relevant to typical commercial Ni-base alloys, for example it excludes the eta and delta phases that are normally thermodynamically stable at heat treatment temperatures but rarely form in practice due to their slow formation. Select an option to include the specified phases in the calculation:

- **All phases**: To include all phases entered in the current system.
- **Gamma and gamma prime only** (γ and γ' only): Includes the disordered Gamma (γ) (FCC_L12) and ordered Gamma-Prime (γ') (FCC_L12#2) phases.

For the **Coarsening - Ni** Property Model, you select **Gamma and selected precipitate(s)** instead and it still includes only gamma (γ) (FCC_L12) and gamma-prime (γ') (FCC_L12#2) phases.

For **Solvus for Ordered Phases - Ni** and **Strain-Age Cracking - Ni**, this option is **Gamma + Gamma Prime**.

- **Typical Ni-base superalloy**: To include phases typically present in Ni-base superalloys,
  - Oxide and metal liquid phases: IONIC_LIQ, IONIC_LIQ#2, LIQUID
  - Gamma (γ) (#1) and Gamma-Prime (γ') (#2): DIC_FCC_A1, FCC_A1, FCC_A1#2, FCC_L12, FCC_L12#2
  - Carbides/Nitrides: FCC_L12#3, HCP_A3#1, HCP_A3#2, M23C6, M6C, M7C3
  - B2 phases: BCC_A2, BCC_A2#2, BCC_B2, BCC_B2#2
  - Gamma Double-Prime (γ"): BCT_D022
  - Additional Phases: PI, NI3B_D011, M2B_TETR, D5A_M3B2, M3B2, MB_B33, MB2_C32, G_PHASE, NI5ZR, NI7ZR2, CR3NI5SI2, CR3NI5SI2, SPINEL, ALPHA_SPINEL, CORUNDUM
- **Typical Ni-base superalloy plus eta and delta**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Delta (δ) phase: NI3TA_D0A
  - Eta (η) phase: NI3TI_D024

- **Typical Ni-base superalloy plus TCP phases**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
    - Topologically close packed (TCP) phases: C14_LAVES, SIGMA, MU_PHASE, R_PHASE, P_PHASE, Z_PHASE, and CR3SI_A15

Evaluate for a Single Phase Only

Select the **Evaluate for a single phase only** checkbox to evaluate the properties of a specific phase or deselect to evaluate the properties for the entire system.

Phase for Evaluation

This setting is available when the **Evaluate for a single phase only** checkbox is selected.

From the **Phase for evaluation** list, select any available phase or **None**.

Equilibrium Minimization Strategy

This setting is NOT available if **Gamma and selected precipitate(s)** is selected.

Select an **Equilibrium minimization strategy**. The default uses the **Global test preferred** option. For this Property Model, and for either Global option, also enter the **Max number of global gridpoints**, where the default is 20000.

The **Minimization Strategy** setting is used to ensure that the most stable minimum under the specified conditions is computed.

With either the *Global test preferred* or *Local minimization preferred* setting, the program cycles through options before it gives up:

- For **Global test preferred** the minimization starts with a global test and if that fails it runs full global minimization.
- For **Local minimization preferred** the minimization starts with a local minimization, in case of failure it tries a global test and finally a full global minimization.

If you choose **Local minimization only** or **Global minimization only**, the program just tries the one setting and gives up if it fails.

For general information about global minimization, see the topic related to the Console Mode command, GLOBAL_MINIMIZATION.

Homogenization Function

The **Homogenization function** is used for the evaluation of the systems thermal and electric properties. The function is applied on thermal- and electrical-resistivity. The electric conductivity, thermal conductivity, and thermal diffusivity are evaluated from the resistivities.

The geometrical interpretation of the Hashin-Shtrikman bounds are concentric spherical shells of each phase.

- **Rule of mixtures (upper Wiener bound)**: the geometrical interpretation are continuous layers of each phase parallel with the direction of evaluation of the property.
- **Inverse rule of mixtures (lower Wiener bound)**: The geometrical interpretation are continuous layers of each phase orthogonal to the direction of evaluation of the property.
- **General lower Hashin-Shtrikman bound**: The outermost shell consists of the phase with the most sluggish property.
- **General upper Hashin-Shtrikman bound**: The innermost shell consists of the phase with the most sluggish property.
- **Hashin-Shtrikman bound with majority phase as matrix phase**: The outermost shell consists of the phase with the highest local volume fraction.

Account for Phase Interface Scattering

The **Account for phase interface scattering** checkbox is selected by default.

The electrical resistivity due to phase interface scattering is evaluated as the scattering constant times sum of the interaction between the volume fraction of all the phases. The default value for the constant is 4.0e-8 Ωm. The contribution to thermal conductivity is assumed to be related to that of electrical resistivity, following the Wiedemann-Franz law.

Phase Interface Scattering Constant

This setting is available when the **Account for phase interface scattering** checkbox is selected.

The **Phase interface scattering constant** default value is 4.0e-8 Ωm.

Set Reference Temperature for Technical CTE

This setting is available when the **Account for phase interface scattering** checkbox is selected.

In the field, enter the **Reference temperature for technical CTE**, where CTE is the coefficient of thermal expansion. Typically room temperature is used as the default 293.15 K (20 °C).

Define User Functions

Select the **Define user functions** checkbox to enter up to two **User-defined functions** using the Console Mode syntax.

For an example of user-defined functions, see T_07: User-Defined Functions.

Dot derivatives (e.g. Hm.T for heat capacity) should NOT be used since these are not consistent with freezing in the amount of phases.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Select from these plot quantities:

- **Density (g/cm^3)**
- **Elastic constants**
- **Elastic moduli**
- **Electric conductivity (S/m)**
- **Electric resistivity (ohm m)** (Ωm)
- **Evaluation temperature**
- **Freeze-in temperature**

- **Heat capacity (J/mol K))**
- **Lattice mismatch Gamma/Gamma-Prime** (γ/γ'): This is an unconstrained misfit between Gamma/Gamma-prime lattice parameters: $100 * \frac{2*(a_{gp}-a_g)}{(a_{gp}+a_g)}$
- **Lattice parameter Gamma** (γ) (a_p): Choose a unit Meter, Micrometer, Nanometer, or Ångström.
- **Lattice parameter Gamma-Prime** (γ') (a_{gp}): Choose a unit Meter, Micrometer, Nanometer, or Ångström.
- **Linear CTE (physical) (1/K)**: Fractional change of length per unit temperature change. Assumed Isotropic material.
- **Linear CTE (technical) (1/K)**: Fractional change of length per unit temperature change. Calculated as (L1-L0)/(T1-T0)/L0, where L0 is the length at a reference temperature T0. T0 is by default equal to room temperature. Assumed Isotropic material.
- **Thermal conductivity (W/(mK))**
- **Thermal diffusivity (m^2/s)**
- **Thermal resistivity (mK/W)**
- **Volume (m^3/mol)**
- **Volumetric CTE (physical) (1/K)**: Fractional change of volume per unit temperature change.
- **User-defined function** and **2nd user-defined function**: Available when the **Define user functions** checkbox is selected and the functions are defined.

Elastic moduli is available to plot when the thermodynamic database selected includes elastic properties. However, even if the database does not have elastic constants, the quantity is visible to select from the list even. In this case there is a message in the Event Log to indicate there is no elastic data and the value will be NaN.

About the Equilibrium with Freeze-in Temperature Nickel Property Model

For an example, see PM_Ni_01: Lattice Parameter of γ/γ'

Solvus for Ordered Phase Property Model Settings

The **Solvus for Ordered Phase - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, calculates the solvus of ordered phases such as FCC_L12, BCC_B2, NI3TA_D0A, NI3TI_D024, TCP-phases (Sigma), and so forth. The Model chooses the correct composition set by minimizing the Gibbs energy, which means that the correct composition set is automatically detected by the software.

Configuration Settings

The settings are found on the Property Model Calculator when **Solvus for Ordered Phase- Ni** is selected under **Nickel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Naming Convention

Select **Conventional phase names** (the default) or **Explicit phase names**.

Select **Conventional phase names** to limit the list to commonly occurring ordered phases, which are **Gamma prime (FCC_L12)**, **Gamma double prime (BCT_D022)**, **Eta (NI3TI_D024)**, **Delta (NI3TA_D0A)**, and **Sigma (SIGMA)**. You can alternatively select a phase from the full list of **Explicit phase names**; phases available in the list are based on the selected database.

Phase to Calculate Solvus For

From the **Phase to calculate solvus for** list, choose a phase. When **Conventional phase names** is selected **Gamma prime (FCC_L12)** is the default.

Phases such as FCC_L12 and BCC_B2 normally exhibit ordering (when used with the TCS Ni-based Superalloys Database (TCNI)).

Subset of Phases

The **Subset of phases** setting allows you to select a subset of phases relevant to the material type under investigation. The purpose is to consider only phases relevant to typical commercial Ni-base alloys, for example it excludes the eta and delta phases that are normally

thermodynamically stable at heat treatment temperatures but rarely form in practice due to their slow formation. Select an option to include the specified phases in the calculation:

- **All phases**: To include all phases entered in the current system.
- **Gamma and gamma prime only** (γ and γ' only): Includes the disordered Gamma (γ) (FCC_L12) and ordered Gamma-Prime (γ') (FCC_L12#2) phases.

  For the **Coarsening - Ni** Property Model, you select **Gamma and selected precipitate(s)** instead and it still includes only gamma (γ) (FCC_L12) and gamma-prime (γ') (FCC_L12#2) phases.

  For **Solvus for Ordered Phases - Ni** and **Strain-Age Cracking - Ni**, this option is **Gamma + Gamma Prime**.

- **Typical Ni-base superalloy**: To include phases typically present in Ni-base superalloys,
  - Oxide and metal liquid phases: IONIC_LIQ, IONIC_LIQ#2, LIQUID
  - Gamma (γ) (#1) and Gamma-Prime (γ') (#2): DIC_FCC_A1, FCC_A1, FCC_A1#2, FCC_L12, FCC_L12#2
  - Carbides/Nitrides: FCC_L12#3, HCP_A3#1, HCP_A3#2, M23C6, M6C, M7C3
  - B2 phases: BCC_A2, BCC_A2#2, BCC_B2, BCC_B2#2
  - Gamma Double-Prime (γ"): BCT_D022
  - Additional Phases: PI, NI3B_D011, M2B_TETR, D5A_M3B2, M3B2, MB_B33, MB2_C32, G_PHASE, NI5ZR, NI7ZR2, CR3NI5SI2, CR3NI5SI2, SPINEL, ALPHA_SPINEL, CORUNDUM
- **Typical Ni-base superalloy plus eta and delta**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Delta (δ) phase: NI3TA_D0A
  - Eta (η) phase: NI3TI_D024
- **Typical Ni-base superalloy plus TCP phases**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Topologically close packed (TCP) phases: C14_LAVES, SIGMA, MU_PHASE, R_PHASE, P_PHASE, Z_PHASE, and CR3SI_A15

Advanced Settings

Click the **Advanced settings** checkbox to edit the following settings.

Initial Temperature

Enter an **Initial temperature**, which is the temperature at which the initial equilibrium state is obtained.

Low Temperature Limit

Enter a **Low temperature limit** for the evaluation.

High Temperature Limit

Enter a **High temperature limit** for the evaluation.

First and Second Sublattices for Ordering

Depending on the phase model for the selected phase, different sets of sublattices can be used to model ordering. For example, the ordering of FCC_L12 in the TCS Ni-based Superalloys Database (TCNI) occurs on sublattice 1 and 2. Enter a number for the **First sublattice for ordering** (default is 1) and **Second sublattice for ordering** (default is 2).

Number of Decimals

Ordering reactions may be continuous and it is necessary to set a numerical precision. This is because the difference in site occupancy in ordered and disordered phases may be small. Enter a **Number of decimals** at which to truncate the site fractions (default is 7).

Max Number of Iterations

Limits the number of iterations. Enter any value in the **Max. number of iterations** field that is greater than 0. The default is 100.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Select from these plot quantities:

- **Composition**
- **First sublattice for ordering**
- **High temperature limit**
- **Initial temperature**
- **Low temperature limit**
- **Max number of iterations**
- **Number of decimals**
- **Second sublattice for ordering**
- **Solvus temperature**

About the Solvus for Ordered Phase Property Model

For an example, see PM_Ni_03: Critical Temperatures of Alloy 718.

Strain-Age Cracking Property Model Settings

The **Strain-Age Cracking - Ni** Property Model, available with the Property Model Calculator and the Nickel Model Library, is used in applications related to welding or additively manufactured components, where there are interface strains between γ' (gamma prime) and the matrix. Strain-age cracking may occur at negative values of the misfit parameter in combination with thermal stresses and the risk for cracking is also related to the gamma prime volume fraction. Misfit strain naturally varies with temperature (thermal expansion) and phase composition (molar volume depends on composition and temperature) and therefore an accurate assessment of the strain-age cracking risk must account for these variables. This is managed using either a *Single temperature* or *Temperature interval* mode setting.

Configuration Settings

These settings are found on the Property Model Calculator when **Strain-Age Cracking - Ni** is selected under **Nickel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Subset of Phases

The **Subset of phases** setting allows you to select a subset of phases relevant to the material type under investigation. The purpose is to consider only phases relevant to typical commercial Ni-base alloys, for example it excludes the eta and delta phases that are normally thermodynamically stable at heat treatment temperatures but rarely form in practice due to their slow formation. Select an option to include the specified phases in the calculation:

- **All phases**: To include all phases entered in the current system.
- **Gamma and gamma prime only** (γ and γ' only): Includes the disordered Gamma (γ) (FCC_L12) and ordered Gamma-Prime (γ') (FCC_L12#2) phases.

> For the **Coarsening - Ni** Property Model, you select **Gamma and selected precipitate(s)** instead and it still includes only gamma (γ) (FCC_L12) and gamma-prime (γ') (FCC_L12#2) phases.

> For **Solvus for Ordered Phases - Ni** and **Strain-Age Cracking - Ni**, this option is **Gamma + Gamma Prime**.

- **Typical Ni-base superalloy**: To include phases typically present in Ni-base superalloys,
  - Oxide and metal liquid phases: IONIC_LIQ, IONIC_LIQ#2, LIQUID
  - Gamma (γ) (#1) and Gamma-Prime (γ') (#2): DIC_FCC_A1, FCC_A1, FCC_A1#2, FCC_L12, FCC_L12#2
  - Carbides/Nitrides: FCC_L12#3, HCP_A3#1, HCP_A3#2, M23C6, M6C, M7C3
  - B2 phases: BCC_A2, BCC_A2#2, BCC_B2, BCC_B2#2
  - Gamma Double-Prime (γ"): BCT_D022
  - Additional Phases: PI, NI3B_D011, M2B_TETR, D5A_M3B2, M3B2, MB_B33, MB2_C32, G_PHASE, NI5ZR, NI7ZR2, CR3NI5SI2, CR3NI5SI2, SPINEL, ALPHA_SPINEL, CORUNDUM
- **Typical Ni-base superalloy plus eta and delta**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Delta (δ) phase: NI3TA_D0A
  - Eta (η) phase: NI3TI_D024
- **Typical Ni-base superalloy plus TCP phases**: To include the phases listed above for a **Typical Ni-base superalloy** plus:
  - Topologically close packed (TCP) phases: C14_LAVES, SIGMA, MU_PHASE, R_PHASE, P_PHASE, Z_PHASE, and CR3SI_A15

Choose Mode

The Strain-Age Cracking (SAC) risk can be evaluated for a single temperature or for a specified temperature interval.

For background information about these settings, see Strain-Age Cracking Property Model Settings.

From the **Choose mode** list, select **Temperature interval** or **Single temperature**. For **Temperature interval** you can further enter a user-defined **Low temperature limit** and **High temperature limit** as needed and described below.

Evaluation Temperature

Available when the **Single temperature** mode is selected. See the theory section, Single Temperature Mode.

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Low Temperature Limit

Available when **Temperature interval** is selected as the mode. See the theory section, Temperature Interval Mode.

Enter a **Low temperature limit** for the evaluation.

Set Maximum Temperature

Available when **Temperature interval** is selected as the mode. See the theory section, Temperature Interval Mode.

The Strain-Age Cracking (SAC) risk is evaluated between the temperature specified in conditions and the γ' solvus. Select the **Set maximum temperature** checkbox if a lower maximum temperature than the γ' solvus is required and thus to skip the γ' solvus calculation.

High Temperature Limit

Available when **Temperature interval** is selected as the mode and the **Set maximum temperature** checkbox is selected. See the theory section, Temperature Interval Mode.

Enter a **High temperature limit** for the evaluation.

This should be below the γ' solvus temperature.

Initial Step Size for Search

Available when **Temperature interval** is selected as the mode. See the theory section, Temperature Interval Mode.

The search for a negative misfit parameter is initiated with the step size entered in the **Initial step size for search** field.

If convergence issues arise, it can be useful to adjust this parameter and increase (or decrease) the lower temperature limit.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Depending on the set up, there are a variety of plot quantities available to choose from. For example, select from these plot quantities:

- **Composition**
- **Evaluation temperature**
- **High temperature limit**
- **Initial step size for search**
- **Low temperature limit**
- **Misfit value at current temperature**
- **SAC risk factor**
- **Solvus of FCC_L12 (gamma prime)**

Learn More

About the Strain-Age Cracking Property Model

For an example, see PM_Ni_04: Strain Age Cracking (SAC).

For best results with this Property Model and the features it uses, it is recommended to use TCNI version 12 and newer.

Nickel Model Library Examples Collection

The **General Models** are available to all users. To run calculations with the **Nickel Models** (as part of the Nickel Model Library) requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases.

These examples use the **Property Model Calculator**, an activity available with Thermo-Calc plus the available Property Models in the Nickel Model Library.

PM_Ni_01: Lattice Parameter of γ/γ'

The example uses the **Property Model Calculator** with the **Equilibrium with Freeze-in Temperature - Ni** Model.

Overview

The lattice parameters are measured experimentally for γ/γ' in a Ni0.6Mo0.92Ta12.5Al1.83Ti10.5Cr3.3W alloy.

The thermodynamically stable equilibrium will not be reached for this alloy during the experimental heat treatment; only the phases γ and γ' are noticed in the experiment. The γ/γ' microstructure is in this calculation example assumed to freeze-in at 1000 °C where the phase compositions do not change during cooling to room temperature.

Some of the key settings to note in this example:

- The **Subset of phases** is selected as **Gamma and gamma-prime only** to match the experimental observations.
- The **Freeze-in temperature** is set to 1000 °C.
- A **One Axis** calculation is used where the evaluation temperatures are within a range of 20 °C to 1000 °C.

Project File and License Information

- Folder: **Property Models → Nickel**
- File name: `PM_Ni_01_Lattice_Parameter_of_Gamma_Gamma_Prime.tcu`

To run calculations with the **Nickel Models** requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Nickel Model Library.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

Property Model Calculator and About the Equilibrium with Freeze-in Temperature Nickel Property Model

PM_Ni_02: Antiphase Boundary Energy of γ'

The example uses the **Property Model Calculator** with the **Antiphase Boundary Energy - Ni** Model.

Overview

This example shows a calculation of the antiphase boundary energy for an Al75Ni alloy at room temperature with increasing amounts of Ti. The plot shows the (111) APB energy in $Ni_3Al_{1-x}Ti_x$ over the whole compositional range together with first-principle calculations from Chandran and Sondhi [2011Cha] and Vamsi and Karthikeyani [2012Vam] evaluated at 0 K. The trend with increasing 111 APBE with an increasing amount of Ti is predicted by all calculations but the absolute values between the first principle calculations are quite different.

Some of the key settings to note in this example:

- γ' is the only stable phase for these compositions. FCC_L12 is therefore selected as the only phase in the System Definer.
- The **Freeze-in temperature** and evaluation temperature are both set at 20 °C with the **Subset of phases** for **All phases**.
- A **One Axis** calculation is used with **Mole percent Ti** between 0 and 25 in 20 steps.
- The plotting quantity **APBE for 111 plane (1/2)** is then compared with the first principle calculations.

Project File and License Information

- Folder: **Property Models → Nickel**
- File name: `PM_Ni_02_Antiphase_Boundary_Energy_of_Gamma_Prime.tcu`

To run calculations with the **Nickel Models** requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Nickel Model Library.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Property Model Calculator and About the Antiphase Boundary Energy Property Model

PM_Ni_03: Critical Temperatures of Alloy 718

The example uses the **Property Model Calculator** with the **Solvus for Ordered Phase-Ni** Model.

Overview

In this example, the respective solvus temperatures of the Delta and Gamma double-prime phases are calculated. For the Delta phase, the **Subset of phases** is set to **All phases** but the result varies very little with the selected subset (provided that the Delta phase is included). For the Gamma double-prime phase, which is a metastable phase, it is necessary to use the **Typical Ni-base superalloy** phase subset.

The resulting solvus temperatures are compared with experimental data from [2010Fra].

Project File and License Information

- Folder: **Property Models → Nickel**
- File name: `PM_Ni_03_Critical_Temperatures_Alloy_718.tcu`

To run calculations with the **Nickel Models** requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Nickel Model Library.

Property Model Calculator and About the Solvus for Ordered Phase Property Model

PM_Ni_04: Strain Age Cracking (SAC)

The example uses the **Property Model Calculator** with the **Strain-Age Cracking - Ni** Model.

Background

Welding or additive manufacturing (AM) of Ni-base alloys has so far been strongly limited by various cracking issues during processing or post-processing. Strain-age cracking (SAC) occurs when the combination of thermal stresses and coherency stresses between the γ matrix and γ’ precipitates exceed the local strength of the alloy structure. Thermal residual stresses originate from the initial processing (welding or AM), while coherency stresses form during post-processing heat treatments, when γ’ re-precipitates in the matrix. Coherency stresses may be tensile or compressive depending on the sign of the lattice misfit.

Furthermore, coherency stresses scale with the fraction of γ’, making conventional high-γ’ alloys virtually impossible to weld or shape via AM. At the same time, high-γ’ fraction alloys offer attractive properties, such as high strength at high service temperatures. In order for such alloys to be processable, it is necessary to reduce the cracking tendency.

Thermal stresses are very difficult to alleviate, as this requires heating, which in turn triggers re-precipitation of γ’. Therefore, an alternative strategy may be to target the coherency stresses, which are determined by the respective lattice parameters of the matrix and precipitate. Such a strategy was adopted by Zhou et al. [2020Zho], where they optimized the composition of the Ni-base alloy to fulfill the above criteria, i.e., high fraction of γ’ and no strain-age cracking tendency.

In this example, the experimental alloys from [2020Zho] are analyzed based on the **Strain-Age Cracking - Ni** Property Model to compare the tendency for cracking using an SAC risk factor.

Project File and License Information

- Folder: **Property Models → Nickel**
- File name: `PM_Ni_04_Strain_Age_Cracking.tcu`

To run calculations with the **Nickel Models** requires a valid maintenance license plus licenses for both the TCNI (version 11 and newer) and MOBNI (version 5 and newer) databases. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Nickel Model Library.

This example uses TCNI12, but in general can be run with version 11 (TCNI11) and newer databases.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

Performing the calculation for the two experimental alloys, along with the CM247LC benchmark alloy and using the temperature interval setting produces a set of relevant output results as shown in a table (Figure 4) and **Parallel coordinates** plot (Figure 5). CM247LC is considered to be very difficult to weld, which is evidenced by the very high value of the SAC risk factor. Comparatively, the two experimental alloys, ExpAM and ExpAMmod, show values very close to zero. Low or negative values of the SAC risk factor can be interpreted as low or no risk for strain-age cracking.

Conventionally, the *weldability* of a given Ni-base alloy has been assessed based on the Ti and Al contents, which correlate with the fraction of γ'. However, such an approach neglects the fact that it is the coherency stresses that cause cracking, and these are also dependent on the lattice misfit. By tailoring an alloy to have low misfit, in relation to the γ' fraction and in the

relevant temperature range, it is possible to design a high-γ' fraction alloy with very low risk for SAC, as shown in [2020Zho]. The SAC model used here captures all of these effects and can be used as a design tool for the purpose of eliminating this cracking tendency.

Visualizations

Plot Renderer 1 | Table Renderer 1

SAC risk factor	Temperature [K]	Mass percent Ni	Mass percent Al	Mass percent C
0.45355	1000.00000	64.69498	4.00000	5.20000
0.84060	1000.00000	65.39995	4.10000	5.00000
345.11631	1000.00000	61.69999	5.60000	9.20000

Figure 4: There are a two ways to view the data in table format. In this example, there is a Table Renderer node added to the Project window that lists the data points in the Visualizations window.

You can also access the same information via the Plot Renderer Configuration window by clicking the **Table View** button followed by clicking **Perform**. This converts the **Parallel coordinates** plot type to the same table of information.

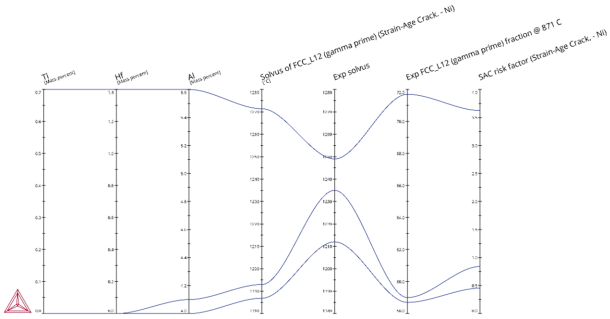

Figure 5: Parallel plot of the resulting SAC risk factor along with experimental and calculated solvus of γ' for the three alloys compared in [2020Zho].

About the Optical Properties - Noble Metals Property Model

The **Optical Properties - Noble** Property Model, available with the Property Model Calculator and the Noble Metal Alloys Model Library, is used to simulate the color, reflection, and transmission of light, based on modeling the alloy microstructure and the resulting optical properties. This model is currently applicable for the Au-Al-Ag-Cu-Pt system.

In the text *CIE* is the abbreviation for *Commission internationale de l'éclairage* (International Commission on Illumination), which is the international authority on light, illumination, color, and color spaces.

Background Theory

The **Optical Properties - Noble** model simulates the color and optical properties such as refractive index n and extinction coefficient k for a given condition. The process to simulate those properties has four steps.

The first step is to calculate the composition and phase fractions for phases using the Equilibrium Calculator. Once that is done, you calculate the dielectric function $\epsilon(\lambda)$ of an alloy:

$$\epsilon(\lambda) = \epsilon_1(\lambda) + i\epsilon_2(\lambda)$$

where $\epsilon(\lambda)$ is the complex dielectric function of wavelength, $\epsilon_1(\lambda)$ is the real part of the dielectric function, representing the material's ability to polarize in response to an electric field, thus affecting refraction, and $\epsilon_2(\lambda)$ is the imaginary part of the dielectric function, representing the energy loss or absorption in the material.

Thermo-Calc calculates the dielectric functions of FCC_A1 and L12_FCC phases with different Al, Au, Ag, Cu, and Pt content. The TCS Noble Metal Alloys Database (TCNOBL) calculates dielectric functions that cover intermetallic phases AL2CU_C16, AL3NI2 (PT)_D513, ALPT_B20, CUPT_L11, AL2AU_C1_CAF2, PTAL2, and CU9AL4. For alloys containing multiple phases, the Bruggeman model [2001Mar] is adopted to get the effective dielectric functions based on the phase fraction and dielectric functions of each individual phase. For N different phases, the generalized Bruggeman model equation is:

[*Eq. 1*] $$\sum_{i=1}^{N} f_i \frac{\epsilon_i - \epsilon_{\text{eff}}}{\epsilon_i + (N-1)\epsilon_{\text{eff}}} = 0$$

Where:

- ϵ_i is the dielectric function of the i-th phase.
- f_i is the volume fraction of the i-th phase, and $\sum_{i=1}^{N} f_i = 1$
- ϵ_{eff} is the effective dielectric constant of the composite material.

The third step is obtaining refractive index n and k from dielectric functions using Eq. 2 and Eq. 3.

[*Eq. 2*] $$n = \sqrt{\frac{\epsilon_1 + \sqrt{\epsilon_1^2 + \epsilon_2^2}}{2}}$$

[*Eq. 3*] $$k = \sqrt{\frac{-\epsilon_1 + \sqrt{\epsilon_1^2 + \epsilon_2^2}}{2}}$$

ϵ_1 and ϵ_2 are the real and imaginary parts of dielectric functions, respectively.

The fourth step is to calculate reflectivity of the material using Fresnel equations (Eq. 4 and Eq. 5) [2023Gri], which describes how much light is reflected and transmitted when it strikes from material 1 to the surface of material 2 at a specific angle. For light striking the surface at an oblique angle θ_i, the Fresnel equations differ for s-polarized and p-polarized light. For more complex situations such as thin films and multiple materials layers, the transfer matrix method (TMM) is used [2016Byr]:

[*Eq. 4*] $$R_s = \left| \frac{n_1 \cos\theta_i - n_2 \cos\theta_t}{n_1 \cos\theta_i + n_2 \cos\theta_t} \right|^2$$

[*Eq. 5*] $$R_p = \left| \frac{n_2 \cos\theta_i - n_1 \cos\theta_t}{n_2 \cos\theta_i + n_1 \cos\theta_t} \right|^2$$

Where:

- R_s: The reflectance for s-polarized light.
- R_p: The reflectance for p-polarized light.
- n_1: The complex refractive index of material 1 (include real and imaginary part). In the current version material 1 is set to be air.
- n_2: The complex refractive index of material 2 (include real and imaginary part).
- θ_i: The angle of incidence (angle between the incident light and the normal to the surface).
- θ_t: The transmission angle (or angle of refraction), calculated using Snell's law: $n_1 \sin\theta_i = n_2 \sin\theta_t$.

The last step is to calculate the color coordinates by using the CIE XYZ color space and integrating over the visible spectrum [2019Pra]:

[*Eq. 6*] $$X = k\int_{380}^{780} R(\lambda)S(\lambda)x(\lambda)d\lambda$$

[*Eq. 7*] $$Y = k\int_{380}^{780} R(\lambda)S(\lambda)y(\lambda)d\lambda\lambda$$

[*Eq. 8*] $$Z = k\int_{380}^{780} R(\lambda)S(\lambda)z(\lambda)d\lambda$$

Where:

- $R(\lambda)$ is the reflectance of the material as a function of wavelength λ, where it is calculated using the calculated materials n and k and Fresnel equations.
- $S(\lambda)$ is the spectral power distribution of the illuminant (for example, the CIE D65 illuminant represents average daylight).
- $x(\lambda)$, $y(\lambda)$, and $z(\lambda)$ are the CIE color-matching functions that model the human eye's response to different wavelengths of light.
- $d\lambda$ is the differential element over the visible spectrum (400 nm to 700 nm).
- k is a normalization constant chosen so that Y = 100 for a perfectly reflective material.

Finally, the tristimulus values for the color of the material is found and based on its reflectance spectrum.

You can further convert these tristimulus values into other color spaces, such as CIE LAB or sRGB, depending on the display or application requirements. See About Color Space.

About DeltaE (ΔE)

Delta E (ΔE, dE) is a metric to understand how the human eye perceives color difference. On a typical scale, the ΔE value ranges from 0 to 100. The larger the ΔE value, the more perceptible the color difference.

If ΔE is:

- Smaller than 2 (ΔE < 2), it is hard to find the color difference.
- In the range of 2 – 10, you can find the difference at a glance.
- Between 11 and 49, colors are more similar than opposite.
- Between 50 to 99, colors are more opposite than similar.
- 100, colors are the exact opposite.

This is a general guideline and it is possible to get a ΔE value below 1.0 for two colors that appear different. This is the case with CIE 1976 and CIE 1994 formulas, in which saturation is either not considered or not weighted properly. For the **Optical Properties** Model there are three methods for calculating ΔE. Because of inconsistencies between the three algorithms, the exact meaning of ΔE changes slightly depending on which formula is used.

ΔE Method

When you select the **Calculate ΔE value** checkbox, an additional setting, **ΔE method** is available. This section describes the options **CIE 1976**, **CIE 1994**, and **CIE 2000** (default).

Over time, several versions of ΔE have been developed to improve how accurately they represent human color perception. The most common versions are ΔE 1976, ΔE 1994, and ΔE 2000. Each one has improvements in accuracy for different use cases.

- ΔE 1976 formula (**CIE 1976**) was the first standardized method to calculate color differences and is based on the CIE 1976 Lab color space. It uses the Euclidean distance between two colors in this three-dimensional space. It is simple and easy to compute, however it has limitations. For example, it treats all changes in color as being equally perceptible, even though the human eye is more sensitive to changes in lightness and less sensitive to changes in chroma (color saturation).
- ΔE 1994 **CIE 1994** was introduced to address the limitations of ΔE 1976 by considering the non-uniformity of human color perception. It adjusts for differences in lightness, chroma, and hue. It is widely used in industrial applications such as textiles, coatings, and plastics but it still does not perfectly match human visual perception.
- ΔE 2000 **CIE 2000** is the most recent and accurate method to calculate color differences. It is designed to improve on ΔE 1994 and provides a more perceptually uniform color difference metric, considering additional corrections for viewing conditions and color perception anomalies. It is the best choice for applications where precise color matching is crucial.

About the Standard Illuminant

There are several options to choose from in the **Standard illuminant** list. These options are related to how the color of alloys is simulated under different lighting conditions. Each option represents a specific type of light source with a defined spectral power distribution (SPD), which describes the intensity of light at different wavelengths. The choice of illuminant affects the perceived color of an object.

The following is an overview of the most common standard illuminants available to select.

- **Single wavelength**: Choose this when you want to know n and k value at certain wavelengths. When selected, color is not calculated.
- **A**: Illuminant A represents typical tungsten incandescent lighting, with a color temperature ~2856 K. Use case: Indoor lighting conditions.
- **B**: Illuminant B represents noon sunlight, with a color temperature ~4874 K. Use case: Daylight conditions with direct sunlight. Often replaced by D series illuminants.
- **C**: Illuminant C represents average daylight, with a color temperature ~6774 K. Use case: Color matching in daylight, superseded by the D-series illuminants.
- Illuminant **D** Series represents different types of daylight with varying color temperatures
    - **D50**: ~5003 K, warm daylight at sunrise or sunset.
    - **D55**: ~5503 K, mid-morning or mid-afternoon daylight.
    - **D65**: ~6504 K, the most common standard for noon daylight conditions. This is the default for the Property Model.
    - **D75**: ~7500 K, used for north sky daylight, that has been largely replaced by D65.
- **E**: Illuminant E is theoretical, equal-energy illuminant, with no color temperature as it is theoretical. Use case: Represents uniform energy across all visible wavelengths, often used in colorimetric calculations as a reference.
- Illuminant **F** Series illuminants represent various types of fluorescent lighting, commonly found in offices, retail environments, and other indoor spaces. The number after "FL" corresponds to different types of fluorescent bulbs.
    - **FL1**: 6430, daylight fluorescent.
    - **FL2**: 4230, cool white fluorescent.
    - **FL3**: 3450, white fluorescent.
    - **FL4**: 2940, warm white fluorescent.

  - **FL5**: 6350, daylight fluorescent.
  - **FL6**: 4150, light white fluorescent.
  - **FL7**: 6500, D65 simulator, daylight simulator.
  - **FL8**: 5000, D50 simulator, Sylvania F40 Design 50.
  - **FL9**: 4150, cool white deluxe fluorescent.
  - **FL10**: 5000, Philips TL85, Ultralume 50.
  - **FL11**: 4000, Philips TL84, Ultralume 40.
- **LED** Illuminants represent different LED lighting sources, which are becoming more common as replacements for traditional incandescent and fluorescent lighting. They often focus on different spectral distributions.
  - **LED-B1** to **LED-B5**: Represents different types of blue-enhanced LED lights.
  - **LED-BH1** defines a blend of phosphor-converted blue and a red LE.
  - **LED-V1** and **LED-V2**: Represents different types of violet-enhanced LED lights
  - **LED-RGB1**: Represents RGB LED lights, where colors are mixed from red, green, and blue LEDs.

In summary:

- D65 is typically used to simulate daylight when designing digital displays or performing color matching in industrial settings.
- Illuminant A is used to simulate indoor lighting conditions with tungsten bulbs.
- Fluorescent (FL series) and LED illuminants are used when you need to simulate environments using these artificial light sources.

About the Viewing Angle

The **Viewing angle** options are **CIE 1931 2 Degree Standard Observer** or **CIE 1964 10 Degree Standard Observer**.

The CIE 2° and CIE 10° Standard Observers are models that describe how an average human eye perceives color. They are based on experiments that measured human color vision using color matching functions. These functions describe how different wavelengths of light are combined by the human eye to match a perceived color. The main difference between the two observers lies in the angle of view they represent, which corresponds to different parts of the eye's visual field.

- CIE 1931 2° Standard Observer model is based on experiments where subjects matched colors within a 2° field of view. This small angle represents the central vision, which is the part of the eye responsible for seeing fine detail. It is most accurate to view small objects or when details are seen up close, such as tiny pixels on a screen or small color samples.
- CIE 1964 10° Standard Observer model represents color perception over a 10° field of view, a much larger area than the 2° observer. This wider field involves more of the peripheral vision, provides a broader and more comprehensive representation of how the eye perceives color in general viewing situations. This is better for measuring color in typical situations where larger objects are viewed, such as printed materials, paints, textiles, or any larger surface.

About Color Space

A color space organizes colors to ensure consistent representation across devices. The **Color space** options are used in two sets of settings and in both you have the option to choose **LAB** (default), **sRGB**, or **XYZ**.

- CIE **LAB** (the default) includes all visible colors and is ideal for color matching, quality control, and any application where accurate perceptual color differences matter.
- CIE **XYZ** covers all perceivable colors and is best for scientific and colorimetric studies, where precise color representation and transformations are needed.
- **sRGB** has a smaller color gamut, but it is widely used for displaying on consumer electronics

CIE LAB Color Space (CIE LAB)

CIE LAB was introduced by the CIE in 1976, and was designed to overcome some of the limitations of CIE XYZ. It created a color space that is perceptually uniform, meaning that a given change in color value should correspond to a similar level of perceived difference to the human eye.

How it Works

- **L**: Lightness (ranging from 0 for black to 100 for white).
- **a**: Green-red axis (with negative values being green and positive values being red).
- **b**: Blue-yellow axis (with negative values being blue and positive values being yellow).

When to Use It

- Color matching and quality control: CIELAB is used extensively in industries like, where precise control of color is required. Like CIE XYZ, LAB is device-independent, meaning it can represent colors regardless of the device displaying or printing them.
- ΔE calculations: The LAB color space is the basis for computing ΔE values, which measure the perceptual difference between two colors. This is important for ensuring that two objects have colors that match closely.
- Easy to interpret and understand by humans: The LAB color space is designed so that small changes in color values are perceived by humans as approximately the same amount of color difference, regardless of where they occur in the color space.

Limitations

- Not well-suited for all applications: Because LAB is not tied to specific devices, it may not be as effective for applications where you're working within the constraints of a particular display or print color gamut (e.g., in digital photography).

CIE XYZ Color Space

Developed in 1931 by the CIE, which was based on tristimulus values—X, Y, and Z—that are hypothetical primaries derived from human vision experiments. It aims to represent all visible colors using a mathematical model grounded in human color perception.

How it Works

The Y value is designed to represent luminance, which corresponds to the brightness or intensity of the color, while X and Z represent the chromaticity (colorfulness) without the influence of brightness.

When to Use It

Scientific research: Since CIE XYZ can represent any perceivable color, it is used in color science and colorimetric applications where precise color measurements are required.

- Device-independent color reproduction: It is used as a foundational color space for transforming colors between different device color profiles, such as between monitors, printers, or cameras.
- Converting to other color space: It's a reference color space, which makes it useful as an intermediary when converting colors between different color spaces.

Limitations

- Not perceptually uniform: While it can represent all colors, it does not account for how humans perceive color differences. A color change of the same magnitude in different areas of the XYZ space might not be perceived as equally different to the human eye.
- Not intuitive for users: The X, Y, and Z coordinates do not correspond to human-perceptible properties like red, green, or blue, making it harder for non-technical users to interpret.

sRGB Color Space

sRGB (Standard Red Green Blue) was created by HP and Microsoft in 1996 as a standard color space for digital displays and the internet webpage. It is based on the typical capabilities of a standard CRT monitor and has become the default color space for web images, digital photography, and many consumer-level devices like cameras and printers.

How It Works

sRGB defines colors in terms of Red, Green, Blue, where each component can range from 0 to 255 or 0 to 1.

When to Use It

- Web and digital content: sRGB is the default color space for the web, and almost all images and digital media you encounter online are in sRGB. This ensures that content looks consistent across different devices.
- Consumer-level photography. Most consumer-grade cameras shoot in sRGB, and it is the standard color space used by default on screens, phones, and printers.

Limitations

sRGB covers a smaller range of colors than spaces like Adobe RGB or LAB. Highly saturated or vivid colors may not be represented accurately in sRGB, which can limit its usefulness for professional printing or design.

Optical Properties - Noble Metals Property Model Settings

The **Optical Properties - Noble** Property Model, available with the Property Model Calculator and the Noble Metal Alloys Model Library, is used to simulate the color, reflection, and transmission of light, based on modeling the alloy microstructure and the resulting optical properties. This model is currently applicable for the Au-Al-Ag-Cu-Pt system.

Configuration Settings

The settings are found on the Property Model Calculator when **Optical Properties - Noble** is selected under **Noble Metal Alloys Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Intercritical Annealing

The **Intercritical annealing** checkbox is selected by default. The model can either accept the given composition as a homogeneous fcc solid solution or perform an equilibrium calculation at the specified annealing temperature to get the phase fractions. Click to clear the checkbox to take the nominal composition and assume the microstructure consists of FCC.

This setting is important since intermetallic phases have a very important effect on the actual color of the alloy.

Annealing Temperature

This setting is available when the **Intercritical annealing** checkbox is selected.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Calculate ΔE Value and ΔE Method Settings

Select the **Calculate ΔE value** checkbox if there is a target color and you want to know the difference between the calculated alloy color and targeting color. Then choose a **ΔE method**: **CIE 2000** (default), **CIE 1976**, or **CIE 1994**.

See About DeltaE (ΔE) in the theory section for more background detail about these settings.

Based on the ΔE method selected, further define these settings.

See About Color Space in the theory section for more detail about the options.

- **Color space of targeting color**: Select **LAB** (default), **sRGB**, or **XYZ**. Then define the index to calculate ΔE, where the range of space for each setting is: **LAB** [0, 100], **sRGB** [0, 1], and **XYZ** [0, 1].
- Enter values into the 1st, 2nd, and 3rd index fields based on the **Color space of targeting color** selection:
- **First index of targeting color**: **X** for XYZ, **L** for LAB, **R** for sRGB.
- **Second index of targeting color**: **Y** for XYZ, **a** for LAB, **G** for sRGB.
- **Third index of targeting color**: **Z** for XYZ, **b** for LAB, **B** for sRGB.

Incident Angle

Enter a value for the **Incident angle [degree]** between 0° and 90° for the incident light angle. The default is 0° (normal light). Incident angle is the angle at which light strikes a surface. This angle is measured between the incoming light ray and the normal (a perpendicular line) to the surface. The incident angle plays a crucial role in determining how light interacts with a material, which in turn affects the perceived color of the material.

Standard Illuminant

Select an option from the **Standard illuminant** list. Choose the incident light wavelength distribution, such as standard daylight illuminant **D65** (the default).

See About the Standard Illuminant in the theory section for more detail about the options.

View Angle of Observer

Select the **View angle of observer**: **CIE 1931 2 Degree Standard Observer** or **CIE 1964 10 Degree Standard Observer** (the default).

In the text *CIE* is the abbreviation for *Commission internationale de l'éclairage* (International Commission on Illumination), which is the international authority on light, illumination, color, and color spaces.

In general:

- **CIE 1931 2 Degree Standard Observer** is most accurate to view small objects or when details are seen up close, such as tiny pixels on a screen or small color samples.
- **CIE 1964 10 Degree Standard Observer** is better for measuring color in typical situations where larger objects are viewed, such as printed materials, paints, textiles, or any larger surface.

See About the Viewing Angle in the theory section for more detail about the options.

Material Thickness

Enter a value for the **Material thickness [nm]**. The default is 10000 nm.

This is an important setting when dealing with thin films or coatings.

Material thickness plays a significant role especially in the context of thin films, coatings, and transparent or semi-transparent materials. It affects how light interacts with the material, influencing reflection, transmission, absorption, and interference effects, all of which contribute to the final perceived color of the material. For example, a several nanometer thin gold film may display red or orange color, and it shows gold color when the film is thick enough. The default thickness is 10000 nm which displays bulk properties. The calculation assumes the two sides of materials are both air.

Color Space

Choose the **Color space** for the resulting color space index 1-3: **LAB** (default), **sRGB**, or **XYZ**.

See About Color Space in the theory section for more detail about the options.

- **LAB** (the default) includes all visible colors and is ideal for color matching, quality control, and any application where accurate perceptual color differences matter.
- **XYZ** covers all perceivable colors and is best for scientific and colorimetric studies, where precise color representation and transformations are needed.
- **sRGB** has a smaller color gamut, but it is widely used for displaying on consumer electronics

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Plot Quantities

- **24-bit color**: To visualize the color, the three color channels need to be merged into a single value. For **sRGB**, 24-bit color is one way to do this.

  Merging three channels (each channel representing an independent axis) into a single value creates a non-linear scale. Thus, the legend option for the Z-axis scale can be considered irrelevant for the actual plot.

- **Annealing temperature**
- **Color space index 1**, **Color space index 2**, and **Color space index 3**: For the **LAB**, **sRGB**, and **XYZ** color spaces, the color is described by three values (the color channels). The **Color space index1**, **2**, and **3** result quantities correspond to these values, e.g., for **sRGB**, **1=R**, **2=G**, **3=B**.
- **Composition**
- **ΔE value**: A metric for understanding how the human eye perceives color difference. On a typical scale, the ΔE value ranges from 0 to 100. The larger the ΔE value, the more perceptible the color difference.
- **First**, **second**, or **third index of targeting color**

- **Incident angle**
- **Material thickness**
- **n for single wavelength** or **k for single wavelength**: Provides the selected part of the refractive index when choosing a single wavelength as the illuminant. The values of **n** and **k** are material properties, but they do depend on the wavelength, wherefore if a multiwavelength illuminant is chosen, these result quantities will give NaN.

PM_Noble_01: Color Prediction

The **Optical Properties - Noble** Property Model, available with the Property Model Calculator and the Noble Metal Alloys Model Library, is used to simulate the color, reflection, and transmission of light, based on modeling the alloy microstructure and the resulting optical properties. This model is currently applicable for the Au-Al-Ag-Cu-Pt system.

This example uses the **Property Model Calculator** with the **Optical Properties - Noble** Property Model. It demonstrates three use cases for simulating color in the Ag-Au-Cu alloy system (1) screening the color of the alloy system (2) designing a green-gold alloy by adjusting Ag content, and (3) visualizing the impact of alloy thickness and light incident angle on color.

Project File and License Information

- Folder: **Property Models → Noble Metals**
- File name: `PM_Noble_01_Color_Prediction.tcu`

To run calculations with the **Noble Metal Alloys Models** (as part of the Noble Metal Alloys Model Library) requires a valid maintenance license plus a license for the TCNOBL (version 3 and newer) database.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

Screening the Color of the Ag-Au-Cu Alloy System

- The entire composition space was screened with a 2 wt.% step size.
- Alloys were annealed at 873.15 K to reach equilibrium phases and compositions for accurate color prediction.
- The standard illuminant is D65 noon daylight, with a 2˚standard observer. The material is assumed to be opaque with a thickness of 10,000 nm.
- Some color predictions near the 20–40 wt.% Cu region require model accuracy improvements.

Visualizations

Delta E plot | Ternary color plot | Angle and thickness dependence | Delta E values

ΔE value (Opt. Prop. - Noble)	Mass percent Au	Mass percent Ag	Temperature [K]	Mass percent Cu

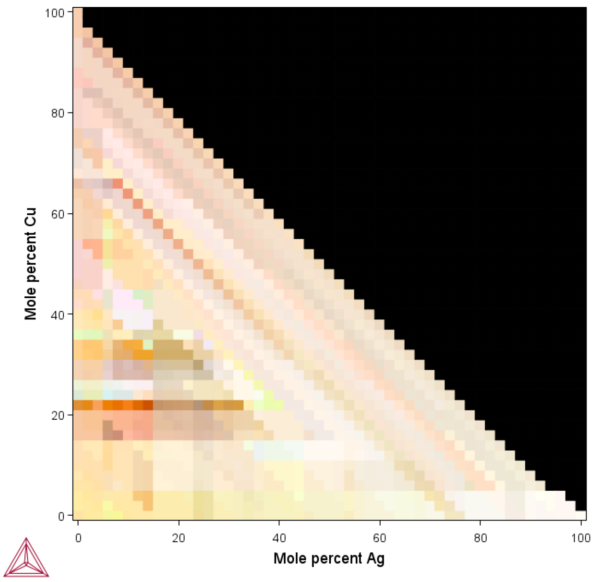

Figure 1: Color prediction for Ag-Au-Cu alloy.

Designing a Green Gold Alloy by Adjusting Ag Content in Au-10Cu-xAg Alloys

- ΔE calculation box was chosen to enable the measurement of color differences.
- Target color in Lab color space is [95, -13, 25], representing a light green shade.

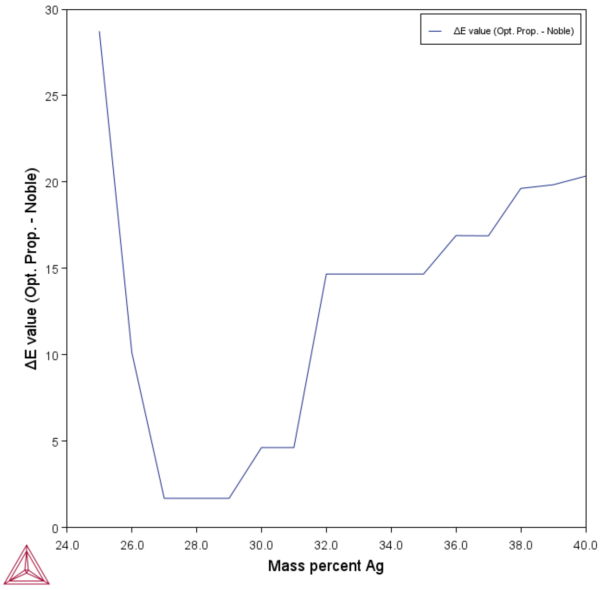

Figure 2: Change of color difference (ΔE) between the targeting light green gold and the simulated alloy when changing Ag content.

Visualizing the Impact of Alloy Thickness and Light Incident Angle on Color

- Intercritical annealing was not selected, as pure gold is in the FCC phase and does not require equilibrium calculations.
- As material thickness increases, the color of gold tends to approach the bulk gold color observed in macroscopic samples.

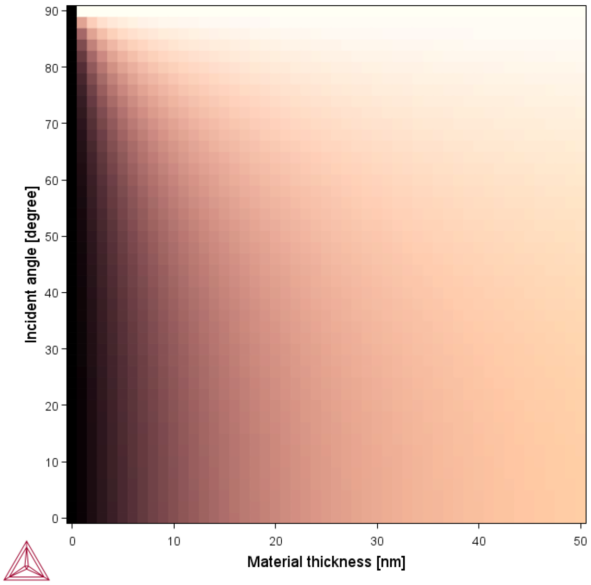

Figure 3: Color of pure gold varies with different light incident angles and material thicknesses.

About the Steel Model Library Property Models

These **Steel Models** are available with the Property Model Calculator. The following are available with the Steel Model Library.

As a starting point, the **Property Navigator** can more quickly help guide you to set up the initial simulation. See Creating a Project with the Property Navigator.

Bainite

The **Bainite** Property Model, available with the Property Model Calculator and the Steel Model Library, describes the thermodynamics and isothermal kinetics of bainite transformation from austenite. Bainite is modeled as ferrite or a ferrite-cementite mixture.

Considered elements: Fe, C, Mn, Si, Cr, Ni, Mo. Other elements in the system are neglected for bainite by mass percent.

See About the Bainite Property Model and Bainite Property Model Settings for background theory and input parameter details.

CCT Diagram

The **CCT Diagram** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the concurrent transformations to ferrite, pearlite, bainite, and martensite under continuous cooling conditions. It can be used to construct a Continuous-Cooling-Transformation (CCT) diagram with a *One Axis* calculation on *Log10(cooling rate[K/s]*). The Model calculates the kinetics of concurrent transformation of austenite into ferrite (grain-boundary allotriomorph, or "polygonal ferrite"), pearlite, bainite, and martensite. The algorithms and parameters for these products are the same as in the individual Property Models (Ferrite, Pearlite, Bainite, Martensite Temperatures, and Martensite Fractions), but the competitive occupation of prior austenite grain boundaries and bulk volume is handled by this model.

See About the CCT Diagram Property Model and CCT Diagram Property Model Settings for background theory and input parameter details.

Critical Transformation Temperatures

The **Critical Transformation Temperatures** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates critical transformation temperatures for steels under equilibrium conditions.

The Model can output the transformation temperatures for the following (assuming cooling):

- *Liquidus*: First austenite or ferrite transformation from the liquid.
- *Solidus*: Liquid fully transformed to solid.
- *A0*: Magnetic transition temperature (Curie temperature) of cementite. The cementite is paramagnetic above A0 and ferromagnetic below.
- *A1*: Temperature at which austenite (FCC_A1) transforms to ferrite (BCC_A2) + carbide (cementite or graphite or M23C6).
- *A2*: Magnetic transition temperature (Curie temperature) of ferrite (BCC_A2). Paramagnetic above A2 and ferromagnetic below.
- *A3*: Temperature at which austenite (FCC_A1) transforms to ferrite (BCC_A2).
- *A4*: Temperature at which delta-ferrite (BCC_A2) transforms to austenite (FCC_A1).
- *Acem*: Temperature at which austenite (FCC_A1) transforms to cementite. This quantity is only available if the **Suspend graphite** checkbox is selected, i.e., graphite is suspended from the calculation).
- *Agraph*: Temperature at which austenite (FCC_A1) transforms to graphite. This quantity is only available if the **Suspend graphite** checkbox is NOT selected, i.e. graphite is not suspended from the calculation.

See About the Critical Transformation Temperatures Property Model and Critical Transformation Temperatures Property Model Settings for background theory and input parameter details.

Ferrite

The **Ferrite** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the thermodynamics and isothermal kinetics of proeutectoid ferrite forming from austenite in hypoeutectoid steels. This model is for the form of proeutectoid ferrite which forms without distinct crystallographic preferences at austenite grain boundaries. This type of ferrite is referred to as *grain boundary allotriomorph*, or *polygonal ferrite*. Another

type, plate-shaped ferrite (*Widmanstätten ferrite*), is treated in the **Bainite** Property Model as a special case of bainite without cementite. Growth is modeled based on a simplified diffusion-control theory with the ferrite/austenite interfacial composition determined by various *Growth mode* settings available—Orthoequilibrium (OE), Paraequilibrium (PE), Orthoprecipitate (OP), or Paraprecipitate (PP).

See About the Ferrite Property Model and Ferrite Property Model Settings for background theory and input parameter details.

Martensite Fractions

The **Martensite Fractions** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the fraction of athermal martensite based on an analytical equation of an available driving force. It is assumed that the first forming martensite morphology is the only forming one. The first morphology is determined based on the Ms-temperatures of all morphologies.

See About the Martensite Fractions Property Model and Martensite Fractions Property Model Settings for background theory and input parameter details.

Martensite Temperatures

The **Martensite Temperatures** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the martensite start (Ms) temperature based on modeling of the transformation barrier with fitted analytical equations. Martensite fractions and formation temperatures (i.e., M50, M90, and Mf) are calculated with the same method used in the **Martensite Fractions** Property Model. The partitionless equilibrium temperature $\mathbf{T_0}$ is calculated using the thermodynamic database. The Model also gives temperatures corresponding to 50%, 90%, and 99% transformations.

See About the Martensite Temperatures Property Model and Martensite Temperatures Property Model Settings for background theory and input parameter details.

Martensitic Steel Strength

The **Martensitic Steel Strength** Property Model, available with the Property Model Calculator and the Steel Model Library, predicts the general flow stress properties of martensitic steels, such as hardness, stress at arbitrary strain, yield strength, ultimate tensile strength, Young's modulus, etc.

The Model evaluates the following in consecutive steps:

- Martensite fraction based on composition, annealing temperature, and quench temperature
- Hardness of the as-quenched microstructure
- Effect of tempering on microstructure and hardness
- Young's modulus based on the composition of the matrix phase and contributions from precipitates
- Strain hardening response (flow stress) based on the final hardness after tempering

See About the Martensitic Steel Strength Property Model, Flow Stress Theory, and Martensitic Steel Strength Property Model Settings for background theory and input parameter details.

Pearlite

The **Pearlite** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the thermodynamics and kinetics of pearlite formation from austenite during isothermal heat treatment. It is assumed that the overall composition of pearlite is the same as the austenite composition, and growth rate is constant over time. Growth rate and lamellar spacing of pearlite are determined by a criterion where either growth rate or Gibbs energy dissipation rate is maximized. The Model considers Gibbs energy dissipation due to formation of ferrite-cementite interface in pearlite, finite austenite-pearlite interfacial mobility, solute drag, and diffusion of elements within austenite and along austenite-pearlite interface.

The included elements for this model are Fe (dependent element), C, Mn, Cr, Mo, W, Si, Al, Ni, Co. Other elements are neglected by weight percent.

See About the Pearlite Property Model and Pearlite Property Model Settings for background theory and input parameter details.

TTT Diagram

The **TTT Diagram** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates a Time-Temperature-Transformation (TTT) diagram with a **One Axis** calculation on temperature. The Model calculates the isothermal kinetics of concurrent transformation of austenite into ferrite (grain-boundary allotriomorph, or "polygonal ferrite"), pearlite, bainite, and martensite.

The algorithms and parameters for ferrite, pearlite, bainite, and martensite are the same as in the individual Property Models (**Ferrite**, **Pearlite**, **Bainite**, **Martensite Temperatures**, and **Martensite Fractions**), but the competitive occupation of prior austenite grain boundaries and bulk volume is handled in the **TTT Diagram** Model.

If the reaction temperature is below martensite-start temperature (Ms), it is assumed that a fraction of (athermal) martensite according to the calculation forms instantaneously at time zero, prior to the formation of any one of ferrite, bainite, and pearlite. Otherwise austenite transforms to ferrite, bainite and/or pearlite.

See About the TTT Diagram Property Model and TTT Diagram Property Model Settings for background theory and input parameter details.

Learn More

To run calculations with the **Steel Models** requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases. Also see our website to learn more about the Steel Model Library and other related examples.

Also see Steel Library CCT Diagram Template, Steel Library TTT Diagram Template, Plot Type: CCT Mode, and Plot Type: TTT Mode.

For the **Ferrite**, **Bainite**, and **Pearlite** Property Models, it is also useful to review the Recommended Composition Ranges for Steel Models.

The associated properties for the Steel Library Property Models—**Bainite**, **Ferrite**, **Pearlite**, **CCT Diagram**, and **TTT Diagram**—are not available with the Property Navigator. For **CCT Diagram** and **TTT Diagram**, you can specifically use the dedicated **Steel CCT** and **Steel TTT** templates instead. For **Bainite**, **Ferrite**, and **Pearlite**, these are simplified TTT calculations, so you can also use the **Steel TTT** template to start.

Recommended Composition Ranges for Steel Models

The Steel Property Models (a.k.a. Steel Models or just Models) included with the Steel Model Library in Thermo-Calc calculate the process of austenite decomposition into ferrite, pearlite, bainite, and martensite. These Models are developed to satisfy the needs for a wide range of steels and are built on the thermodynamic and kinetic descriptions in the TCS Steel and Fe-alloys Database (TCFE) and TCS Steels/Fe-Alloys Mobility Database (MOBFE) databases, which are widely validated. However, the Steel Models also include their own modeling approach and parameters, which may limit the applicability to certain ranges of compositions and temperature, often due to some underlying assumptions of the modeling approaches and/or availability of calibration data.

Background

In general, the Models for ferrite, bainite, and pearlite are for low-alloy, low-to-medium carbon steels involving austenite (Fe-rich disordered FCC_A1) transforming into ferrite (Fe-rich disordered BCC_A2) and cementite. For steels with higher Cr contents, it is also possible to select M7C3 and M23C6 to be the carbide in pearlite, and M7C3 for bainite. Otherwise, the Models are not designed for other phase relations, for example:

- Austenite transforming into a mixture of ferrite and another type of carbide (e.g. kappa carbide for high-Mn high-Al alloys).
- Precipitation (e.g. FCC-Cu, FCC-carbides due to microalloying elements Ti, V, Nb) taking place concurrently while austenite is transforming into ferrite (and possibly cementite).

If some other phases coexist with austenite prior to its transformation, the Steel Models assume these do not participate in or affect the transformations by any means (e.g. by providing extra nucleation sites). The only effect of these phases is to determine the austenite composition (which is now different from the nominal composition). In this case, the setting **Equilibrium composition at annealing temperature** is selected from the **Austenite composition from** list on the **Configuration** window.

For an explanation of **Austenite composition from** see the individual configuration settings for the different Steel Models (**Ferrite**, **Bainite**, and **Pearlite**). Links to these are listed in About the Steel Model Library Property Models.

Ferrite and bainite calculations rely on carbon partitioning from ferrite to austenite. Therefore, the Models are *not* suitable for the ferrite transformed from austenite in a "massive" manner (composition invariant), in some "interstitial-free" ferrous alloys with very low carbon contents.

Pearlite is assumed to be steady-state, i.e. growth rate and lamellar spacing are constant over time under isothermal conditions. This is reasonable if composition and transformation temperature lie in the ferrite-cementite two-phase region of a phase diagram. The Pearlite Model does *not* cover the so-called "divergent pearlite", or "partitioned pearlite", which usually forms in the austenite-ferrite-cementite three-phase region with growth rate and lamellar spacing changing over time. Also, pearlite nucleation is modeled to be on austenite grain boundaries only. In practice, however, pearlite nucleation at grain edges and corners may also be considerable if the undercooling is small.

Parameters within the Steel Models are calibrated against experimental data on nucleation, growth, and overall transformation kinetics. However, the composition space covered by the calibration data, on which the Steel Models calculations are checked, is limited. As a result, together with the limitations from modeling approach discussed above, some recommended composition ranges are listed below. The Models may not give reasonable results when the composition in question is far outside the recommended ranges.

Steel Model Library Recommended Composition Ranges

Element	*Ferrite*	*Bainite*		*Pearlite*[3]
		Bainite Start Temperature [2018Lea][1]	*Bainite Growth, Nucleation, Transformation Kinetics*[2]	
C	Max. 0.7	Max. 0.7	0.2-1.5	0.6-1
Mn	Max. 3	Max. 5.5	Max. 0.6	Max. 1.8
Ni	Max. 5	Max. 9	Max. 5.3	Max. 3
Si	Max. 2	Max. 2	Max. 1	Max. 2

Element	Ferrite	Bainite		Pearlite[3]
		Bainite Start Temperature [2018Lea][1]	Bainite Growth, Nucleation, Transformation Kinetics[2]	
Al	Max. 1.4	–	–	(unknown, assuming similar to Si)
Co	Max. 3.2	–	–	Max. 2.2
Cr	Max. 3	Max. 5.7	Max. 5	Max. 13[4]
Mo	Max. 2	Max. 4	(unknown)	Max. 0.6
W	–	–	–	Max. 0.37

[1] The model is from [2018Lea]. The supporting bainite start data is compiled and published in [2019Lea].

[2] Parameters are not assessed to be composition dependent. The listed composition ranges come from the data of growth considered in a “universal” fitting.

[3] References in [2020Yan].

[4] Requires calculation setting **Custom** for type of carbide. Estimated boundaries: CEMENTITE for <5 wt.% Cr, M7C3 for 5~10 wt. % Cr, M23C6 for >10 wt.% Cr.

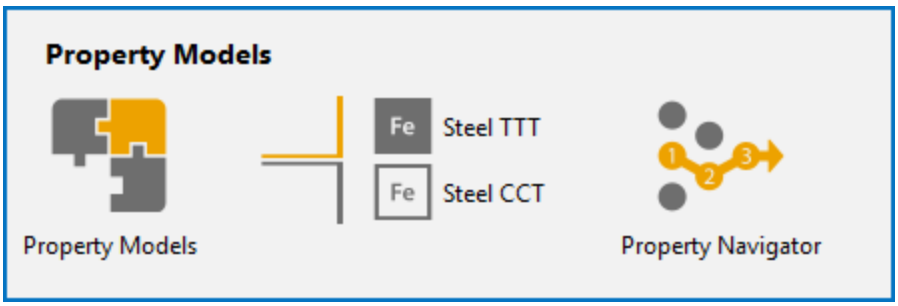
Steel Library TTT Diagram Template

Use a **Steel TTT** template to add all the activities for a Time-Temperature-Transformation (TTT) diagram calculation. The **TTT Diagram** Property Model is automatically selected with all settings by default on the Property Model Configuration window. This makes it easy to add the project to the tree and examine the progress of transformation as a function of time at a fixed temperature.

Adding a Steel Library TTT Template to a Project

1. In the **Project** window click the **My Project** node to display the templates in the **Configuration** window.
2. Under **Property Models**, click the top icon **Steel TTT**.



A **System Definer**, *Property Model Calculator* (renamed to **Steel Models**) and a *Plot Renderer* (renamed to **TTT**) are added to the **Project** window. Also see Property Model Calculator and Plot Type: TTT Mode.

You can also add templates by right-clicking the **My Project** node and choosing an option from the **Create New Activity → Use Template** menu.

About the Bainite Property Model

The **Bainite** Property Model, available with the Property Model Calculator and the Steel Model Library, describes the thermodynamics and isothermal kinetics of bainite transformation from austenite. Bainite is modeled as ferrite or a ferrite-cementite mixture.

Considered elements: Fe, C, Mn, Si, Cr, Ni, Mo. Other elements in the system are neglected for bainite by mass percent.

Background Theory

For a given austenite composition, the bainite start temperature, WB_S, is calculated following Leach et al. [2018Lea] (see Eqs. 8 and 9 and Table 1 in the paper). At WB_S, the driving force for ferrite to precipitate out of austenite under the “para” condition (i.e. no partitioning of substitutional elements, carbon in equilibrium) is balanced by a barrier, which is modeled as a function of composition.

At a temperature below WB_S, there is a net driving force (over the barrier) for the growth of bainitic ferrite. The steady-state lengthening rate of ferrite plate is calculated based on the method from Leach et al. [2019Lea] with modifications. In the Bainite Model, unlike in [2019Lea], local equilibrium of carbon at the ferrite/austenite is sought, and a finite interfacial friction term is added to the dissipation terms. Otherwise the two methods are both based on a driving-force–dissipation balance and the Zener-Hillert equation, with a unique lengthening rate determined by maximizing it with respect to radius of curvature at the plate tip.

The Bainite Model also considers the case where cementite (under the “para” condition) can precipitate on the ferrite/austenite interface and grow into ferrite, forming a ferrite-cementite mixture. The formation of para-cementite usually accelerates lengthening, by enlarging the driving force of transformation while reducing carbon partitioning from bainite to austenite. Carbon partitioning to austenite vanishes if para-cementite forms in bainite to its maximum fraction allowed by mass balance.

Thickening of bainitic plates is usually much slower than lengthening. In the Bainite Model, it is assumed that whenever there is a positive driving force of precipitating para-cementite on the ferrite/austenite interface, the final state of the bainite transformation should be a mixture of

ferrite and cementite, with austenite being completely transformed. Otherwise, the final state is a ferrite-austenite mixture with no cementite but a finite fraction of retained austenite (incomplete transformation).

The overall kinetics of bainite transformation is calculated in the extended-volume approach devised by Cahn [1956Cah] and generalized for ellipsoids. Both grain boundary (GB) nucleation and volume nucleation are considered, the former being very temperature-sensitive, the latter temperature-insensitive. This is used to model the kinks at about 350 °C in the TTT diagrams of some medium- and high-carbon steels—At higher temperatures GB nucleation is predominant, whereas at lower temperatures it is effectively suppressed, and volume nucleation becomes significant.

Configuration Settings

The input parameters are entered on the **Configuration** window for the Property Model Calculator. There are also settings on the Plot Renderer where you can choose from the available and relevant axis variables.

See Bainite Property Model Settings for details.

Example

For an example, see PM_Fe_05: Fe-C-Mn-Si-Ni-Cr-Mo Bainite.

About the CCT Diagram Property Model

The **CCT Diagram** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the concurrent transformations to ferrite, pearlite, bainite, and martensite under continuous cooling conditions. It can be used to construct a Continuous-Cooling-Transformation (CCT) diagram with a *One Axis* calculation on *Log10(cooling rate[K/s]*). The Model calculates the kinetics of concurrent transformation of austenite into ferrite (grain-boundary allotriomorph, or "polygonal ferrite"), pearlite, bainite, and martensite. The algorithms and parameters for these products are the same as in the individual Property Models (Ferrite, Pearlite, Bainite, Martensite Temperatures, and Martensite Fractions), but the competitive occupation of prior austenite grain boundaries and bulk volume is handled by this model.

About the Critical Transformation Temperatures Property Model

The **Critical Transformation Temperatures** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates critical transformation temperatures for steels under equilibrium conditions.

The Model can output the transformation temperatures for the following (assuming cooling):

- *Liquidus*: First austenite or ferrite transformation from the liquid.
- *Solidus*: Liquid fully transformed to solid.
- *A0*: Magnetic transition temperature (Curie temperature) of cementite. The cementite is paramagnetic above A0 and ferromagnetic below.
- *A1*: Temperature at which austenite (FCC_A1) transforms to ferrite (BCC_A2) + carbide (cementite or graphite or M23C6).
- *A2*: Magnetic transition temperature (Curie temperature) of ferrite (BCC_A2). Paramagnetic above A2 and ferromagnetic below.
- *A3*: Temperature at which austenite (FCC_A1) transforms to ferrite (BCC_A2).
- *A4*: Temperature at which delta-ferrite (BCC_A2) transforms to austenite (FCC_A1).
- *Acem*: Temperature at which austenite (FCC_A1) transforms to cementite. This quantity is only available if the **Suspend graphite** checkbox is selected, i.e., graphite is suspended from the calculation).
- *Agraph*: Temperature at which austenite (FCC_A1) transforms to graphite. This quantity is only available if the **Suspend graphite** checkbox is NOT selected, i.e. graphite is not suspended from the calculation.

The input parameters are entered on the **Configuration** window for the Property Model Calculator and described in Critical Transformation Temperatures Property Model Settings.

Example

For an example, see PM_Fe_04: Critical Temperatures.

About the Ferrite Property Model

The **Ferrite** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the thermodynamics and isothermal kinetics of proeutectoid ferrite forming from austenite in hypoeutectoid steels. This model is for the form of proeutectoid ferrite which forms without distinct crystallographic preferences at austenite grain boundaries. This type of ferrite is referred to as *grain boundary allotriomorph*, or *polygonal ferrite*. Another type, plate-shaped ferrite (*Widmanstätten ferrite*), is treated in the **Bainite** Property Model as a special case of bainite without cementite. Growth is modeled based on a simplified diffusion-control theory with the ferrite/austenite interfacial composition determined by various *Growth mode* settings available—Orthoequilibrium (OE), Paraequilibrium (PE), Orthoprecipitate (OP), or Paraprecipitate (PP).

Included Elements and Important Notes

- Austenite must contain at least Fe and C for this model to function.
- Elements that are quite soluble in both austenite and ferrite—Mn, Ni, Si, Al, Co, Cr, and Mo—have their effects on overall kinetics assessed.
- Cu and strong carbide-formers—W, V, Nb, Ta, Ti, and Zr—can be included, but only to a certain extent not to cause phases other than austenite and ferrite to form at the calculation temperature. Otherwise, the model calculation may give unrealistic results or even fail. If carbide is expected to form at an austenitizing temperature, use the setting **Equilibrium composition at annealing temperature** for **Austenite composition from**, then enter an annealing temperature.

Elements not listed above are excluded in mass percent from the austenite composition used to calculate the transformation.

Growth Models

Growth is modeled based on a simplified diffusion-control theory with the ferrite/austenite interfacial composition determined by:

- *Orthoequilibrium (OE)*: The ferrite and austenite compositions at the interface are fixed to the final equilibrium compositions
- *Paraequilibrium (PE)*: Only carbon is allowed to partition, reaching PE at the interface
- *Negligible-partitioning local equilibrium (NPLE)*
- *Orthoprecipitate (OP)*: Austenite interfacial composition being the bulk composition, ferrite interfacial composition from the maximum driving force condition (parallel tangent construction in Gibbs energy-composition diagram)
- *Paraprecipitate (PP)*: Only carbon is allowed to partition, otherwise the same as OP

The growth is parabolic if only diffusion-controlled. The parabolic rate constant can be modified by a *phase addition* because the driving force and interfacial compositions are changed. With a finite interfacial mobility and solute drag effects, the growth is then mixed-controlled. The effect is handled in the overall transformation kinetics but not reflected in the parabolic rate constant.

Nucleation Rate and Interfacial Mobility

Nucleation rate of ferrite allotriomorph on austenite grain boundaries is calculated from classical nucleation theory assuming a pillbox shape of the ferrite nucleus [1988Lan].

When you are setting up the model, parameters for nucleation rate (site density, edge energy, and epsilon, see [1988Lan] for definition) and interfacial mobility (pre-exponential factor and activation energy) can be customized. Otherwise, default values assessed by Thermo-Calc are used. The overall kinetics of isothermal transformation is calculated in the extended-volume framework by numerical integration over time. Austenite composition changes over time due to partitioning of elements, and its effects on growth and nucleation are handled.

About the Martensite Fractions Property Model

The **Martensite Fractions** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the fraction of athermal martensite based on an analytical equation of an available driving force. It is assumed that the first forming martensite morphology is the only forming one. The first morphology is determined based on the Ms-temperatures of all morphologies.

The analytical equation is derived in Huyan et al. [2016Huy].

Example

For an example see PM_Fe_01: Fe-Cr-C Martensite with Intercritical Annealing.

About the Martensite Temperatures Property Model

The **Martensite Temperatures** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the martensite start (Ms) temperature based on modeling of the transformation barrier with fitted analytical equations. Martensite fractions and formation temperatures (i.e., M50, M90, and Mf) are calculated with the same method used in the **Martensite Fractions** Property Model. The partitionless equilibrium temperature $\mathbf{T_0}$ is calculated using the thermodynamic database. The Model also gives temperatures corresponding to 50%, 90%, and 99% transformations.

The model is based on Stormvinter et al. [2012Sto] with subsequent update and extension by Gulapura Hanumantharaju [2017Gul] and Thermo-Calc internal assessment.

About the Martensitic Steel Strength Property Model

The **Martensitic Steel Strength** Property Model, available with the Property Model Calculator and the Steel Model Library, predicts the general flow stress properties of martensitic steels, such as hardness, stress at arbitrary strain, yield strength, ultimate tensile strength, Young's modulus, etc.

The Model evaluates the following in consecutive steps:

- Martensite fraction based on composition, annealing temperature, and quench temperature
- Hardness of the as-quenched microstructure
- Effect of tempering on microstructure and hardness
- Young's modulus based on the composition of the matrix phase and contributions from precipitates
- Strain hardening response (flow stress) based on the final hardness after tempering

About Hardness and Flow Stress

The hardness is evaluated by considering the individual contributions to hardness considered by the given flow stress model, such as intrinsic hardness, solid solution hardening and martensite hardening.

The resulting hardness forms the foundation for evaluating the flow stress by means of estimating the strain hardening response of the alloy. Deviations in predicted flow stress properties can be corrected by changing key parameters in the settings, which are:

- Pre-straining (accounts for cold work the material may have been subjected to)
- Flow stress model (Ramberg-Osgood or Voce) and model specific parameters
- Young's modulus
- Constant strength addition

The effect of tempering temperature is described on the basis of a physical model, with an applied correction using a neural network model describing the effect of tempering time. It is possible to predict precipitates forming at the tempering temperature and their individual properties will add to the total strength of the steel.

Graphite, Diamond, and Gas phases are all suspended throughout the calculation.

Background Theory

Steels undergoing austenitization, or at least partial austenitization (i.e., intercritical annealing), may form martensite upon quenching. The mechanical properties of martensite depend heavily on the content of interstitial elements in the parent austenite but are of course also affected by other elements and secondary phases. In general, a martensitic steel exhibits the following contributions to strength (or hardness):

[*Eq. 1*] $$\sigma_{tot} = \sigma_i + \sigma_{ss.} + \Delta\sigma_{mart.}$$

where σ_i is the total intrinsic hardness of the phases in the material, σ_{ss} is the contribution from solid solution hardening from each phase, and $\Delta\sigma_{mart.}$ is the additional hardening due to formation of martensite from the parent austenite.

The σ_i and σ_{ss} terms are modeled in the same way as in the **Yield Strength** Model. See About the Yield Strength Property Model.

The last term ($\Delta\sigma_{mart.}$) in Eq. 1 can further be decomposed into:

[*Eq. 2*] $$\Delta\sigma_{mart.} = \sigma_{mart.} \cdot f_{transf.}$$

where $\Delta\sigma_{mart.}$ is the hardening effect of the formation of martensite and $f_{transf.}$ is the fraction of parent austenite that has transformed to martensite. In the **Martensitic Steel Strength** Property Model, the fraction transformed is evaluated using the **Martensite Fractions** Model.

About the Martensite Fractions Property Model and Martensite Fractions Property Model Settings.

This means that the evaluation of the fraction of martensite is dependent on composition, Annealing temperature, Quench temperature, and other parameters. These parameters are also available from within the Martensitic Steel Strength model.

Be aware of the absence of the contribution from grain size in Eq. 1. It has been shown that parent austenite grain boundaries contribute very little to the overall strength, due to the numerous other defects and interfaces that form during a martensitic transformation. The grain size may, however, affect the martensitic transformation itself in terms of the residual austenite content, which is modeled separately.

Eq. 1 is valid for the as-quenched condition, however, martensitic steels are most often tempered, which decomposes the martensite (and the residual austenite), to reduce brittleness. In the tempered condition, the martensite hardening contribution is reduced by reduction of dislocation density and precipitation of carbides. The carbides may also contribute significantly to the overall hardness and thus reduce the softening or even cause what is known as a secondary hardening peak. Eq. 2 thus becomes:

[*Eq. 3*] $$\Delta\sigma_{mart.tempered} = \sigma_{mart.} \cdot f_{transf.} \cdot \delta_{temper}$$

where δ_{temper} is a number between 0 and 1 and depends on Tempering temperature and composition. In addition to this, the first two terms of Eq. 1 now also contain contributions from any tempering carbides that form. Tempering carbides are obtained from a constrained equilibrium calculation using the parent austenite composition and Tempering temperature, where during set up you can select what phases are allowed on the **System Definer Configuration** window. This is justified by the abundant nucleation sites (due to very high dislocation density) and the fact that the carbides that form are very small, which implies very short diffusion distances.

The tempering behavior as function of time is modeled using a neural network trained on a large dataset covering mainly carbon and low-alloy steels, which provides a correction term to the total calculated hardness of the steel in the quench and tempered condition based on the physical model described above. For most of the steels considered, a very rapid decrease of hardness is expected with time, resulting in an asymptotic approach to an apparent stable value. Such a highly non-linear behavior, also exhibiting dependency on composition, lends itself well to machine learning (ML) based models.

The use of the predicted hardness to further predict flow stress is detailed in the theory for Flow Stress Theory. Since the framework for evaluating flow stress is generally applicable, it is described as a separate section.

FCC_A1, BCC_A2, and Cementite must be selected on the **System Definer Configuration** window but can be suspended with settings available on the **Property Model Configuration** window. If these phases are excluded on the System Definer, the calculation does not work.

The Model only accepts phases that have had the intrinsic strength assessed. For a list of available phases see the section in the theory for Yield Strength Property Model regarding the Intrinsic Strength model.

Flow Stress Theory

The following Property Models provide flow stress:

- **Martensitic Steel Strength** in the Steel Model Library
- **Alloy Strength - Ti** in the Titanium Model Library

When flow stress is available, it enables you to predict stress at arbitrary strain with these properties:

- True stress
- True strain (this requires user input)
- Engineering strain
- Engineering stress

The Model has a **Flow stress mode** to predict engineering properties such as:

- Yield strength
- Yield strain
- Ultimate tensile strength
- Uniform elongation
- Fracture strength
- Elongation at fracture
- Young's modulus

True strain is not available as an input parameter when using the *engineering properties mode* (i.e. $\mathbf{E}, \sigma_{\mathbf{y}}$ **and** $\sigma_{\mathbf{UTS}}$, which is selected as a **Flow stress mode**).

Additional Information

This section is specifically about the flow stress theory and is a continuation from the main theory described in About the Martensitic Steel Strength Property Model and About the Alloy Strength - Ti Property Model.

The input parameters are entered on the **Configuration** window for the Property Model Calculator. There are also settings on the Plot Renderer where you can choose from the available and relevant axis variables.

For details about the various settings mentioned in this theory section, see

- For **Martensitic Steel Strength** see Martensitic Steel Strength Property Model Settings. You can also open an installed example to see the application of these features. See PM_Fe_12: Flow Stress 15-5PH Steel for more information.
- For **Alloy Strength - Ti**, see Alloy Strength - Ti Property Model Settings. You can also open an installed example to see the application of these features. SeePM_Ti_03: Flow Stress in a Ti-based Alloy.

Main Implementation

The flow stress model relies on the Ramberg-Osgood equation to predict flow stress, which can be expressed as:

$$\varepsilon = \frac{\sigma}{E} + 0.002\left(\frac{\sigma}{\sigma_y}\right)^{(1/n)}$$

where

- ε is the strain,
- σ is the stress,
- E is the Young's modulus,
- σ_y is the yield strength, and
- n is the strain hardening exponent.

To calculate stress at an arbitrary strain, the parameters E, σ_y, and n need to be determined.

The Young's modulus of the material is obtained by averaging the Young's moduli of individual phases.

Elastic properties (the elastic constants and moduli) are available with the TCS Steel and Fe-alloys Database (TCFE) starting with version 14 (TCFE14) and with TCS Ti/TiAl-based Alloys Database (TCTI) starting with version 6 (TCTI6). If you are using earlier versions of these databases, i.e., no elastic properties are available, then the Young's moduli of individual phases are estimated using simple rules.

For the **Martensitic Steel Strength** model, the yield strength (σ_y) is determined based on its relationship with hardness, where the work by Pavlina and Van Tyne [2008Pav] is extended to consider a larger dataset.

The hardness itself is predicted by the model as described in the primary theory sections, About the Martensitic Steel Strength Property Model and About the Alloy Strength - Ti Property Model.

User-defined Flow Stress Parameters

Young's modulus (E) and the strain hardening exponent (n) can be set manually by selecting the **User-defined flow stress parameters** checkbox on the **Configuration** window. The yield strength, σ_y, is then inferred from these parameters and the known hardness.

After selecting the checkbox, you can further choose to use the **Voce** equation (select this option from the **Flow stress model** list), which is expressed as:

$$\sigma = \sigma_y + (\sigma_s - \sigma_y)(1 - e^{-k\varepsilon_p})$$

where

- σ_s is the saturation stress,
- ε_p is the plastic strain, and
- k is the hardening rate.

As the Voce equation is only expressed in terms of plastic strain, the model uses $\sigma = \varepsilon E$ for strains lower than the yield strain. To use the Voce model, you must specify the following additional settings:

- E (**Young's modulus**)
- σ_s (**Saturation stress**)
- k (**Hardening rate**)

Pre-deformed Materials

The flow stress model can be used to predict flow stress in pre-deformed materials, using the parameter **Pre-straining [%]**. The value given should correspond to the plastic strain that the material is exposed to beforehand. Pre-straining shifts the yield point and affects the yield strain, where uniform elongation and total elongation is then reduced by a corresponding amount.

Strain-rate Dependence

Strain-rate dependence on stress is implemented in the model and expressed as:

$$\sigma(\dot{\varepsilon}) = \sigma(\dot{\varepsilon_0}) \left(\frac{\dot{\varepsilon}}{\dot{\varepsilon_0}}\right)^m$$

where

- ε is the applied strain rate,
- $\dot{\varepsilon}_0$ is the reference strain rate (corresponding to quasi-static conditions), and
- m is the strain rate sensitivity, where m can be predicted by the model or user-defined.

Fracture Properties

Elongation and Fracture

Neither the Ramberg-Osgood nor Voce models can be used to predict fracture properties as they are only valid for uniform deformation. In fact, modeling, e.g., total elongation in a general manner based on some physical or empirical model is a challenging task. For this reason, the total elongation is modeled using a machine learning approach. Together with other properties, total elongation can then be used to estimate the fracture strength. In the stress vs. strain mode, any engineering stress at engineering strains beyond the predicted elongation is set to NaN, signifying that the material has fractured completely.

Post-uniform True vs. Engineering Stress and Strain

The conversion between engineering and true quantities is mathematically valid in the entire range of strain, however, the conversion assumes constant volume. This assumption is not valid in the necking regime as the deformation is not distributed evenly. Furthermore, void formation would decrease the density and cross-sectional area of the specimen. These issues

are not easily corrected for as they require detailed knowledge on the geometry of the necking region as a function of strain and the progression of void formation etc. Therefore, the post-uniform elongation and total elongation are only available as engineering quantities.

Gauge Length

Total elongation is the sum of uniform elongation and elongation in the necking regime, where deformation is highly localized. Therefore, post-uniform elongation scales with cross-sectional area rather than length of the test piece. Since total elongation is expressed as a percentage of the length of the test piece, the measured value of the elongation in the necking regime is dependent on the actual length of the test-piece (so-called gauge length), and thus the same is valid for total elongation. This is an artifact of improper normalization and not a material dependence. The elongation model is trained on data mostly from tests performed on samples with 50 or 80 mm gauge lengths. For martensitic steels, the difference in total elongation between these gauge lengths would not, in most cases, exceed the experimental scatter.

About the Pearlite Property Model

The **Pearlite** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the thermodynamics and kinetics of pearlite formation from austenite during isothermal heat treatment. It is assumed that the overall composition of pearlite is the same as the austenite composition, and growth rate is constant over time. Growth rate and lamellar spacing of pearlite are determined by a criterion where either growth rate or Gibbs energy dissipation rate is maximized. The Model considers Gibbs energy dissipation due to formation of ferrite-cementite interface in pearlite, finite austenite-pearlite interfacial mobility, solute drag, and diffusion of elements within austenite and along austenite-pearlite interface.

The included elements for this model are Fe (dependent element), C, Mn, Cr, Mo, W, Si, Al, Ni, Co. Other elements are neglected by weight percent.

Background Theory

Divergent pearlite, of which growth rate and lamellar spacing change with time, is not considered. This Model only considers the transformation from FCC_A1 phase to pearlite consisting of BCC_A2 and CEMENTITE_D011 (for TCFE9 this is CEMENTITE). Pearlite with other phases is not implemented.

The Pearlite Property Model was developed by Yan, Ågren, and Jeppsson [2020Yan]. Pearlite is assumed to nucleate on austenite grain boundaries. Grain boundary nucleation rate is modeled as a function of composition and Evaluation temperature. The isothermal transformation kinetics follows Cahn [1956Cah]. Start, half, and finish times are taken as 2%, 50%, and 98% transformation, respectively.

Austenite composition can be taken either as the nominal composition or from an equilibrium calculation at an annealing temperature. The latter option can be useful when austenite coexists with other phase(s), e.g. primary carbide or ferrite, before pearlite starts to form in austenite. But the Model only considers the effect of other phase(s) on austenite composition.

Model parameters have been determined from published data of maximal growth rate, minimal lamellar spacing, partition coefficients, and isothermal transformation kinetics in ternary and multicomponent systems.

About the TTT Diagram Property Model

The **TTT Diagram** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates a Time-Temperature-Transformation (TTT) diagram with a **One Axis** calculation on temperature. The Model calculates the isothermal kinetics of concurrent transformation of austenite into ferrite (grain-boundary allotriomorph, or "polygonal ferrite"), pearlite, bainite, and martensite.

The algorithms and parameters for ferrite, pearlite, bainite, and martensite are the same as in the individual Property Models (**Ferrite**, **Pearlite**, **Bainite**, **Martensite Temperatures**, and **Martensite Fractions**), but the competitive occupation of prior austenite grain boundaries and bulk volume is handled in the **TTT Diagram** Model.

If the reaction temperature is below martensite-start temperature (Ms), it is assumed that a fraction of (athermal) martensite according to the calculation forms instantaneously at time zero, prior to the formation of any one of ferrite, bainite, and pearlite. Otherwise austenite transforms to ferrite, bainite and/or pearlite.

Bainite Property Model Settings

The **Bainite** Property Model, available with the Property Model Calculator and the Steel Model Library, describes the thermodynamics and isothermal kinetics of bainite transformation from austenite. Bainite is modeled as ferrite or a ferrite-cementite mixture.

Considered elements: Fe, C, Mn, Si, Cr, Ni, Mo. Other elements in the system are neglected for bainite by mass percent.

Configuration Settings

These settings are found on the Property Model Calculator when **Bainite** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Austenite Composition From

Select an option from the **Austenite composition from** list:

- **Nominal composition** uses the system composition as austenite composition.
- **Equilibrium composition at annealing temperature**. Select to enter an **Annealing temperature**. The austenite composition is determined from an equilibrium calculation at the annealing temperature (if austenite is stable). This option is useful when austenite coexists with other phase(s), e.g. primary carbide, before the transformation (s) being calculated starts. But the Model only considers the effect of other phase(s) on austenite composition.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Annealing Temperature

This setting is available when **Equilibrium composition at annealing temperature** is selected from the **Austenite composition from** list.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Grain Size

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Plot Renderer Settings

Plot Renderer, Plot Renderer: Configuration Settings, and Plot Type: TTT Mode

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

These plot quantities are available:

- **Annealing temperature**
- **Bainite start temperature**
- **Cementite fraction in bainite**
- **Evaluation temperature**
- **Finish time (98% bainite)**
- **Half time (50% bainite)**
- **Lengthening rate [m/s]**
- **Retained austenite fraction**
- **Start time (2% bainite)**

Learn More

About the Bainite Property Model

For the **Ferrite**, **Bainite**, and **Pearlite** Property Models, it is also useful to review the Recommended Composition Ranges for Steel Models.

For an example, see PM_Fe_05: Fe-C-Mn-Si-Ni-Cr-Mo Bainite.

CCT Diagram Property Model Settings

The **CCT Diagram** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the concurrent transformations to ferrite, pearlite, bainite, and martensite under continuous cooling conditions. It can be used to construct a Continuous-Cooling-Transformation (CCT) diagram with a *One Axis* calculation on *Log10(cooling rate[K/s]*). The Model calculates the kinetics of concurrent transformation of austenite into ferrite (grain-boundary allotriomorph, or "polygonal ferrite"), pearlite, bainite, and martensite. The algorithms and parameters for these products are the same as in the individual Property Models (Ferrite, Pearlite, Bainite, Martensite Temperatures, and Martensite Fractions), but the competitive occupation of prior austenite grain boundaries and bulk volume is handled by this model.

Configuration Settings

These settings are found on the Property Model Calculator when **CCT Diagram** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Austenite Composition From

Select an option from the **Austenite composition from** list:

- **Nominal composition** uses the system composition as austenite composition.
- **Equilibrium composition at annealing temperature**. Select to enter an **Annealing temperature**. The austenite composition is determined from an equilibrium calculation at the annealing temperature (if austenite is stable). This option is useful when austenite coexists with other phase(s), e.g. primary carbide, before the transformation (s) being calculated starts. But the Model only considers the effect of other phase(s) on austenite composition.

Annealing Temperature

This setting is available when **Equilibrium composition at annealing temperature** is selected from the **Austenite composition from** list.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Grain Size

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Start Temperature

Enter a **Start temperature**, which is the temperature at which the property evaluation starts.

End Temperature

Enter an **End temperature**, which is the temperature at which the property evaluation ends.

Log10(cooling rate [K/s])

Enter a **Log10(cooling rate [K/s])** , which is the 10-base logarithm of cooling rate in K/s.

The unit must be Kelvin per second, and it does NOT follow the unit selection in the GUI. This is the *Axis Quantity* if a CCT diagram is to be constructed.

Calculation Setting

Select **Quick** (the default), **Accurate**, or **Custom** to balance accuracy and calculation time. Choose **Custom** to define the numerical settings yourself, which are otherwise set in the background when **Quick** or **Accurate** is selected. See the separate section below about the details for the **Custom** settings.

Quick Calculation Setting

Quick is used for a relatively quick and rough calculation to reveal the general feature of a CCT diagram. Interpolation is used when necessary, in order to avoid calculating the growth rates and nucleation rates of pearlite and bainite at every time step.

For simplicity, **Ferrite mode** is **PE** (paraequilibrium), and **Pearlite mode** is **Para-pearlite**.

Calculation times may vary between 30 minutes and several hours.

Accurate Calculation Setting

Accurate evaluates the growth rates and nucleation rates at every time step accurately (without interpolation). The time step control is also tighter than when using the **Quick** setting.

- **Ferrite mode** is **PE if possible, otherwise OE** so as to handle any ortho-para transition.
- **Pearlite mode** is **Optimal pearlite**, but its rate calculation becomes slower if austenite contains many alloying elements.

Calculation times may vary between several hours and tens of hours.

Details about the Quick and Accurate Calculation Settings

When you choose **Quick** or **Accurate** as the calculation setting, the following is what is automatically set in the background for each of the sections. These sections are visible to you and also can be edited when **Custom** is chosen:

Setting	*Quick*	*Accurate*
Ferrite selected	checkbox selected (yes)	checkbox selected (yes)
Pearlite selected	checkbox selected (yes)	checkbox selected (yes)

Setting	*Quick*	*Accurate*
Bainite selected	checkbox selected (yes)	checkbox selected (yes)
Martensite selected	checkbox selected (yes)	checkbox selected (yes)
Ferrite mode	PE only	Faster start (TTT); PE if possible otherwise OE (CCT)
Pearlite criterion	Maximize growth rate	Maximize growth rate
Pearlite mode	Para-pearlite	Optimal pearlite
Use interpolation when necessary	checkbox selected (yes)	checkbox NOT selected (no)
Interpolation error tolerance	0.1	(does not apply)
Maximum phase fraction change (absolute) in a time step	0.005	0.005
Maximum phase fraction change (relative) in a time step	0.05	0.05
Error tolerance for austenite fraction	1E-3	1E-4

Custom Calculation Setting

The following settings are available when **Custom** is selected as the *Calculation Setting*. Otherwise these settings are handled in the background as described above for when **Quick** or **Accurate** is selected.

Ferrite/Pearlite/Bainite/Martensite Selected Checkboxes

By default the **Ferrite selected**, **Pearlite selected**, **Bainite selected**, and **Martensite selected** checkboxes are selected. For ferrite and pearlite, additional settings are then available.

Click to deselect as required to exclude one or more from the calculation.

Allow Competing Morphology Growth

From the **Allow for competing morphology growth** list, choose **Yes** (the default), which means that all phase transformations (bainite, pearlite, ferrite, and martensite) are evaluated from the start temperature down to the end temperature.

If **No** is selected, then the diffusional transformations are progressively suppressed as follows:

- After 2% bainite formed, stop pearlite and ferrite calculations.
- After 2% martensite formed, stop bainite, pearlite, and ferrite calculation.
- Martensite continues to be updated at every step until the final temperature.

When **No** is selected, the software automatically halts any competing diffusional transformations when the relevant critical temperature is reached. This provides performance improvements in the form of reduced computation time, as pearlite and ferrite are no longer evaluated after the bainite start temperature (Bs) and in the same manner bainite is not evaluated below the martensite start temperature (Ms). Disallowing competitive growth is to be treated as a further approximation, as competitive growth normally occurs to some extent. However, the growth rates are usually very low once another morphology has been activated and the contribution of competitive growth to the overall shape of the CCT diagram is therefore often negligible.

Ferrite Mode

This setting is available when the **Ferrite selected** checkbox is selected.

From the **Ferrite mode** list choose an option.

- **OE only** and **PE only** are the same as in the **Ferrite** Property Model. i.e.
    - *Orthoequilibrium (OE)*: The ferrite and austenite compositions at the interface are fixed to the final equilibrium compositions
    - *Paraequilibrium (PE)*: Only carbon is allowed to partition, reaching PE at the interface

- **PE if possible, otherwise OE** means ferrite grows in PE mode if this mode has a positive driving force, otherwise ferrite grows in OE mode. This is usually useful to handle an ortho-to-para transition as temperature decreases.

Pearlite Criterion

This setting is available when the **Pearlite selected** checkbox is selected.

Select an option from the **Criterion** list to determine the pearlite growth condition. This list is called **Pearlite criterion** for the CCT Diagram and TTT Diagram Property Models.

- For **Maximize growth rate**, pearlite growth rate is maximized with respect to lamellar spacing (and for optimal pearlite, partition coefficients of substitutional alloying elements between ferrite and cementite). The calculation gives maximal growth rate and minimal lamellar spacing. This is the default criterion.
- For **Maximize Gibbs energy dissipation rate**, Gibbs energy dissipation rate is maximized with respect to lamellar spacing (and for optimal pearlite, partition coefficients of substitutional alloying elements between ferrite and cementite). The calculation gives a smaller growth rate than the maximal, and a larger lamellar spacing than the minimal, which may better represent the average growth rate and lamellar spacing of all pearlite colonies in the material.

Pearlite Mode

This setting is available when the **Pearlite selected** checkbox is selected. It is used to determine how substitutional alloying elements partition between ferrite and cementite in pearlite. Select an option from the **Pearlite mode** list.

- For **Optimal pearlite**, the partitioning of substitutional alloying elements between ferrite and cementite is optimized according to the **Criterion** while keeping carbon equilibrium between the two phases. This is the default mode. This mode realizes a smooth transition between ortho-pearlite and para-pearlite.
- For **Para-pearlite**, ferrite and cementite are in para-equilibrium where substitutional alloying elements do not partition and carbon reaches equilibrium.
- For **Ortho-pearlite**, ferrite and cementite are in ortho-equilibrium.

Carbide in Pearlite

From the **Carbide in pearlite** list, select the carbide to be present in pearlite: **CEMENTITE** (default), **M7C3**, or **M23C6**. For M23C6, this usually depends on Cr content.

When M23C6 is selected, parameters optimized for stainless steels are invoked.

Recommended Composition Ranges for Steel Models

Carbide in Bainite

From the **Carbide in bainite** list, select the carbide to be present in pearlite: **CEMENTITE** (default) or **M7C3**. For M7C3, this usually depends on Cr content.

Use Interpolation When Necessary

If the **Use interpolation when necessary** checkbox is selected, and depending on alloy composition and temperature, if the code determines that an interpolation is necessary and possible to implement, then a composition grid (TTT diagram) or composition-temperature grid (CCT diagram) is generated and refined as needed.

The growth rates and nucleation rates of pearlite and bainite, as functions of composition (TTT diagram) or composition and temperature (CCT diagram), are determined by interpolation (if sufficiently accurate). This is intended to avoid direct calculations of pearlite and bainite rates for every time step, which is usually time-consuming.

Interpolation Error Tolerance

This setting is available when the **Use interpolation when necessary** checkbox is selected.

The growth and nucleation rates of pearlite and bainite, if determined from interpolation, are accepted only when the relative interpolation error estimated is below the value entered here. A large number implies few grid points necessary (shorter calculation time) and lower accuracy, and a small number implies the opposite.

Maximum Phase Fraction Change (Absolute/Relative) in a Time Step

The **Maximum phase fraction change (absolute) in a time step** and **Maximum phase fraction change (relative) in a time step** settings are used to control time step size during time integration.

The phase fraction (X) of ferrite, pearlite, and bainite cannot change more than $atol + X * rtol$ during a time step, where $atol$ and $rtol$ are the absolute and relative maximum change, respectively. If the change is too large, the new time step is rejected, and time integration is retried with a smaller time step.

Error Tolerance for Austenite Fraction

The **Error tolerance for austenite fraction** setting is used to control the accuracy for austenite fraction during time integration. Finite time steps cause an error in austenite volume fraction. When the error is larger than the tolerance, time integration is backed up and retried with a smaller time step.

Plot Renderer Settings

Plot Renderer, Plot Renderer: Configuration Settings, Plot Type: CCT Mode, and Plot Type: TTT Mode

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

- **Annealing temperature**
- **End temperature**
- **Error tolerance for austenite fraction**
- **Grain size**
- **Log(10) cooling rate**
- **Maximum phase fraction change (absolute) in a time step**
- **Maximum phase fraction change (relative) in a time step**
- **Start temperature**

Each quantity is defined in both time **(t)** and temperature **(T)**:

- **Austenite transformed 2%**, time **(t)**, and temperature **(T)**
- **Austenite transformed 10%**, time **(t)**, and temperature **(T)**
- **Austenite transformed 50%**, time **(t)**, and temperature **(T)**
- **Austenite transformed 90%**, time **(t)**, and temperature **(T)**
- **Austenite transformed 98%**, time **(t)**, and temperature **(T)**
- **Bainite start (2%)**, time **(t)**, and temperature **(T)**
- **Ferrite start (2%)**, time **(t)**, and temperature **(T)**
- **Martensite start**, time **(t)**, and temperature **(T)**
- **Pearlite start (2%)**, time **(t)**, and temperature **(T)**
- **Total ferrite start (2%)**, time **(t)**, and temperature **(T)**: The start of the sum of polygonal ferrite and bainitic ferrite.
- **Total ferrite+cementite start (2%)**, time **(t)**, and temperature **(T)**: The start of the sum of pearlite and cementite-containing bainite.
- **Total ferrite + cementite finish (98%)**, time **(t)**, and temperature **(T)**: 98% austenite transformed to ferrite, pearlite, and bainite.

Fractions of transformation products at the last time step (unit-free) are also available:

- **Terminal fraction of bainite**
- **Terminal fraction of ferrite**
- **Terminal fraction of martensite**
- **Terminal fraction of pearlite**
- **Terminal fraction of total ferrite**
- **Terminal fraction of total ferrite+cementite**

The **CCT Mode** on the Plot Renderer the time-temperature pairs are automatically identified and arranged in the plot to give a CCT diagram. Selected cooling curves are also given in the CCT Mode.

About the CCT Diagram Property Model and Steel Library CCT Diagram Template

For an example, see PM_Fe_08: CCT Diagram for Fe-C-Mn-Si-Cr-V

Critical Transformation Temperatures Property Model Settings

The **Critical Transformation Temperatures** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates critical transformation temperatures for steels under equilibrium conditions.

The Model can output the transformation temperatures for the following (assuming cooling):

- *Liquidus*: First austenite or ferrite transformation from the liquid.
- *Solidus*: Liquid fully transformed to solid.
- *A0*: Magnetic transition temperature (Curie temperature) of cementite. The cementite is paramagnetic above A0 and ferromagnetic below.
- *A1*: Temperature at which austenite (FCC_A1) transforms to ferrite (BCC_A2) + carbide (cementite or graphite or M23C6).
- *A2*: Magnetic transition temperature (Curie temperature) of ferrite (BCC_A2). Paramagnetic above A2 and ferromagnetic below.
- *A3*: Temperature at which austenite (FCC_A1) transforms to ferrite (BCC_A2).
- *A4*: Temperature at which delta-ferrite (BCC_A2) transforms to austenite (FCC_A1).
- *Acem*: Temperature at which austenite (FCC_A1) transforms to cementite. This quantity is only available if the **Suspend graphite** checkbox is selected, i.e., graphite is suspended from the calculation).
- *Agraph*: Temperature at which austenite (FCC_A1) transforms to graphite. This quantity is only available if the **Suspend graphite** checkbox is NOT selected, i.e. graphite is not suspended from the calculation.

Configuration Settings

These settings are found on the Property Model Calculator when **Critical Transformation Temperatures** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Calculate Solidus and Liquidus

Select the **Calculate solidus and liquidus** checkbox to calculate these temperatures.

Calculate Ax Temperatures

Select the **Calculate Ax temperatures** checkbox to calculate A0, A1, A3, Acem, and Agraph temperatures. Typically, only one temperature of A3, Acem, and Agraph exists. See below for additional details about these temperatures.

- A0: Magnetic transition temperature (Curie temperature) of cementite. The cementite is paramagnetic above A0 and ferromagnetic below
- A1: Austenite (FCC_A1) transforms to ferrite (BCC_A2) + carbide (cementite or graphite or M23C6)
- A2: Magnetic transition temperature (Curie temperature) of ferrite (BCC_A2). Paramagnetic above A2 and ferromagnetic below
- A3: Austenite (FCC_A1) transforms to ferrite (BCC_A2)
- A4: Delta-ferrite (BCC_A2) transforms to austenite (FCC_A1)
- Acem: Austenite (FCC_A1) transforms to cementite (requires that the **Suspend graphite** checkbox is selected, which it is by default)
- Agraph: Austenite (FCC_A1) transforms to graphite (requires that the **Suspend graphite** checkbox is NOT selected, i.e. graphite is not suspended)

Suspend Graphite

By default the **Suspend graphite** checkbox is selected and suspends the graphite phase. Click to clear the checkbox as needed to enable the graphite.

Suspend Gas

By default the **Suspend gas** checkbox is selected and suspends the gas phase. Click to clear the checkbox as needed.

Manual Temperature Search Limits

By default the temperature search limits are automatically defined. Select the **Manual temperature search limits** checkbox to manually change the limits for the **Low temperature limit**, **High temperature limit**, and **Max temperature step**.

Low Temperature Limit

Available when the **Manual temperature search limits** checkbox is selected.

Enter a **Low temperature limit** for the evaluation.

High Temperature Limit

Available when the **Manual temperature search limits** checkbox is selected.

Enter a **High temperature limit** for the evaluation.

Max Temperature Step

Available when the **Manual temperature search limits** checkbox is selected.

In the **Max temperature step** field, enter the largest temperature step. This is most often reduced when changes in driving force or the amount of the phases indicate a phase transformation at a shorter temperature step.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

- **Composition**
- **High temperature limit**
- **Low temperature limit**
- **Max temperature step**

Output the transformation temperatures:

- **A0**: Magnetic transition temperature (Curie temperature) of cementite. The cementite is paramagnetic above A0 and ferromagnetic below
- **A1**: Austenite (FCC_A1) transforms to ferrite (BCC_A2) + carbide (cementite or graphite or M23C6 or M7C3)
- **A2**: Magnetic transition temperature (Curie temperature) of ferrite (BCC_A2). Paramagnetic above A2 and ferromagnetic below
- **A3**: Austenite (FCC_A1) transforms to ferrite (BCC_A2)
- **A4**: Delta-ferrite (BCC_A2) transforms to austenite (FCC_A1)
- **Acem**: Austenite (FCC_A1) transforms to cementite (only possible if graphite is suspended)
- **Agraph**: Austenite (FCC_A1) transforms to graphite (only possible if graphite is enabled)
- **Liquidus**: First austenite or ferrite transformation from the liquid
- **Solidus**: Liquid fully transformed to solid

Learn More

About the Critical Transformation Temperatures Property Model

For an example, see PM_Fe_04: Critical Temperatures.

Ferrite Property Model Settings

The **Ferrite** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the thermodynamics and isothermal kinetics of proeutectoid ferrite forming from austenite in hypoeutectoid steels. This model is for the form of proeutectoid ferrite which forms without distinct crystallographic preferences at austenite grain boundaries. This type of ferrite is referred to as *grain boundary allotriomorph*, or *polygonal ferrite*. Another type, plate-shaped ferrite (*Widmanstätten ferrite*), is treated in the **Bainite** Property Model as a special case of bainite without cementite. Growth is modeled based on a simplified diffusion-control theory with the ferrite/austenite interfacial composition determined by various *Growth mode* settings available—Orthoequilibrium (OE), Paraequilibrium (PE), Orthoprecipitate (OP), or Paraprecipitate (PP).

Included Elements and Important Notes

- Austenite must contain at least Fe and C for this model to function.
- Elements that are quite soluble in both austenite and ferrite—Mn, Ni, Si, Al, Co, Cr, and Mo—have their effects on overall kinetics assessed.
- Cu and strong carbide-formers—W, V, Nb, Ta, Ti, and Zr—can be included, but only to a certain extent not to cause phases other than austenite and ferrite to form at the calculation temperature. Otherwise, the model calculation may give unrealistic results or even fail. If carbide is expected to form at an austenitizing temperature, use the setting **Equilibrium composition at annealing temperature** for **Austenite composition from**, then enter an annealing temperature.

Elements not listed above are excluded in mass percent from the austenite composition used to calculate the transformation.

Configuration Settings

These settings are found on the Property Model Calculator when **Ferrite** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Austenite Composition From

Select an option from the **Austenite composition from** list:

- **Nominal composition** uses the system composition as austenite composition.
- **Equilibrium composition at annealing temperature**. Select to enter an **Annealing temperature**. The austenite composition is determined from an equilibrium calculation at the annealing temperature (if austenite is stable). This option is useful when austenite coexists with other phase(s), e.g. primary carbide, before the transformation (s) being calculated starts. But the Model only considers the effect of other phase(s) on austenite composition.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Annealing Temperature

This setting is available when **Equilibrium composition at annealing temperature** is selected from the **Austenite composition from** list.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Grain Size

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Growth Mode

Select a **Growth mode**: **Orthoequilibrium (OE)**, **Paraequilibrium (PE)**, **Negligible-partitioning local equilibrium (NPLE)**, **Orthoprecipitate (OP)**, or **Paraprecipitate (PP)**. This defines the compositions on the two sides of the ferrite-austenite interface and therefore affects growth rate.

For definitions of these modes, see About the Ferrite Property Model.

Phase Addition

Enter a **Phase addition** in J/mol. This applies a Gibbs energy shift to ferrite.

Skip Time Integration

Click to select the **Skip time integration** checkbox to skip this step in the calculations. Time integration is required for calculating ferrite start/half/finish times, but is usually time-consuming. Skipping time integration allows you to get the other result quantities more quickly.

Custom Parameters

Select the **Custom parameters** checkbox to choose to set more advanced settings as listed below.

- **Site density**, **Edge surface energy**, and **Epsilon** are for calculating grain-boundary nucleation rate (see [1988Lan] for definition and details).
- **M0** and **Q** are to define an interfacial mobility in the Arrhenius equation.

Site Density

Available when **Custom parameters** is selected. Enter a **Site density** in $1/m^2$.

Edge Surface Energy

Available when **Custom parameters** is selected. Enter an **Edge surface energy** in J/m^2.

Epsilon

Available when **Custom parameters** is selected. Enter a value for **Epsilon** in J/m^2.

M0

Available when **Custom parameters** is selected. Enter a value for **M0** in m mol/(Js). This is the pre-exponential factor for interfacial mobility.

Q

Available when **Custom parameters** is selected. Enter a value for **Q** in J/mol. This is the activation energy for interfacial mobility.

Maximum Phase Fraction Change (Absolute) in a Time Step

Available when **Custom parameters** is selected, and is used for time integration.

Enter the **Maximum phase fraction change (absolute) in a time step**.

Maximum Phase Fraction Change (Relative) in a Time Step

Available when **Custom parameters** is selected, and is used for time integration.

Enter the **Maximum phase fraction change (relative) in a time step**

Plot Renderer Settings

Plot Renderer, Plot Renderer: Configuration Settings, and Plot Type: TTT Mode

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

- **Annealing temperature**
- **Driving force [J/mol]**
- **Evaluation temperature**
- **Ferrite molar fraction (OE or PE)**: The ferrite molar fraction at the end of the transformation, determined from orthoequilibrium (for **Ferrite mode** “OE” or “OP”) or paraequilibrium (for **Ferrite mode** “PE”, “NPLE”, or “PP”).
- **Ferrite start**, **Ferrite half**, or **Ferrite finish**: The times at ferrite fraction being 0.02, 0.50, and 0.98, respectively.

- **Ferrite start (relative)**, **Ferrite half (relative)**, or **Ferrite finish (relative)**: The times at 2%, 50%, and 98% of the final ferrite fraction, respectively.
- **Nucleation rate [1/(m2 s)]**: Steady-state nucleation rate of ferrite per unit austenite grain boundary area.
- **Parabolic growth rate constant [m/s(1/2)]**: The ratio of half-thickness to square root of time. This is calculated from interfacial composition and diffusion coefficients in austenite.

About the Ferrite Property Model

For the **Ferrite**, **Bainite**, and **Pearlite** Property Models, it is also useful to review the Recommended Composition Ranges for Steel Models.

For an example, see PM_Fe_09: Fe-C-Ni Ferrite.

To run calculations with the **Steel Models** requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases. Also see our website to learn more about the Steel Model Library and other related examples.

Martensite Fractions Property Model Settings

The **Martensite Fractions** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the fraction of athermal martensite based on an analytical equation of an available driving force. It is assumed that the first forming martensite morphology is the only forming one. The first morphology is determined based on the Ms-temperatures of all morphologies.

Configuration Settings

The settings are found on the Property Model Calculator when **Martensite Fractions** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Intercritical Annealing

Click to select the **Intercritical annealing** checkbox to assume intercritical annealing. Click to clear the checkbox if the specified composition is used directly. When selected, an equilibrium calculation is performed at the specified temperature and the composition of the austenite phase is used for the martensite temperature calculation.

Annealing Temperature

This setting is available when the **Intercritical annealing** checkbox is selected.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Quench Temperature

Enter a **Quench temperature**, which is the temperature at which the quench occurs.

Grain Size [µm]

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Parent Phase Gibbs Energy Addition

In the **Parent phase Gibbs energy addition [J/mol]** field enter a value in J/mol to add a Gibbs energy offset to the parent austenite phase. This can be used, for example, to correct database offsets. The default is 0 J/mol.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

These plot quantities are available:

- **Annealing temperature**
- **Quench temperature**
- **Retained austenite percentage**: The retained austenite percentage at these conditions.
- **Total martensite percentage**: The martensite percentage at these conditions.

Learn More

About the Martensite Fractions Property Model

For an example see PM_Fe_01: Fe-Cr-C Martensite with Intercritical Annealing.

Martensite Temperatures Property Model Settings

The **Martensite Temperatures** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the martensite start (Ms) temperature based on modeling of the transformation barrier with fitted analytical equations. Martensite fractions and formation temperatures (i.e., M50, M90, and Mf) are calculated with the same method used in the **Martensite Fractions** Property Model. The partitionless equilibrium temperature $\mathbf{T_0}$ is calculated using the thermodynamic database. The Model also gives temperatures corresponding to 50%, 90%, and 99% transformations.

Configuration Settings

The settings are found on the Property Model Calculator when **Martensite Temperatures** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Intercritical Annealing

Click to select the **Intercritical annealing** checkbox to assume intercritical annealing. Click to clear the checkbox if the specified composition is used directly. When selected, an equilibrium calculation is performed at the specified temperature and the composition of the austenite phase is used for the martensite temperature calculation.

Annealing Temperature

This setting is available when the **Intercritical annealing** checkbox is selected.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Grain Size [µm]

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Parent Phase Gibbs Energy Addition

In the **Parent phase Gibbs energy addition [J/mol]** field enter a value in J/mol to add a Gibbs energy offset to the parent austenite phase. This can be used, for example, to correct database offsets. The default is 0 J/mol.

Plot Renderer Settings

Plot Renderer, Plot Renderer: Configuration Settings, and Plot Type: TTT Mode

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

- **Annealing temperature**
- **Epsilon Ms**: Martensite start temperature of epsilon martensite
- **Lath Ms**: Martensite start temperature of lath alpha or alpha-prime martensite
- **M50**: 50% martensite temperature
- **M90**: 90% martensite temperature
- **M99**: 99% martensite temperature
- **Ms temperature**: Martensite start temperature
- **Plate Ms**: Martensite start temperature of plate alpha or alpha-prime martensite

About the Martensite Temperatures Property Model

For examples see PM_Fe_01: Fe-Cr-C Martensite with Intercritical Annealing and PM_Fe_02: Fe-Mn Martensite Morphologies.

Martensitic Steel Strength Property Model Settings

The **Martensitic Steel Strength** Property Model, available with the Property Model Calculator and the Steel Model Library, predicts the general flow stress properties of martensitic steels, such as hardness, stress at arbitrary strain, yield strength, ultimate tensile strength, Young's modulus, etc.

The Model evaluates the following in consecutive steps:

- Martensite fraction based on composition, annealing temperature, and quench temperature
- Hardness of the as-quenched microstructure
- Effect of tempering on microstructure and hardness
- Young's modulus based on the composition of the matrix phase and contributions from precipitates
- Strain hardening response (flow stress) based on the final hardness after tempering

System Definer Configuration Settings

The following details relate to choosing the phases on the System Definer.

Then on the Property Model Calculator Configuration Settings window you can suspend as needed using the Suspend FCC, BCC, or Cementite settings described below.

FCC_A1, BCC_A2, and Cementite must be selected on the **System Definer Configuration** window but can be suspended with settings available on the **Property Model Configuration** window. If these phases are excluded on the System Definer, the calculation does not work.

The Model only accepts phases that have had the intrinsic strength assessed. For a list of available phases see the section in the theory for Yield Strength Property Model regarding the Intrinsic Strength model.

Property Model Calculator Configuration Settings

The settings are found on the Property Model Calculator when **Martensitic Steel Strength** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Annealing Temperature

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Quench Temperature

Enter a **Quench temperature**, which is the temperature at which the quench occurs.

Tempering Temperature

The **Tempering temperature** is the temperature at which tempering is performed. This is used to estimate martensite hardness after tempering.

The default is `673.15`.

Tempering Time

Add a **Tempering time [s]**. The default is 3600 seconds. The time dependency is predicted using a machine learning model. If tempering time is set to a negative value, no tempering correction is applied to the total hardness.

Suspend FCC, BCC, or Cementite

Select the **Suspend FCC, BCC, or cementite** checkbox to choose to suspend one or more of these phases. All other phases can be deselected on the System Definer to exclude from the calculation as required.

> Austenite (FCC_A1), ferrite (BCC_A2), and Cementite phases all need to be selected on the System Definer. However, for some alloys it might be necessary to suspend one or more of these from the tempering calculation.

Then from one or more of the **FCC_A1**, **BCC_A2**, or **Cementite** lists choose **Entered** or **Suspended**.

More Options

Select the **More options** checkbox to adjust settings for **Grain size**, the **Parent phase Gibbs energy addition**, and **Constant strength addition**.

Grain Size

This setting is available when **More options** is selected.

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Parent Phase Gibbs Energy Addition

This setting is available when **More options** is selected.

In the **Parent phase Gibbs energy addition [J/mol]** field enter a value in J/mol to add a Gibbs energy offset to the parent austenite phase. This can be used, for example, to correct database offsets. The default is `0` J/mol.

Constant Strength Addition

This setting is available when **More options** is selected.

Enter a value for the **Constant strength addition [MPa]**. You can also enter expressions such as `T*w(cr)+10` or similar.

Flow Stress Settings

For specific theory, see Flow Stress Theory.

Flow Stress Mode

Select a **Flow stress mode**:

- $\mathbf{E, \sigma_y \text{ and } \sigma_{UTS}}$ (the default) to calculate engineering properties. This is generally referred to as the *engineering properties mode* in the theory section.
- $\boldsymbol{\sigma}$ vs $\boldsymbol{\epsilon}$ to calculate the stress at a total specified strain.

True Strain [%]

Available when $\boldsymbol{\sigma}$ vs $\boldsymbol{\epsilon}$ is selected.

Enter a value for **True strain [%]** to evaluate the stress at a specified true strain (elastic plus plastic).

Pre-straining [%]

Enter a value for the **Pre-straining [%]** to specify the strain the material is exposed to before calculation. This is useful in cases where prior deformation needs to be accounted for, e.g., cold work, as it affects the calculated flow stress.

The value entered does not affect the calculated hardness

User-defined Flow Stress Parameters

Select the **User-defined flow stress parameters** checkbox to define additional parameters related to the flow stress calculation.

When the checkbox is selected also define other settings such as the **Flow stress model** and **Young's modulus**. Then based on the **Flow stress model**, also define **Strain hardening exponent**(Ramberg-Osgood) or **Saturation stress**, and **Hardening rate** (Voce). In addition, a value for the Young's modulus needs to be given.

Flow Stress Model

This is available when the **User-defined flow stress parameters** checkbox is selected.

Select a **Flow stress model** to use for the calculation: **Ramberg-Osgood** or **Voce**.

Elongation Correction

This is available when the **User-defined flow stress parameters** checkbox is selected.

Enter a value for the **Elongation correction**, which is a correction factor applied to the predicted elongation at fracture, with a value of 1 implying no correction is made.

Young's Modulus

This is available when the **User-defined flow stress parameters** checkbox is selected.

Enter a value for the **Young's modulus** in **GPa**.

Strain Hardening Exponent

This is available when the **User-defined flow stress parameters** checkbox is selected and **Ramberg-Osgood** is the **Flow stress model**.

Enter a value for the **Strain hardening exponent**.

Saturation Stress

This is available when the **User-defined flow stress parameters** checkbox is selected and **Voce** is the **Flow stress model**.

Enter a **Saturation stress**, which is the stress value in MPa approached asymptotically with strain.

Hardening Rate

This is available when the **User-defined flow stress parameters** checkbox is selected and **Voce** is the **Flow stress model**.

Enter a **Hardening rate**, which is the rate at which strain hardening progresses according to the Voce model.

Apply Strain Rate

Select the **Apply strain rate** checkbox to account for the effect of strain rate on flow stress. If the checkbox is not selected (the default), flow stress is calculated for quasi-static conditions only.

When the checkbox is selected also define other settings such as **Strain rate [1/s]**, **Reference strain rate**, and **Strain rate sensitivity**.

Strain Rate

This is available when the **Apply strain rate** checkbox is selected.

Enter a value for the **Strain rate** in **1/s**.

Reference Strain Rate

This is available when the **Apply strain rate** checkbox is selected.

Specify the **Reference strain rate** in 1/s. This should correspond to the strain rate at quasi-static conditions, i.e., in the range of 10^{-4} to 10^{-3}

Apply User-defined Strain Rate Sensitivity

This is available when the **Apply strain rate** checkbox is selected.

Select the **Apply user-defined strain rate sensitivity** checkbox to enter a **Strain rate sensitivity** exponent. If the checkbox is not selected (the default), the strain rate sensitivity exponent is estimated by the model.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Plot Quantities

These plot quantities are available:

- **Annealing temperature**
- **Constant strength addition**
- **Elongation at fracture**
- **Engineering strain**
- **Engineering stress**
- **Evaluation temperature**
- **Fracture strength**
- **Martensite hardening as-quenched**
- **Martensite hardening quenched and tempered**
- **Precipitate fraction (Annealing)**: The fraction of any given phase present at the annealing temperature before quenching.
- **Precipitate fraction (Tempering)**: The fraction of any given phase present after quenching and tempering (precipitates after temper are added to those at annealing, if any).
- **Quench temperature**
- **Retained austenite percentage**: The percentage of retained austenite after quenching.
- **Solid solution hardening after temper**
- **Tempering temperature**
- **Total hardness of the as-quenched steel**
- **Total hardness of the tempered steel**
- **Total martensite percentage**: The percentage of martensite after quenching.
- **Total solid solution hardening**
- **True strain**
- **True stress**
- **Ultimate tensile strength**
- **Uniform elongation**

- **Yield strain**
- **Yield strength**
- **Young's modulus**

Learn More

Background theory and a more indepth description of the model related to these settings is found in About the Martensitic Steel Strength Property Model and Flow Stress Theory.

For examples see PM_Fe_10: Martensitic Steel Strength, PM_Fe_11: Steel Design Using the Parallel Coordinates Plot, and PM_Fe_12: Flow Stress 15-5PH Steel.

Pearlite Property Model Settings

The **Pearlite** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates the thermodynamics and kinetics of pearlite formation from austenite during isothermal heat treatment. It is assumed that the overall composition of pearlite is the same as the austenite composition, and growth rate is constant over time. Growth rate and lamellar spacing of pearlite are determined by a criterion where either growth rate or Gibbs energy dissipation rate is maximized. The Model considers Gibbs energy dissipation due to formation of ferrite-cementite interface in pearlite, finite austenite-pearlite interfacial mobility, solute drag, and diffusion of elements within austenite and along austenite-pearlite interface.

The included elements for this model are Fe (dependent element), C, Mn, Cr, Mo, W, Si, Al, Ni, Co. Other elements are neglected by weight percent.

Configuration Settings

The settings are found on the Property Model Calculator when **Pearlite** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Austenite Composition From

Select an option from the **Austenite composition from** list:

- **Nominal composition** uses the system composition as austenite composition.
- **Equilibrium composition at annealing temperature**. Select to enter an **Annealing temperature**. The austenite composition is determined from an equilibrium calculation at the annealing temperature (if austenite is stable). This option is useful when austenite coexists with other phase(s), e.g. primary carbide, before the transformation (s) being calculated starts. But the Model only considers the effect of other phase(s) on austenite composition.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Annealing Temperature

This setting is available when **Equilibrium composition at annealing temperature** is selected from the **Austenite composition from** list.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Grain Size [µm]

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Criterion

This setting is available when the **Pearlite selected** checkbox is selected.

Select an option from the **Criterion** list to determine the pearlite growth condition. This list is called **Pearlite criterion** for the CCT Diagram and TTT Diagram Property Models.

- For **Maximize growth rate**, pearlite growth rate is maximized with respect to lamellar spacing (and for optimal pearlite, partition coefficients of substitutional alloying elements between ferrite and cementite). The calculation gives maximal growth rate and minimal lamellar spacing. This is the default criterion.
- For **Maximize Gibbs energy dissipation rate**, Gibbs energy dissipation rate is maximized with respect to lamellar spacing (and for optimal pearlite, partition coefficients of substitutional alloying elements between ferrite and cementite). The calculation gives a smaller growth rate than the maximal, and a larger lamellar spacing than the minimal, which may better represent the average growth rate and lamellar spacing of all pearlite colonies in the material.

Pearlite Mode

This setting is available when the **Pearlite selected** checkbox is selected. It is used to determine how substitutional alloying elements partition between ferrite and cementite in pearlite. Select an option from the **Pearlite mode** list.

- For **Optimal pearlite**, the partitioning of substitutional alloying elements between ferrite and cementite is optimized according to the **Criterion** while keeping carbon equilibrium between the two phases. This is the default mode. This mode realizes a smooth transition between ortho-pearlite and para-pearlite.
- For **Para-pearlite**, ferrite and cementite are in para-equilibrium where substitutional alloying elements do not partition and carbon reaches equilibrium.
- For **Ortho-pearlite**, ferrite and cementite are in ortho-equilibrium.

Plot Renderer Settings

Plot Renderer, Plot Renderer: Configuration Settings, and Plot Type: TTT Mode

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

- **Annealing temperature**
- **Cementite molar fraction in pearlite**
- **Driving force of pearlite formation [J/mol]**
- **Evaluation temperature**
- **Finish time (98% pearlite)**
- **Growth rate [m/s]**
- **Half time (50% pearlite)**
- **Lamellar spacing [m]**
- **Start time (2% pearlite)**

Learn More

About the Pearlite Property Model

For the **Ferrite**, **Bainite**, and **Pearlite** Property Models, it is also useful to review the Recommended Composition Ranges for Steel Models.

For an example see PM_Fe_03: Fe-C-Mn Pearlite.

TTT Diagram Property Model Settings

The **TTT Diagram** Property Model, available with the Property Model Calculator and the Steel Model Library, calculates a Time-Temperature-Transformation (TTT) diagram with a **One Axis** calculation on temperature. The Model calculates the isothermal kinetics of concurrent transformation of austenite into ferrite (grain-boundary allotriomorph, or "polygonal ferrite"), pearlite, bainite, and martensite.

The algorithms and parameters for ferrite, pearlite, bainite, and martensite are the same as in the individual Property Models (**Ferrite**, **Pearlite**, **Bainite**, **Martensite Temperatures**, and **Martensite Fractions**), but the competitive occupation of prior austenite grain boundaries and bulk volume is handled in the **TTT Diagram** Model.

If the reaction temperature is below martensite-start temperature (Ms), it is assumed that a fraction of (athermal) martensite according to the calculation forms instantaneously at time zero, prior to the formation of any one of ferrite, bainite, and pearlite. Otherwise austenite transforms to ferrite, bainite and/or pearlite.

Configuration Settings

These settings are found on the Property Model Calculator when **TTT Diagram** is selected under **Steel Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Austenite Composition From

Select an option from the **Austenite composition from** list:

- **Nominal composition** uses the system composition as austenite composition.
- **Equilibrium composition at annealing temperature**. Select to enter an **Annealing temperature**. The austenite composition is determined from an equilibrium calculation at the annealing temperature (if austenite is stable). This option is useful when austenite coexists with other phase(s), e.g. primary carbide, before the transformation (s) being calculated starts. But the Model only considers the effect of other phase(s) on austenite composition.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Annealing Temperature

This setting is available when **Equilibrium composition at annealing temperature** is selected from the **Austenite composition from** list.

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Grain Size

Enter the **Grain size** of the austenite in micrometers (µm). The default is `100` µm.

Calculation Setting

Select **Quick** (the default), **Accurate**, or **Custom** to balance accuracy and calculation time. Choose **Custom** to define the numerical settings yourself, which are otherwise set in the background when **Quick** or **Accurate** is selected. See the separate section below about the details for the **Custom** settings.

Quick Calculation Setting

Quick is used for a relatively quick and rough calculation to reveal the general feature of a TTT diagram. Interpolation is used when necessary in order to avoid calculating the growth rates and nucleation rates of pearlite and bainite at every time step.

- For simplicity, **Ferrite mode** is **PE** (paraequilibrium), and **Pearlite mode** is **Para-pearlite**.
- Recommended temperature interval: 50-100 K.

Each temperature can take several minutes.

Accurate Calculation Setting

Accurate evaluates the growth rates and nucleation rates at every time step accurately (without interpolation). The time step control is also tighter than when using the **Quick** setting.

- **Ferrite mode** is *faster start*, meaning the mode between OE and PE which gives a faster initial transformation.
- **Pearlite mode** is **Optimal pearlite**, but its rate calculation becomes slower if austenite contains many alloying elements.
- Recommended temperature interval: 20-50 K or even lower.

Calculating the whole TTT diagram may take several hours.

Details about the Quick and Accurate Calculation Settings

When you choose **Quick** or **Accurate** as the calculation setting, the following is what is automatically set in the background for each of the sections. These sections are visible to you and also can be edited when **Custom** is chosen:

Setting	*Quick*	*Accurate*
Ferrite selected	checkbox selected (yes)	checkbox selected (yes)
Pearlite selected	checkbox selected (yes)	checkbox selected (yes)
Bainite selected	checkbox selected (yes)	checkbox selected (yes)
Martensite selected	checkbox selected (yes)	checkbox selected (yes)
Ferrite mode	PE only	Faster start (TTT); PE if possible otherwise OE (CCT)
Pearlite criterion	Maximize growth rate	Maximize growth rate

Setting	*Quick*	*Accurate*
Pearlite mode	Para-pearlite	Optimal pearlite
Use interpolation when necessary	checkbox selected (yes)	checkbox NOT selected (no)
Interpolation error tolerance	0.1	(does not apply)
Maximum phase fraction change (absolute) in a time step	0.005	0.005
Maximum phase fraction change (relative) in a time step	0.05	0.05
Error tolerance for austenite fraction	1E-3	1E-4

Custom Calculation Setting

The following settings are available when **Custom** is selected as the *Calculation Setting*. Otherwise these settings are handled in the background as described above for when **Quick** or **Accurate** is selected.

Ferrite/Pearlite/Bainite/Martensite Selected Checkboxes

By default the **Ferrite selected**, **Pearlite selected**, **Bainite selected**, and **Martensite selected** checkboxes are selected. For ferrite and pearlite, additional settings are then available.

Click to deselect as required to exclude one or more from the calculation.

Pearlite Criterion

This setting is available when the **Pearlite selected** checkbox is selected.

Select an option from the **Criterion** list to determine the pearlite growth condition. This list is called **Pearlite criterion** for the CCT Diagram and TTT Diagram Property Models.

- For **Maximize growth rate**, pearlite growth rate is maximized with respect to lamellar spacing (and for optimal pearlite, partition coefficients of substitutional alloying elements between ferrite and cementite). The calculation gives maximal growth rate and minimal lamellar spacing. This is the default criterion.
- For **Maximize Gibbs energy dissipation rate**, Gibbs energy dissipation rate is maximized with respect to lamellar spacing (and for optimal pearlite, partition coefficients of substitutional alloying elements between ferrite and cementite). The calculation gives a smaller growth rate than the maximal, and a larger lamellar spacing than the minimal, which may better represent the average growth rate and lamellar spacing of all pearlite colonies in the material.

Carbide in Pearlite

From the **Carbide in pearlite** list, select the carbide to be present in pearlite: **CEMENTITE** (default), **M7C3**, or **M23C6**. For M23C6, this usually depends on Cr content.

When M23C6 is selected, parameters optimized for stainless steels are invoked.

Recommended Composition Ranges for Steel Models

Carbide in Bainite

From the **Carbide in bainite** list, select the carbide to be present in pearlite: **CEMENTITE** (default) or **M7C3**. For M7C3, this usually depends on Cr content.

Pearlite Mode

This setting is available when the **Pearlite selected** checkbox is selected. It is used to determine how substitutional alloying elements partition between ferrite and cementite in pearlite. Select an option from the **Pearlite mode** list.

- For **Optimal pearlite**, the partitioning of substitutional alloying elements between ferrite and cementite is optimized according to the **Criterion** while keeping carbon equilibrium between the two phases. This is the default mode. This mode realizes a smooth transition between ortho-pearlite and para-pearlite.

- For **Para-pearlite**, ferrite and cementite are in para-equilibrium where substitutional alloying elements do not partition and carbon reaches equilibrium.
- For **Ortho-pearlite**, ferrite and cementite are in ortho-equilibrium.

Use Interpolation When Necessary

If the **Use interpolation when necessary** checkbox is selected, and depending on alloy composition and temperature, if the code determines that an interpolation is necessary and possible to implement, then a composition grid (TTT diagram) or composition-temperature grid (CCT diagram) is generated and refined as needed.

The growth rates and nucleation rates of pearlite and bainite, as functions of composition (TTT diagram) or composition and temperature (CCT diagram), are determined by interpolation (if sufficiently accurate). This is intended to avoid direct calculations of pearlite and bainite rates for every time step, which is usually time-consuming.

Interpolation Error Tolerance

This setting is available when the **Use interpolation when necessary** checkbox is selected.

The growth and nucleation rates of pearlite and bainite, if determined from interpolation, are accepted only when the relative interpolation error estimated is below the value entered here. A large number implies few grid points necessary (shorter calculation time) and lower accuracy, and a small number implies the opposite.

Maximum Phase Fraction Change (Absolute/Relative) in a Time Step

The **Maximum phase fraction change (absolute) in a time step** and **Maximum phase fraction change (relative) in a time step** settings are used to control time step size during time integration.

The phase fraction (X) of ferrite, pearlite, and bainite cannot change more than $atol + X * rtol$ during a time step, where $atol$ and $rtol$ are the absolute and relative maximum change, respectively. If the change is too large, the new time step is rejected, and time integration is retried with a smaller time step.

Error Tolerance for Austenite Fraction

The **Error tolerance for austenite fraction** setting is used to control the accuracy for austenite fraction during time integration. Finite time steps cause an error in austenite volume fraction. When the error is larger than the tolerance, time integration is backed up and retried with a

smaller time step.

Plot Renderer Settings

Plot Renderer, Plot Renderer: Configuration Settings, and Plot Type: TTT Mode

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

- **Annealing temperature**
- **Austenite transformed 2%**
- **Austenite transformed 10%**
- **Austenite transformed 50%**
- **Austenite transformed 90%**
- **Austenite transformed 98%**
- **Bainite start (2%)**
- **Evaluation temperature**
- **Ferrite start (2%)**
- **Martensite 50%**
- **Martensite 98%**
- **Martensite start**
- **Pearlite start (2%)**
- **Total ferrite start (2%)**: The start of the sum of polygonal ferrite and bainitic ferrite.
- **Total ferrite + cementite start (2%)**: The start of the sum of pearlite and cementite-containing bainite.
- **Total ferrite + cementite finish (98%)**: 98% austenite transformed to ferrite, pearlite, and bainite.

Fractions of transformation products at the last time step are also available:

- **Terminal fraction of bainite**
- **Terminal fraction of ferrite**
- **Terminal fraction of martensite**

- **Terminal fraction of pearlite**
- **Terminal fraction of total ferrite**
- **Terminal fraction of total ferrite+cementite**

Martensite start, Martensite 50%, and Martensite 98% are temperature quantities. Terminal fractions are unit-free quantities. The others are time quantities.

In the **TTT Mode** of a Plot Renderer, the three temperature quantities for martensite are plotted as horizontal lines because these are independent of time. The other time quantities are plotted as functions of temperature.

PM_Fe_01: Fe-Cr-C Martensite with Intercritical Annealing

The example uses the **Property Model Calculator** with the **Martensite Fractions** and **Martensite Temperatures** Models to calculate martensite fractions and martensite temperatures [martensite start (Ms) and 90% transformation temperature (M90)].

The alloy is first intercritically annealed and then quenched. Austenite composition is determined by an equilibrium calculation at the annealing temperature. Martensite fraction is calculated as a function of temperature which the alloy is quenched to. The example also shows how Cr content in the alloy influences Ms and M90 after intercritical annealing.

Project File and License Information

Property Model Calculator and About the Martensite Temperatures Property Model

PM_Fe_03: Fe-C-Mn Pearlite

The example uses the **Property Model Calculator** and with the **Pearlite** Property Model and shows how to calculate pearlite growth rate, lamellar spacing, and times of start (2% transformation) and finish (98% transformation) as functions of isothermal heat treating temperature in an Fe-0.69C-1.80Mn alloy (mass %). With *maximize growth rate* set as the *criterion*, the model gives maximal growth rate and minimal lamellar spacing. With *optimal pearlite* as the *pearlite mode*, the model optimizes partitioning of substitutional alloying element(s) (Mn in this example) according to the criterion, which realizes a smooth transition between ortho-pearlite at high temperature and para-pearlite at low temperature.

Project File and License Information

- Folder: **Property Models → Steel**
- File name: `PM_Fe_03_Fe-C-Mn_Pearlite.tcu`

To run calculations with the **Steel Models** requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases. Also see our website to learn more about the Steel Model Library and other related examples.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

PM_Fe_04: Critical Temperatures

The example uses the **Property Model Calculator** and the **Critical Transformation Temperatures** Model to calculate the distribution of the typical phase transition temperatures for a low alloy steel (Fe-0.3Cr-1.0Mn-0.3Mn-0.18C) when the composition is varied within the specification for the alloy.

Overview

In the set up of the example, the **Critical Transformation Temperatures** model is used with a Property Model Calculator **Uncertainty** calculation to plot a histogram showing the distribution of A1- and A3-temperatures (Figure 7). As a comparison, an Equilibrium Calculator, **One Axis** calculation results in a property diagram showing the phase transitions for the nominal composition (Figure 8).

The phase transition temperatures are defined as:

- Liquidus: First austenite or ferrite transformation from the liquid
- Solidus: Liquid fully transformed to solid
- A0: Magnetic transition temperature (Curie temperature) of cementite. The cementite is paramagnetic above A0 and ferromagnetic below
- A1: Austenite (FCC_A1) transforms to ferrite (BCC_A2) + carbide (cementite or graphite or M23C6)
- A2: Magnetic transition temperature (Curie temperature) of ferrite (BCC_A2). Paramagnetic above A2 and ferromagnetic below
- A3: Austenite (FCC_A1) transforms to ferrite (BCC_A2)

Project File and License Information

- Folder: **Property Models → Steel**
- File name: `PM_Fe_04_Critical_Temperatures.tcu`

The **FEDEMO: Iron Demo Database** is used and this example is available to all users. However, in general a license is required to run the Steel Models.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

Property Model Calculator and About the Critical Transformation Temperatures Property Model

PM_Fe_05: Fe-C-Mn-Si-Ni-Cr-Mo Bainite

The example uses the **Property Model Calculator** and the **Bainite** Steel Model to calculate a Time-Temperature-Transformation (TTT) diagram for an Fe-0.97C-0.72Mn-0.32Si-1.54Ni-0.8Cr-0.26Mo alloy. The result is compared to experimental results from [1948Jaf]. Other elements with low amount in the experimental alloy are omitted for the calculation.

A Property Model Calculator is used with a *One Axis* calculation and the *TTT mode* selected on the Plot Renderer to plot the TTT diagram.

Considered elements: Fe, C, Mn, Si, Cr, Ni, and Mo. Other elements in the system are neglected for bainite by mass percent.

Project File and License Information

- Folder: **Property Models → Steel**
- File name: `PM_Fe_05_Fe-C-Mn-Si-Ni-Cr-Mo_Bainite.tcu`

To run calculations with the **Steel Models** requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases. Also see our website to learn more about the Steel Model Library and other related examples.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

PM_Fe_07: Hardenability Design of Steel

This application example, which has some step-by-step instructions available on our website, shows how the Steel Model Library in Thermo-Calc can be used to find the optimal compositions for an Fe-Mn-C steel to achieve high hardenability for the purpose of strength.

Hardenability of steel is an important aspect of steel design because it affects the ability of the steel to develop optimum strength and toughness. Hardenability refers to the ability of steel to form martensite on quenching. It is a measure of the capacity of a steel to be hardened in depth when quenched from its austenitizing temperature, meaning that the steel forms martensite not only at the surface of the steel, but throughout the interior. This is usually a prerequisite for the subsequent tempering treatment for an optimal combination of strength and toughness. Insufficient hardenability can make the tempering treatment ineffective and lead to low uniformity of mechanical properties in a steel component. The two most important factors that influence hardenability of steel are grain size and composition, and in this example, we will investigate composition.

Project File and License Information

- Folder: **Property Models → Steel**
- File name: `PM_Fe_07_Hardenability_Design_of_Steel.tcu`

Although this example uses the FEDEMO and MFEDEMO databases, running the calculation requires a license for Thermo-Calc 2022b or newer and for the Steel Model Library.

Visualizations

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes several hours to complete the calculations.

PM_Fe_08: CCT Diagram for Fe-C-Mn-Si-Cr-V

The example uses the **Property Model Calculator** and the **CCT Diagram** Property Model to calculate a Continuous-Cooling-Transformation (CCT) diagram for an Fe-C-Mn-Si-Cr-V alloy (Steel 42CrV6). The calculation is compared to an experimental CCT diagram for the same steel (with some other impurities) from data in [1958Wev].

A **One Axis** *Calculation Type* is selected on the Property Model Calculator and then the **CCT Mode** selected as the *Plot type* on the Plot Renderer in order to plot the final CCT diagram. A second plot also shows the calculated terminal fractions of ferrite, pearlite, bainite, and martensite.

Project File and License Information

- Folder: **Property Models → Steel**
- File name: `PM_Fe_08_Fe-C-Mn-Si-Cr-V_CCT.tcu`

To run calculations with the **Steel Models** requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases. Also see our website to learn more about the Steel Model Library and other related examples.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

PM_Fe_10: Martensitic Steel Strength

The **Martensitic Steel Strength** Property Model, available with the Property Model Calculator and the Steel Model Library, predicts the general flow stress properties of martensitic steels, such as hardness, stress at arbitrary strain, yield strength, ultimate tensile strength, Young's modulus, etc.

The Model evaluates the following in consecutive steps:

- Martensite fraction based on composition, annealing temperature, and quench temperature
- Hardness of the as-quenched microstructure
- Effect of tempering on microstructure and hardness
- Young's modulus based on the composition of the matrix phase and contributions from precipitates
- Strain hardening response (flow stress) based on the final hardness after tempering

In this example, data for AISI4068 from [1956Gra] are compared to calculations using the **Martensitic Steel Strength** model. In the set up, one **System Definer** and two **Experimental File Reader** activities are used along with four **Property Model Calculators**. The **Martensitic Steel Strength** Property Model is used in all cases with **One Axis** calculations to produce two plots that compare the tempering temperature and time to the total hardness of tempered steels.

Project File and License Information

- Folder: **Property Models → Steel**
- File name: `PM_Fe_10_Martensitic_Steel_Strength.tcu`

To run calculations with the **Steel Models** requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases. Also see our website to learn more about the Steel Model Library and other related examples.

This example uses TCFE13. Earlier versions of this database can be used although there may be slight differences in the results.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

For some Windows-based systems, performing the full calculation from the top **My Project** node can result in out of memory issues due to the number of calculators. If this happens, perform individual calculations for each Property Model Calculator (e.g. right-click the node and select **Perform Now**). This produces the full plots that are output to the Visualizations window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

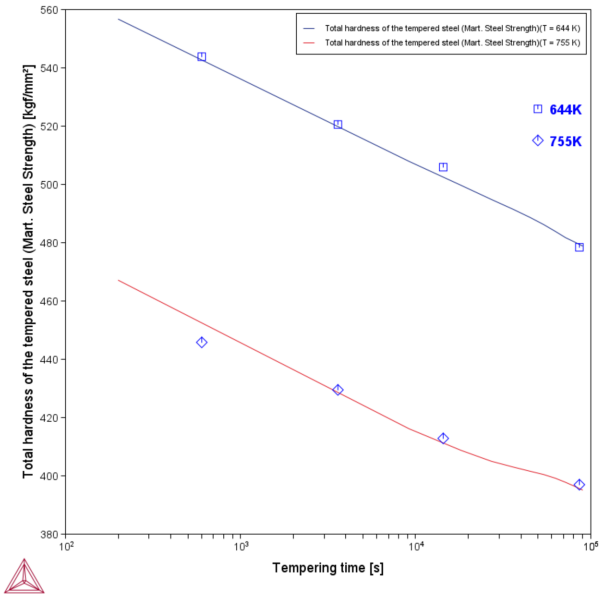

Figure 17: Total hardness of the tempered steel versus tempering time, for two tempering temperatures, compared to data from [1956Gra].

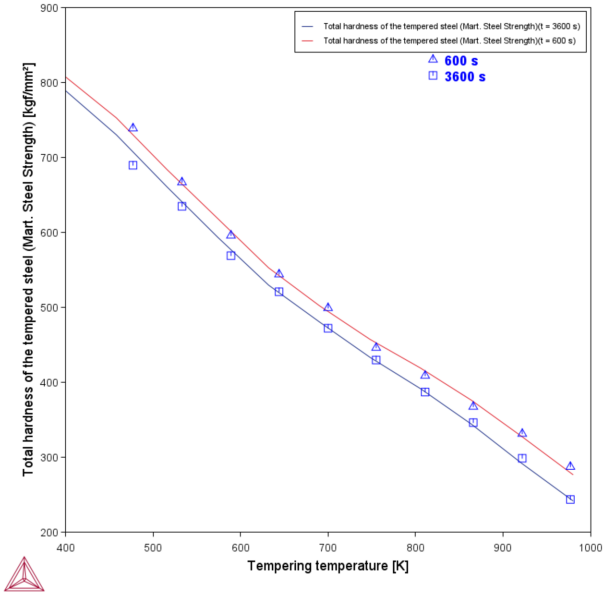

Figure 18: Total hardness of the tempered steel versus tempering temperature, for two tempering times, compared to handbook data from [1956Gra].

For more information about the Property Model, see About the Martensitic Steel Strength Property Model and Martensitic Steel Strength Property Model Settings.

PM_Fe_11: Steel Design Using the Parallel Coordinates Plot

The example uses the **Property Model Calculator** and three Property Models to plot a property diagram and a **Parallel coordinates** plot for chemistries centered around an Fe1.5Cr2.0Ni0.31C1.0Mn alloy. The Ni, Cr, and C chemistries are varied to understand their influence on some key properties. This can be used to optimize a material chemistry to meet specific design criteria.

Overview

A **One Axis** calculation using the **Equilibrium Calculator** produces a property diagram to show the equilibrium fractions of the alloy.

A second calculation uses a **Grid** calculation with the Property Model Calculator and the **Driving Force**, **Martensite Temperatures**, and **Martensitic Steel Strength** models to demonstrate the use of the **Parallel coordinates** plot type. The driving force model in this example calculates the driving force for Cementite to form at 500 °C (tempering temperature). The driving force gives a good idea of how fine a dispersion of carbides could form. Higher driving force means a finer distribution.

When using a parallel coordinates plot type, you can interpret multidimensional data to compare how different parameters affect each other. In this example this includes the *composition of Ni, Cr, and C* (each in mass percent), the *Driving force per mole*, the *Total hardness of the tempered steel*, and the *Ms temperature*.

Project File and License Information

- Folder: **Property Models → Steels**
- File name: `PM_Fe_11_Steel_Design_Using_Parallel_Plot.tcu`

To run calculations with the **Steel Models** requires a valid maintenance license plus licenses for both the TCFE (version 9 and newer) and MOBFE (version 4 and newer) databases. Also see our website to learn more about the Steel Model Library and other related examples.

This example uses TCFE13. Earlier versions of this database can be used although there may be slight differences in the results.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

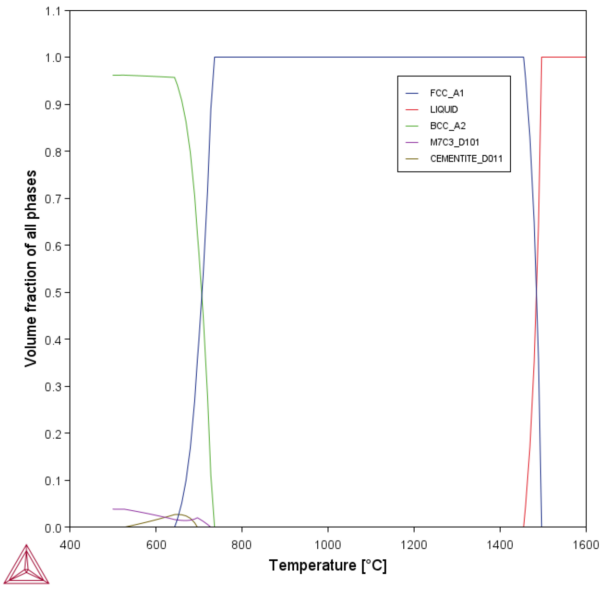

Figure 19: A Property Diagram to observe the change in volume fraction of all phases as the temperature increases.

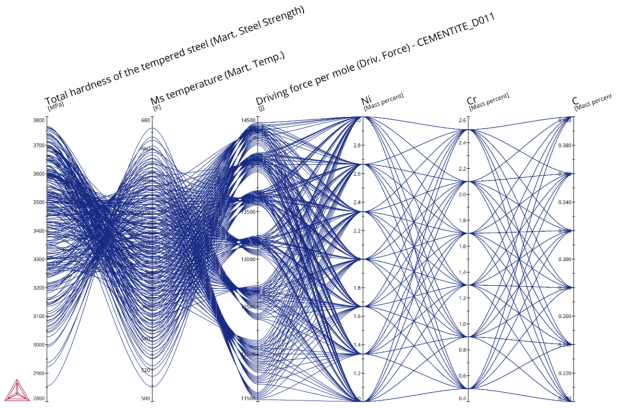

Figure 20: A parallel coordinates plot with multidimensional data comparing the Ni, Cr, and C compositions, the Driving force per mole, the Total hardness of the tempered steel, and the Ms temperature.

Tips to Interpret the Plot Data

- When most lines between two parallel axes are somewhat parallel to each other, there is a positive relationship between these two dimensions.
- When lines cross in a kind of superposition of X-shapes, that is a negative relationship.
- When lines cross randomly it means that there is no particular relationship.

About the Titanium Model Library Property Models

These **Titanium Models** are available with the Property Model Calculator and as part of the Titanium Model Library.

As a starting point, the **Property Navigator** can more quickly help guide you to set up the initial simulation. See Creating a Project with the Property Navigator.

Alloy Strength - Ti

The **Alloy Strength - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the hardness, flow stress, and strength of Ti-base alloys. The model can be configured to include contributions from intrinsic hardness, solid solution hardening, grain boundary hardening, precipitation hardening, martensitic transformation, pre-straining, as well as by specifying a user-defined constant strength addition. The solid solution contribution is modeled considering all Ti binary interactions relevant to the TCS Ti/TiAl-based Alloys Database (TCTI) (version 7 and newer).

The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

The addition of the capability to consider martensitic transformations allows for accurate prediction of hardness, Young's modulus, and flow stress properties in alloys where such a transformation is commonplace upon quenching.

See About the Alloy Strength - Ti Property Model and Alloy Strength - Ti Property Model Settings for background theory and input parameter details.

Martensite Temperatures - Ti

The **Martensite Temperatures - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the martensite start temperature (Ms) and T-Zero temperatures for Ti-base alloys.

Choose between **HCP** (α, α', or α'') and **B19_PRIME** or **B19_ORTHO** as the **Martensite phase**:

- The HCP phase is the common choice for alloys such as Ti-6Al-4V and other structural alloys.

> The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

- The B19_PRIME and B19_ORTHO options are intended for TiNi-based shape-memory alloys.
- The B19_ORTHO is useful for TiNiCu-based shape-memory alloys.

See About the Martensite Temperatures - Ti Property Model and Martensite Temperatures - Ti Property Model Settings for background theory and input parameter details.

About the Alloy Strength - Ti Property Model

The **Alloy Strength - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the hardness, flow stress, and strength of Ti-base alloys. The model can be configured to include contributions from intrinsic hardness, solid solution hardening, grain boundary hardening, precipitation hardening, martensitic transformation, pre-straining, as well as by specifying a user-defined constant strength addition. The solid solution contribution is modeled considering all Ti binary interactions relevant to the TCS Ti/TiAl-based Alloys Database (TCTI) (version 7 and newer).

The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

The addition of the capability to consider martensitic transformations allows for accurate prediction of hardness, Young's modulus, and flow stress properties in alloys where such a transformation is commonplace upon quenching.

The **Alloy Strength - Ti** model is built from individual models for five strength contributions. The effect of impurities on the strength of Ti-base alloys is very strong [1981Con; 1998Ouc] and this model has therefore been equipped with a functionality to select base grades, according to the ASTM definitions of purity, for cases where the exact impurity content is not known.

Intrinsic Strength

The *intrinsic strength* is calculated as the combination of the strength for the pure elements in the system, weighted by the mole fraction of each element. In the **Alloy Strength - Ti** model you can choose the **Titanium base grade**, which are base grades of "commercially pure" titanium and represent the impurity elements allowed in each grade. The compositions defined for the available grades are as listed:

- **Iodide Titanium**: Pure Ti with no impurity elements (the default)
- **Grade 1 (35A)**: Ti-0.2Fe-0.18O-0.08C-0.03N-0.015H (wt%)

- **Grade 2 (50A)**: Ti-0.3Fe-0.25O-0.08C-0.03N-0.015H (wt%)
- **Grade 3 (65A)**: Ti-0.3Fe-0.35O-0.08C-0.05N-0.015H (wt%)
- **Grade 4 (75A)**: Ti-0.5Fe-0.4O-0.08C-0.05N-0.015H (wt%)

The intrinsic strength for the different grades is given as the linear combination of the strength for the elements in the system plus the calculated strengthening contribution from solid solution of the impurity elements.

Grain Boundary Strengthening

For the *grain boundary strengthening*, after selecting the **Grain boundary strengthening** checkbox you can include an effect of **Grain size** on the strength/hardness. This contribution is given by the Hall-Petch equation [2016Cor]. When setting up the model, you can either specify a **User-defined Hall-Petch coefficient** or otherwise it is calculated by default.

For additional background information, see About the Yield Strength Property Model.

Solid Solution Strengthening

The *solid solution strengthening* contribution is evaluated as per the model by Walbrühl et al. [2017Wal], where the parameters for each Ti binary system are optimized against a compiled collection of experimental studies on titanium. There is no specific input required for solid solution strengthening when setting up the model. This calculation uses the composition of the alpha and/or beta phase of the system, which is automatically calculated in the model.

For additional background information, see About the Yield Strength Property Model.

Precipitation Strengthening

After selecting the **Precipitation strengthening** checkbox on the **Configuration** window, there are several settings you can define. One phase can be chosen to contribute to the alloy strength by *precipitation strengthening*, which in this Property Model is given by the model by Deschamps et al. [1998Des].

On the **Configuration** window for this setting, the following input parameters can be defined:

- **Precipitate radius**: The mean radius of the precipitates.
- **Critical radius**: The mean precipitate radius where the mechanism that dislocations pass precipitates changes from shearing ($r < r_{critical}$) to looping ($r > r_{critical}$).
- **Taylor factor**: The Taylor factor accounts for the texture of the material, normally the value is between 2.24 and 3.06 for randomly oriented grains.
- **Shear modulus**: The shear modulus of the matrix phase, given in Pascal (Pa).
- **Burgers vector**: The burgers vector of the matrix phase, given in meters (m).

Starting with TCS Ti/TiAl-based Alloys Database (TCTI) version 6, it is possible to calculate the **Shear modulus** of individual phases. The option is enabled by default for the precipitation strengthening contribution. See the settings information or the tooltip.

Constant Strength Addition

The *Constant strength addition* contribution can be used to displace the calculated result in the *y*-direction.

About Hardness and Flow Stress

The hardness is evaluated by considering the individual contributions to hardness considered by the given flow stress model, such as intrinsic hardness, solid solution hardening and martensite hardening.

The resulting hardness forms the foundation for evaluating the flow stress by means of estimating the strain hardening response of the alloy. Deviations in predicted flow stress properties can be corrected by changing key parameters in the settings, which are:

- Pre-straining (accounts for cold work the material may have been subjected to)
- Flow stress model (Ramberg-Osgood or Voce) and model specific parameters
- Young's modulus
- Constant strength addition

Read more in Flow Stress Theory.

Configuration Settings

The input parameters are entered on the **Configuration** window for the Property Model Calculator. There are also settings on the Plot Renderer where you can choose from the available and relevant axis variables.

See Alloy Strength - Ti Property Model Settings.

Examples

For examples see PM_Ti_02: Alloy Strength for Ti-O and PM_Ti_03: Flow Stress in a Ti-based Alloy.

Flow Stress Theory

The following Property Models provide flow stress:

- **Martensitic Steel Strength** in the Steel Model Library
- **Alloy Strength - Ti** in the Titanium Model Library

When flow stress is available, it enables you to predict stress at arbitrary strain with these properties:

- True stress
- True strain (this requires user input)
- Engineering strain
- Engineering stress

The Model has a **Flow stress mode** to predict engineering properties such as:

- Yield strength
- Yield strain
- Ultimate tensile strength
- Uniform elongation
- Fracture strength
- Elongation at fracture
- Young's modulus

True strain is not available as an input parameter when using the *engineering properties mode* (i.e. $\mathbf{E}, \sigma_{\mathbf{y}}$ **and** $\sigma_{\mathbf{UTS}}$, which is selected as a **Flow stress mode**).

Additional Information

This section is specifically about the flow stress theory and is a continuation from the main theory described in About the Martensitic Steel Strength Property Model and About the Alloy Strength - Ti Property Model.

The input parameters are entered on the **Configuration** window for the Property Model Calculator. There are also settings on the Plot Renderer where you can choose from the available and relevant axis variables.

For details about the various settings mentioned in this theory section, see

- For **Martensitic Steel Strength** see Martensitic Steel Strength Property Model Settings. You can also open an installed example to see the application of these features. See PM_Fe_12: Flow Stress 15-5PH Steel for more information.
- For **Alloy Strength - Ti**, see Alloy Strength - Ti Property Model Settings. You can also open an installed example to see the application of these features. SeePM_Ti_03: Flow Stress in a Ti-based Alloy.

Main Implementation

The flow stress model relies on the Ramberg-Osgood equation to predict flow stress, which can be expressed as:

$$\varepsilon = \frac{\sigma}{E} + 0.002\left(\frac{\sigma}{\sigma_y}\right)^{(1/n)}$$

where

- ε is the strain,
- σ is the stress,
- E is the Young's modulus,
- σ_y is the yield strength, and
- n is the strain hardening exponent.

To calculate stress at an arbitrary strain, the parameters E, σ_y, and n need to be determined.

The Young's modulus of the material is obtained by averaging the Young's moduli of individual phases.

> Elastic properties (the elastic constants and moduli) are available with the TCS Steel and Fe-alloys Database (TCFE) starting with version 14 (TCFE14) and with TCS Ti/TiAl-based Alloys Database (TCTI) starting with version 6 (TCTI6). If you are using earlier versions of these databases, i.e., no elastic properties are available, then the Young's moduli of individual phases are estimated using simple rules.

For the **Martensitic Steel Strength** model, the yield strength (σ_y) is determined based on its relationship with hardness, where the work by Pavlina and Van Tyne [2008Pav] is extended to consider a larger dataset.

The hardness itself is predicted by the model as described in the primary theory sections, About the Martensitic Steel Strength Property Model and About the Alloy Strength - Ti Property Model.

User-defined Flow Stress Parameters

Young's modulus (E) and the strain hardening exponent (n) can be set manually by selecting the **User-defined flow stress parameters** checkbox on the **Configuration** window. The yield strength, σ_y, is then inferred from these parameters and the known hardness.

After selecting the checkbox, you can further choose to use the **Voce** equation (select this option from the **Flow stress model** list), which is expressed as:

$$\sigma = \sigma_y + (\sigma_s - \sigma_y)(1 - e^{-k\varepsilon_p})$$

where

- σ_s is the saturation stress,
- ε_p is the plastic strain, and
- k is the hardening rate.

As the Voce equation is only expressed in terms of plastic strain, the model uses $\sigma = \varepsilon E$ for strains lower than the yield strain. To use the Voce model, you must specify the following additional settings:

- E (**Young's modulus**)
- σ_s (**Saturation stress**)
- k (**Hardening rate**)

Pre-deformed Materials

The flow stress model can be used to predict flow stress in pre-deformed materials, using the parameter **Pre-straining [%]**. The value given should correspond to the plastic strain that the material is exposed to beforehand. Pre-straining shifts the yield point and affects the yield strain, where uniform elongation and total elongation is then reduced by a corresponding amount.

Strain-rate Dependence

Strain-rate dependence on stress is implemented in the model and expressed as:

$$\sigma(\dot{\varepsilon}) = \sigma(\dot{\varepsilon_0}) \left(\frac{\dot{\varepsilon}}{\dot{\varepsilon_0}}\right)^m$$

where

- ε is the applied strain rate,
- $\dot{\varepsilon}_0$ is the reference strain rate (corresponding to quasi-static conditions), and
- m is the strain rate sensitivity, where m can be predicted by the model or user-defined.

Fracture Properties

Elongation and Fracture

Neither the Ramberg-Osgood nor Voce models can be used to predict fracture properties as they are only valid for uniform deformation. In fact, modeling, e.g., total elongation in a general manner based on some physical or empirical model is a challenging task. For this reason, the total elongation is modeled using a machine learning approach. Together with other properties, total elongation can then be used to estimate the fracture strength. In the stress vs. strain mode, any engineering stress at engineering strains beyond the predicted elongation is set to NaN, signifying that the material has fractured completely.

Post-uniform True vs. Engineering Stress and Strain

The conversion between engineering and true quantities is mathematically valid in the entire range of strain, however, the conversion assumes constant volume. This assumption is not valid in the necking regime as the deformation is not distributed evenly. Furthermore, void formation would decrease the density and cross-sectional area of the specimen. These issues

are not easily corrected for as they require detailed knowledge on the geometry of the necking region as a function of strain and the progression of void formation etc. Therefore, the post-uniform elongation and total elongation are only available as engineering quantities.

Gauge Length

Total elongation is the sum of uniform elongation and elongation in the necking regime, where deformation is highly localized. Therefore, post-uniform elongation scales with cross-sectional area rather than length of the test piece. Since total elongation is expressed as a percentage of the length of the test piece, the measured value of the elongation in the necking regime is dependent on the actual length of the test-piece (so-called gauge length), and thus the same is valid for total elongation. This is an artifact of improper normalization and not a material dependence. The elongation model is trained on data mostly from tests performed on samples with 50 or 80 mm gauge lengths. For martensitic steels, the difference in total elongation between these gauge lengths would not, in most cases, exceed the experimental scatter.

About the Martensite Temperatures - Ti Property Model

The **Martensite Temperatures - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the martensite start temperature (Ms) and T-Zero temperatures for Ti-base alloys.

Choose between **HCP** (α, α', or α'') and **B19_PRIME** or **B19_ORTHO** as the **Martensite phase**:

- The HCP phase is the common choice for alloys such as Ti-6Al-4V and other structural alloys.

  The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

- The B19_PRIME and B19_ORTHO options are intended for TiNi-based shape-memory alloys.
- The B19_ORTHO is useful for TiNiCu-based shape-memory alloys.

An initial equilibrium is calculated to set the starting composition and internal constitution (in case of ordering) of the parent phase. This should be performed at a temperature that reflects the thermal history of the studied alloy. The starting composition and constitution is held fixed throughout the calculation as it is expected that the alloy cannot equilibrate during a martensitic transformation.

The model then calculates the T_0 temperature and the associated offset to the Ms temperature, which occurs due to the thermodynamic barrier for nucleation of martensite. The offset is parameterized using conventional Redlich-Kister polynomials.

Alloy Strength - Ti Property Model Settings

The **Alloy Strength - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the hardness, flow stress, and strength of Ti-base alloys. The model can be configured to include contributions from intrinsic hardness, solid solution hardening, grain boundary hardening, precipitation hardening, martensitic transformation, pre-straining, as well as by specifying a user-defined constant strength addition. The solid solution contribution is modeled considering all Ti binary interactions relevant to the TCS Ti/TiAl-based Alloys Database (TCTI) (version 7 and newer).

The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

The addition of the capability to consider martensitic transformations allows for accurate prediction of hardness, Young's modulus, and flow stress properties in alloys where such a transformation is commonplace upon quenching.

About the Contributions

The model can be configured to include contributions from:

- *Intrinsic strength / hardness*: The base line strength expressed as the weighted average of the strength for the pure elements in the system. If any of grade 1-4 is chosen as the base, a solid solution strengthening contribution stemming from impurities of Fe, C, N, H, and O is added to the weighted average of pure element strength.
- *Solid solution strengthening / hardening*: The contribution to strength from solid solution calculated as the sum of contributions from binary interactions.
- Martensitic transformation.
- *Grain boundary strengthening / hardening*: The contribution to strength from grain boundaries described by the Hall-Petch relationship is described by the Hall-Petch relation.
- *Precipitation strengthening / hardening*: The contribution to strength from precipitation, described by the model developed by Deschamps.

- *Constant strength / hardness*: This contribution is a constant addition to the overall strength. It is a true constant in the sense that it is not converted between either strength or hardness, nor between Mpa or Vickers units.

For more details about these contributions, see About the Alloy Strength - Ti Property Model.

Configuration Settings

The settings are found on the Property Model Calculator when **Alloy Strength - Ti** is selected under **Titanium Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Titanium Base Grade

Select a **Titanium base grade** from the list. Impurities have a strong solid solution hardening effect. When you select a Ti-grade as the base for the alloys system, this effect is taken into account. The default, **Iodide Titanium**, is pure Ti with no impurity elements, i.e. this excludes this contribution to the intrinsic hardness. Otherwise choose a Ti-base grade from the list, where the compositions for the available grades are also listed:

- **Grade 1 35A**: Ti-0.2Fe-0.18O-0.08C-0.03N-0.015H (wt%)
- **Grade 2 50A**: Ti-0.3Fe-0.25O-0.08C-0.03N-0.015H (wt%)
- **Grade 3 65A**: Ti-0.3Fe-0.35O-0.08C-0.05N-0.015H (wt%)
- **Grade 4 75A**: Ti-0.5Fe-0.4O-0.08C-0.05N-0.015H (wt%)

Annealing Temperature

Enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

Evaluation Temperature

Enter a value for the **Evaluation temperature**. This is the temperature at which the property evaluation occurs, and corresponds to the measurement temperature.

Allow Martenstic Transformation

Select the **Allow martenstic transformation** checkbox to enter a **Quench temperature**.

Quench Temperature

Enter a **Quench temperature**, which is the temperature at which the quench occurs.

Grain Boundary Strengthening

The **Grain boundary strengthening** checkbox is selected by default to include calculated grain boundary strengthening (σ_{gb}). Click to deselect the checkbox to exclude it as needed.

When the checkbox is selected, enter the **Grain size [um]**, which is the grain diameter in micrometers (µm).

Grain Size

This setting is available when the **Grain boundary strengthening** checkbox is selected.

Enter the **Grain size [µm]**, which is the grain diameter in micrometers (µm). The default is `100` µm.

User-defined Hall-Petch Coefficient

This setting is available when the **Grain boundary strengthening** checkbox is selected. By default, a suitable default **Hall-Petch coefficient** is automatically calculated by the model.

Alternatively, select the **User defined Hall-Petch coefficient** checkbox and enter a different **Hall-Petch coefficient**: k_{h-p} in MPa $\mu m^{1/2}$.

Precipitation Strengthening

Click to select the **Precipitation strengthening** checkbox to include calculated precipitation strengthening (σ_p). Then continue to define the settings under Additional Precipitation Strengthening Settings.

Constant Strength Addition

Enter a **Constant strength addition**. This strength contribution can be used to displace the calculated result in the *y*-direction. Function input is allowed, e.g., `1000*w(Al)`.

Flow Stress Settings

For specific theory, see Flow Stress Theory.

Flow Stress Mode

Select a **Flow stress mode**:

- $\mathbf{E, \sigma_y \text{ and } \sigma_{UTS}}$ (the default) to calculate engineering properties. This is generally referred to as the *engineering properties mode* in the theory section.
- $\boldsymbol{\sigma}$ **vs** $\boldsymbol{\varepsilon}$ to calculate the stress at a total specified strain.

True Strain [%]

Available when $\boldsymbol{\sigma}$ **vs** $\boldsymbol{\varepsilon}$ is selected.

Enter a value for **True strain [%]** to evaluate the stress at a specified true strain (elastic plus plastic).

Pre-straining [%]

Enter a value for the **Pre-straining [%]** to specify the strain the material is exposed to before calculation. This is useful in cases where prior deformation needs to be accounted for, e.g., cold work, as it affects the calculated flow stress.

The value entered does not affect the calculated hardness

User-defined Flow Stress Parameters

Select the **User-defined flow stress parameters** checkbox to define additional parameters related to the flow stress calculation.

When the checkbox is selected also define other settings such as the **Flow stress model** and **Young's modulus**. Then based on the **Flow stress model**, also define **Strain hardening exponent**(Ramberg-Osgood) or **Saturation stress**, and **Hardening rate** (Voce). In addition, a value for the Young's modulus needs to be given.

Flow Stress Model

This is available when the **User-defined flow stress parameters** checkbox is selected.

Select a **Flow stress model** to use for the calculation: **Ramberg-Osgood** or **Voce**.

Elongation Correction

This is available when the **User-defined flow stress parameters** checkbox is selected.

Enter a value for the **Elongation correction**, which is a correction factor applied to the predicted elongation at fracture, with a value of 1 implying no correction is made.

Young's Modulus

This is available when the **User-defined flow stress parameters** checkbox is selected.

Enter a value for the **Young's modulus** in **GPa**.

Strain Hardening Exponent

This is available when the **User-defined flow stress parameters** checkbox is selected and **Ramberg-Osgood** is the **Flow stress model**.

Enter a value for the **Strain hardening exponent**.

Saturation Stress

This is available when the **User-defined flow stress parameters** checkbox is selected and **Voce** is the **Flow stress model**.

Enter a **Saturation stress**, which is the stress value in MPa approached asymptotically with strain.

Hardening Rate

This is available when the **User-defined flow stress parameters** checkbox is selected and **Voce** is the **Flow stress model**.

Enter a **Hardening rate**, which is the rate at which strain hardening progresses according to the Voce model.

Apply Strain Rate

Select the **Apply strain rate** checkbox to account for the effect of strain rate on flow stress. If the checkbox is not selected (the default), flow stress is calculated for quasi-static conditions only.

When the checkbox is selected also define other settings such as **Strain rate [1/s]**, **Reference strain rate**, and **Strain rate sensitivity**.

Strain Rate

This is available when the **Apply strain rate** checkbox is selected.

Enter a value for the **Strain rate** in **1/s**.

Reference Strain Rate

This is available when the **Apply strain rate** checkbox is selected.

Specify the **Reference strain rate** in 1/s. This should correspond to the strain rate at quasi-static conditions, i.e., in the range of 10^{-4} to 10^{-3}

Apply User-defined Strain Rate Sensitivity

This is available when the **Apply strain rate** checkbox is selected.

Select the **Apply user-defined strain rate sensitivity** checkbox to enter a **Strain rate sensitivity** exponent. If the checkbox is not selected (the default), the strain rate sensitivity exponent is estimated by the model.

Additional Precipitation Strengthening Settings

The following settings are available when the **Precipitation strengthening** checkbox is selected.

Precipitate Phase

Select a **Precipitate phase** from the list. One phase can be chosen to contribute to the alloy strength.

The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

Precipitate Radius

Enter a **Precipitate radius**, which is the mean radius of the precipitates. The default is `1.0E-8`.

Critical Radius

Enter a **Critical radius**. This is the mean precipitate radius where the mechanism that dislocations pass precipitates changes from shearing ($r < r_{critical}$) to looping ($r > r_{critical}$). The default is `1.0E-8`.

Taylor Factor

Enter a value for the **Taylor factor**. The default is `3.0`.

The value of the Taylor factor accounts for texture in the material. Normally the value is between 2.24 and 3.06 for random orientations.

Shear Modulus

Enter the word `Calculated` (not case sensitive) in this field to calculate the shear modulus of the matrix phase from the parameters in the thermodynamic TCS Ti/TiAl-based Alloys Database (TCTI) (version TCTI6 and higher), which contains the elastic properties.

Additionally, values or functions, expressed in Pa, are also accepted as input. If the shear modulus cannot be calculated or evaluated from the input, a default value of `4.5E10` Pa is used, which is close to the value for pure Ti at room temperature.

Burgers Vector

Enter a value for the **Burgers vector**, which is the burgers vector of the matrix phase. The unit is meter (m) and the default is `2.5E-10`.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

The various *hardness* or *hardening* quantities are treated separately from the various *strength* or *strengthening* quantities and each (hardness and strength) are plotted on the respective axes. When setting up the simulation, the **Configuration** window (when in *Grouped Mode*) shows either *Vickers Hardness* or *Strength*. This corresponds to the labeling of axes in the **Visualizations** window when plotting two or more quantities of the same type. The legend then lists the specific quantity names selected on the **Configuration** window.

Plot Quantities

- **Amount of Phases**
- **Annealing temperature**

About the Alloy Strength - Ti Property Model

For examples see PM_Ti_02: Alloy Strength for Ti-O and PM_Ti_03: Flow Stress in a Ti-based Alloy

Martensite Temperatures - Ti Property Model Settings

The **Martensite Temperatures - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the martensite start temperature (Ms) and T-Zero temperatures for Ti-base alloys.

Choose between **HCP** (α, α', or α'') and **B19_PRIME** or **B19_ORTHO** as the **Martensite phase**:

- The HCP phase is the common choice for alloys such as Ti-6Al-4V and other structural alloys.

  The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

- The B19_PRIME and B19_ORTHO options are intended for TiNi-based shape-memory alloys.
- The B19_ORTHO is useful for TiNiCu-based shape-memory alloys.

Configuration Settings

The settings are found on the Property Model Calculator when **Martensite Temperatures - Ti** is selected under **Titanium Models**.

For the details about the *Condition Definitions*, *Calculation Type*, *Timeout in minutes*, *Parallel Calculation*, and other calculation associated settings, see Configuration Window Settings.

Annealing and Annealing Temperature

To account for the presence of secondary phases, click to select the **Annealing** checkbox and then enter an **Annealing temperature**, which is the temperature at which the annealing occurs.

If the **Annealing** checkbox is NOT selected, then the overall composition is taken as the composition of the parent phase.

For parent phases exhibiting ordering, such as in shape-memory alloys, an initial equilibrium is calculated to set the starting composition and internal constitution of the parent phase, which is used to track the composition set throughout the calculation. In this case it is recommended you select the checkbox and enter an **Annealing temperature** so that a representative composition set is selected. This should be performed at a temperature that reflects the thermal history of the studied alloy.

The model then calculates the **T-Zero temperature** and the associated offset to the **Ms temperature**, which occurs due to the thermodynamic barrier for nucleation of martensite. The offset is parameterized using conventional Redlich-Kister polynomials. The starting composition and constitution are held fixed throughout the calculation as it is expected that the alloy cannot equilibrate during a martensitic transformation.

Martensite Phase

Select a **Martensite phase** from the list: **HCP** (α, α', or α''), **B19_PRIME (shape-memory alloys)**, or **B19_ORTHO (shape-memory alloys)**.

- **HCP** (α, α', or α'') is the common choice for alloys such as Ti-6Al-4V and other structural alloys.
- **B19_PRIME (shape-memory alloys)** for TiNi-based shape-memory alloys.
- **B19_ORTHO (shape-memory alloys)** for TiNi-based shape-memory alloys. This setting is particularly useful for TiNiCu-based shape-memory alloys.

Parent Phase Energy Addition

In the **Parent phase energy addition [J/mol]** field enter a value in J/mol to add a Gibbs energy shift for the parent phase. This should normally only be used for calculating T-Zero since it might produce unpredictable results for Ms.

The expression can be a function of temperature, T, and composition, w(el) or x(el), for example:

```
50*T/1000+10*x(Cr)+5*x(Cr)^2
```

The default is `0` J/mol.

Plot Renderer Settings

Plot Renderer and Plot Renderer: Configuration Settings

When setting up your calculation on the Plot Renderer and/or Table Renderer, the following axis variables are available for the conditions defined on the Property Model Calculator.

Plot Quantities

- **Annealing temperature**
- **Composition**
- **Ms temperature**: Martensite start temperature
- **Parent phase composition (Mole percent)**
- **Parent phase energy addition**
- **Stable phases (Volume percent)**
- **T-Zero temperature**

PM_Ti_01: Martensite Temperatures for Ti-Zr

The **Martensite Temperatures - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the martensite start temperature (Ms) and T-Zero temperatures for Ti-base alloys.

Choose between **HCP** (α, α', or α'') and **B19_PRIME** or **B19_ORTHO** as the **Martensite phase**:

- The HCP phase is the common choice for alloys such as Ti-6Al-4V and other structural alloys.

> The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

- The B19_PRIME and B19_ORTHO options are intended for TiNi-based shape-memory alloys.
- The B19_ORTHO is useful for TiNiCu-based shape-memory alloys.

This example uses the **Martensite Temperatures - Ti** Property Model with a simple Ti-Zr system to show the use of this model. A **One Axis** calculation is used to plot the Ms and T-Zero temperatures as a function of mole fraction of Zr with experimental data from [1952Du, 1965McM, and 1970Hua].

Project File and License Information

- Folder: **Property Models → Titanium**
- File name: `PM_Ti_01_Martensite_Temperatures_Ti-Zr.tcu`

> To run calculations with the **Titanium Models** requires a valid maintenance license plus a license for the TCTI (version 6 and newer) database. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Titanium Model Library.

Visualizations

Many of our Graphical Mode examples have video tutorials, which you can access in a variety of ways. When in Thermo-Calc, from the menu select **Help → Video Tutorials**, or from the main My Project window, click **Video Tutorials**. Alternately, you can go to the website or our YouTube channel.

Open the example project file to review the node setup on the **Project** window and the associated settings on the **Configuration** window for each node. For some types of projects, you can also adjust settings on the **Plot Renderer Configuration** window to preview results before performing the simulation. Click **Perform Tree** to generate plots and tables to see the results on the **Visualizations** window.

When you run (Perform) this example, it takes a few minutes for the calculations to complete.

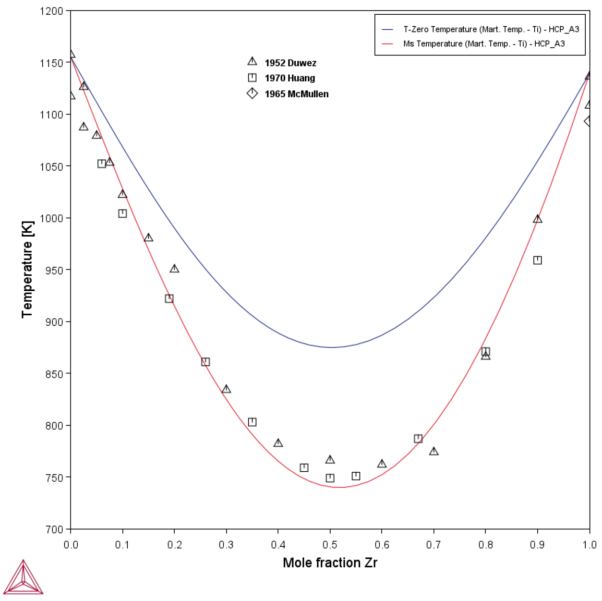

Figure 1: Ms and T-Zero temperatures as a function of mole fraction of Zr with experimental data from [1952Du, 1965McM, and 1970Hua].

PM_Ti_02: Alloy Strength for Ti-O

The **Alloy Strength - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the hardness, flow stress, and strength of Ti-base alloys. The model can be configured to include contributions from intrinsic hardness, solid solution hardening, grain boundary hardening, precipitation hardening, martensitic transformation, pre-straining, as well as by specifying a user-defined constant strength addition. The solid solution contribution is modeled considering all Ti binary interactions relevant to the TCS Ti/TiAl-based Alloys Database (TCTI) (version 7 and newer).

The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

The addition of the capability to consider martensitic transformations allows for accurate prediction of hardness, Young's modulus, and flow stress properties in alloys where such a transformation is commonplace upon quenching.

Overview

This example uses the **Alloy Strength - Ti** Property Model to determine the total hardness of a Ti-0.04Fe-0.03C-0.005N-0.01O alloy.

A **One Axis** calculation is done using the latest version of the TCS Ti/TiAl-based Alloys Database (TCTI) to compare the total hardness vs oxygen content (in mole %). Two **Experimental File Readers** provide the data from [1950Fin] and [1973Oka] for comparison with the calculated values.

As is clearly illustrated in this example, the effect of typical impurity elements on the strength and hardness of Ti is very large. It is therefore important to keep in mind that the impurity elements and their respective contents should be included in the calculation, either explicitly, as is done in this example, or by selecting an appropriate base grade with a pre-defined impurity content for the calculation.

Project File and License Information

- Folder: **Property Models → Titanium**
- File name: `PM_Ti_02_Alloy_Strength_Ti-O.tcu`

To run calculations with the **Titanium Models** requires a valid maintenance license plus a license for the TCTI (version 6 and newer) database. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Titanium Model Library.

PM_Ti_03: Flow Stress in a Ti-based Alloy

The **Alloy Strength - Ti** Property Model, available with the Property Model Calculator and the Titanium Model Library, calculates the hardness, flow stress, and strength of Ti-base alloys. The model can be configured to include contributions from intrinsic hardness, solid solution hardening, grain boundary hardening, precipitation hardening, martensitic transformation, pre-straining, as well as by specifying a user-defined constant strength addition. The solid solution contribution is modeled considering all Ti binary interactions relevant to the TCS Ti/TiAl-based Alloys Database (TCTI) (version 7 and newer).

The various forms of alpha martensite (α, α', or α'') are not explicitly distinguished and are therefore collectively described by HCP_A3 in terms of thermodynamic properties.

The addition of the capability to consider martensitic transformations allows for accurate prediction of hardness, Young's modulus, and flow stress properties in alloys where such a transformation is commonplace upon quenching.

Overview

This example uses the **Alloy Strength - Ti** Property Model to perform a flow stress calculation using the σ vs ε *Flow stress mode* for a novel Ti-0.28Cr-0.45Zr-0.052Al-0.12O-0.014N-0.01C-0.001H nano-martensitic alloy. This example compares the default Ramberg-Osgood flow stress model with a Voce model using user-defined parameters. The purpose is to show that the default Ramberg-Osgood model gives a reasonable prediction, while the Voce model parameters can be tuned by a user to improve the fit to experimental data.

Two **One Axis** calculations are done using a Property Model Calculator and the latest version of the TCS Ti/TiAl-based Alloys Database (TCTI) in both cases. One **Experimental File Reader** provides the data from [2022Zha] for comparison with the calculated values, and the **Plot Renderer** compares the **Engineering strain** and **Engineering stress** in the final visualization.

For the Voce flow stress model, the user-defined parameters that are set (*Elongation correction*, *Young's modulus*, and *Saturation stress*) together adjust the strain extent, initial elastic response, and stress level of the Voce curve. These should be interpreted as optimized model parameters for this example, not as general constants for all martensitic Ti alloys.

Property Model Calculator Settings

The first Property Model Calculator, renamed to **R-O model with default parameters**, sets up to use the default Ramberg-Osgood model. The second Property Model Calculator, renamed to **Voce model with optimized parameters**, uses the **Voce** *Flow stress model*. Below are the settings that differ from the defaults and then compared between each Calculator.

Settings Changed From Default	***Property Model Calculator 1 (Ramberg-Osgood)***	***Property Model Calculator 2 (Voce)***	***Comments***
Titanium base grade	Iodide Titanium	Iodide Titanium	
Annealing temperature	920 °C	920 °C	These temperatures are taken from the experimental conditions reported in the literature [2022Zha] and define the thermal history and temperature at which the flow stress is evaluated.
Evaluation temperature	25 °C	25 °C	
Quench temperature	25 °C	25 °C	
Allow martensitic transformation	Selected	Selected	
Flow stress mode	σ vs ε	σ vs ε	
User-defined flow stress parameters	Not selected	Selected	
Flow stress model	(default is Ramberg-Osgood, not shown specifically)	Voce	

Settings Changed From Default	Property Model Calculator 1 (Ramberg-Osgood)	Property Model Calculator 2 (Voce)	Comments
Elongation correction	not applicable	1.3	This coefficient adjusts the strain range of the calculated curve. A value greater than 1 extends the curve to larger strain, helping the calculated result better match the experimentally observed elongation.
Young's modulus		110.0	This defines the elastic stiffness used by the Voce flow stress model. The value, 110 GPa, is representative of titanium alloys and helps define the initial slope of the calculated stress-strain curve before plastic deformation dominates.
Saturation stress		1480.0	The saturation stress controls the upper stress level that the calculated curve approaches as strain increases and work hardening gradually saturates. The value, 1480 MPa, matches well with the high flow stress of the nano-martensitic Ti-0.28Cr-0.45Zr-0.052Al-0.12O-0.014N-0.01C-0.001H alloy.

Project File and License Information

- Folder: **Property Models → Titanium**
- File name: `PM_Ti_03_Flow_stress_Ti_base_alloys.tcu`

To run calculations with the **Titanium Models** requires a valid maintenance license plus a license for the TCTI (version 6 and newer) database. For some Property Models, additional recommendations for the database version to use is indicated in its description. Also see our website to learn more about the Titanium Model Library.

Visualizations

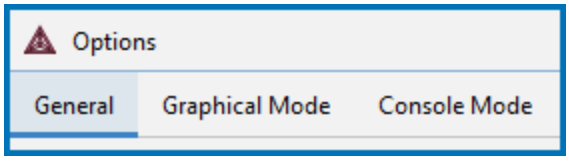
Global General Settings

Make global changes to the various defaults used for the settings for both Graphical Mode and Console Mode.

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **General** tab.



General Settings

Tooltips Enabled

Select whether to turn on tooltips information. By default the **Tooltips enabled** checkbox is selected. Hover the cursor above some buttons or other settings to display text with more information about the settings.

Localization

To change the GUI language from the **Localization** list choose **English** (the default), **Swedish**, **Spanish**, **German**, **Russian**, **Chinese**, **Japanese**, or **French**.

Look and Feel

To change the **Look and feel** of the GUI layout, choose **Light** (the default) or **Dark**.

For macOS, there are also the options **macOS Light** and **macOS Dark**.

The primary difference for the macOS themes is that the buttons and panels are a closer match to the Mac operating system. In addition, macOS Dark is darker than the standard Dark (more black than gray), although the macOS Light version is only slightly darker. It is recommended that users experiment with the options to determine which is best for your needs.

Also see Global Plot Settings: Design the Look and Feel for details about the **Color switching options** available and related to the **Light** and **Dark** modes. The use of these modes is also related to being able to right-click and access the **Plot Properties** options for local plots. See Changing the Plot Properties.

Log Level

Select the level and type of information to display in the **Event Log** window using the **Log level** slide bar. Choose from a **Debug**, **Info** (the default), **Warning**, or **Error** level of detail.

Database Directory

In the **Database directory** field, the default path is to the **data** directory where all the database files and data are located. Click **Modify** to open the default folder to change this default but first review the important information below.

Modifying the Database Directory Path (Graphical Mode Only)

Important Note: Database Directory Path (Graphical Mode only)

When you open a database for the first time, it is stored in a cache (an intermediate storage area), that is maintained even if you close the program. This improves the speed of loading the next time you open that database. The cache is used for all databases that are listed in the database initialization file, typically all the standard databases that are included with Thermo-Calc.

If you modify your own user-defined database, or if you choose to edit an unencrypted database, it is recommended that you create a separate directory to store these database files. This way the most recent version of the user-defined or edited databases are loaded into the program when the System Definer is performed.

About the Database Files

Model Directory

In the **Model directory** field, this is the default file location where the predefined and custom Property Models (used with the Property Model Calculator or TC-Python) are saved and stored. Click **Modify** to open the default folder or to create a custom folder for your own models.

All Property Models (whether these are predefined or custom models) must be located in a subdirectory of the Property Model directory. For that reason it is recommended that you do not change the directory location.

See Property Model Calculator for information about using the predefined models.

Temporary Directory

In the **Temporary directory** field this is the default file path to the temporary folder, where files are stored during calculation, such as Console Mode state files (e.g. `State_4064824901731140183.POLY3`), log files, and so forth.

Click **Modify** to open the default folder, which is set during installation and based on your operating system.

Property Model Python Interpreter

This is the path to the executable Python file that is needed to work with custom property models.

See the **Property Model Framework → Best Practices** section in the TC-Python help on the website.

Check Update Interval

From the **Check update interval** list, choose **Do not check** (the default) or **On startup**.

You can also manually check for updates – choose **Help** → **Check for Updates**.

Preferred Gibbs Energy System

Use this setting to globally set the default GES version to be either GES6 (**Version 6** the default) or GES5 (**Version 5**).

About the Gibbs Energy System (GES) Module

This setting is useful if you are using the POURBAIX module (aqueous solutions) or if you have a custom database that is not compatible with GES6. The SET_GES_VERSION Console Mode command can also be used to change GES versions for a single Thermo-Calc session.

Contact Thermo-Calc Software AB at info@thermocalc.com for more information about the changes or if you encounter any issues you think are related to the new version of the calculation engine.

Parallel Calculation for Property Model Calculator

By default, the **Parallel calculation** (Property Model Calculator Configuration window) and **Parallel calculation for Property Model Calculator** (Options window for a Global setting) checkbox is selected.

The number of parallel branches (the **No. of worker processes**) can only be changed globally via the Options window. The default number of worker processes is based on the number of physical cores available on the computer. You can adjust the number of worker processes as needed, however it is still dependent on the available cores on the computer.

This checkbox is used for all the calculation types available with the Property Model Calculator in Graphical Mode. When you click **Perform**, the grid points calculated are distributed among these worker processes, which enables parallel calculations and speeds up the calculation. Click to deselect the checkbox as needed to not use these worker processes.

Use GPU for 3D Plots in Additive Manufacturing Module

By default, CPU rendering is used with the AM Calculator 3D plots. To switch to GPU rendering, which can be somewhat faster, click to select the **Use GPU for 3D plots in Additive Manufacturing Module** checkbox. In some cases using the GPU rendering can result in a black/empty plot in the **Visualizations** window. Turning the GPU setting OFF can help you troubleshoot if this behavior is observed.

Reset all Settings and the Database Cache to Defaults

Click **Factory reset** to reset all the settings to the original defaults, including clearing the database cache. The changes are applied when Thermo-Calc is restarted.

This may be useful when there are several versions of Thermo-Calc installed and there are conflicts between settings or loading databases becomes problematic. See About Cached Database Files.

Reset to Original Settings

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Graphical Mode: Default Units

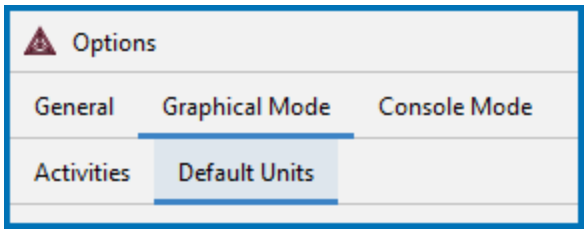
Make global changes to the default units used for the settings.

Options Window > Default Units

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Graphical Mode** → **Default Units** tabs.



Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Default Units

Setting	*Options*
Temperature	**Kelvin** (the default), **Celsius**, or **Fahrenheit**
Pressure	**Pascal** (the default), **Atmospheres**, or **Bar**
Amount	**Mole** (the default), **Gram**, **Kilogram**, **Tonne**, or **Pound**
Mass	**Tonne** (the default), **Kilogram**, **Gram**, or **Pound**

Setting	*Options*
Composition	**Mass percent** (the default), **Mole percent**, **Mass fraction**, or **Mole fraction**
Mass composition	**Mass percent** (the default) or **Mass fraction**
Energy	**Joule** (the default), **Calorie**, **Electron volt**, **Gigajoule**, **Watt hour**, or **Kilowatt hour**
Power	**Watt** (the default), **Kilowatt**, or **Megawatt**
Volume	**Cubic meter** (the default), **Cubic decimeter**, **Cubic centimeter**, or **Normal cubic meter**
Density	**Kilogram per cubic meter**, **Gram per cubic meter**, **Gram per cubic centimeter** (the default), or **Pound per cubic inch**.
Heat capacity	**Joule per mole Kelvin** (the default), **Calorie per mole Kelvin**, **Joule per kilogram Kelvin**, or **BTU per pound Fahrenheit**
Entropy	**Joule per Kelvin** (the default), **Calorie per Kelvin**, or **Electron volt per Kelvin**
Dynamic viscosity	**Pascal-second** (the default), **milliPascal-second**, **Poise**, or **centiPoise**
Kinematic viscosity	**Square meter per second** (the default), **Stokes**, or **Centistokes**
Length	**Meter** (the default), **Millimeter**, **Micrometer**, **Nanometer**, or **Ångström**
Time	**Seconds** (the default), **Minutes**, **Hours**, or **Days**
Velocity	**m/s** (the default), **mm/s**, **µm/s**, or **nm/s**
Solidification rate	**m/s** (the default), **mm/s**, **µm/s**, or **nm/s**
Strength	**Megapascal** (the default) or **Kilogram-force per square millimeter**
Stress	**Megapascal** (the default)
Vickers hardness	**Megapascal** (the default) or **Kilogram-force per square millimeter**

Setting	*Options*
Surface tension	**Joule per m^2** (the default) or **Millijoule per m^2**
Thermal gradient	**Kelvin per m** (the default)
Surface energy	**Joule per m^2** (the default) or **Millijoule per m^2**
Strain	**Percent** (the default)

Graphical Mode: Activities

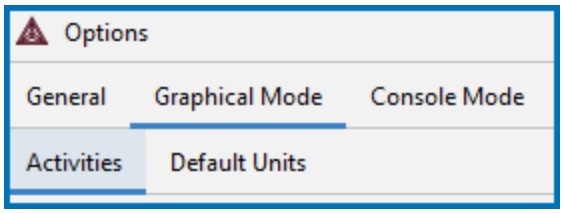
Make global changes to the various defaults used for the settings.

Options Window > Activities

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Graphical Mode** → **Activities** tabs.



Links to the Global Settings Topics

Under **Default Configurations**, there are **System definition**, **Calculation**, **Precipitation**, **Diffusion**, **Scheil**, **Process Metallurgy**, **Plotting**, and **Tabulation** setting nodes. These are described individually.

- Global Settings: System Definer
- Global Settings: Equilibrium Calculator
- Global Settings: Precipitation Calculator
- Global Settings: Diffusion Calculator
- Global Settings: Scheil Calculator
- Global Settings: Process Metallurgy
- Global Settings: Graphical and Console Mode Plotting
- Global Settings: Tables

Global Settings: System Definer

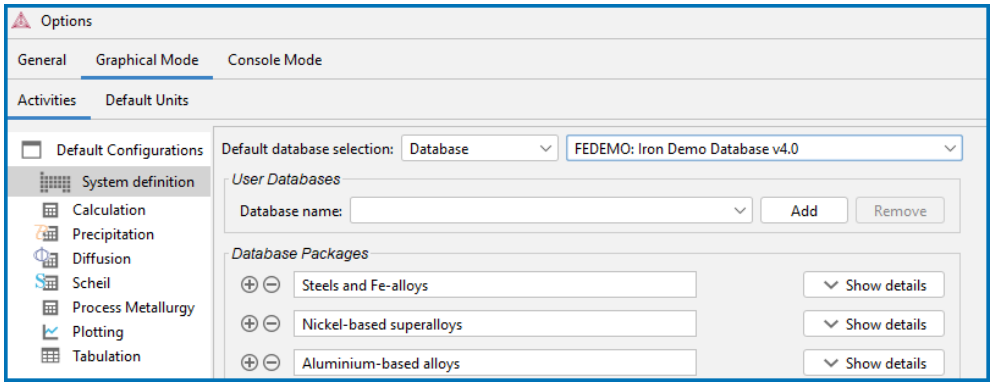
When you create a new **System Definer**, the default databases are taken from these defaults. The database selections for each System Definer can then be configured individually. Once created, the specific (local) settings for a System Definer are not affected if you later make changes to the global defaults.

Options Window > System Definition

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **System definition** node in the tree.



Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

System Definer Global Settings

Default Database Selection

The **Default database selection** can be either for a **Database** or a **Database Package**.

- If you choose **Database**, then select the default installed database to use globally for all System Definer nodes. For example, choose the latest version of the TCS Steel and Fe-alloys Database (TCFE) from the list if you have a license.
- If you choose **Database Package**, select an option from the list. These Database Packages are defined in the *Database Packages* section described below.

User Databases

Under *User Databases*, define the **Database name** after adding a custom database.

Click **Add** to navigate to a custom database on your computer. After you have added the user database it is available from the list to choose as the default.

Once a user database is added to the **Database name** list, you can also click the **Remove** button to delete it from your project.

Database Packages

Based on the installed databases, there are also default *Database Packages* available. Use this section to organize your own sets of databases that you use together often.

Create and remove *Database Packages* by clicking the **Add a database package** ⊕ button or **Remove this database package** ⊖ button.

> The addition or removal of a database package does not take effect until a new System Definer node is defined.

Click **Show Details** to display the list of databases included with the package. Click **Hide Details** to only display the name of the package.

Learn More

System Definer, Creating a Database Package, and Clearing a Database Package Message

Global Settings: Equilibrium Calculator

When you create a new **Equilibrium Calculator**, its initial settings are taken from these defaults. The settings of each Equilibrium Calculator can then be configured individually. Once created, the specific (local) settings for an Equilibrium Calculator are not affected if you later make changes to the global defaults.

The available default settings that you set here are described in the topic Options Tab Settings.

Options Window > Calculation

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **Calculation** node in the tree.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Global Settings: Diffusion Calculator

When you create a new **Diffusion Calculator**, its initial settings are taken from these defaults. The settings for each Diffusion Calculator can then be configured individually. Once created, the specific (local) settings are not affected if you later make changes to the global defaults.

The available default settings that you set here are described in the topic Options Tab Settings.

Options Window > Diffusion

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **Diffusion** node in the tree.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Global Settings: Precipitation Calculator

When you create a new **Precipitation Calculator**, some of its initial settings are taken from these defaults. The settings for each Precipitation Calculator can then be configured individually. Once created, the specific (local) settings for a Precipitation Calculator are not affected if you later make changes to the global defaults.

The available default settings that you set here are described in the topics Matrix Phase Settings and Precipitate Phase Settings.

Options Window > Precipitation

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **Precipitation** node in the tree.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

The available default settings

Global Settings: Process Metallurgy

When you create a new **Process Metallurgy Calculator**, its initial settings are taken from these defaults. The settings for each Process Metallurgy Calculator can then be configured individually. Once created, the specific (local) settings are not affected if you later make changes to the global defaults.

The available default settings that you set here are described in the topic Options Tab.

Options Window > Process Metallurgy

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab then the **Process Metallurgy** node in the tree.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Global Settings: Scheil Calculator

When you create a new **Scheil Calculator**, its initial settings are taken from these defaults. The settings of each Scheil Calculator can then be configured individually. Once created, the specific (local) settings for a Scheil Calculator are not affected if you later make changes to the global defaults.

The available default settings that you set here are described in the topic Advanced Options.

Options Window > Scheil

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **Scheil** node in the tree.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Global Settings: Tables

When you create a new **Table Renderer**, its initial settings are taken from these default settings. The settings of each Table Renderer can then be configured individually. Once created, the settings of a Table Renderer are not affected by changes in the default settings.

Table Renderer: Configuration Settings

Options Window > Tabulation

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Activities** tab and the **Tabulation** node in the tree.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Global Settings: Graphical and Console Mode Plotting

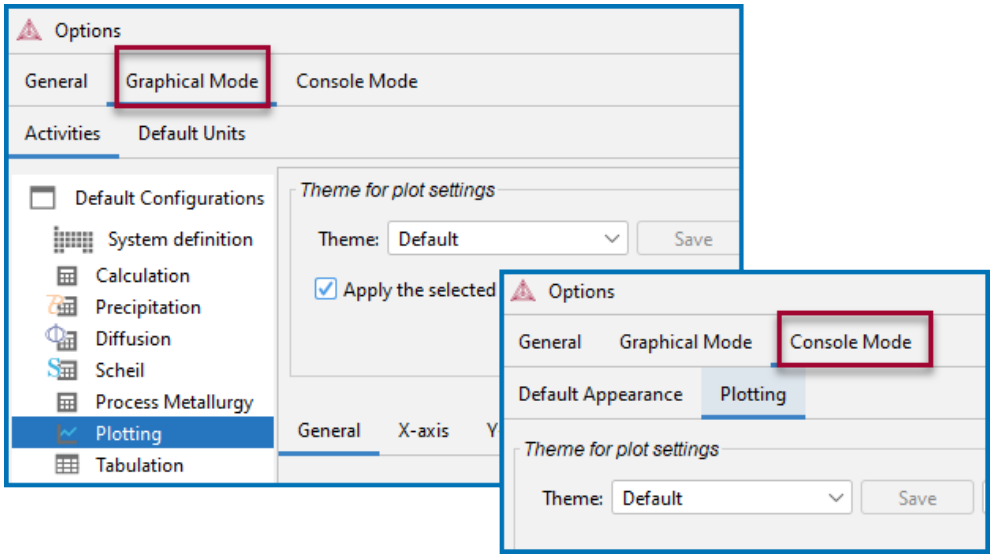
Globally configure several default plot settings or work with a **Theme**. There are many options available and these are generally divided into these topics:

- Global Plot Settings: Design the Look and Feel to set a variety of options for titles, legends, labels, fonts, colors, lines, grids, data points, anchors, data points, numbers, and to adjust image quality.
- Global Plot Settings: About Plot Themes to create, edit, import, export, rename, or delete plot themes.
- Global Plot Settings: Plot Area Size to set the Plot Area Size.

Options Window > Plotting

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.



On the **Options** window you can access the same settings either from the **Graphical Mode** or **Console Mode** tabs.

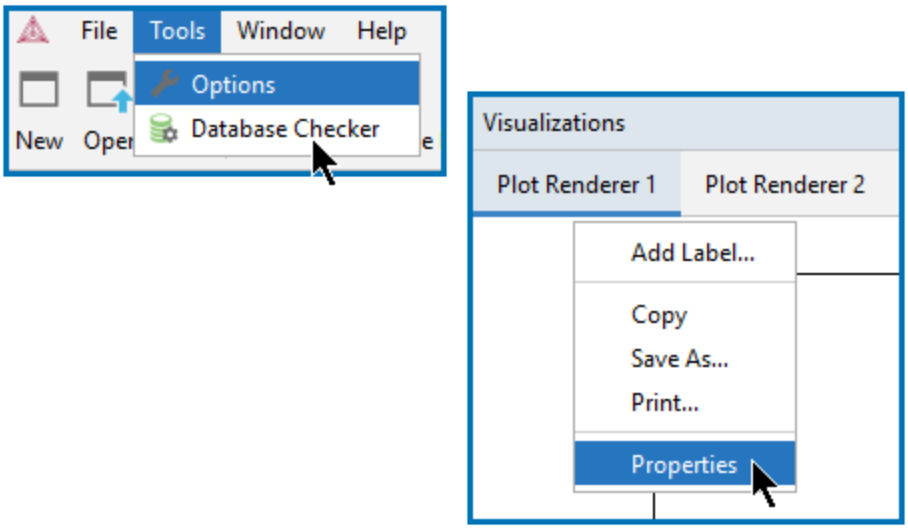
- Click the **Graphical Mode → Activities** tabs and then click the **Plotting** node in the tree, or
- Click the **Console Mode → Plotting** tabs.

The Console Mode and Graphical Mode plot settings are independent of each other once you start making changes to any predefined or custom Themes, or when applying changes to individual plots in either Mode.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Global vs Local Plot Settings

For both Graphical Mode and Console Mode, you can work with plots and themes from both the global or local settings windows. Global settings are accessed on the **Options** window and local plot settings from the **Visualizations** window when you right-click an individual plot and choose **Properties**.



Local Plot Property Settings

Plot Renderer (Graphical Mode)

When you create a new Plot Renderer in Graphical Mode, its initial settings are taken from the default settings and theme. The settings can then be configured individually. Once created, the settings of a Plot Renderer are not affected by changes to the default global settings unless you are working with themes and then save or create a custom theme. See Global Plot Settings: About Plot Themes.

Visualizations Window Individual Plots (Graphical or Console Mode)

To make local changes to the appearance of a specific plot for either Graphical Mode or Console Mode, in the **Visualizations** window right-click a plot and select **Properties**. In the **Plot Properties** window a variety of settings can be made. These are mostly the same settings as in the **Options** window.

You can also edit some properties for individual plot lines (the color, the line width and type, and whether data points are included). In the **Visualizations** window, hover the mouse over a plot line. The crosshair cursor turns into a cursor resembling a pointing hand when it is over a line that can be clicked. Alternatively, hold down the <Ctrl> key while you move the cursor around the plot to only display it as a crosshair and prevent unintended edits.

When changes are made that differ from the plot theme applied (i.e. a predefined or custom theme) then blue text next to the theme section alerts you to the change. See Global Plot Settings: About Plot Themes for details.

Global Plot Settings: About Plot Themes

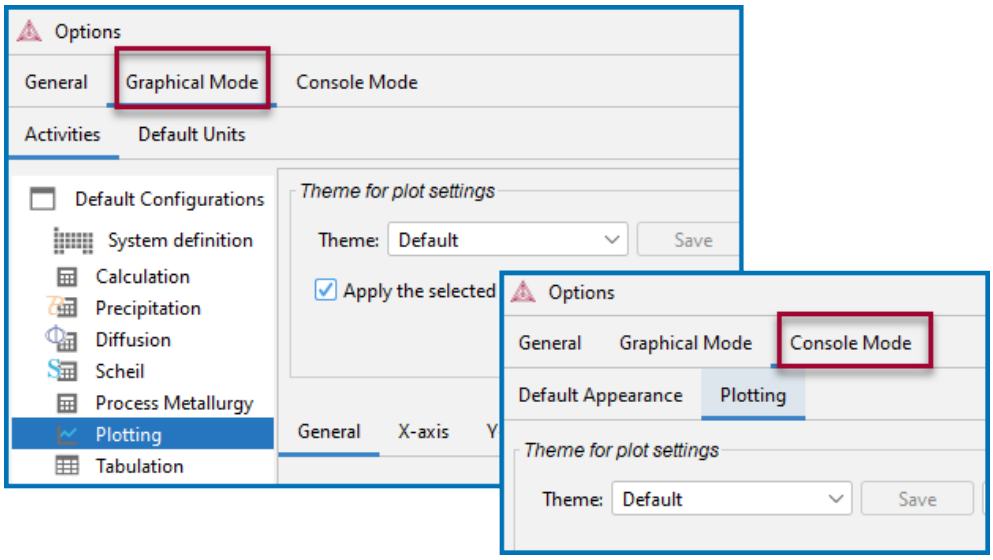
Make global changes to the various defaults used for the settings.

Working with Plot Themes

Options Window > Plotting

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.



On the **Options** window you can access the same settings either from the **Graphical Mode** or **Console Mode** tabs.

- Click the **Graphical Mode** → **Activities** tabs and then click the **Plotting** node in the tree, or
- Click the **Console Mode** → **Plotting** tabs.

The Console Mode and Graphical Mode plot settings are independent of each other once you start making changes to any predefined or custom Themes, or when applying changes to individual plots in either Mode.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Location of Local and Global Theme Settings

Plot **Theme** settings are accessed in the *Theme for plot settings* section:

- Locally on the **Plot Properties** window (right-click any plot in the **Visualizations** window).
- Globally on the **Options** window for both Graphical Mode and Console Mode.

Predefined Plot Themes

There are these predefined plot themes available: **Default**, **Large**, **Small**, or **Publication**. For these themes, you can use them as a template to create your own custom theme or export the json file for use elsewhere.

The predefined plot themes have many of the same settings where key differences include font sizes, plot area size and type, scaling, data point marker radius, tick mark length, and line width. For all predefined themes, the default font is SansSerif with the style Plain (normal).

See Predefined Theme Settings for details and differences.

Custom Themes

You can create, edit, delete, rename, import, and export custom themes.

Plotting Input is Changed: Ignore, Create, Update, or Discard the Changes

When any change is made to a predefined or custom theme, either locally or globally, a blue text message under the *Theme for plot settings* section reminds you that *at least one plotting input has changed*.

When you see this blue text you can:

- Ignore it and apply the local changes to a specific plot. In this case when you click **Perform** or **Perform Tree** to update the plot in the **Visualizations** window the change only applies to this one plot. The blue text continues to be visible.
- Create a new custom theme (click **Save as**). If this is done locally on the **Plot Properties** window, the new theme is added to the global list but only applied locally to the plot. The blue text is gone.
- Update an existing custom theme (click **Save**). If this is done on the **Plot Properties** window, the changes are applied globally and applied locally to the plot. The blue text is gone.
- Discard the changes and click **Reset to original settings** (for global **Options** windows you may need to scroll, it is in the bottom right of the window) or **Reset** (for local settings on the **Plot Properties** window). The blue text is gone.

Working with Plot Themes

Whether working with a predefined or custom theme, there are common tasks you can do such as using a theme as a template to create a new custom theme, or you can import and export .json files.

Once created, there is more flexibility with the custom themes.

Applying Predefined or Custom Themes to a Plot Globally or Locally

1. In the *Theme for plot settings* section, choose an option from the **Theme** list.
2. Click **OK** to apply the theme. Click close (X) or **Cancel** to exit without saving, or **Reset** to revert any changes to the original saved settings.

- On the **Options** window this is applied globally.
- On the **Plot Properties** window this is applied locally to the specific plot in the **Visualizations** window.

Applying Plot Themes to Project Files (Graphical Mode Only)

There is some interaction between these checkboxes as detailed in the table below.

Checkbox	*Location*	*Actions*	*Comments*
Apply the selected theme to opened file [.tcu]	**Options** window.	Select the checkbox to apply a theme globally to all project files being opened. Click to clear the checkbox to allow each file to keep existing plot settings.	When this checkbox is selected or deselected, it also changes the **Apply plot theme from Tools/Options** checkbox to match, i.e. these are connected in one direction.
Apply plot theme from Tools/Options	**Open File** window. See Opening Project Files	Select the checkbox to apply a theme locally to the specific project file being opened.	If this checkbox is selected or deselected it only applies to the specific project file being opened, i.e. the **Apply the selected theme to opened file [.tcu]** checkbox does not change.

Checkbox	*Location*	*Actions*	*Comments*
		Click to clear the checkbox to allow the specific file to keep existing plot settings.	

If you have a project file with calculated results and local settings applied to plots i.e. applied from the **Visualizations** window to a specific plot via the **Plot Properties** settings window, then click to clear the local setting as you open the file using **Apply plot theme from Tools/Options** checkbox. Otherwise the default global settings are applied to all plots and you would need to individually change these settings back to your original design. Alternatively, experiment with applying a predefined theme, e.g. **Publication**, as this could be sufficient for your final output.

Creating a Custom Plot Theme in Thermo-Calc

To create a custom theme, you start by making changes to the selected theme type and then save it with a new name using the **Save as** option.

You can work with themes from both the global or local settings windows. Global settings are accessed on the **Options** window (Windows: **Tools** → **Options**; Mac: **Thermo-Calc** *<version>* → **Preferences**) and local plot settings accessed from the **Visualizations** window when you right-click an individual plot and choose **Properties**.

For example, the **Background color** is changed to RGB **#FF4EE2** for the **Default** theme. Next to the *Theme for plot settings* section, a message in blue alerts you that *at least one plotting input has changed*.

To save the new settings including the change to the background color (you cannot replace the predefined themes), you also must make sure to click **OK** at the end.

1. In the *Theme for plot settings* section, click **Save as**. The **New theme plot setting** window opens.
2. In the **Theme name** field enter the new custom theme name. The new theme is now available from the list.
3. On the **Plot Properties** or **Options** window, click **OK** to finish. Click close (X) or **Cancel** to exit without saving, or **Reset** to revert any changes to the original saved settings.

Importing a Custom Theme

Use the **Import** option to add your own theme with the file type of *.json. Once the file is imported, you can make further changes and save the new theme settings as needed. If you import a theme that uses the same name one already in the list (e.g. **Publication**), the imported theme name is changed automatically by adding a number at the end of its name (e.g. **Publication_1**). You can then **Rename** the theme to give it a unique name.

1. In the *Theme for plot settings* section, click **Import**.
2. Navigate to where you saved the .json file, select it, then click **Open**.
3. During the import, and if there are incorrect input values, you are prompted with an error message describing the issue with the file.

   This could be for various reasons, such as entering a value that is not available (i.e. it is out of bounds), or the file contains information about an unavailable setting. In particular these settings must be correctly entered in the import file: font sizes, tie line, number of decimals, border width, data points marker radius, x and y axis tick marks length, and jpeg compression level.

4. If it is a successful import, click **Rename** to give the theme a unique name.
5. On the **Plot Properties** or **Options** window, click **OK** to finish. Click close (X) or **Cancel** to exit without saving, or **Reset** to revert any changes to the original saved settings.

Exporting a Theme

Use the **Export** option to export an existing theme or after creating a custom theme.

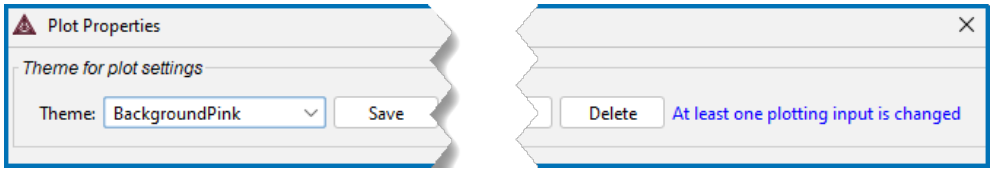
You can also export an existing theme, edit it in a text editor (making sure to save the file with file extension .json), and then **Import** this new .json file. However, it is better to use the Graphical User Interface to prepare your custom theme in order to minimize errors during import.

1. In the *Theme for plot settings* section, select the **Theme** to export.
2. Click **Export**.
3. Navigate to where you want to save the .json file. Enter a **File name** as required then click **Save**.

Deleting a Custom Theme

After you have created a custom theme, it can be deleted from the list. Predefined themes cannot be deleted.

If the selected theme is deleted from the global Options section, and you open a project or plot that uses the now deleted theme, the default theme is selected but it includes the message in blue next to the section to remind you that *at least one plotting input has changed*. In the example the custom theme, **BackgroundPink**, was deleted at the global level but at the local level for the specific plot open in the **Visualizations** window the settings are retained and the message displays.



1. In the *Theme for plot settings* section, select the **Theme** to delete.
2. Click **Delete**.
3. Click **OK** on the window that opens.
4. On the **Plot Properties** or **Options** window, click **OK** to finish. Click close (X) or **Cancel** to exit without saving, or **Reset** to revert any changes to the original saved settings.

Renaming a Custom Theme

After you have created or imported a custom theme, it can be renamed. Predefined themes cannot be renamed.

1. In the *Theme for plot settings* section, select the custom **Theme** to rename.
2. Click **Rename**.
3. Enter the new name in the field. Click **OK**.
4. On the **Plot Properties** or **Options** window, click **OK** to finish. Click close (X) or **Cancel** to exit without saving, or **Reset** to revert any changes to the original saved settings.

Predefined Theme Settings

The following lists the applied attributes for each of the predefined themes: **Default**, **Large**, **Small**, or **Publication**.

Global Plot Settings: About Plot Themes

Image Quality

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Default file format and DPI	.png and Use default resolution (300 DPI)	.png and Use default resolution (400 DPI)	.png and Use default resolution (300 DPI)	.png and 600 DPI

Fonts, Style, Size, and Format

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Title font (SansSerif) and Style (Plain/normal). The size is different for each.	18	26	16	24
Legend font (SansSerif) and Style (Plain/normal). The size is different for each	11	22	9	20
Label font (SansSerif) and Style (Plain/normal). The size is different for each.	16	24	14	22
Header font (SansSerif) and Style (Plain/normal). The size is different for each.	12	18	10	16
X and Y Axis Label font (SansSerif) and Style (Plain/normal). The size is different for each.	18	28	16	26

Plot Setting	*Default*	*Large*	*Small*	*Publication*
X and Y Axis Tick Label font (SansSerif) and Style (Plain/normal). The size is different for each.	14	24	12	22
Title format, Label format, Axis label format (X- and Y-axis)	Plain text			

Colors

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Title color, Legend color, Label color, Header color, Border color, Axis label color (X- and Y-axis), Axis tick label color (X- and Y-axis)	rgb ff000000			
Legend background color, Background color, and Canvas color	rgb ffffffff			
Color option	Vivid (in json file it is PlotColorOption 6)			

Checkbox Selections

Selected = Yes

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Show grid	No			
Show legend	Yes			
Show anchor	Yes			
Retain labels	Yes			
Show header	No			

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Show tick labels (X- and Y-axis)	Yes			
Tick marks outside (X- and Y-axis)	Yes			

Plot Area Size

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Fit the plot area size to the enclosing window (selected), with the plot area height and width preset as indicated	400 x 400	700 x 700	400 x 400	Not selected. By default it is 600 x 600
Fit the plot area size to a square with a width/height of the enclosing window	Not selected (in json file it is plotAreaSizeType: Window_Fit)			Selected (in json file it is Square_Fit)
Define the plot area size	Not selected			
Scale plot attributes using the system scaling factor	Yes			

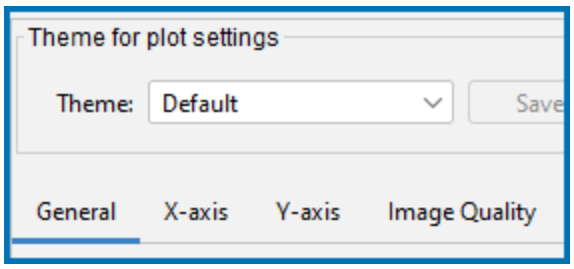
Other Settings

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Show every Nth tieline (only relevant for phase diagrams)	1			
Border width	1	1	1	3
Data points marker	None (in json file this is called Symbol and set to 0)			
Legend phase caption style	None (in json file it is set to 0)			

Plot Setting	*Default*	*Large*	*Small*	*Publication*
Data points marker size (if you choose a data points marker symbol, then this is the default size applied)	3	5	3	5
Tick mark length (X- and Y-axis)	6	8	4	6
Number of decimals	2			
Numeric format	Auto (in json file it is 2)			
Line width	0	2	0	3

Global Plot Settings: Design the Look and Feel

Make global changes to the various defaults used for the settings. The following global design settings are available for both Graphical Mode and Console Mode from the **General** tab or as indicated for the **X-axis**, **Y-axis**, and **Image Quality** tabs.



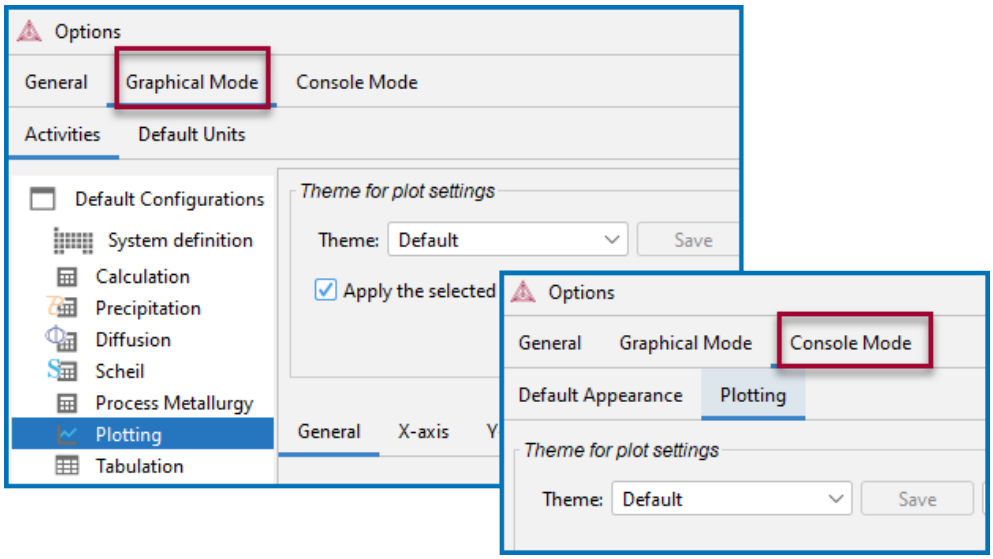
The plot settings listed below are grouped into these general categories

- Titles, Legends, Headers, and Labels
- Fonts and Colors
- Lines and Grids
- Data Points, Anchors, and Numbers
- Image Quality

Options Window > Plotting

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** <*version*> → **Preferences** or **Settings** or press <⌘> on the keyboard.



On the **Options** window you can access the same settings either from the **Graphical Mode** or **Console Mode** tabs.

- Click the **Graphical Mode → Activities** tabs and then click the **Plotting** node in the tree, or
- Click the **Console Mode → Plotting** tabs.

The Console Mode and Graphical Mode plot settings are independent of each other once you start making changes to any predefined or custom Themes, or when applying changes to individual plots in either Mode.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Titles, Legends, Headers, and Labels

Title Format, Label Format, and Axis Label Format

On the **General** tab (**Title format** and **Label format**) and the **X-axis** and **Y-axis** tabs (**Axis label format**) select **Plain text** (the default) or **LaTeX formatted text**.

For **LaTeX formatted text** you can use the LaTeX math text to enter text. See ADD_LABEL_TEXT and Plot Labels for more details.

Show Legend

Select the **Show legend** checkbox to include a legend on the plot. By default no legend is displayed.

Tick Mark Length, Location, and Show Tick Labels

On the **X-axis** and **Y-axis** tabs, choose or enter a **Tick mark length** (**6** is the default).

The defaults are to have the **Tick marks outside the chart** and to **Show tick labels**. Click to clear the checkboxes as required.

Legend Phase Caption Style

For the **Legend phase caption style**, choose **None**, **All**, **Constitution description**, or **Ordering description**.

About Legend Styles

Retain Labels

By default the **Retain labels** checkbox is selected. Plot labels are kept (retained) when plots are updated. It can be applied globally or locally to individual plots.

Show Header

Click to select the **Show header** checkbox to display the basic details about the plot along the top. This includes the date and time the plot is generated, the database used, and the properties.

Fonts and Colors

Color Switching

This is related to the **Light** and **Dark** look and feel modes set under **Tools → Options** then on the **General** tab. See Global General Settings.

This section is about Global changes to the default output for all plots for any future project files. Global settings take effect for *new* project files and/or *new* plots *added* to existing projects. That is, the default setting only affects how the plots start out initially. Once a plot is created the settings are locked to the mode and can only be changed locally.

You can locally change an existing plot in a project. See Changing the Plot Properties for details.

Select a **Color switching** option: **Switch automatically between Light mode and Dark mode** (the default), **Always use Light mode colors**, or **Always use Dark mode colors**.

Tie lines and invariant lines are the same color for both Light and Dark modes, i.e. these colors do not change.

Use the **Color switching** option to override the look and feel settings that may not be optimal. For example, when preparing a plot for publication, the **Dark** mode plot or line colors may not work well or do not follow a journal's guidelines. In other words, you can view and export the plot with **Light** mode color settings even though the interface is using Dark mode, and vice versa.

Fonts: Title, Legend, Label, Header, Axis Label, and Tick Label

On the **General** tab (**Title**, **Legend**, **Label**, **Header**, and on the **X-axis** and **Y-axis** tabs (**Axis Label**, **Tick Label**, click **Modify** to edit the **Font Name**, **Style**, **Size**, and **Color**.

Legend Background Color, Background Color, Canvas Color, Border Color

To change various background color attributes, click **Modify** to choose a color or enter a specific color.

Lines and Grids

Show Grid

Click to select the **Show grid** checkbox to include a grid on the plot. By default no grid is displayed.

Show Every Nth Tieline

Tielines are only applicable to phase diagrams.

Choose an integer value ranging from 0 to 99.

Color Option (Plot Lines)

For the for plot line colors, choose a **Color option** from the list: **Legacy**, **Printer friendly**, **JFree chart**, **Pastel**, **Medium dark**, **Bright dark**, **Vivid**, or **Earth**.

This option is also available for specific plot lines. To change the color of an individual plot line double-click it in the **Visualizations** window and use the color palette to define it or enter a specific color.

Border Width

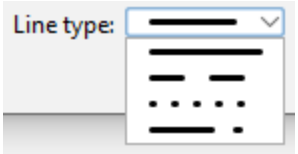
Choose a plot **Border width** between **1** (thin, the default) and **10** (thick).

Line Width

For the plot line width, choose a **Line width** from the list. These options are also available for specific plot lines. To change an individual plot line width double-click it in the **Visualizations** window.

Line Type

This option is only available for individual plot lines. To change an individual plot line type double-click it in the **Visualizations** window and choose a **Line type** from the list.



Data Points, Anchors, and Numbers

Show Anchor

Click to select the **Show anchor** checkbox. By default, an anchor between the label and the plot point is displayed.

Data Points Marker

From the **Data points marker** list, scroll to select a symbol to use to display the data points on plot lines. This option is also available for specific plot lines. To show data points on an individual plot line double-click it in the **Visualizations** window and select a symbol from the **Marker** list.

Data Points Marker Size

Choose the **Data points marker size** between **1** (small) and **10** (large). The default is 3.

Number of Decimals

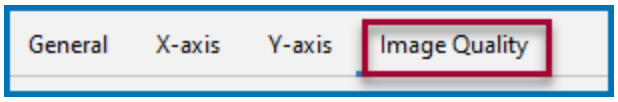
Choose the **Number of decimals** to display in the plot. The default is 2.

Numeric Format

Choose the **Numeric format** to display in the plot **Auto**, **Decimal**, or **Scientific**.

Image Quality

Click the **Image Quality** tab to access the settings below.



Choose a **Default file format**: **Portable Network Graphics .png** (the default), **Graphical Interchange Format .gif**, **Enhanced Windows Metafile .emf**, **Portable Document Format .pdf**, **PostScript .ps**, **Scalable Vector Graphics .svg**, or **Joint Photographic Experts Group .jpg**.

The following settings are only available for .png and .jpg file formats.

To change the resolution of a *.png or *.jpg image, click to clear the **Use default resolution** checkbox. Then enter a numerical value in the **Dots per inch (DPI)** field. For .*jpg files, you can also use the slider to choose a number between 0 and 1 for the **JPG quality**. The default is 0.9. The lower the number, the smaller the file.

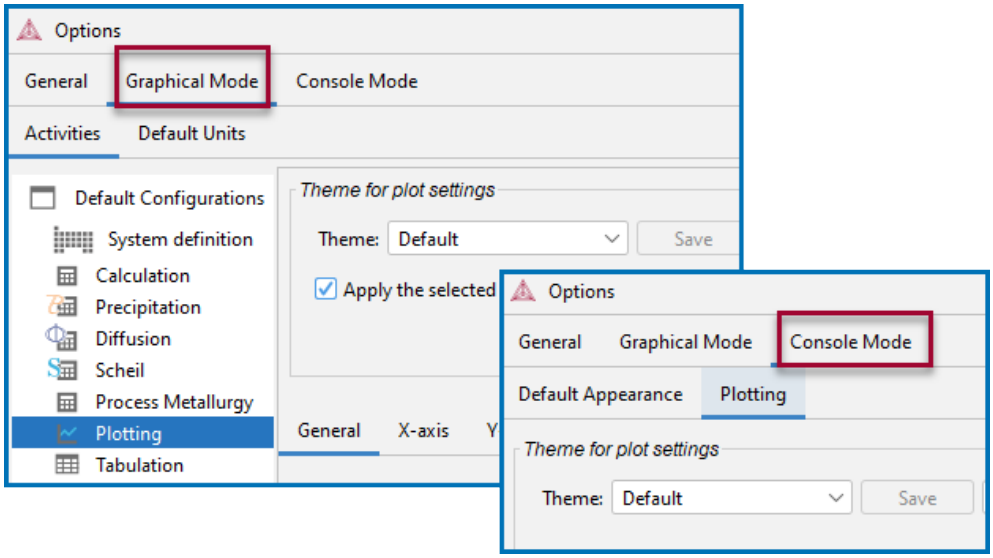
Global Plot Settings: Plot Area Size

Make global changes to the various defaults used for the settings.

Options Window > Plotting

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.



On the **Options** window you can access the same settings either from the **Graphical Mode** or **Console Mode** tabs.

- Click the **Graphical Mode** → **Activities** tabs and then click the **Plotting** node in the tree, or
- Click the **Console Mode** → **Plotting** tabs.

The Console Mode and Graphical Mode plot settings are independent of each other once you start making changes to any predefined or custom Themes, or when applying changes to individual plots in either Mode.

Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Plot Area Size Settings

For local or global application, the default settings applied in the *Plot Area Size* section are initially based on the selected predefined theme. Once a custom theme is available from the list, these default settings can also be related to how the custom theme is set up.

See Predefined Theme Settings for details and differences between the predefined themes initially available in the list.

In the *Plot Area Size* section, choose an option.

Click **Fit the plot area size to the enclosing window** and as the **Visualizations** window is resized, the plot moves and adjusts at the same time. This setting is the default for the **Default**, **Large**, and **Small** themes.

Click **Fit the plot area size to a square with a width/height of the enclosing window**. With this option, the minimum value of the width and height of the **Visualizations** window is used as the dimension of the fixed plot area and in a square.

Click **Define the plot area size** to enter a **Plot area height** and **Plot area width (not applicable to triangular plots**. The units are pixels and the size is kept as the size on the screen (96 dpi). This is the default for the **Publication** theme.

For the predefined themes this is already set for each as indicated below. As needed, you can change these defaults for one plot or create a new theme.

- **Default** and **Small** are set to 400 x 400
- **Large** is set to 700 x 700
- **Publication** is set to 600 x 600

Click to deselect the **Scale plot attributes using the system scaling factor** checkbox to scale all plot attributes (i.e. labels, font size, axes, tick marks, etc.) independently of the screen size and resolution. This maintains consistent attribute sizing between different plots.

The minimum value of the width and height of the **Visualizations** window, or the fixed plot is used for resizing, in the following parts of the plot:

- X- and Y-axis label
- Legend font
- Tick label font
- Tick mark length
- Title
- Header
- Line width
- Data point width
- Experiment data size
- Logo

Global Settings: Console Mode Default Appearance

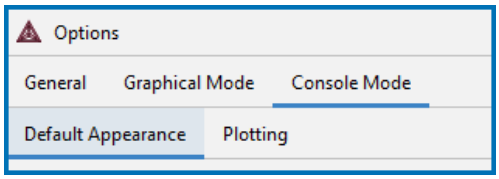
Make global changes to the various defaults used for the settings.

Options Window > Console Mode

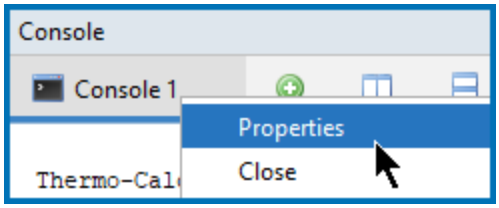
To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

then click the **Console Mode** → **Default Appearance** tabs.



To change these defaults for an individual Console tab, in Console Mode, right-click the tab and select **Properties**.



Reset to original settings: In the lower corner of the window, click the **Reset to original settings** button to restore the original settings. You may have to scroll or expand the window to see the button. For local plot settings, there is a **Reset** button available instead.

Default Appearance Settings

Console Name

The default **Console name** prefix is `Console` or enter another name to display as the tab label.

Buffer Size

The default **Buffer size** is 40,000.

In Console Mode, sometimes the output overflows the window text buffer. This is how to increase the buffer size.

1. In the Console window right-click the tab to edit. For example, if this is the first tab, it is labeled **Console 1**.
2. Select **Properties** and either enter a number in the field or use the arrows to increase or decrease the **Buffer size**.

Fonts: System Output, Command Prompt, or User Input

Click **Modify** to open the **Select Font** window and makes changes to the **Font Name**, **Style**, **Size**, or choose from a variety of color options for the font as required. The **Show only fonts that support Greek characters** checkbox is selected by default.

Background Color

Click **Modify** to open the **Select Color** window to choose a background color for the Console Mode window where you enter commands.

Default Directory

Click **Modify** to change the default directory file path to where the various file types are saved.

Parameters, Functions, and Variables

This section is applicable to both Console Mode and Graphical Mode with respect to understanding the format these are to be written in for Thermo-Calc to use the parameter, function, or variable. However, many of the sections are specific to Console Mode where the explicit use of these terms is more often used.

To learn about using variables and functions, in Graphical Mode, see T_07: User-Defined Functions and in Console Mode, see example 44 .

Topics to Explore ›

Specifying Parameters **3141**

Default Parameters Values *3141*

Specifying Parameters

This section or topic is specific to Console Mode.

Running a command typically requires that several parameter values are specified, which can be done directly in the command line after the command name. For example, to set an axis variable for a stepping or mapping operation, enter:

```
SET_AXIS_VARIABLE 1 X(FCC,FE) 0 0.89 0.025
```

You can also use SET_AXIS_VARIABLE and press <Enter>. At the command line prompt, you then specify the parameters one at a time.

On all command lines, you can enter a question mark (`?`) for help. For some parameters, enter two question marks (`??`) for more detailed information.

Default Parameters Values

When you are requested to specify a parameter, Thermo-Calc usually suggests an appropriate default value, which is displayed at the prompt between two slash signs (//). For example, this prompt means the default answer is `TERMINAL`:

```
OUTPUT FILE /TERMINAL/:
```

Press <Enter> to accept the default.

If you specify some parameters directly after the command name, then you can still choose to accept default values for some parameters.

To accept the default value for a parameter, type a comma (,) instead of a value for that parameter. For the comma to be interpreted correctly, type a blank space on each side of the comma. However, if you accept the default values for several parameters that follow each other, then the commas can be typed in without blank spaces separating them: (, , ,) is interpreted in the same way as (, , ,).

For some commands and parameters, Thermo-Calc treats the values previously assigned as default values if the command is used again. For example, if the first stepping or mapping axis variable is specified as:

```
SET_AXIS_VARIABLE 1 X(FCC,FE) 0 0.89 0.025
```

Then if you want to change a parameter value for this axis variable, type:

```
SET_AXIS_VARIABLE 1 , 0.1 ,,,
```

This changes the minimum value from 0 to 0.1 at which a stepping or mapping operation halts. The other parameter values remain the same. Consequently, what is typed is equivalent to:

```
SET_AXIS_VARIABLE 1 X(FCC,FE) 0.1 0.89 0.025
```

Thermodynamic Variables and Units

The following topics are about the different thermodynamic variables recognized by Thermo-Calc. The topics have information about how to define new derived variables and functions and how to express thermodynamic variables in non-default units.

The POLY module only recognizes default units, which are SI units.

About Operators and Functions

Sometimes you need to specify functions when setting up a system. For example, to make global conditions vary as a function of time.

The following operators can be used in writing functions. Use a semi-colon (;) to mark the end of a function.

Available Operators for Writing Functions

Operator	*Description*
+, -, *, /	Addition, subtraction, multiplication, division
**	Exponentiation, raising one quantity to the power of another, e.g. x^2.
ABS()	Absolute value
ERF(X)	Error function
EXP(X)	Exponential
LOG(X)	Natural logarithm
LOG10(X)	Base 10 logarithm
SIGN(X)	Sign function SIGN(X) is -1 when X<0, is 0 when X=0 and is 1 when X>0.
SIN(X), COS(X), TAN(X), ASIN(X), ACOS(X), ATAN (X)	• Trigonometric functions: sine, cosine, tangent • Inverse trigonometric functions: arcsine, arccosine, arctangent
SINH(X), COSH(X), TANH(X), ASINH(X), ACOSH (X), ATANH(X)	• Hyperbolic trigonometric functions • Inverse hyperbolic functions

Operator	*Description*
SQRT(X)	Square root

Thermodynamic Variables

Thermophysical Properties Variables and Elastic Properties Variables

There are different thermodynamic variables in Thermo-Calc. Some are *state variables*, for example temperature, pressure and mole fraction. These characterize the equilibrium state of a system. You set them when you define your system in the POLY module before performing a calculation. They are also used in other modules such as DATA, GIBBS and PARROT. State variables that involve components can be used for the defined components, but not for any species. (To define new components in a defined system, use DEFINE_COMPONENTS).

Other useful thermodynamic variables are derive from state variables with a mathematical function. Some derived variables are pre-defined by Thermo-Calc, such as normalized energetic and compositional extensive state variables for example. You use these by appending various normalizing suffixes to abbreviations that are associated with the state variables.

Thermodynamic variables can also be divided into extensive variables and intensive variables. An extensive variable is a variable whose value depends on the size of the system, whereas an intensive variable is a variable whose value is independent of system size.

More information about thermodynamic variables is available. Use the command INFORMATION, with a subject keyword such as one of the following as argument: STATE VARIABLES, INTENSIVE VARIABLES, EXTENSIVE VARIABLES, DERIVED VARIABLES, CONDITIONS (for condition settings), AXIS-VARIABLES (for stepping/mapping variable settings).

Common Thermodynamic Variables

The tables below list common thermodynamic variables. Most of these can be used to define equilibrium conditions in the POLY module unless otherwise indicated.

The variables are divided into the following tables:

- Intensive variables
- Energy-related extensive variables for whole system or for a phase
- Compositional extensive variables (overall amount of components in the whole system, or amount of a component in system or in a phase)
- Constitutional composition-related extensive variables (amount of a constituent/species on a sublattice site in a phase)
- Special quantities

How to Read the Tables

- The *Abbrev*. column shows the abbreviation that you use in the POLY module for referring to the variable. If the variable must be given any arguments, then these are given in parenthesis directly after the abbreviation. For most variables, this is also the abbreviation that you use to refer to the variable in other modules. However, some variables are referred to with a different abbreviation in the POST module. If this is the case, then this is noted at the bottom of the table.
- Variables that are specific to a species, in which case the species is specified as an argument (*sp* in the table below). If there are two or more sublattices in a given phase, then this argument is given as `constituent#sublattice`. This indicates a constituent on a specific sublattice or site in the phase (referred to by the # sign and a digit). For example, `y(BCC,C#2)` stands for the site fraction of the C species on the second sublattice site of the BCC_A2 solution phase.
- The *Unit* column show which unit that you can use to express the variable in the POLY module. This unit is always the SI unit. In other modules, state variables may be expressed in other units.
- The *Suffix* column shows the suffixes you can append to the variables. The `R` suffix can be used with all compositional extensive state variables, but the suffix does not always change the value of the variable. This is indicated by putting the `R` in parenthesis.

Links to Topics

These types of variables are listed in the following topics:

- Intensive Variables
- Extensive Variables
- Special Quantities
- The u-Fraction Variable
- Suffixes

Intensive Variables

V	Abbrev.	Unit	Description	Domain	Suffix
T	T[1]	K	Temperature	System	
P	P	Pa	Pressure	System	
μ	MU(comp)	J/mol	Chemical potential	Component	R
	MU(sp,ph)[2]			Species relative to a solution phase	R
a	AC(comp)	N/A	Activity	Component	R
	AC(sp,ph)[2]			Species relative to a solution phase	R
	LNAC (comp)[3]		ln(Activity)	Component	R
	LNAC (sp,ph)[2]			Species relative to a solution phase	R

[1] When plotting in POST, besides T (Kelvin), you can also use T_C or T_F to plot temperature in °C or °F.

[2] Only for single-substitutional-lattice solution phases such as AQUEOUS solution and GASeous mixture phases and for interacting species on the substitutional sublattice of two-sublattice solution phases (such as the phases BCC_A2 and M6C phases).

[3] In natural logarithm (lnAC=MU/RT).

Extensive Variables

- Energy-Related Extensive Variables for Whole System or for a Phase
- Compositional Extensive Variables
- Constitutional Composition-Related Extensive Variable

Energy-Related Extensive Variables for Whole System or for a Phase

V	Abbrev.	Unit	Description	Domain	Suffix
V	V	m^3	Volume	System	M, W, V, R
	V(ph)[1]			Phase	M, W, F, R
	VP(ph) [2]			Phase	M, W, V, R
G	G	J	Gibbs energy	System	M, W, V, R
	G(ph) [1]			Phase	M, W, V, F, R
A	A	J	Helmholtz energy	System	M, W, V, R
	A(ph) [1]			Phase	M, W, V, F, R
U	U	J	Internal energy	System	M, W, V, R
	U(ph) [1]			Phase	M, W, V, F, R
H	H	J	Enthalpy[6]	System	M, W, V, R
	H(ph)			Phase	M, W, V, F
S	S	J/K	Entropy[6]	System	M, W, V, R
	S(ph) [1]			Phase	M, W, V, F, R

V	Abbrev.	Unit	Description	Domain	Suffix
Cp	HM.T[3]	J/mol/K	Heat capacity at constant pressure	System	R
	HM(ph).T[3]			Phase	R
Cv	UM.T[4]	J/mol/K	Heat capacity at constant volume	System	R
	UM(ph).T[4]			Phase	R
D	DG(ph) [5]	N/A	Driving force (thermodynamic factor)	Phase	Always use with M, W, V or F. R can also be used.

[1] For this variable, if the phase is unstable, then the variable gets a value of zero.

[2] Do not use VP(ph) as a condition in POLY. Instead, use CHANGE_STATUS PHASE <PHASE>=FIX <AMOUNT> where the fixed <AMOUNT> is roughly equal to VPF(ph), which cannot be directly evaluated or listed. If the phase is unstable, then VP(ph) and its normalized quantities get zero value.

[3] Use only if pressure has been set as a condition.

[4] Use only if volume has been set as a condition.

[5] Already divided by RT.

[6] When working in the POST module you can also enter the abbreviation for this variable into the Console, for example, `enth` or `enthalpy`, which corresponds to `HM`, and `entr` and `entropy`, which corresponds to `SM`.

Compositional Extensive Variables

These are for the overall amount of components in whole system, or amount of a component in system or in a phase.

Do not use NP(ph) or BP(ph) as conditions in the POLY module. Instead use CHANGE_STATUS PHASE <PHASE>=FIX <AMOUNT> where the fixed <AMOUNT> is roughly equal to NPF(ph) or BPF(ph), which cannot be directly evaluated or listed. If the phase is unstable, then NP(ph) or BP(ph) (and its normalized quantities) get zero value.

When plotting the following quantities in POST, refer to each as indicated:

- X(comp) -> `Mole-Fraction <comp>` (or `M_F`)
- W(comp) -> `Weight-Fraction <comp>` (or `W_F`)
- X%(comp) -> `Mole-Percent <comp>` (or `M_P`)
- W%(comp) -> `Weight-Percent <comp>` (or `W_P`).
- u-f(ph,comp) -> `U-F`

V	Abbrev.	Unit	Description	Domain	Suffix	Comment
n	N	mole	Moles	All components	M, W, V, (R)	
	N(comp)			Component	M, W, V, (R)	
	N(ph,comp)			Component in a phase	M, W, V, (R)	
	NP(ph)[1]			Phase	M, W, V, (R)	See above
b	B	gram	Mass	All components	M, W, V, (R)	
	B(comp)			Component	M, W, V, (R)	
	B(ph,comp)			Component in a phase	M, W, V, (R)	
	BP(ph) [1]			Phase	M, W, V, (R)	See above
x	X(comp)	N/A	Mole fraction	Component	(R)	See above
	X(ph,comp)			Component in a phase	(R)	
w	W(comp)	N/A	Mass (weight) fraction	Component	(R)	See above
	W(ph,comp)			Component in a phase	(R)	

V	Abbrev.	Unit	Description	Domain	Suffix	Comment
x%	X%(comp)[2]	N/A	Mole percent	Component	(R)	See above
w%	W%(comp)[2]	N/A	Mass (weight) percent	Component	(R)	See above
u	u-f (ph,comp)[1]	N/A	u-fraction	Component in a stable phase	(R)	See above
in	IN(sp)[2]	mole	Input mole number	Phase species in the system	(R)	See above
im	IM(sp)[2]	gram	Input mass unit	Phase species in the system	(R)	See above

[1] Do not use as a condition in the POLY module.

[2] Only available in TQ-Interface.

Constitutional Composition-Related Extensive Variable

This is the amount of a constituent/species on a sublattice site in a phase.

V	Abbrev.	Unit	Description	Domain
y	Y(ph,cons#sub)	N/A	Site fraction	Constituent on a sublattice site (denoted by # and a digit) in a phase

Special Quantities

Variable	Abbrev.	Unit	Description or Example	Domain	Suffix
Q	QF(ph)[1]	n/a	Phase stability function	Phase	R Under a condition and system definition, QFR(ph) = QF (ph)
Tc	TC(ph) [2]	K	Curie temperature	Phase	R Under a condition and system definition, TCR(ph) = TC (ph)
Mb	BMAG(ph)[3]	n/a	Bohr magneton number	Phase	R Under a condition and system definition, BMAGR (ph) = BMAG (ph)
D1G	D1G(phase, site-fraction)	n/a	For example, D1G(FCC_ A1#1, Cr#1) for first derivative of G for first composition set of FCC_ A1 phase with respect to Cr site fraction on first sublattice.	Phase	n/a
D2G	D2G(phase, site-fraction, site-fracton)	n/a	For example, D2G(FCC_ A1#2, Cr#1, Cr#1) for second derivative of G for second composition set of FCC_A1 phase with respect to Cr site fraction on first sublattice.	Phase	n/a

Variable	Abbrev.	Unit	Description or Example	Domain	Suffix

[1] Negative when phase composition is inside a spinodal, otherwise positive. Can be used to find out if an equilibrium is within the miscibility gap for a solution phase. Cannot be used as a condition.

[2] Calculated for phases with magnetic contributions in an equilibrium state. Cannot be used as a condition, but can be plotted in POST or evaluated in POLY using SHOW_VALUE.

[3] Calculated for phases with magnetic contributions in an equilibrium state.

n/a = not applicable

The u-Fraction Variable

The u-fraction is an important quantity in some single-point or stepping paraequilibrium calculations in the POLY module and in the DICTRA module. You can apply the variable in a paraequilibrium calculation to the substitutional matrix component, the substitutional alloying components or the interstitial component. The u-fraction is denoted as ui for the i-th system component *n* of a whole system or of a specific phase in various equilibrium states (such as full-equilibria, partial-equilibria, para-equilibria, local-equilibria).

Generally, the u-fraction is defined as:

$$\frac{x_i}{\sum_{j \in S} x_j}$$

The sum of x_j in the denominator is calculated for all substitutional alloying elements in the whole system or in a specific phase. The variable x_i in the numerator stands for the mole-fraction of the *i*-th component in the whole system or in the specific phase.

Suffixes

Suffixes may be appended to all extensive variables and to some intensive variables. Some suffixes can be used to enter the value of variables in normalized form. These are referred to as normalizing suffixes. If the variable that you create with a normalizing suffix is based on a state variable that can be set as a condition in POLY, then the normalized variable can also be set as a condition in POLY.

Normalizing Suffixes

The normalizing suffixes are M (per mole), W (per mass in gram), V (per volume in m^3) and F (per mole formula unit). There is also a reference state suffix `R`, which you can use if you want the value of a thermodynamic variable to be calculated with respect to a reference state that have previously set.

When variables that express system and phase quantities are normalized, the following general rules are used:

- System quantities are normalized by the total system size (in terms of N, B or V).
- Phase quantities are normalized by the phase amount [in terms of NP(ph), BP(ph) or VP(ph)].

The normalized quantities of G(ph), A(ph), U(ph), H(ph), S(ph) and V(ph) are calculated according to the thermodynamic model used for the phase (e.g. GM(ph), AM(ph), UM(ph), HM(ph), SM(ph) and VM(ph)). These quantities are calculated using the first derivatives of the Gibbs energy expressed for the phase with respect to the current composition of the system.

The tables describe the normalizing suffixes for the different state variables.

- G, A, U, H, S. and V of a Whole System
- G(ph), A(ph), U(ph), H(ph), S(ph) and V(ph) of a Phase
- DG(ph) of a Phase
- N and B of a System
- N (comp) and B(comp) of a Component in the System
- NP(ph), BP(ph) and VP(ph) of a Phase in the System
- N(ph,comp) and B(ph,comp) of a Component in a Phase
- The Reference State Suffix R

G, A, U, H, S, and V of a Whole System

Suffix	Description	Example
M (per mole)	Total system size in terms of N.	GM is the Gibbs energy per mole of the system (J/mol). $\mathbf{GM = G/N}$
W (per mass in gram)	The total system size in terms of B.	GW is the Gibbs energy per mass of the system (J/g). $\mathbf{GW = G/B}$
V (per volume in m^3)	The total system size in terms of V. VV does not have to be evaluated.	GV is the Gibbs energy per volume of the system (J/m^3). $\mathbf{GV = G/V}$

G(ph), A(ph), U(ph), H(ph), S(ph), and V(ph) of a Phase

Suffix	Example
M (per mole)	For example, GM(ph) is Gibbs energy of the phase per mole of the phase (J/mol). $\mathbf{GM(ph) = G(ph)/NP(ph)}$
W (per mass in gram)	For example, GW(ph) is Gibbs energy of the phase per mass of the phase (J/mol). $\mathbf{GW(ph) = G(ph)/BP(ph)}$
V (per volume in m^3)	For example, GV(ph) is Gibbs energy of the phase per volume of the phase (J/mol). $\mathbf{GV(ph) = G(ph)/V(ph)}$
F (per mole formula unit)	For example, GF(ph) is the Gibbs energy of the phase per formula unit of the phase (J/mol). $\mathbf{GF(ph) = G(ph)/NP(ph)*NA}$

DG(ph) of a Phase

Suffix	Description	Example(s)
M (per mole)	Theoretically, the first derivative of the variable with regard to the phase amount in terms of NP(ph). Since DG(ph) is not directly calculated, the second derivative of the Gibbs energy expressed for the phase in question with respect to the current compositions in the equilibrium state of the system is calculated instead. DGM(ph) cannot not be set as a condition since it is only calculated under a certain type of equilibrium state.	DGM(ph) is driving force for precipitation of the phase per mole of components. $\mathbf{DGM(ph)} = \partial \mathbf{DG(ph)} / \partial \mathbf{NP(ph)}$
W (per mass in gram)	Theoretically, the first derivative of the variable with regard to the phase amount in terms of BP(ph). Since DG(ph) is not directly calculated, the second derivative of the Gibbs energy expressed for the phase in question with respect to the current compositions in the equilibrium state of the system is calculated instead. DGW(ph) cannot not be set as a condition since it is only calculated under a certain type of equilibrium state.	DGW(ph) is driving force for precipitation of the phase per mass of components. $\mathbf{DGW(ph)} = \partial \mathbf{DG(ph)} / \partial \mathbf{BP(ph)}$
V (per volume in m^3)	Theoretically, the first derivative of the variable with regard to the phase amount in terms of VP(ph). Since DG(ph) is not directly calculated, the second derivative of the Gibbs energy expressed for the phase in question with respect to the current compositions in the equilibrium state of the system is calculated instead. DGV(ph) cannot not be set as a condition since it is only calculated under a certain type of equilibrium state.	DGV(ph) is driving force for precipitation of the phase per volume of components. $\mathbf{DGV(ph)} = \partial \mathbf{DG(ph)} / \partial \mathbf{VP(ph)}$

Suffix	Description	Example(s)
F (per mole formula unit)	Theoretically, the first derivative of the variable with regard to the phase amount in terms of NP(ph) and NA (NA is the total atomic number in the phase formula). Since DG(ph) is not directly calculated, the second derivative of the Gibbs energy expressed for the phase in question with respect to the current compositions in the equilibrium state of the system is calculated instead. DGF(ph) cannot not be set as a condition since it is only calculated under a certain type of equilibrium state.	DGF(ph) is driving force for precipitation of the phase per formula unit of components. $\mathrm{DGF(ph)} = \partial \mathrm{DG(ph)} / \partial \mathrm{NP(ph)} * \partial \mathrm{NA}$

N and B of a System

Suffix	Description	Example(s)
M (per mole)	The total system size in terms of N. NM does not have to be evaluated. BM cannot be set as a condition.	BM is mass (gram) of components per mole of the system (g/mol). $\mathrm{BM} = \mathrm{B}/\mathrm{N}$
W (per mass in gram)	The total system size in terms of B. BW does not have to be evaluated. NW cannot be set as a condition.	NW is mole number of components per mass of the system (mol/g). $\mathrm{NW} = \mathrm{N}/\mathrm{B}$
V (per volume in m^3)	The total system size in terms of V. BV is the density of the entire system.	NV is mole number of components per volume of the system (mol/m^3). $\mathrm{NV} = \mathrm{N}/\mathrm{V}$ BV is the density of the entire system (g/m^3). $\mathrm{BV} = \mathrm{B}/\mathrm{V}$

N (comp) and B(comp) of a Component in the System

Suffix	Description	Example(s)
M (per mole)	The total system size in terms of N. BM(comp) cannot be set as a condition.	NM(comp) is the mole of a component per mole of the system (i.e. mole fraction, which also is expressed as X(comp)). $\mathbf{NM(comp) = N(comp)/N}$
W (per mass in gram)	The total system size in terms of B. NW(comp) cannot be set as a condition.	BW(comp) is mass (gram) of a component per mass of the system (i.e. mass fraction, which also is expressed as W(comp)). $\mathbf{BW(comp) = B(comp)/B}$
V (per volume in m^3)	The total system size in terms of V.	NV(comp) is mole number of a component per volume of the system (mol/m^3). $\mathbf{NV(comp) = N(comp)/V}$

NP(ph), BP(ph) and VP(ph) of a Phase in the System

Suffix	Description	Example(s)
M (per mole)	BPM(ph) and VPM(ph): The phase amount in terms of NP(ph). NPM(ph): The total system size in terms of N.	BPM(ph) is mass (gram) of a phase per moles of the system (g/mol). $\mathbf{BPM(ph) = BP(ph)/N}$ NPM(ph) is number of moles of a phase per moles of the system (mole fraction). $\mathbf{NPM(ph) = NP(ph)/N}$
W (per mass in gram)	NPW(ph) and VPW(ph): The phase amount in terms of BP(ph). BPW(ph):The total system size in terms of B.	VPW(ph) is volume (m^3) of a phase per mass of the system (m^3/g) $\mathbf{VPW(ph) = VP(ph)/B}$ BPW(ph) is mass (gram) of a phase per mass of the system (mass fraction) $\mathbf{BPW(ph) = BP(ph)/B}$

Suffix	Description	Example(s)
V (per volume in m^3)	NPV(ph) and BPV(ph): The phase amount in terms of VP(ph). VPV(ph): The total system size in terms of V.	NPV(ph) is number of moles of a phase per volume of the system (mol/m^3). $\mathbf{NPV(ph) = NP(ph)/V}$ VPV(ph) is volume (m^3) of a phase per volume of the system (volume fraction). $\mathbf{VPV(ph) = VP(ph)/V}$

N(ph,comp) and B(ph,comp) of a Component in a Phase

Suffix	Description	Example(s)
M (per mole)	The phase amount in terms of NP(ph) of the phase.	NM(ph,comp) is number of moles of a component per mole of a phase (i.e. mole fraction of a component in a phase, which is equivalent to X(ph, comp)). $\mathbf{NM(ph,comp) = N(ph,comp)/NP(ph)}$
W (per mass in gram)	The phase amount in terms of BP(ph) of the phase.	BW(ph,comp) is mass (gram) of a component per mass of a phase (i.e. mass fraction of a component in a phase, which is equivalent to W(ph,comp)). $\mathbf{BW(ph,comp) = B(ph,comp)/BP(ph)}$
V (per volume in m^3)	The phase amount in terms of VP(ph) of the phase.	NV(ph,comp) is mole number of a component per volume of a phase (mol/m^3). $\mathbf{NV(ph,comp) = N(ph,comp)/VP(ph)}$

The Reference State Suffix R

SET_REFERENCE_STATE

You can use the reference state suffix R for some thermodynamic variables to calculate their value with respect to a reference state that you have previously set for a system component with the SET_REFERENCE_STATE command in POLY (or in response-driven modules such as the POURBAIX module). The value of energy-related variables that are used with the R suffix

depends on the reference states of all the components in the defined system.

It is possible to use an R suffix on all compositional extensive state variables as well, but the value of the state variable is always the same, with or without the suffix.

If the reference state for a system component is the default reference state (the stable reference state (SER) which is defined in a Thermo-Calc database), then MUR(comp)= MU (comp), ACR(comp)= AC(comp) and LNACR(comp)= LNAC(comp).

In the case of some thermodynamic variables, you can also use the R suffix to express chemical potentials and activities of species relative to some single-substitutional-lattice solution phases (such as aqueous solution, gaseous mixture, metallic liquid solution, slag mixture or MO solid solution). These state variables are MU(sp,ph), MUR(sp,ph), AC(sp,ph), ACR(sp,ph), LNAC(sp,ph) and LNACR(sp,ph).

The reference states and standard states of various solution species are pre-defined for some solution phases in some databases. For all solution species in any solution model in any database, it is always the case that MUR(sp,ph)= MU(sp,ph), ACR(sp,ph)= AC(sp,ph) and LNACR (sp,ph)= LNAC(sp,ph).

Derived Variables and Partial Derivatives

Many derived variables can be obtained easily by using partial derivatives of state variables, such as heat capacity, thermal expansivity, isothermal compressibility, among others.

Derivatives of state variables can be defined or evaluated by putting a dot (.) between two state variables. The variable after the dot must be a condition that you have set when you defined your system. For example, the heat capacity (at constant pressure or volume) of a system is the partial derivative of the state variable enthalpy with respect to temperature. To evaluate this derivative, use the designation HM.T, where temperature is a state variable that you have set already.

Any partial derivative of a state variable with respect to another can be defined or evaluated as a derived variable by using the dot (.) notation.

Derived Variables Dot Notation Examples

The following table shows some examples:

Derived Variable	Description
$\mathrm{HM.T} = \partial \mathrm{HM}/\partial \mathrm{T}$	Heat capacity for the system at either constant P if pressure is a condition or constant V if volume is a condition.
$\mathrm{HM(ph).T} = \partial \mathrm{HM(ph)}/\partial \mathrm{T}$	Heat capacity for a phase at either constant P if pressure is a condition or constant V if volume is a condition.
$\mathrm{H.T} = \partial \mathrm{H}/\partial \mathrm{T}$	Heat capacity for the system multiplied by total mole number of components, i.e., $\partial \mathrm{H}/\partial \mathrm{T} = \mathrm{C_p}^*\mathrm{N}$ if pressure is a condition in a closed system or $\partial \mathrm{H}/\partial \mathrm{T} = \mathrm{C_v}^*\mathrm{N}$ if volume is a condition in a closed system.
$\mathrm{H(ph).T} = \partial \mathrm{H(ph)}/\partial \mathrm{T}$	Heat capacity for a phase multiplied by the sum of $\mathrm{NP(ph)}$ and $\mathrm{HM(ph)}^*\partial \mathrm{NP(ph)}/\partial \mathrm{T}$, i.e., $\mathrm{C_p(ph)}^*\mathrm{NP(ph)}+\mathrm{HM(ph)}^*\partial \mathrm{NP(ph)}/\partial \mathrm{T}$ if pressure is a condition or $\mathrm{C_{v(ph)}}^*\mathrm{NP(ph)}+\mathrm{HM(ph)}^*\partial \mathrm{NP(ph)}/\partial \mathrm{T}$ if volume is a condition.
$\mathrm{VM.T} = \partial \mathrm{VM}/\partial \mathrm{T}$	Thermal expansivity of the system (already multiplied by the total molar volume), i.e., $\partial \mathrm{VM}/\partial \mathrm{T} = \alpha^*\mathrm{VM}$.

Derived Variable	Description
$\mathbf{VM(ph).T = \partial VM(ph)/\partial T}$	Thermal expansivity of a phase (already multiplied by its molar volume), i.e., $\mathbf{\partial VM(ph)/\partial T = \alpha(ph)^{*}VM(ph)}$.
$\mathbf{V.T = \partial V/\partial T}$	Thermal expansivity of the system (already multiplied by the total volume), i.e., $\mathbf{\partial V/\partial T = \alpha^{*}V}$.
$\mathbf{V(ph).T = \partial V(ph)/\partial T}$	Thermal expansivity of a phase (already multiplied by the phase volume) plus the $\mathbf{VM(ph)^{*}\partial NP(ph)/\partial T}$ term, i.e., $\mathbf{\partial V(ph)/\partial T = \alpha(ph)^{*}V(ph) = \alpha(ph)^{*}VM(ph)^{*}NP(ph)+VM(ph)^{*}\partial NP(ph)/\partial T}$.
$\mathbf{VM.P = -\partial VM/\partial P}$	Isothermal compressibility of the system (already multiplied by the total molar volume), i.e., $\mathbf{\partial VM/\partial P - \kappa^{*}VM}$.
$\mathbf{VM(ph).P = -\partial VM(ph)/\partial P}$	Isothermal compressibility of a phase (already multiplied by its molar volume), i.e., $\mathbf{\partial VM(ph)/\partial P = -\kappa(ph)^{*}VM(ph)}$.
$\mathbf{V.P = -\partial V/\partial P}$	Isothermal compressibility of the system (already multiplied by the total volume), i.e., $\mathbf{\partial V/\partial P = -\kappa^{*}V}$
$\mathbf{V(ph).P = -\partial V(ph)/\partial P}$	Isothermal compressibility of a phase (already multiplied by the phase volume) plus the $\mathbf{VM(ph)^{*}\partial NP(ph)/\partial P}$ term, i.e., $\mathbf{\partial V(ph)/\partial P = -\kappa(ph)^{*}V(ph) = -\kappa(ph)^{*}VM(ph)^{*}NP(ph)+VM(ph)^{*}\partial NP(ph)/\partial P}$.
$\mathbf{T.X(comp) = \partial T/\partial X(comp)}$	Slope of a phase boundary on a T-X(comp) phase diagram with respect to mole fraction of the component in the system.
$\mathbf{T.W(comp) = \partial T/\partial W(comp)}$	Slope of a phase boundary on a T-W(comp) phase diagram with respect to mass of the component in the system.
$\mathbf{T.X(ph,comp) = \partial T/\partial X(ph,comp)}$	Slope of a phase boundary on a T-X(ph,comp) phase diagram with respect to mole fraction of the component in the phase.
$\mathbf{T.W(ph,comp) = \partial T/\partial W(ph,comp)}$	Slope of a phase boundary on a T-W(ph,comp) phase diagram with respect to mole fraction of the component in the phase.
$\mathbf{P.T = \partial P/\partial T}$	Slope of a phase boundary on a P-T phase diagram (Note that the equilibrium with phase assemblage must be calculated first).

Defining New Derived Variables and Functions

You can define additional derived variables or functions based on a state variable by using ENTER_SYMBOL. Any derived variable or function must have a unique name that starts with a letter and has a maximum number of eight characters. These characters can include both uppercase and lowercase letters, numerical digits and the underscore (_). No other characters are allowed.

The difference between new derived variables introduced with the ENTER_SYMBOL command and new functions introduced with the same command is as follows. Whenever Thermo-Calc calculates the value of a function (as part of an equilibrium calculation for example), all functions related to the defined system is evaluated. An entered derived variable, on the other hand, is only evaluated when it is defined and when it is re-evaluated with EVALUATE_FUNCTIONS.

Derived Variables for Aqueous Solutions

This section is applicable to the Console Mode POURBAIX diagram module only.

Learn More about the Aqueous Calculator

Standard state variables used for other phases can be directly applied to the aqueous solution phase. In addition, there are pre-defined derived variables for the aqueous solution phase in particular.

Examples of predefined derived variables for the aqueous solution phase are listed and briefly described in the following tables. Some derived variables for a gaseous mixture phase are also shown. This is because EOS (Equation of State) expressions, standard thermodynamic properties and transport properties of the pure solvent H2O are also expressions and properties of the pure gaseous species H2O.

For Aqueous Solution Phase

Name	Abbrev.	Units	Description	Comments
pH	PH	N/A	Acidity	of the aqueous solution phase pH = -log10(AC(H+)) = -log10(ACR(H+,AQ))

Name	Abbrev.	Units	Description	Comments
Eh	EH	V, mV	Hypothetical electric potential	of the aqueous solution phase Eh = u(ZE)/96485.309
Pe	PE	N/A	Logarithm of the hypothetical electron activity	of the aqueous solution phase pe = u(ZE)/(2.3025851*RT)
Ah	AH	kJ, kcal	Thermodynamic affinity per electron	of a redox couple wrt the standard hydrogen electrode in the aqueous solution phase Ah = u(ZE)
yw	YH2O	N/A	Mole fraction	of the solvent H2O in the aqueous solution phase YH2O = Y(AQ,H2O)
Nw	AH2O	mole	Mole number	of 1.0 kg of solvent H2O AH2O = 55.508435
Nsp	NSH2O	mole	Mole number, NS(AQ,H2O)	of the solvent (H2O) in the aqueous solution phase NS(AQ,H2O) = YH2O*NP(AQ)
	NS#		Mole number, NS(AQ,sp)	of a solute species in the aqueous solution phase NS(AQ,sp) = Y(AQ,sp)*NP(AQ)
M	ML#	mol/kg_H2O	Molality, ML(AQ,sp)	of a solute species in the aqueous phase ML(AQ,sp) = Y(AQ,sp)*AH2O/YH2O
m*	TIM	equivalent molality	Total molality	of all solute species in the aqueous solution phase TIM = sum[ML(AQ,sp)]ions + sum [ML(AQ,sp)]complexes
mt	TIC#	equivalent molality	Total ionic concentration, TIC (AQ,sp)	of a cation I in the aqueous phase TIC(AQ,spI) = sum[ML(AQ,spJ)*V (spI-in-spJ)]

Name	Abbrev.	Units	Description	Comments
I	ISTR	N/A	Ionic strength	of the aqueous solution phase ISTR=1/2*sum[ML(AQ,sp)*Z(AQ,sp)**2]
γ	RCH2O	N/A	Activity coefficient, RC(H2O,AQ)	of the solvent (H2O) RC(H2O,AQ) = ACR(H2O,AQ)/YH2O
	RC#		Activity coefficient, RC(sp,AQ)	of a solute species RC(sp,AQ) = ACR(sp,AQ)/Y(AQ,sp)*YH2O
αi	AIH2O	N/A	Activity, AI(H2O,AQ)	of the solvent (H2O), AI(H2O,AQ) = ACR(H2O,AQ)
	AI#		Activity, AI(sp,AQ)	of a solute species related to the aqueous solution phase, AI(sp,AQ) = ACR(sp,AQ)*AH2O
	LogAI#		Log10 Activity, LogAI(H2O,AQ), LogAI(sp,AQ)	of the solvent or a solute species related to the aqueous solution phase in common logarithm, LogAI(H2O,AQ) = log10[AI(H2O,AQ)] LogAI(sp,AQ) = log10[AI(sp,AQ)]
αw	AW	N/A	Activity	of H2O in the aqueous solution phase AW = ACR(H2O,AQ)
ϕ	OS	N/A	Osmotic coefficient	of aqueous solution phase OS = -55.508435*lnAW/TIM
At1	AT1	equil_mol/kg_H2O	Titration alkalinity (definition 1)	of the aqueous solution phase Generally defined as the equivalent molality of carbonate and bicarbonate at the methyl orange endpoint (pH=4.5).

Name	Abbrev.	Units	Description	Comments
At2	AT2	equil_mol/kg_H2O	Titration alkalinity (definition 2)	of the aqueous solution phase Generally defined as the equivalent molality of carbonate and bicarbonate, plus sulfide, at the methyl orange endpoint (pH=4.5).

For Gaseous Mixture Phase

Name	Abbrev.	Units	Description	Comments
γ	RA#	N/A	Activity coefficient, RA(sp,GAS)	of a gaseous species in the gaseous mixture RA(sp,GAS) = function(Y,T,P)
γ*	RF#	N/A	Fugacity coefficient, RF(sp,GAS)	of a pure gaseous species under TP RF(sp,GAS) = function(T,P/V)
F	FUG#	pa, bar, psi	Fugacity, FUG(sp,GAS)	of a gaseous species in the gaseous mixture FUG(sp,GAS) = RA(sp,GAS)*RF(sp,GAS)*Y(GAS,sp)*P
ft	TFUG	pa, bar, psi	Total gas fugacity	of the gaseous mixture phase TFUG = sum[FUG(sp,GAS)]

Defining New Derived Variables for Aqueous Solutions

This section is applicable to the Console Mode POURBAIX diagram module only.

Learn More about the Aqueous Calculator

You can define many different additional derived variables and functions. For instance, the partition coefficient of a component between two phases is defined as follows:

```
Pc<name> = X(phase1,component)/X(phase2,component)
```

Another example is the activity coefficient of a component in the system. It is defined as follows:

```
Rc<name> = ACR(component)/X(component)
```

The activity coefficient of a species in a solution phase depends on which model definitions on the reference states that are used and it depends on the standard states for the species. If the standard state of a species is defined to be the same as the pure species in a substitutional phase, then the activity coefficient of the species can be calculated as:

```
RC<name> = ACR(species,phase)/Y(phase,species)
```

In some cases, there are more than one sublattice in the phase and the reference states for the phase species cannot be presented by the pure species, as in the case of C in FCC [(Fe)1 (C,N,VA)1], where the model may end at fifty percent C and fifty percent Fe. In those cases, the chemical potential and activity of all phase constituents is not well defined and you cannot properly define the activity coefficients of the species in the phase.

For an aqueous solution phase, no matter what model is used, the reference state and standard state for both the solvent and solutes are defined in a special way in the Thermo-Calc software. The reference state for the solvent is set as pure water, the same as its standard state (according to Raoults's Law). The standard state for a solute species is set the hypothetical solute species, whilst its reference state is defined as the hypothetical state at unit molality (one mole dissolved into 1.0 kg of solvent) but in which the environment of each molecular is the same as at infinite dilution (according to Henry's Law). Under these definitions, the activity coefficients for solvent species can be calculated as follows:

```
RC<H2O> = ACR(H2O,aqueous)/ Y(aqueous,H2O)
```

The coefficients for the solute species can be calculated as follows:

```
RC<spec> = AI(species,aqueous)/ML(aqueous,species)
= ACR(species,aqueous)/ Y(aqueous,species)*Y(aqueous,H2O)
```

AI is here the activity of solute species calculated from the model, and ML is the molality of the species.

Thermodynamic Variables and Wildcard Characters

The ACR (species,phase) and the MUR (species,phase) quantities can only be appropriately and meaningfully applied to substitutional solution phases (such as GAS, AQUEOUS, LIQUID) and to solution phases without an interstitial sublattice set. This means that the wild card characters `*` and `$` normally don’t work properly for the activity and/or chemical potential properties.

For example, do not use ACR(*,*) or MUR(*,*) for all the species relative to all phases, nor ACR (*,phase) or MUR(*,phase) for all the species relative to a specific phase, nor ACR(species,*) or MUR(species,*) for a specific species relative to all phases.

Instead, use specific names for species and (applicable) phase, as in the following examples:

```
SHOW_VALUE acr(fe+2,aqueous)Lists activity of the Fe+2 species referred to AQUEOUS
solution phase

SHOW_VALUE mur(c2,gas)Lists chemical potential of the C2 species referred to GAS
mixture phase

SET_AXIS_VAR y ac(o2,gas)Sets activity of the O2 species referred to GAS mixture
phase as Y-axis
```

Learn More about the Aqueous Calculator

As of Thermo-Calc 2026a, the **Aqueous Calculator** is available in Graphical Mode. Both the Aqueous Calculator and the **Aqueous Calculation** template allows for efficient setup of advanced aqueous calculations (including Pourbaix diagrams) compared to the classic Console Mode POURBAIX module.

Search the help (press F1 when in Thermo-Calc) for information about the Graphical Mode **Aqueous Calculator**, its template with predefined settings, and the aqueous properties. The help also has detailed information about the compatible and recommended database for use with all aqueous calculations.

Units of State Variables and Derived Variables

The units for the state variables in the Units column in the table in User-Specified Units are the SI units that are used in the POLY module. However, in the POST module, you can both use pre-defined symbols and define your own symbols which are based on state variables and derived variables. By doing this, you can express the value of the thermodynamic variables in non-default units. The following topic briefly describes how you can create your own symbols and suggests expressions that you can use to convert default units into other standard units which are not default units in Thermo-Calc.

The topic Examples of User-Defined Units describes some variables of specific species in a phase and the units in which they are expressed. These variables are not used in POLY or POST, but in the GIBBS, DATA, PARROT and ED_EXP modules.

User-Specified Units

You do not always need to use the default units for variables. Using ENTER_SYMBOL, you can convert the value of variable from the default unit to your preferred unit. (Some response-driven modules also allow you to set conditions in non-default units.) User-defined symbols in the form of functions can be used for plotting in the POST module, but they cannot be used as conditions in POLY. User defined symbols in the form of variables can be used as conditions.

For example, if you want pressure to be plotted in bar rather than Pa, then you define the following function `PB`:

```
Enter_symbol function PB = P/1E5 ;
```

If you wanted heat capacity of a system to be shown as in terms of J/mol/K, then you can define the following function Cp:

```
Enter_symbol function Cp = Hm.T ;
```

If the variable you want to convert is a function of one or more derivatives, then you must enter the symbol as a variable rather as a function. For instance, a symbol expressing heat capacity of a system in a unit of cal/mol/K can be defined as the following variable `Cp2`:

```
Enter_symbol variable Cp2 = Hm.T/4.1858 ;
```

Examples of User-Defined Units for information about entering conventional functions and the associated units.

Examples of User-Defined Units

The following tables give examples of expressions you can use to enter symbols. This enables you to show the values of thermodynamic variables in a variety of units.

Units of State Variables and Derived Variables and User-Specified Units

You can also use thermodynamic variables with normalizing suffixes in the expression when you enter a symbol. However, the tables do not have examples of these expressions.

In the expressions these are defined as follows:

- `i` is for an auxiliary index or letter that corresponds to the component `c`
- `j` is for an auxiliary index or letter that corresponds to the phase `ph`, and
- `ij` stands for an auxiliary index or letter that corresponds to the component `c` in the phase `ph`.

Intensive Variables of a Defined System

Quantity	Suggested Name and Expression	Unit
Temperature	TempC = T-273.15	Celsius (C)
	TempF = 1.8*T-459.67	Fahrenheit (F)
	TempF = 1.8*TempC+32	

Quantity	Suggested Name and Expression	Unit
Pressure	PB = P/1E5	bars (bar)
	PKb = P/1E8	kilobars (kbar)
	PAtm = P/101325	atmosphere (atm)
	PSI = P/6894.76	pounds/sq. inch (psi)
	PIHg = P/3342.11	inches of Hg
	PTor = P/133.322	Tors (millimeters of Hg)

Extensive Variables of a Defined System

Quantity	Suggested Name and Expression	Unit
Amount	BKg = 1E-3*B	kilograms (kg)
	BTon = 1E-6*B	tons
Volume	VDM = 1E-3*V	cubic decimeters (dm^3, l)
	VCM = 1E-6*V	cubic centimeters (cm^3)
	VMM = 1E-9*V	cubic millimeters (mm^3)
	VCI = 1.6387064E-5*V	cubic inches (in^3)
	VLi = 1E-3*V	liters (l)

Quantity	Suggested Name and Expression	Unit
Energy	GCal = G/4.1858	cal
	ACal = A/4.1858	cal
	UCal = U/4.1858	cal
	HCal = H/4.1858	cal
	SCal = S/4.1858	Cal/K
Heat Capacity	Cp2 = HM.T/4.1858	cal/mol/K
	Cp3 = HW.T/4.1858	cal/g/K
	Cp4 = HV.T/4.1858	cal/m^3/K
Thermal Expansion	A2 = VM.T*1E-6/VM	1/K
	A3 = VW.T*1E-6/VW	1/K
Isothermal Compressibility	B2 = -VM.P*1E-9/VM	1/Pa
	B3 = -VW.P*1E-9/VW	1/Pa

Intensive Variables of a System Component

The **Aqueous Calculator** and a predefined template is available in Graphical Mode and recommended for aqueous calculations (including Pourbaix diagrams).

Quantity	Suggested Name and Expression	Unit
Chemical Potential	MUi = MU(c)/4.1858	cal/mol
	MURi = MUR(c)/4.1858	cal/mol
Special quantity for aqueous solution	pH = -LOG10(ACR(H+1))	dimensionless
	Eh = MUR(ZE)/RNF where RNF=96485.309	volts (V)

Extensive Variables of a System Component

Quantity	Suggested Name and Expression	Unit
Amount	MFi = N(c)/N = X(c)	dimensionless
	MPi = N(c)/N*100	dimensionless
	WFi = B(c)/B = W(c)	dimensionless
	WPi = B(c)/B*100	dimensionless
	BKgi = 1E-3*B(c)	kilograms (kg)
	BToni = 1E-6*B(c)	tons

Extensive Variables of a Phase

Quantity	Suggested Name and Expression	Unit
Amount	MFj = NP(ph)/N	dimensionless
	MPj = NP(ph)/N*100	dimensionless
	WFj = BP(ph)/B	dimensionless
	WPj = BP(ph)/B*100	dimensionless
	BKgj = 1E-3*BP(ph)	kilograms (kg)
	BTonj = 1E-6*BP(ph)	tons
Volume	VCMj = 1E-3*V(ph)	cubic decimeters (dm^3, l)
	VCMj = 1E-6*V(ph)	cubic centimeters (cm^3)
	VMMj = 1E-9*V(ph)	cubic millimeters (mm^3)
Energy	GCalj = G(ph)/4.1858	cal
	ACalj = A(ph)/4.1858	cal
Isothermal Compressibility	B2j = -VM(ph).P/VM(ph)	1/Pa

Extensive Variables of a Component in a Phase

Quantity	Suggested Name and Expression	Unit
Amount	MFij = N(ph,c)/NP(ph) = X(ph,c)	dimensionless
	MPij = N(ph,c)/NP(ph)*100	dimensionless
	WFi = B(ph,c)/BP(ph) = W(ph,c)	dimensionless
	WPij = B(ph,c)/BP(ph)*100	dimensionless
	BKgij = 1E-3*B(ph,c)	kilograms (kg)
	BTonij = 1E-6*B(ph,c)	tons

Intensive Variables of a Species in a Phase

The **Aqueous Calculator** and a predefined template is available in Graphical Mode and recommended for aqueous calculations (including Pourbaix diagrams).

Quantity	Suggested Name and Expression	Unit
Chemical Potential	MUCalij = MU(sp,ph)/4.1858	cal/mol
	MUErgij = MU(sp,ph)*1E7	cal/mol
Fugacity	FAij = AC(sp,ph)*PATM	atmosphere (atm)
	FBij = AC(sp,ph)*PB	bars (bar)
	FCij = AC(sp,ph)*PKB	kilobars (kbar)
	FTij = AC(sp,ph)*PTOR	Tors (millimeters of Hg)

Quantity	Suggested Name and Expression	Unit
ln(Fugacity)	LnFAij = LNAC(sp,ph)+LN(PATM)	atmosphere (atm)
	LnFBij = LNAC(sp,ph)+LN(PB)	bars (bar)
	LnFCij = LNAC(sp,ph)+LN(PKB)	kilobars (kbar)
	LnFTij = LNAC(sp,ph)+LN(PTOR)	Tors (millimeters of Hg)
Special quantity for aqueous solution	AIij=ACR(FE+3,AQ)*AH2O	dimensionless
	RCij=ACR(FE+3,AQ)*YH2O/Y(AQ,FE+3) where AH2O=55.508435 and YH2O=Y(AQ,H2O)	dimensionless
	WRCalij = WR(AQ,sp)/4.1858 (WR(AQ,sp) is only valid for aqueous species in a system in which the AQUEOUS solution phase is considered)	cal/mol

Extensive Variables of a Species in a Phase

The **Aqueous Calculator** and a predefined template is available in Graphical Mode and recommended for aqueous calculations (including Pourbaix diagrams).

Quantity	Suggested Name and Expression	Unit
Special quantity for aqueous solution	MLij=Y(AQ,FE+3)*AH2O/YH2O	molality (m)
	ISTR=1*IS1+1*IS2+1*IS3 where AH2O=55.508435, YH2O=Y(AQ,H2O) and ISn=.5*MLi*Zi**2+.5*MLj*Zj**2+.5*MLk*Zk**2	molality (m)

Units for Variables of Specific Species in a Phase

In the GIBBS, DATA, PARROT, and ED_EXP modules, there are quantities that describe various thermodynamic, physical, chemical and transport properties for a compound phase, and for a certain species or a given species combination in a specific solution phase. The following table describes the units for those variables.

These variables cannot be directly used in the POLY or POST modules.

Variables	Description and Unit
G(ph,sp) G(ph,sp;0) G(ph,sp1;sp2;...;0)	Gibbs energy (J/mol) of a pure substance or end-member.
G(ph,sp1,sp2,...) L(ph,sp1,sp2,...) G(ph,sp1,sp2,...;0) L(ph,sp1,sp2,...;0) G(ph,sp1,sp2,...;...;0) L(ph,sp1,sp2,...;...;0)	Zero-order interaction parameter (J/mol) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
G(ph,sp1,sp2,...;i) L(ph,sp1,sp2,...;i) G(ph,sp1,sp2,...;...;i) L(ph,sp1,sp2,...;...;i)	The ith -order interaction parameter (J/mol) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
TC(ph,sp) TC(ph,sp;0) TC(ph,sp1;sp2;...;0)	Curie temperature (K) of a pure substance or end-member.
TC(ph,sp1,sp2,...) TC(ph,sp1,sp2,...;0) TC(ph,sp1,sp2,...;...;0)	Zero-order Curie-temperature contribution (K) to a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.

Variables	Description and Unit
TC(ph,sp1,sp2,...;i) TC(ph,sp1,sp2,...;...;i)	The ith -order Curie-temperature contribution (K) to a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
BMAGN(ph,sp) BMAGN(ph,sp;0) BMAGN (ph,sp1;sp2;...;0)	Bohr magneton number (dimensionless) of a pure substance or end-member.
BMAGN(ph,sp1,sp2,...) BMAGN (ph,sp1,sp2,...;0) BMAGN (ph,...;sp1,sp2,...;0)	Zero-order Bohr magneton number (dimensionless) to a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
BMAGN (ph,sp1,sp2,...;i) BMAGN (ph,sp1,sp2,...;...;i)	The ith -order Bohr magneton number (dimensionless) to a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
V0(ph,sp) V0(ph,sp;0) V0(ph,sp1;sp2;...;0)	Molar volume (m^3) at 1 bar and reference T0 of a pure substance or end-member.
V0(ph,sp1,sp2,...) V0(ph,sp1,sp2,...;0) V0(ph,sp1,sp2,...;...;0)	Zero-order composition-dependent molar volume (m^3) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
V0(ph,sp1,sp2,...;i) V0(ph,sp1,sp2,...;...;i)	The ith-order composition-dependent molar volume (m^3) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
VA(ph,sp) VA(ph,sp;0) VA(ph,sp1;sp2;...;0)	Integrated thermal expansivity (m^3/mol/K) of a pure substance or end-member.
VA(ph,sp1,sp2,...) VA(ph,sp1,sp2,...;0) VA(ph,sp1,sp2,...;...;0)	Zero-order composition-dependent thermal expansivity (m^3/mol/K) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.

Variables	Description and Unit
VA(ph,sp1,sp2,...;i) VA(ph,sp1,sp2,...;...;i)	The ith -order composition-dependent thermal expansivity (m^3/mol/K) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
VC(ph,sp)	High pressure fitting parameter (m^3/mol) of a pure substance or endmember.
VC(ph,sp1,sp2,...)	Zero-order composition-dependent high pressure fitting parameter (m^3/mol) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
VC(ph,sp1,sp2,...i)	The ith -order composition-dependent high pressure fitting parameter (m^3/mol) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
VK(ph,sp)	Isothermal compressibility (m^3/mol/Pa) of a pure substance or endmember.
VK(ph,sp1,sp2,...)	Zero-order composition-dependent isothermal compressibility (m^3/mol/Pa) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
VK(ph,sp1,sp2,...i)	The ith -order composition-dependent isothermal compressibility (m^3/mol/Pa) of a specified binary, ternary or higher-order interactions on a certain sublattice site in a solution phase.
WR(ph,sp) WR(ph,sp;0)	Standard Born function (J/mol) of a specific aqueous species in the AQUEOUS solution phase (always with a single sublattice) under the reference-state temperature and pressure. The **Aqueous Calculator** and a predefined template is available in Graphical Mode and recommended for aqueous calculations (including Pourbaix diagrams).

State Variables for Scheil

Post processing is done the same way as POLY-3: specific variables for plotting in the Scheil module are listed.

For a comparable list in Graphical Mode, see Scheil Calculator Available Plot Variables.

The variables can be plotted along the X- and Y-axes. In the table, *ph* is an abbreviation of *phase*, and *el* is an abbreviation of *element*. An asterisk (*) can be used as a wild character for *el* and *ph*. Use the abbreviations of the variables when you specify what the X- and Y-axes represent in a diagram.

Abbreviation	*State Variable*
T	Temperature in Celsius
NL/BL/VL	Mole/mass fraction of liquid
NS/BS/VS	Mole/mass fraction of all solid phases
NS(ph)/BS(ph)	Mole/mass fraction of a solid phase
VS(ph)	Volume fraction of a solid phase
W(ph,el)	Weight fraction of an element in a phase
X(ph,el)	Mole fraction of an element in a phase
Y(ph,el)	Site fraction of an element in a phase
NN(ph,el)	Distribution of an element in a phase
NH/BH	Total heat per mole/gram (top curve) and Latent heat per mole/gram (bottom curve)
CP/BCP	Apparent heat capacity per mole/gram
NV/NV(ph)	Molar volume of the system or a phase
DS/DS(ph)	Average density of the system or a phase
BT	Apparent volumetric CTE of the system

Abbreviation	*State Variable*
DVIS(ph)	Dynamic viscosity of a phase
KVIS(ph)	Kinematic viscosity of a phase
SURF(ph)	Surface tension of a liquid phase
ELRS/ELRS(ph)	Electrical resistivity of the system or a phase
ELCD/ELCD(ph)	Electrical conductivity of the system or a phase
THCD/THCD(ph)	Thermal conductivity of the system or a phase
THRS/THRS(ph)	Thermal resistivity of the system or a phase
THDF/THDF(ph)	Thermal diffusivity of the system or a phase
DGV	Driving force for evaporation
DHV	Evaporation enthalpy
MMG	Molar mass of gas
XAVG(el)	Mole fraction of an element in solid phases
WAVG(el)	Mass fraction of an element in solid phases

State Variables in Console Mode DICTRA

Also see SET_DIAGRAM_AXIS and ENTER_SYMBOL in the DICTRA POST module.

State variables in the DICTRA POST module are similar to those defined in Thermo-Calc POLY-3 module. Examples of state variables are temperature, mole fraction, enthalpy, etc. In POLY-3 a general notation method based on character mnemonics is designed for a predefined set of state variables.

The numerical values of some state variables, e.g. activity, chemical potential, and the energetic extensive properties, are given relative to some reference state which has been defined in the thermodynamic database file. Sometimes you may have specified a reference state using SET_REFERENCE_STATE. To get numerical values relative to the user-defined reference state, append an R to the mnemonic names as defined.

For all extensive properties a suffix can be added to the mnemonic name to indicate a normalized extensive property. The extensive properties tables describe each mnemonic.

Intensive Properties

Mnemonic	Description
T	temperature
P	pressure
AC(component)	activity
MU(component)	chemical potential

Extensive Property `Z at Each Grid Point

Mnemonic	Description
Z	Extensive property `Z at each grid point.

Mnemonic	Description
ZM	Extensive property `Z per moles of atoms.
ZW	Extensive property `Z per mass (gram).
ZV	Extensive property `Z per volume (m^3).

Extensive Property `Z for a Phase at Each Grid Point

Mnemonic	Description
Z	Extensive property `Z for the current amount of the phase.
ZM	Extensive property `Z per mole of atoms of the phase.
ZW	Extensive property `Z per mass (gram) of the phase.
ZV	Extensive property `Z per volume (m^3) of the phase.
ZF	Extensive property `Z per mole formula unit of the phase.

Energetic Extensive Properties

Suffixes M, W, V and F can be applied.

Mnemonic	Description
S	entropy
S(phase)	entropy of a phase
V	volume

Mnemonic	Description
V(phase)	volume of a phase
G	Gibbs energy
G(phase)	Gibbs energy of a phase
H	enthalpy
H(phase)	enthalpy of a phase
A	Helmholtz energy
A(phase)	Helmholtz energy of a phase

Extensive Property: Amount of Components

Suffixes M, W and V can be applied.

Mnemonic	Description
N(component)	Number of moles of a component.
N(phase,component)	Number of moles of a component in a phase.
B(component)	Mass of a component.
B(phase,component)	Mass of a component in a phase.

Extensive Property Total Amount

Suffixes M, W and V can be applied.

Mnemonic	Description
N	Number of moles
B	Mass The legal combination BW is not very interesting as it will always be unity. BV is the density

Extensive Property: Amount of a Phase

Suffixes M, W and V can be applied.

The normalizing properties are calculated at each grid point.

Mnemonic	Description
NP(phase)	Number of moles of a phase.
BP(phase)	Mass of a phase.
VP(phase)	Volume of a phase.
Y(phase,species#sublattice)	site fraction This quantity is dependent upon the model chosen for the phase.

Extensive Property: Constitution

This quantity is dependent upon the model chosen for the phase.

Mnemonic	Description
Y(phase,species#sublattice)	site fraction

About Thermophysical Properties Data Parameters

The Thermo-Calc databases have a variety of properties data included such as molar volume, thermal conductivity, dynamic and kinematic viscosity, thermal resistivity, electrical resistivity, and surface tension. These properties data are being integrated into databases as each new version of a database is released.

Availability of properties data is dependent on both the database and its version. Some information is specific to use in Console Mode. There is more information also available for Graphical Mode, TC-Python, or TC-Toolbox for MATLAB® for each of the databases where the properties data is included. More advanced information is also contained in the *Database Manager User Guide* PARAMETER section.

To determine if the database you are using has this properties data, search the help (press F1) to review the technical information. The availability of properties data is also included with the Database Overview document available on the Thermo-Calc website.

The so-called classic syntax is used in the examples below. It can be used in Console Mode or when using the APIs, e.g. TC-Python or TC-Toolbox for MATLAB®. Graphical Mode in Thermo-Calc has readable names for all of these.

All Available Properties Data Parameters and Variables

Below is a summary of the available thermophysical parameters and variables for the databases when working in Thermo-Calc. There are differences when you are working in Console Mode (CM) versus Graphical Mode (GM) as well as if you use an SDK such as TC-Python or TC-Toolbox for MATLAB®.

Property (Variable Name GM)	*Model Parameters*	*Variables to Show or Plot in CM or the SDKs*
Molar volume	V0, VA	VM for a system `VM(PHI)` for phase PHI
Electrical conductivity	ELQ**	ELCD for a system `ELCD(PHI)` for phase PHI
Electrical resistivity	ELRS, ESPD	ELRS for a system `ELRS(PHI)` for a phase PHI
Thermal conductivity	THCD	THCD for a system `THCD(PHI)` for phase PHI
Thermal resistivity		THRS for a system `THRS(PHI)` for phase PHI
Thermal diffusivity		THDF for a system `THDF(PHI)` for phase PHI
Surface tension	SIGM, XI*	`SURF(LIQUID)` `SURF(ION)`**
Dynamic viscosity	VISC	`DVIS(LIQUID)` `DVIS(ION)`**
Kinematic viscosity		`KVIS(LIQUID)` `KVIS(ION)`**

* XI is not used in the TCOX database (all versions). As of 2023b it is also not used starting with the following versions of these databases: TCFE13, TCNI12.1, TCTI5.1, TCNOBL3, TCPMAG2, and TCCU6. As of 2024a, TCMG7, TCAL9, and TCHEA7. As of 2024b, TCSLD5. **`ION` is used in the TCS Metal Oxide Solutions Database (TCOX)

The examples listed for the SDKs (TC-Python and TC-Toolbox for MATLAB) are using CM syntax. The quantities can also be accessed in both `ThermodynamicQuantity` and `ScheilQuantity` classes. See the various model descriptions or the SDK help for details.

Viscosity Model

Viscosity of the Metallic Liquids Model

Viscosity of the Ionic Liquids Model

To use this model, the database parameter VISC is needed. It can be used for liquids.

- Dynamic viscosity (DVIS)
- Kinematic viscosity (KVIS)

Examples in Console Mode:

- In POLY module: SHOW DVIS(LIQUID)
- Set as plot variable: SET-DIAGRAM-AXIS Y KVIS(LIQUID)

Thermal Conductivity Model

Thermal Conductivity Model

To use the thermal conduction parameters, the database parameter THCD is needed. The other two related properties are derived from THCD. These properties can be obtained for a phase or for the whole system.

- Thermal conductivity (THCD)
- Thermal diffusivity (THDF)
- Thermal resistivity (THRS)

Examples in Console Mode:

- In POLY module: SHOW THCD
- Set as plot variable: SET-DIAGRAM-AXIS Y THDF(FCC_A1)

Electrical Conductivity and Electrical Resistivity Models

Electrical Resistivity Model

To use the electric properties parameters, the database parameter ELRS is needed. ELCD is derived from that. These properties can be obtained for a phase or for the whole system.

- Electrical conductivity (ELCD)
- Electrical resistivity (ELRS)

Examples in Console Mode:

- In POLY module: SHOW ELCD
- Set as plot variable: SET-DIAGRAM-AXIS Y ELRS(FCC_A1)

Electrical Conductivity of Molten Slag Model

Electrical Conductivity for Ionic Liquid Model

To use the electric properties parameters, the database parameter ELQ is needed. The model parameters are the activation Gibbs energy of end-members and excess activation Gibbs energy.

- Electrical conductivity of molten slags `ELCD(IONIC)`
- Electrical resistivity of molten slags `ELRS(IONIC)`

Surface Tension Model

Surface Tension of Metallic Liquid Alloys Model

Surface Tension Model for Oxide Slag

Surface tension for liquids can be calculated if the database contains the two database parameters SIGM and XI. From these, the surface energy is calculated:

- Surface energy (SURF)

XI is not used in the TCS Metal Oxide Solutions Database (TCOX)

Examples in Console Mode:

- In POLY module: SHOW SURF(LIQUID)
- Set as plot variable: SET-DIAGRAM-AXIS Y SURF(LIQUID)

Thermophysical Properties Variables

The Thermo-Calc databases have a variety of properties data included such as molar volume, thermal conductivity, dynamic and kinematic viscosity, thermal resistivity, electrical resistivity, and surface tension. These properties data are being integrated into databases as each new version of a database is released.

Availability of properties data is dependent on both the database and its version. Some information is specific to use in Console Mode. There is more information also available for Graphical Mode, TC-Python, or TC-Toolbox for MATLAB® for each of the databases where the properties data is included. More advanced information is also contained in the *Database Manager User Guide* PARAMETER section.

To determine if the database you are using has this properties data, search the help (press F1) to review the technical information. The availability of properties data is also included with the Database Overview document available on the Thermo-Calc website.

Variables	Abbrev.	Unit	Description	Domain
DVIS	DVIS(ph)	Pa·s	Dynamic viscosity	Liquid phase
KVIS	KVIS(ph)	m^2/s	Kinematic viscosity	Liquid phase
ELCD	ELCD	S/m	Electric conductivity	System
ELCD	ELCD(ph)	S/m	Electric conductivity	Phase
ELRS	ELRS	Ωm	Electric resistivity	System
ELRS	ELRS(ph)	Ωm	Electric resistivity	Phase
THCD	THCD	W/(mK)	Thermal conductivity	System

Variables	Abbrev.	Unit	Description	Domain
THCD	THCD(ph)	W/(mK)	Thermal conductivity	Phase
THRS	THRS	mK/W	Thermal resistivity	System
THRS	THRS(ph)	mK/W	Thermal resistivity	Phase
THDF	THDF	m^2/s	Thermal diffusivity	System
THDF	THDF(ph)	m^2/s	Thermal diffusivity	Phase
SURF	SURF(ph)	J/m^2	Surface tension	Liquid phase

Electrical Resistivity Model

The modeling starts with unaries in their stable and metastable structures. The temperature dependence of electrical resistivity is described with polynomials for each unary and each end-member of compounds. In order to guarantee the reliability of the extrapolation, experimental data were first fitted to a semi-empirical model, which was established based on relevant theories. The experimental data, together with the extrapolated values, are then used for deriving the polynomials that are saved in the database. The magnetic contribution to electrical resistivity can be separately treated with a model implemented in Thermo-Calc.

The composition dependence of electrical resistivity is described with the Redlich-Kister expression. All binary systems are modeled by using experimental data or theoretical estimations. Ternary and higher-order parameters can be used if necessary.

Electrical resistivity is modeled and its descriptions are stored in the databases. Electrical conductivity is derived from electrical resistivity and can be retrieved from calculated results as well.

Model Description

The semi-empirical model for electrical resistivity is built based on the Matthiessen's rule [1997DeB]. In general, the electrical resistivity of a metallic alloy consists of residual resistivity (ρ_0) and electron-phonon resistivity (ρ_{e-p}), as well as magnetic resistivity (ρ_m). The residual resistivity is due to the scatterings of impurities and defects that exist in well-annealed and high purity alloys, and the value of ρ_0 is generally considered independent of temperature.

[*Eq. 1*] $$\rho = \rho_0 + \rho_{e-p} + \rho_m$$

ρ_{e-p} is described with the modified Bloch-Grüneisen equation [1928Blo; 1933Gru] and corrections can be made in cases where other types of scatterings play considerable roles.

[*Eq. 2*] $$\rho_{e-p} = A \cdot \left(\frac{T}{\theta_R}\right)^5 \cdot J_5\left(\frac{\theta_R}{T}\right)$$

[*Eq. 3*] $$A = \frac{\frac{3}{2} h q_D^6 (G')^2}{4e^2 (m^*)^2 n_c k_B \theta_D k_F^2 \nu_F^2}$$

[*Eq. 4*] $$J_n\left(\frac{\theta_D}{T}\right) = \int_0^{\frac{\theta_D}{T}} \frac{x^n e^x}{(e^x - 1)^2} dx$$

The characteristic temperature θ_R plays a similar role and is also approximated as the Debye temperature (θ_D), which can be readily obtained from low-temperature heat capacity and elastic constants data as well as theoretical computations. The approximation of θ_R as θ_D indicates that transverse phonons play a role in electron scattering. k_F is the electron wave number at the Fermi surface. q_D is the phonon Debye wave number. h is the Planck constant. G' is a constant representing the strength of the e-p interaction and cannot be easily estimated. m^* is the electron effective mass. n_c is the number of unit cells per unit volume. v_F is the electron velocity at the Fermi surface.

To describe the drastic change of the magnetic resistivity (ρ_m) around the Curie (or Neel) temperature, T_C, of a magnetic alloy, an empirical model is proposed using the dimensionless temperature T/T_C and a parameter ρ_{spd} that stands for the resistivity due to spin disordering. According to this model, Eq. 5, ρ_m approaches ρ_{spd}, when the temperature is well above T_C, and is 0 when the temperature is far below T_C. ρ_{spd} depends only on composition and is described with the Redlich-Kister (R-K) expression. Apparently, ρ_{spd} has a positive value for magnetic elements, and compounds as well as endmembers, and is 0 for non-magnetic ones.

In a typical binary system made of a magnetic element A and a non-magnetic element B, ρ_{spd} decreases usually from ρ_{spd}^{A} to 0 at a certain composition (x_*). Such a behavior is also seen in magnetic moment and Curie temperature. ρ_{spd} is expected to be zero in the composition range from x_* to element B, and will be forced to zero when the R-K expansion leads inevitably to negative values over this composition range. T_C is available from the thermodynamic description in the database.

[*Eq. 5*]
$$\rho_m = \rho_{spd} \cdot \left(1 - e^{\left(-\frac{3}{2}\left(\frac{T}{T_c}\right)^3\right)}\right)$$

The semi-empirical model (as given in Eq. 1 to Eq. 5) is first fitted to experimental data. The description is then extrapolated to a wider temperature range if necessary, either to extreme temperatures where the structure is no longer stable or to where experimental data are missing. Polynomials are then derived with the experimental data, together with the extrapolated values, and stored in the database. The model as given in Eq. 5 is implemented in Thermo-Calc, so the magnetic contribution can be excluded from the polynomials and separately modeled, and it will be automatically included during the calculations.

Model Parameters

The extended TDB format accepts parameters describing electrical resistivity and thermal conductivity, together with spin disordering resistivity. Examples for unary and binary systems are given below:

```
ELRS(FCC_A1,AL:VA;0)
```

```
ELRS(FCC_A1,AL,CO:VA;0)
ESPD(FCC_A1,CO:VA;0)
ESPD(FCC_A1,AL,CO:VA;0)
```

Calculation and Plot Variables

- `ELRS` – Electrical resistivity
- `ELCD` – Electrical conductivity

All the above quantities can be calculated, retrieved, shown and plot in Thermo-Calc via the variables in the Console Mode or via the quantity names in the Graphical Mode (see sections below).

Console Mode

The quantities corresponding to the variables of `ELRS` and `ELCD` can be calculated in Console Mode for a phase, e.g. `ELRS(FCC_A1)`, or for a system, i.e. `ELRS`. The results can be shown in the POLY module with the command SHOW_VALUE or illustrated as a plot in the POST module with the command PLOT_DIAGRAM.

Graphical Mode

On the **Plot Renderer** in Graphical Mode, electrical resistivity, electrical conductivity, thermal conductivity, thermal resistivity, and thermal diffusivity can be selected from the axes lists, tabulated and plotted using the quantity names, with options for a specific phase, all phases or for a system.

TC-Python and TC-Toolbox for MATLAB®

With these Software Development Kits (SDKs), the quantities of `ELRS` and `ELCD` can be retrieved, for a phase, e.g. `ELRS(FCC_A1)`, or for a system, i.e. `ELRS`, via `get_value_of()` or `get_values_of()`, from most phase equilibrium calculations in TC-Python, for instance,

- `with_single_equilibrium_calculation()`,
- `with_property_digram_calculation()` or
- `with_batch_equilibrium_calculation()`.

These can also be accessed in both `ThermodynamicQuantity` and `ScheilQuantity`classes. You can, for example, use `ThermodynamicQuantity.electrical_resistivity()` for electrical resistivity.

Electrical Conductivity for Ionic Liquid Model

The model for the electrical conductivity of molten slags is mainly based on the theory of the electrical conductivity of ionic solutions. The total conductivity is the sum of the contributions from all cations including those network-forming cations modeled as neutrals in the two sublattice ionic liquid model, such as liquid silicon oxide. For slags containing transition metal ions of different oxidation states, the electronic contribution due to the electron or hole exchange between these ions is also considered.

Model Description

In short, the electrical conductivity of molten slags consists of the following:

1. Ionic conductions contributed by cations in the ionic liquid.
2. Electronic conductions from the cations having more than one oxidation states (Fe^{2+}-Fe^{3+}, Mn^{2+}- Mn^{3+} and so on).

The composition and temperature dependence of the total electrical conductivity of molten slags, σ, is represented by:

$$\sigma = \sum x_{C_i}\sigma_{C_i} - x_{MeO}y_{MeO_3}\sigma_{Me^{2+}} + x_{B_k^0}\sigma_{B_k^0}$$

$$= x_{Ca^{2+}}\sigma_{Ca^{2+}} + x_{Mg^{2+}}\sigma_{Mg^{2+}} + \ldots + x_{Fe^{2+}}\sigma_{Fe^{2+}} - x_{FeO}y_{FeO_3}\sigma_{Fe}^{2+} + \ldots + x_{SiO_2}\sigma_{SiO_2}$$

where x_{Ci} is the mole fraction of cation C_i, and its electrical conductivity, σ_{Ci}, is written in the form of the Nernst-Einstein equation as:

$$\sigma_{C_i} = \frac{1}{RT}\exp\left[-\frac{Q_{C_i}}{RT}\right] = \frac{1}{RT}\exp\left[-\frac{\sum_j y_{C_i}y_{A_j}Q_{C_i:A_j} + \sum_j y_{C_i}y_{B_k^0}Q_{C_i:B_k^0} + Q_{C_i}^E}{RT}\right]$$

where Q_{Ci} is the activation Gibbs energy, of which the composition dependence has been expanded in a CALPHAD fashion.

Model Parameters

The model parameters are the activation Gibbs energy of end-members and excess activation Gibbs energy in the above equation. They can be entered in the GES module or TDB file by using the keyword `ELQ`, for example,

```
PARAM ELQ(IONIC_LIQ&Ca+2,CA+2:O-2;0)
```

```
PARAM ELQ(IONIC_LIQ&Ca+2,CA+2:SIO4-4;0)
PARAM ELQ(IONIC_LIQ&Ca+2,CA+2:SIO2;0)
```

Calculation and Plot Variables

All the quantities can be calculated, retrieved, shown and plot in Thermo-Calc via the variables in the Console Mode or via the quantity names in the Graphic Mode.

Console Mode

The electrical conductivity and resistivity of molten slags modeled as the ionic liquid phase can be calculated usually through a single point or step equilibrium calculation in Console Mode. The results can be shown or plotted by using the variables `ELCD(IONIC)` and `ELRS(IONIC)`, respectively.

Graphical Mode

On the **Plot Renderer** in Graphical Mode, the electrical conductivity and resistivity of molten slags modeled as the ionic liquid phase can be calculated by using the **Single** point or **One Axis** calculation type in Graphical Mode. The corresponding tabulation or plot variables are **Electrical Conductivity** and **Electrical Resistivity**, respectively.

TC-Python and TC-Toolbox for MATLAB®

With these Software Development Kits (SDKs), this property can be plotted using `property-diagram_calculation()` or `with_batch_ equilibrium_calculation()`. The plot variables are `ELCD(IONIC)` and `ELRS(IONIC)`.

These can also be accessed in both `ThermodynamicQuantity` and `ScheilQuantity`classes. You can, for example, use `ThermodynamicQuantity.electrical_conductivity("IONIC")` and `ThermodynamicQuantity.electrical_resitivity("IONIC")` for electrical conductivity and electrical resistivity, respectively.

You can also get the individual values e.g. from an equilibrium calculation and use in whatever way you want, e.g. feed into other models: `result.get_value_of("ELCD(IONIC_LIQ)")`, where 'result' is the result of one equilibrium calculation. It matches SHOW_VALUE in Console Mode.

This can also be written `result.get_value_of(ThermodynamicQuantity.electrical_conductivity("IONIC_LIQ"))` or `result.get_value_of (ThermodynamicQuantity.electrical_resitivity("IONIC_LIQ"))`.

Thermal Conductivity Model

The modeling starts with unaries in their stable and metastable structures. The temperature dependence of thermal conductivity is described with polynomials for each unary and each end-member of compounds. Thermal resistivity and thermal diffusivity can be derived from thermal conductivity and retrieved from calculated results. The composition dependence is described with the Redlich-Kister expression in the CALPHAD spirit, but the relation is applied to thermal resistivity (or the inverse of thermal conductivity).

Model Description

Experimental data of thermal conductivity are used to derive descriptions in polynomials, which are stored in the database, despite that it consists of two components, electronic thermal conductivity (κ_e) and lattice thermal conductivity κ_g. In other words, they are not separately treated.

In cases where experimental data are absent or sparse, however, κ_e and κ_g can be separately predicted and summed up to give the total thermal conductivity. κ_e can be predicted from ρ or vice versa, by employing the Wiedemann-Franz Law [1853Fra; 1985Jon], respectively, to the residual resistivity, magnetic resistivity and intrinsic resistivity.

[*Eq. 1*] $$\frac{1}{\kappa_e} = W_e = \frac{\rho_0 + \rho_m + \rho_i}{L_0 T}$$

L_0 is known as the Sommerfeld value of the Lorenz number: $2.4453 \times 10^{-8} W\Omega/K^2$.

[*Eq. 2*] $$\rho_i = \frac{A}{L_0 T} \cdot \left(\frac{T}{\theta_R}\right)^5 \cdot J_5\left(\frac{\theta_R}{T}\right) \cdot f$$

[*Eq. 3*] $$f = 1 + \frac{3}{\pi^2} \cdot \left(\frac{k_F}{q_D}\right)^2 \cdot \left(\frac{\theta_R}{T}\right)^2 - \frac{1}{2\pi^2} \cdot \frac{J_7\left(\frac{\theta_R}{T}\right)}{J_5\left(\frac{\theta_R}{T}\right)}$$

The intrinsic resistivity (ρ_i) is based on Eq. 4

[*Eq. 4*] $$\rho_{e-p} = A \cdot \left(\frac{T}{\theta_R}\right)^5 \cdot J_5\left(\frac{\theta_R}{T}\right)$$

for the e-p processes, but corrections are provided, as given in Eq. 3: the first term corresponds to large-angle scattering that satisfies the original Wiedemann-Franz Law; the second one is due to inelastic small-angle (vertical processes) and has no counterpart in the

electrical resistivity; the third term is a correction that accounts for situations where large-angle scattering can reverse the electron direction without actually assisting to restore the distribution back to equilibrium.

κ_g can be predicted with the Slack model in a temperature range where only anharmonic Umklapp phonon-phonon interactions are important. In other words, normal processes are neglected as a first approximation [1979Sla; 2002Mor]. The most reasonable version among several ones is given below [1965Jul].

[*Eq. 5*]
$$\kappa_p^U = A' \cdot \frac{M_a \cdot \theta_D^3 \cdot \delta}{\gamma^2 \cdot n_c^{\frac{2}{3}}} \cdot \frac{1}{T}$$

[*Eq. 6*]
$$A' = \frac{2.43 \cdot 10^{-5}}{1 - \frac{0.514}{\gamma} + \frac{0.228}{\gamma^2}}$$

The Debye temperature, θ_D can be obtained from low-temperature heat capacity or elastic constant data. M_a is the average atomic mass, δ^3 the volume per atom, n_c the number of atoms in a unit cell, and γ the Grüneisen coefficient. A typical value for A' is evaluated to be 3×10^{-5} using $\gamma = 2$ as the Grüneisen coefficient, and can be used in the absence of experimental information. It can also be obtained from e.g. DFT calculations of elastic properties.

Model Parameters

The extended TDB format accepts parameters describing electrical resistivity and thermal conductivity, together with spin disordering resistivity. Examples for unary and binary systems are given below:

```
THCD(FCC_A1,AL:VA;0)
THCD(FCC_A1,AL,CO:VA;0)
```

Calculation and Plot Variables

- `THCD` – Thermal conductivity
- `THRS` – Thermal resistivity
- `THDF` – Thermal diffusivity

All the above quantities can be calculated, retrieved, shown and plot in Thermo-Calc via the variables in the Console Mode or via the quantity names in the Graphic Mode (see sections below).

Console Mode

The quantities corresponding to the variables of `THCD`, `THRS`, and `THDF` can be calculated in Console Mode for a phase, e.g. `THCD(FCC_A1)`, or for a system, i.e. `THCD`. The results can be shown in the POLY module with the command SHOW_VALUE or illustrated as a plot in the POST module with the command PLOT_DIAGRAM.

Graphical Mode

On the **Plot Renderer** in Graphical Mode, electrical resistivity, electrical conductivity, thermal conductivity, thermal resistivity, and thermal diffusivity can be selected from the axes lists, tabulated and plotted using the quantity names, with options for a specific phase, all phases or for a system.

TC-Python and TC-Toolbox for MATLAB®

The quantities of `THCD`, `THRS`, and `THDF` can be retrieved, for a phase, e.g. `THCD(FCC_A1)`, or for a system, i.e. `THCD`, via `get_value_of()` or `get_values_of()`, from most phase equilibrium calculations in these Software Development Kits (SDKs), for instance,

- `with_single_equilibrium_calculation()`,
- `with_property_diagram_calculation()` or
- `with_batch_equilibrium_calculation()`.

These can also be accessed in both `ThermodynamicQuantity` and `ScheilQuantity` classes. You can, for example, use `ThermodynamicQuantity.thermal_resistivity()` for thermal resistivity.

Surface Tension of Metallic Liquid Alloys Model

In general, for liquid metal alloys, the surface tension is assessed for all the elements and binary systems where experimental data are available. When experimental data are not available, the Butler model [1932But] is used to estimate the composition dependence of the surface tension. The experimental or estimated data are modeled with either the modified Guggenheim model [2019Ver] or the Redlich-Kister-Muggianu sub-regular solution model [1948Red; 1975Mug].

Search the help (press F1) to review the technical information for the database you are using.

Modified Guggenheim Model Description

The surface tension of metallic liquid alloys by the modified Guggenheim model [2019Ver] and is expressed as:

$$\sigma(x_i^B,T) = -\frac{RT}{S(x_i^B,T)}\ln\left[x_1^B \exp\left(-(1+\Xi_1 \cdot x_2^S(x_i^B,T))\frac{\sigma_1(T)S_1(T)}{RT}\right) + x_2^B \exp\left(-(1+\Xi_2 \cdot x_1^S(x_i^B,T))\frac{\sigma_2(T)S_2(T)}{RT}\right)\right]$$

where

- x_i^B is the bulk composition
- σ_i is the surface tension
- S and S_i are the total and the partial molar surface of species i defined as

  $$S_{(i)} = 1.901 \cdot N_A^{1/3} \cdot V_{m,(i)}^{2/3}$$

- N_A being the Avogadro number and $V_{m,(i)}$ the molar volume of the system or the species i.
- x_i^S is the composition of i in surface, which is a function of bulk composition and T and defined as follows:

$$x_i^{S,id}(x_i^B, T) = \frac{x_i^B}{x_i^B + x_j^B \exp\left(\frac{S(x_i^B,T)[\sigma_i(T)-\sigma_j(T)]}{RT}\right)}$$

- Ξ_1 and Ξ_2 are called damping factors and these parameters are fitted for species 1 and 2 of binary systems.

The extrapolation to higher-order systems is straightforward. The ideal surface composition for a multicomponent system is:

$$x_i^{S,id}(T, x_i^B, x_j^B, \dots) = \frac{x_i^B}{x_i^B + \sum_{j\neq i} x_j^B \exp\left(\frac{S_{ij}(x_i^B,T)\cdot[\sigma_i(T)-\sigma_j(T)]}{RT}\right)}$$

and the surface tension of a multicomponent alloy is obtained from:

$$\sigma(T, x_i^B, x_j^B, \dots) = -\frac{RT}{S(T, x_i^B, x_j^B, \dots)} \cdot \ln\left[\sum_{i=1}^{n}\sum_{j\neq i} x_i^B \exp\left(-(1 + x_j^S(T, x_i^{B,ij}) \cdot \Xi_i^{ij})\frac{\sigma_i(T) S_i(T)}{RT}\right)\right]$$

Corresponding Variable - Modified Guggenheim

The corresponding variable for surface energy of pure elements is `SIGM`. For instance, the surface tension of pure A is written as `SIGM(LIQUID,A;0)`. The corresponding X_1 and X_2 parameters for A-B binary system are respectively written as following:

```
PARAMETER XI(LIQUID,A,B:0)
PARAMETER XI(LIQUID,A,B:1)
```

Redlich-Kister-Muggianu Model Description

In the case of using the Redlich-Kister-Muggianu (R-K-M) [1948Red; 1975Mug] sub-regular solution model for modeling the surface tension, the surface tension is given by:

$$\sigma = \sum y_i \sigma_i + \sigma^E$$

where y_i and σ_i are the site fraction and surface tension for pure component i, and the excess term is expressed using (R-K) for binary and (R-K-M) for ternary interactions.

Corresponding Variable Redlich-Kister-Muggianu

The corresponding variable for surface energy of pure elements is `SIGM`. For instance, the surface tension of pure A is written as `SIGM(LIQUID,A;0)`. The corresponding L parameters for the A-B binary system are written as follows:

```
PARAMETER SIGM (IONIC_LIQ, A, B; 0)
PARAMETER SIGM (IONIC_LIQ, A, B; 1)
PARAMETER SIGM (IONIC_LIQ, A, B; 2)
```

Plot Variables (Both Models)

Console Mode

The surface energy can be calculated through various calculations in Console Mode, e.g. a step. The plot variable is `SURF(LIQUID)`.

Graphical Mode

On the **Plot Renderer** in Graphical Mode, the plot variable **Surface tension** can be selected from the axes lists, tabulated and plotted using the quantity names, with options for a specific liquid phase based on the database.

TC-Python and TC-Toolbox for MATLAB®

The quantity `SURF(LIQUID)` can be retrieved, for a liquid phase, e.g. `SURF(LIQUID)`), via `get_value_of()` or `get_values_of()`, from most phase equilibrium calculations in these Software Development Kits (SDKs), for instance,

- `with_single_equilibrium_calculation()`,
- `with_property_diagram_calculation()` or
- `with_batch_equilibrium_calculation()`.

These can also be accessed in both `ThermodynamicQuantity` and `ScheilQuantity` classes. You can, for example, use `ThermodynamicQuantity.surface_tension("LIQUID")`.

Graphical Mode and Console Mode Examples

There are two basic examples included with your software installation and that use demonstration (DEMO) databases. There are also many examples for the individual databases not listed here.

Search the help (press F1 when in Thermo-Calc) for brief descriptions of these examples, or browse to the examples located in your installation. From the main menu, **Help→ Examples Files**:

- Graphical Mode **T_11_Surface_tension_in_Cu-Zr.tcu**
- Console Mode `tcex56`

Surface Tension Model for Oxide Slag

The model for TCS Metal Oxide Solutions Database (TCOX) surface tension of oxide slag:

$$\sigma = \sum y_i \sigma_i + \sigma^E$$

$$\sigma^E = \sum_i y_A \cdot y_B (y_A - y_B)^i \cdot SIGM^i$$

where y_i and σ_i indicate the site fraction and surface tension for pure component i. For pure component, the surface tension is described with $a + b * T$. The excess term is expressed using Redlich-Kister polynomial, as one can find the example of a binary A-B.

SIGM is the parameter used for optimization, for example,

```
PARAMETER SIGM (IONIC_LIQ, A;0)
PARAMETER SIGM (IONIC_LIQ, B;0)
PARAMETER SIGM (IONIC_LIQ, A:B,0)
```

The user can calculate the surface tension of liquid oxide by calling the variable `SURF(IONIC)`.

Viscosity of the Metallic Liquids Model

This section provides details about calculating the dynamic and kinematic viscosities.

Model Description

The viscosity of metallic liquid alloys is modeled as follows:

$$RT\ln\eta = RT\ln\eta_0 + E$$

where

- η is the dynamic (or shear) viscosity of the liquid,
- η_0 is the viscosity at finite temperatures,
- E is the activation energy in J/mole,
- R is the gas constant, and
- T is the absolute temperature.

The SI unit of viscosity is pascal.second (Pa.s). The viscosity parameters are expanded via Redlich-Kister polynomials.

For example, viscosity of a liquid A-B alloy is:

$$\begin{aligned} RT\ln\eta_{alloy} = {} & x_A(E_A + RT\ln\eta_0^A) \\ & + x_B(E_B + RT\ln\eta_0^B) \\ & + x_A x_B(L_0 + (x_A - x_B)\cdot L_1) \end{aligned}$$

The two first terms are the contributions for the end-members, A and B elements and the last term accounts for the excess viscosity. Basically, the activation energies are optimized. L_0 and L_1 etc. are the parameters that are optimized to fit the viscosity data.

The kinematic viscosity, ν, is the ratio of the dynamic viscosity, η, to the density, ρ, of the alloy:

$$\nu = \eta/\rho$$

The SI unit of kinematic viscosity is square meter per second (m^2/s).

Calculation and Plot Variables

Both the dynamic viscosity and kinematic viscosity can be calculated, retrieved, shown, and plotted in Thermo-Calc via the variables in Console Mode, using the quantity names in Graphical Mode, and also via the quantities in the SDKs.

Console Mode

The values for dynamic viscosity and kinematic viscosity in Console Mode are obtained with the variables `DVIS` (dynamic viscosity) and `KVIS` (kinematic viscosity). For example, once the equilibrium is calculated in Console Mode, you can get the viscosity value by `show DVIS (LIQUID)` or `show KVIS(LIQUID)`.

Graphical Mode

On the **Plot Renderer** in Graphical Mode, the dynamic viscosity and kinematic viscosity each can be directly plotted when the variables are available to select.

TC-Python and TC-Toolbox for MATLAB®

The quantities of `DVIS` (dynamic viscosity) and `KVIS` (kinematic viscosity) can be retrieved, for a phase, e.g. `DVIS(FCC_A1)`, or for a system, i.e. `DVIS`, via `get_value_of()` or `get_values_of()`, from most phase equilibrium calculations in these Software Development Kits (SDKs), for instance,

- `with_single_equilibrium_calculation()`,
- `with_property_diagram_calculation()` or
- `with_batch_equilibrium_calculation()`.

These can also be accessed in both `ThermodynamicQuantity.kinematic_viscosity ("LIQUID")` or `ThermodynamicQuantity.dynamic_viscosity("LIQUID")`.

Graphical Mode and Console Mode Examples

There are two basic examples included with your software installation and that use demonstration (DEMO) databases. There are also many examples included with the individual databases.

Search the help (press F1 when in Thermo-Calc) for brief descriptions of these examples, or browse to the examples located in your installation. From the main menu, **Help→ Examples Files**:

- Graphical Mode T_12: Viscosity in Cr-Ni
- Console Mode `tcex55` (Thermophysical Properties Examples)

Viscosity of the Ionic Liquids Model

The model for TCS Metal Oxide Solutions Database (TCOX) viscosity of slag:

$$RTln\eta = RTln\eta_0 + E$$

where η is viscosity, $\eta_0 = \frac{hN_A}{V_m}$ and E is activation energy.

The excess parameters are expanded via R-K. An example of viscosity of A-B liquid oxide:

$$RTln\eta_{A-B} = y_A(RTln\eta_0^A + E_A) + y_B(RTln\eta_0^B + E_B) + \sum_i y_A \cdot y_B(y_A - y_B)^i \cdot VISC^i$$

The parameter of *VISC* stands for *R· T· ln(viscosity)*. In Thermo-Calc software, VISC is implemented as *VISC(ionic)*. In order to quickly acquire the actual viscosity, the parameter of *DVIS(ionic)* should be used. By coupling to the database, it makes use of the site fractions of each species, which reflects the structural change in the oxide melt.

Units for the viscosity of oxide slag:

- Pa·s (pascal-second) is the SI unit, mostly used for oxide slag
- CGS unit is poise (P), 1 poise=0.1 Pa·s
- Centipoise is also common (cP) because it is equivalent to mPa·s.

Molar Volume Model

Molar volume can be used to establish a connection with some significant physical properties, for example, viscosity, electrical conductivity and surface tension. It is the reciprocal of density multiplied by molar mass.

Model Description

The model used to describe the molar volume at ambient pressures is:

$$V_m(T) = V_0 exp(\int_{T_0}^{T} 3\alpha dT)$$

A simple polynomial is used to model non-magnetic volumetric expansivity above 298 K:

$$3\alpha = a + bT + cT^2 + dT^3 + eT^{-2}$$

The model described above is implemented in Thermo-Calc software with two parameters, V0 and VA, and α is the linear thermal expansivity at 1 bar and 3α is the volumetric thermal expansivity.

Molar Volume Descriptions

Parameter	*Unit*	*Description*
V0 (phase, constituent array)	m^3/mol	Volume at 1 bar and reference temperature T0
VA (phase, constituent array)	None	$\int_{T_0}^{T} 3\alpha dT$

About the Elastic Properties

As of Thermo-Calc version 2026b, elastic properties are available with Thermo-Calc and the TCS Ti/TiAl-based Alloys Database (TCTI) (TCTI6 and newer), TCS Steel and Fe-alloys Database (TCFE) (TCFE14 and newer), TCS High Entropy Alloys Database (TCHEA) (TCHEA8 and newer), TCS Ni-based Superalloys Database (TCNI) (TCNI13 and newer), TCS Al-based Alloys Database (TCAL) (TCAL11 and newer), and TCS Mg-based Alloys Database (TCMG) (TCMG9 and newer). The elastic properties will be added to additional databases over time. Subscribe to our newsletter to be kept up-to-date on the latest product releases, webinars, user group meetings, applications examples, and more.

To use the elastic properties parameters, the database parameter `ECij` is needed. The elastic stiffness tensor is described by its independent tensor elements (elastic constants) given by the indices ij in Voigt notation. Both indices i and j run from 1 to 6 and the number of independent tensor elements depends on the symmetry of the crystal lattice (i.e., three independent constants for cubic crystals and five for hexagonal crystals). The elastic moduli are derived from the elastic constants.

Elastic properties are only available for cubic (FCC and BCC) or hexagonal (HCP) phases.

Elastic Properties Model

The modeling process begins with determining the independent elastic constants for each phase.

- For cubic (FCC, BCC) phases, the independent elastic constants are: C_{11}, C_{12}, C_{44}.
- For hexagonal (HCP) phases, the independent elastic constants are: $C_{11}, C_{12}, C_{13}, C_{33}, C_{44}$.

The temperature dependence of the elastic constants is represented by exponential and polynomial functions for each phase's end-member. To ensure reliable interpolation and extrapolation, both experimental and theoretical data are fitted to a robust model based on

relevant theories, following the CALPHAD methodology. For magnetic materials, the magnetic contribution to the elastic constants is treated separately and incorporated into the model implemented in Thermo-Calc [2021Joh].

The elastic constants assessed for single crystalline phases are related to the polycrystalline elastic moduli (bulk, shear, and Young's moduli) using the Voigt-Reuss-Hill averaging method. These moduli are expressed in terms of the Voigt (upper bound) and Reuss (lower bound) limits of the elastic moduli as follows:

Bulk modulus

$$B = \frac{1}{2}\left(B_V + B_R\right)$$

Shear modulus

$$G = \frac{1}{2}\left(G_V + G_R\right)$$

Young's modulus

$$E = \frac{9BG}{3B+G}$$

Cubic Symmetry

The Voigt and Reuss bounds depend on crystal symmetry. For cubic (FCC, BCC) phases with 3 independent elastic constants (C_{11}, C_{12}, C_{44}), the Voigt and Reuss bounds are given as:

$$B_V = B_R = \frac{1}{3}\left(C_{11} + 2C_{12}\right)$$

$$G_V = \frac{1}{5}\left(C_{11} - C_{12} + 3C_{44}\right)$$

$$G_R = \frac{5\left(C_{11}-C_{12}\right)C_{44}}{3\left(C_{11}-C_{12}\right)+4C_{44}}$$

Hexagonal Symmetry

For hexagonal (HCP) phase with 5 independent elastic constants ($C_{11}, C_{12}, C_{13}, C_{33}, C_{44}$), the Voigt and Reuss bounds are calculated as:

$$B_V = \frac{1}{9}\left[2\left(C_{11} + C_{12}\right) + 4C_{13} + C_{33}\right]$$

$$G_V = \frac{1}{30}\left(7C_{11} - 5C_{12} - 4C_{13} + 2C_{33} + 12C_{44}\right)$$

$$B_R = \frac{\left(C_{11}+C_{12}\right)C_{33}-2C_{13}^2}{C_{11}+C_{12}-4C_{13}+2C_{33}}$$

$$G_R = \frac{\frac{5}{2} h C_{44} C_{66}}{3B_V C_{44} C_{66} + h(C_{44} + C_{66})}$$

Where the symmetry relation $C_{66} = (C_{11} - C_{12})/2$ and help function $h = (C_{11} + C_{12})C_{33} - 2C_{13}^2$ are used to further condense G_R.

Model Parameters

The extended TDB format accepts parameters describing elastic constants and magnetic ordering effects. Examples for unary and binary systems are given below for C11:

```
EC11(HCP_A3,TI:VA;0)
EC11(HCP_A3,TI,MO:VA;0)
EC11(BCC_A2,FE:VA;0)
EC11MAG(BCC_A2,FE:VA;0)
EC11(BCC_A2,FE,CR:VA;0)
```

Where `EC11MAG` is the scaling factor for the magnetic contribution.

PARAMETER

Calculation and Plot Variables

- Elastic constants (Cij)
- Bulk modulus
- Shear modulus
- Young's modulus

All of the above quantities can be calculated, retrieved, shown, and plotted in Thermo-Calc via the variables in Console Mode or via the axes quantity names in Graphical Mode.

Elastic Properties Variables

Graphical Mode

In the **Plot Renderer** in Graphical Mode, elastic constants and moduli can be selected from the drop-down list of axis variables.

The independent elastic constants are selected on the **Plot Renderer** as an axis variable **Elastic constant** and then choose an option (**C11**, **C12**, **C13**, **C33**, or **C44**) from the drop-down list.

The elastic moduli, **Bulk modulus**, **Shear modulus**, and **Young's modulus**, are directly available from the **Axis variable** list.

All can be tabulated and plotted using the quantity names, with options for a specific phase or all phases.

Console Mode

The quantities corresponding to the individual elastic constants and elastic moduli (derived from the elastic constants) can be can be calculated in Console Mode for individual phases or all phases. The results can be shown in the POLY module with the command SHOW_VALUE or shown as a plot in the POST module with the command PLOT_DIAGRAM using:

- `Cij(<phase name>)` or `Cij(*)`
- Bulk modulus: `BULKMOD(<phase name>)` or `BULKMOD(*)`
- Shear modulus: `SHEARMOD(<phase name>)` or `SHEARMOD(*)`
- Young's modulus: `YOUNGMOD(<phase name>)` or `YOUNGMOD(*)`

TC-Python and TC-Toolbox for MATLAB®

For the Software Development Kits (SDKs), i.e. TC-Python and TC-Toolbox, the quantities of elastic constants, bulk modulus, shear modulus, and Young's modulus can be retrieved for individual phases or all phases via `get_value_of()` or `get_values_of()` from any equilibrium calculation types using:

- `Cij(<phase name>)` or `Cij(ALL_PHASES/*)`
- `ThermodynamicQuantity.bulk_modulus(<phase name>)` or `ThermodynamicQuantity.bulk_modulus(ALL_PHASES/*)`
- `ThermodynamicQuantity.shear_modulus (<phase name>)` or `ThermodynamicQuantity.shear_modulus(ALL_PHASES/*)`
- `ThermodynamicQuantity.youngs_modulus(<phase name>)` or `ThermodynamicQuantity.youngs_modulus(ALL_PHASES/*)`

See the relevant SDK documentation for details.

Units

When plotting or tabulating the elastic moduli in Graphical Mode you can choose between several units of pressure. The default unit for elastic moduli in the Plot Renderer and Table Renderer is GPa.

The elastic moduli and elastic constants are given in SI units, i.e. the values calculated in TC-Python, TC-Toolbox, and Console Mode are in Pascal.

Specific Database Use Case Examples

Each of the following databases have examples available to show how the elastic properties are applied within Thermo-Calc.

An example of the effect of oxygen concentration on Young's modulus in HCP_A3 titanium is included with the Thermo-Calc installation and available to all users. See T_19: Young's Modulus for Ti-O with Elastic Properties.

Al-based Alloys (TCAL)

The TCS Al-based Alloys Database (TCAL) has an example using elastic properties. You can find it either in the Thermo-Calc help or via the Examples Collection PDF, which is available on our website.

High Entropy Alloys (TCHEA)

The TCS High Entropy Alloys Database (TCHEA) Validation and Calculation Examples Collection has an example using elastic properties. You can find it either in the Thermo-Calc help or via the Examples Collection PDF, which is available on our website.

Nickel-Based Alloys (TCNI)

The TCS Ni-based Superalloys Database (TCNI) Validation and Calculation Examples Collection has an example using elastic properties. You can find it either in the Thermo-Calc help or via the Examples Collection PDF, which is available on our website.

Steel and Fe-Alloys (TCFE)

The *TCS Steel and Fe-alloys Database (TCFE) Validation and Calculation Examples Collection* has an example using elastic properties. You can find it either in the Thermo-Calc help or via the Examples Collection PDF, which is available on our website.

Titanium and Titanium Aluminide-based Alloys (TCTI)

The *TCS Ti/TiAl-based Alloys Database (TCTI) Validation and Calculation Examples Collection* has examples using elastic properties. You can find a description of these either in the Thermo-Calc help or via the Examples Collection PDF, which is available on our website.

Learn more on our website about the CALPHAD Method and how it is applied to the Thermo-Calc databases. Also visit the video tutorials on our website or our YouTube playlist.

Elastic Properties Variables

As of Thermo-Calc version 2026b, elastic properties are available with Thermo-Calc and the TCS Ti/TiAl-based Alloys Database (TCTI) (TCTI6 and newer), TCS Steel and Fe-alloys Database (TCFE) (TCFE14 and newer), TCS High Entropy Alloys Database (TCHEA) (TCHEA8 and newer), TCS Ni-based Superalloys Database (TCNI) (TCNI13 and newer), TCS Al-based Alloys Database (TCAL) (TCAL11 and newer), and TCS Mg-based Alloys Database (TCMG) (TCMG9 and newer). The elastic properties will be added to additional databases over time. Subscribe to our newsletter to be kept up-to-date on the latest product releases, webinars, user group meetings, applications examples, and more.

You can find information on our website about the properties that can be calculated with Thermo-Calc and the Add-on Modules. Additional resources are added on a regular basis so keep checking back or subscribe to our newsletter.

About the Elastic Properties

For information about thermophysical properties such as surface tension, viscosity, etc, see About Thermophysical Properties Data Parameters.

Elastic Constants and Moduli Variables

The so-called classic syntax is used in the examples below. It can be used in Console Mode or when using the APIs, e.g. TC-Python or TC-Toolbox for MATLAB®. Graphical Mode in Thermo-Calc has readable names for all of these.

The quantities corresponding to individual elastic constants and elastic moduli (derived from the elastic constants) can be calculated in Console Mode for individual phases or for all phases. The results can be shown in the POLY module with the command SHOW_VALUE or shown as a plot in the POST module with the command PLOT_DIAGRAM using:

- `Cij(<phase name>)` or `Cij(*)`
- Bulk modulus: `BULKMOD(<phase name>)` or `BULKMOD(*)`
- Shear modulus: `SHEARMOD(<phase name>)` or `SHEARMOD(*)`
- Young's modulus: `YOUNGMOD(<phase name>)` or `YOUNGMOD(*)`

Variables	Unit	Description
`BULKMOD`	Pascal	Bulk modulus
`SHEARMOD`	Pascal	Shear modulus
`YOUNGMOD`	Pascal	Young's modulus
`Cij`	Pascal	Elastic constants i.e. C11, C12, C13, C33, or C44

About the Database Files

In this section learn about Encrypted vs Unencrypted Database Files, Database Initialization File, and User Database Files.

Encrypted vs Unencrypted Database Files

Any licensed databases purchased from Thermo-Calc Software are encrypted in files with the extension `.TDC`; these files cannot be edited. These are referred to as *encrypted databases*.

Unencrypted databases have the file extension `.TDB` and can be edited. For example, PURE5 or PG35 (the free databases), or a user-defined database file.

Editing the Database Initialization File or Unencrypted Database File

If you develop your own databases on a regular basis, also see About the TDB Editor.

Database Initialization File

The *database initialization file* is called `tc_initd.tdb`. Individual licenses are still required to use each database.

The file is used differently by the program depending on whether you are working with databases in Console Mode or Graphical Mode. For this reason, editing the file can be problematic if you do not understand the differences.

About Cached Database Files and Editing the Database Initialization File or Unencrypted Database File

User Database Files

A user-defined database is considered to be an unencrypted database because you can make changes to it.

In Graphical Mode you can add user databases via the **Options** window. Once you have added the user database it is available from the database list in the System Definer Configuration window.

Global Settings: System Definer to add a user database.

In Console Mode, users can decide to add their own user-defined database to the database initiation file, which then makes it available in the Console window.

Editing the Database Initialization File or Unencrypted Database File

Custom Databases: GES5 and GES6 Calculation Engine Version

As of Thermo-Calc version 2019b, the default calculation engine is set to GES6. For custom database users, you may sometimes see messages in the log indicating that additional preparation is being done by Thermo-Calc prior to a calculation. The preparation is carried out automatically; it is usually fast and only needed the first time a custom database is used after a modification. While databases with warnings are tolerated, databases that contain errors can only be loaded by GES6 after the errors are corrected.

The Database Checker tool uses the same parser as GES6 and can be used to verify the consistency and correctness of databases during development, before the databases are actually used.

Database Checker

To globally set the default from GES6 back to GES5, go to the **Options** window Global General Settings tab and click **Version 5** for the *Preferred Gibbs Energy System* setting. The SET_GES_VERSION Console Mode command is used to change GES versions for a single Thermo-Calc session.

Contact Thermo-Calc Software AB at info@thermocalc.com for more information about the changes or if you encounter any issues you think are related to the new version of the calculation engine.

Database Installation Folder

The standard Thermo-Calc databases and the database initialization file `tc_initd.tdb` are located in a subfolder to the Thermo-Calc installation. For example, in a Windows Standalone installation, you can find these in a folder called **data**.

Installation File Paths

The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements.

After installation, you can go to **Tools > Options > Database directory** to confirm the file path, which can be useful for troubleshooting purposes.

Single Users (Local, Non-Admin Installation)

```
C:\Users\<username>\AppData\Local\Programs\Thermo-
Calc\2026b\data.
```

The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click **View > Show > Hidden Items**. For more control, you can also make changes to more than one folder via the **Folder Options > View > Advanced Settings** window then select **Show hidden files, folders, and drives**. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.

All Users (Admin)

```
C:\Program Files\Thermo-Calc\2026b\data
```

Common Phase Names

In some database folders, there is a *Common Phase Name* file, which is used to include common phase names in plotting (when applicable). This file can also be used as a guide to create your own user-defined file.

Search the Help (press F1) for *Working with Common Phase Names* to learn how to add your own and where this is found.

About Cached Database Files

This is applicable to Graphical Mode.

Also see Global Settings Global General Settings where you can set the default database directory path. There is also an option to clear the database cache, which may be helpful if you are having issues.

The first time you open a database in Graphical Mode it can take a little while for it to load, especially if it is one of the large databases such as TCFE or TCNI. However, the next time the database opens quickly because the databases are now cached, or stored, in Graphical Mode.

Think of a cache as an intermediate storage area. Once a database cache is established the file is made easily accessible, even if you close the software program. It is the same concept as when you load a web page for the first time. The next time the page opens faster. This is also how it works for the databases in Thermo-Calc Graphical Mode.

Thermo-Calc caches the database files, both encrypted and unencrypted types, at two points—when you first open a database, sometimes called an *in-memory cache*, and then as a *disk-based cache*. The disk-based cache is what speeds up database loading and it is at this point that Thermo-Calc refers to the database initialization file for information. The disk-based cache uses a lookup key to find the abbreviated database name (e.g. TCFE or TCNI) contained in this initialization file.

It is important to understand the way databases are cached in Graphical Mode to ensure best practices for those who also use Console Mode, especially if the database initialization file is edited. If you plan to edit this file, see Editing the Database Initialization File or Unencrypted Database File.

Editing the Database Initialization File or Unencrypted Database File

Some advanced users may decide to edit the database initialization file, for example to reorder the list of encrypted databases displaying in the Console window or to add a user-defined database for use in Console Mode. It is important to understand that changes to this file impact the database caching process used in Graphical Mode.

The following recommendations are also applicable if you edit an unencrypted database file, which includes user databases and free databases such as PURE5 or PG35.

Best Practice Recommendations

If you edit the database initialization file (`tc.initd.tdb` in Windows or `initd.tdb` in Mac and Linux), then:

- If a user database is added to the file, it is subject to the same caching as the encrypted databases. This means that further changes (to the user database) are not detected when you are working with databases in the System Definer in Graphical Mode.

If you have a user database, which is subject to regular updates, then:

- If you make changes to a user database, you then need to clear the cache.
- It is recommended that you create a separate directory to store unencrypted database files.

If you edit an unencrypted database file included with the installation (such as the PURE5 and PG35 files):

- Do not edit the file in the installation folder. Instead make a local copy and load it into the application as a user database.

Database Checker

The Thermo-Calc software package includes a program to check that the syntax of unencrypted database files is correct. The program applies the syntax rules set out in the *Database Manager User Guide* and reports errors and issues warnings. This program is intended for advanced users who develop and manage databases.

Thermo-Calc accepts some deviations from these syntax rules. Although warnings can be ignored, errors must be corrected. Reported errors must be corrected in the TDB file before the database can be loaded by the application. Sometimes the warnings can also reveal the need for additional corrections as shown in the example below.

For example, a warning is generated if a phase name is detected that is also an abbreviation of another phase name in the database. Although allowed, it is not recommended as this can (in some cases) lead to unexpected results because abbreviations are also used when entering commands in the Console and included in macro files. The following shows why in this case an abbreviation is not recommended.

Imagine that a macro file uses the abbreviation `ABC` to refer to a phase in a database that is named `ABCDE`. As long as there is no other phase in the database with the same exact name or initial abbreviation, it works. But if a new phase is added to the database and is actually named `ABC` then the macro can in error refer to the wrong phase. The macro still runs but now refers to the phase `ABC` instead of `ABCDE` because `ABC` is an exact match, *which takes precedence over abbreviations*. The Database Checker displays a warning because this situation can only occur when one phase name is an abbreviation of another.

With respect to using this tool, the executable `DatabaseChecker` file is found in the Thermo-Calc home directory.

The program can also be launched by selecting **Tools** → **Database Checker** from the main menu in Thermo-Calc.

Technical Note: Pipe or Redirect Output Data from Console Mode **3239**

Technical Note: Pipe or Redirect Output Data from Console Mode

Audience:	Advanced Programmers and Users
OS:	Windows, Linux, or macOS
Application:	For users who want to pipe or redirect data from Thermo-Calc running a macro in Console Mode. For example, you can start the application with the Thermo-Calc.bat file and the entire application closes when you enter the EXIT command in the Console prompt.
Command examples:	**Windows**: `Thermo-Calc.bat macro.tcm > output.log` **Linux**: `./Thermo-Calc.sh batch macro.tcm > output.log` **macOS**: `./Thermo-Calc.command batch macro.tcm > output.log`
Command line definitions	
>	Redirection command. The arrow indicates the flow of data. For example in `./Thermo-Calc.sh macro.tcm > output.log`, the contents of macro.tcm is used as input to the Thermo-Calc.sh script file and the resulting output (standard out) is then written to `output.log` instead of to the screen.

Key to Using this Guide

In this guide learn how to:

- Download and install the software on Windows, macOS, and Linux operating systems. This is applicable to new users and existing users who are installing a new or updated version of Thermo-Calc, where the new version is installed next to the old version.
- Activate your license using user credentials or a license file/license server.
- Locate various items in the default installation directories (i.e. databases, Database Checker, TDB Editor, materials, custom Property Models).
- Install selected components using the custom installation option.
- Install the *TC-Python* and *TC-Toolbox for MATLAB®* SDKs.
- Work with existing installations, i.e. add new components, update, or uninstall the software.
- Deactivate online or offline user credentials licenses.
- Install silently over a network (unattended installations).
- Troubleshoot to solve common installation problems related to the license file/license server activation type.

Educational Package Installations

This guide is NOT applicable to installations of the Free Educational Package, which does not require a license file and is not currently available with the new license system. Installation instructions are available separately after you request the free version from this page on our website.

License Activation Types

Starting with the 2025a release, Thermo-Calc Software began to migrate to a new License Entitlement System. The new license system greatly simplifies the licensing process and has many advantages. Licenses are now handled through a login (where *user credentials* are entered), rather than downloading and storing license files on a computer. The majority of users are already migrated to this new system. However, for the short term, a few users continue to use the old license file system. For more information about the changes and migration plan, contact us by email at info@thermocalc.com.

Installation instructions are generally organized based on the *license activation type*:

- **User credentials**: The new License Entitlement System, where a user name and password are entered after the installation is complete. This new system is available for standalone (SUNLL) and floating network licenses (NWL) (i.e. on a Cloud Hosted License Server), but not currently for On Premise License Servers.
- **License file**: The soon-to-be phased out license system where the license file is installed on either a standalone computer or a network server. This includes On Premise License Server installations involving the Sentinel license management software.

Visit our website to watch the installation video showing how to install with user credentials (in both online and offline mode), which will replace the license files. The video library also includes the installation videos using the old method (license files) and other installations such as for TC-Python.

Learn More

In addition to being included in the help, this installation guide is available in PDF format on the website.

Quick Installation Guides for Windows and macOS are available via the Download Center pages or on the Documentation page on our website. The same information is provided in this guide. Linux users should refer to this guide for information.

Typographical Conventions and Terminology

Learn about the typographical conventions and terminology used in this guide.

Typographical Conventions

Convention/Name	*Definition*
User credentials	This indicates that the information is applicable to the new license entitlement system. **User credentials** are a type of *license activation type* where a user name and password are entered after installation and when Thermo-Calc is first launched. The information is managed via an online portal system as well as from within Thermo-Calc.
License file	This indicates details related to the Thermo-Calc **license file**, which contains the license keys and is installed on either a standalone computer or a network server. This is a *license activation type* that is being replaced by *user credentials*.
Important	Provides important information and indicates that more detail is located in the linked or named topic.
Note	The information can be of use to you. It is recommended that you read the text or follow the link.
Forward arrow →	The forward arrow symbol → instructs you to select a series of menu items in a specific order. For example, **File → Save Project** is equivalent to: From the **File** menu, select **Save Project**.
Boldface font	A **boldface** font indicates that the given word(s) are shown that way in on a toolbar button or as a menu selection. For example, if you are told to select a menu item in a particular order, such as **File → Save Project**, or to click **Save**.

Convention/Name	*Definition*
Italic font	An *italic* font indicates the introduction of important terminology. Expect to find an explanation in the same paragraph or elsewhere in the guide.
`code` and **`code bold`**	A `code` font indicates you are to make a keyboard entry. It also shows a programming code or code examples. The **`code bold`** font highlights the entry.

Installation Terminology

Term	*Definition*
client*	A computer without a license file of its own but connected through the network to a computer with the license information. The client receives a license token from the computer where the license management software is installed.
consolidated network*	A type of network installation where the Thermo-Calc software and a Thermo-Calc licensing software are installed on a single server computer. This allows all computers in the network to access both the software and a license on the server via a client installation.
distributed network*	A type of network installation where the Thermo-Calc software is installed on one server computer in a network and the Thermo-Calc licensing software is installed on a different computer. After a thin client installation, all computers in the network can access both the software and the network license key via the server.
host ID*	The MAC address on the computer that a license is locked to.
license file*	The file (called *lservrc*) that contains all the purchased license keys. It is issued by Thermo-Calc Software, usually by email. This is a *license activation type* that is being replaced by user credentials.
license key*	The information contained in the license file that represents the products purchased and which is then authorized for installation.
license management software (see Sentinel RMS License Software)*	The Thermo-Calc license management software. When working in Windows it is called *License Manager* (full name is Sentinel RMS License Manager by SafeNet) and on Linux it is called *License Server* (full name is Sentinel License Sever by Safenet).

Term	*Definition*
license server*	The use of the term *license server* (lower case letters) is reserved for use for scripts and option files (for example, in an Unattended or Silent Network Client Installations (License File)). For the purposes of the step-by-step instructions it is not used to refer to the type of network installation that runs the license management program. See *Sentinel RMS Software* below.
Network Floating License (NWL)	A license type available and activated using user credentials. A NWL can only be used on one specific computer that hosts the licensing software. It is still referred to as an NWL license but is different than the one used with license file activations. The software may be used on the number of sites you have paid for and by the number of persons you have paid for on any number of network connected computers.
Network License (NWL)*	The license type used with the Sentinel RMS licensing software. The NWL can only be used on one specific computer that hosts the licensing software. This restricts license usage to a certain subnet or subnets. The software may be used on the number of sites you have paid for and by the number of persons you have paid for on any number of network connected computers.
Operating system	The operating system is named when the information is specific to a *Windows*, *macOS*, or *Linux* machine.
Sentinel RMS License Software*	The Thermo-Calc license management software that supplies the client computers in your network with license tokens when it runs the Thermo-Calc software. This is available for both Windows (called the License Manager) and Linux (called the License Server, but not to be confused with *license server* in lower case letters reserved for scripts).
Single User Node Locked License (SUNLL)	A unique license that can be used for one designated computer at one designated site. It cannot be copied or moved outside the site. If the software is installed on a portable computer, it can be temporarily used off-site. For *license file* activation types, a file is automatically installed on the computer, upon activation, and the license can be used without network access (to the License Server).
standalone computer	A computer which uses a SUNLL license type.
TC-Toolbox	The short name for the TC-Toolbox for MATLAB® SDK.

Term	*Definition*
thin client*	An installation where the software is installed on a file server but is run from a client computer. The licensing software may be installed on the file server (consolidated network installation) or on a different computer (distributed network installation).
user credentials	A type of *license activation type* where user credentials (a user name and password) are entered after installation and when Thermo-Calc is first launched. The information is managed via an online portal system as well as from within Thermo-Calc.
XQuartz	An open-source X Windows System, which is required to run Thermo-Calc on a Mac.
* A term only applicable to license files or license server systems, which are being replaced by the user credentials licensing.	

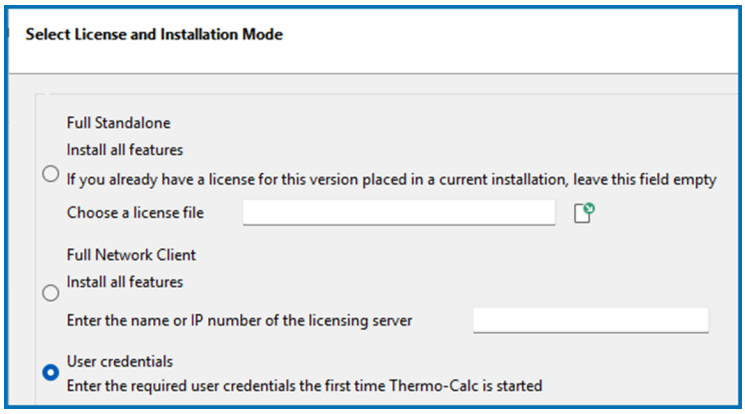
About the Thermo-Calc Installed Components

Learn about what features or products are installed and about the custom option.

What is Installed?

At the start of the installation process, you choose the *license activation type* (license file, licensing server, or user credentials) and whether to install all features.

The following components are installed when you choose any of the options, **Full Standalone**, **Full Network Client**, or **User credentials**. If you want to exclude a component (perhaps one of the SDKs), then click the **Custom** button instead (see below).



A full installation (*Install all features*) means that all listed feature components are installed but the availability of the individual components is based on the license you have. This is also applicable to the user credentials option, as well as databases and software development kits (SDKs).

Thermo-Calc

The Thermo-Calc software "component" includes several add-on features and capabilities that are packaged with the software and included with a full standalone, network client, or user credentials type installation. For example, there are the specialized add-on products, such as the Diffusion Module (DICTRA), Precipitation Module (TC-PRISMA), Process Metallurgy Module, and Additive Manufacturing (AM) Module. There are also material specific Property Model libraries included such as the Steel Model Library, Nickel Model Library, etc. For some of these specialized features, demonstration (*demo*) versions and examples are available for all users but advanced features are only available with a license.

Databases

All the latest databases are installed. As with the software features, availability of a specific database in the software itself is based on license. However, several demonstration (*demo*) databases are included and available to all users.

Software Development Kits (SDKs)

When the **Full Standalone**, **Full Network Client**, or **User credentials** option is chosen, it also installs the software development kits (SDKs).

- **TC-Python**: The TC-Python program is installed when the **Full Standalone**, **Full Network Client**, or **User credentials** option is chosen, but there are additional steps required to complete the installation as described in the *TC-Python Installation Guide*, which is available in this guide or as a standalone guide.
- **TC-Toolbox for MATLAB®**: If a MATLAB® installation on your computer is found during this installation process, the TC-Toolbox for MATLAB® (available only for Windows) is automatically installed, otherwise you may need to do a manual installation.
- **TQ-Interface**: The TQ-Interface program is installed when the **Full Standalone**, **Full Network Client**, or **User credentials** option is chosen.

What is the Custom Option?

During the installation process, there is some flexibility to choose what to include or exclude with the installation by choosing the **Custom** option. This is primarily to the level of being able to choose the SDKs or to exclude all databases or Thermo-Calc itself. That is, you cannot choose specific Thermo-Calc features or databases as these are controlled by the license and not the installation procedure.

Learn More

In addition to being included in the help, this installation guide is available in PDF format on the website.

System Requirements

A full list of system requirements and program availability is found on the Thermo-Calc website. You can also see the roadmap for platform support to use for planning purposes.

About the Thermo-Calc Installed Components

Network Client Installations: Sentinel RMS License Software

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

Network client installations using the Sentinel RMS license management software require the use of the most recent version, 9.7.

For details of the system requirements to install Sentinel RMS, see Windows: About Installing the License Manager and Linux: About Installing the License Server.

For macOS, the Sentinel RMS License software is installed on a Windows or Linux computer server where the Thermo-Calc license file must also be located.

Platforms Tested and SDK Availability

A full list of system requirements and program availability is found on the Thermo-Calc website. You can also see the roadmap for platform support to use for planning purposes.

Platforms Tested

Thermo-Calc 2026b and its components were tested on this platform at the time of release. Technical support and bug fixes are available for this platform as long as you have the latest version of the software.

Windows	*macOS*	*Linux*[2]
Windows 11	• Tahoe (26.x) • Sequoia (15.1)[1]	• Red Hat RHEL 10 • Red Hat RHEL 9 • Ubuntu 24.04 (Noble Numbat)

[1] Works with Rosetta 2 emulation on all M1, M2 and M3 Macs (2020, 2022, 2023).

[2] Thermo-Calc Software cannot guarantee full functionality if the software is installed on other Linux distributions.

SDK Availability by Platform

The software development kits (SDKs) are available as follows for the indicated platforms:

SDK	*Windows*	*macOS*	*Linux*
TC-Python	x	x	x
TQ-Interface	x	not available	x
TC-Toolbox for MATLAB®	x	not available	not available

License Activation and Installation Types

Installation procedures are based on the license types, license activation types, installation type, and the operating system.

There are two **license activation types** available with Thermo-Calc 2026b: One using a *license file* that is installed on your computer (this also includes the different network installation types using Sentinel License Management Software), and the new type where *user credentials* (user name and password) are entered after installation and when you first open (launch) Thermo-Calc.

Educational Package Installations

This guide is NOT applicable to installations of the Free Educational Package, which does not require a license file and is not currently available with the new license system. Installation instructions are available separately after you request the free version from this page on our website.

User Credentials Activations

About User Credentials License Activations and Troubleshoot User Credential License Activations

License type	*Installation Type*	*Windows*	*macOS*	*Linux*
Single User Node Locked License (SUNLL)	Standalone (aka Single User)	Yes	Yes	Yes

License type	*Installation Type*	*Windows*	*macOS*	*Linux*
Floating Network License (NWL)	Cloud Hosted License Server	Yes	Yes	Yes
	On Premise License Server*	No	No	No

* A few users will continue to use the License Management Software system for the short term until the change over is complete and implemented in a future release. Until then, users who require an On Premise License Server need to use License File and License Server Activations, see the next section. For more information about the changes and migration plan, contact us at info@thermocalc.com.

License File and License Server Activations

For macOS, the Sentinel RMS License software is installed on a Windows or Linux computer server where the Thermo-Calc license file must also be located.

License type	*Installation Type*	*Windows*	*macOS*	*Linux*
Single User Node Locked License (SUNLL)	Standalone	Yes	Yes	Yes
Network License (NWL)	Consolidated network	Yes	No	Yes
	Distributed network	Yes	No	Yes
	License installations on a server network	Yes	Yes	Yes

Sentinel RMS License Management Software: Use Current Version

The most recent version (9.7) of the Sentinel RMS License Manager (Windows) and License Server (Linux) is included with the network license Thermo-Calc software download.

However, due to security issues reported by the vendor, it is important that previous network license installations of the Sentinel RMS are upgraded to this version number.

For more information for your operating system, see Windows: About Installing the License Manager and Linux: About Installing the License Server

User Credential License Activation Installations

Starting with the 2025a release, Thermo-Calc Software began to migrate to a new License Entitlement System. The new license system greatly simplifies the licensing process and has many advantages. Licenses are now handled through a login (where *user credentials* are entered), rather than downloading and storing license files on a computer. The majority of users are already migrated to this new system. However, for the short term, a few users continue to use the old license file system. For more information about the changes and migration plan, contact us by email at info@thermocalc.com.

About User Credentials License Activations

All users are being migrated to this new *user credentials* license activation type. For this type of activation, the information is managed via an online portal system as well as accessible from within Thermo-Calc. Customers are being contacted directly by email to provide the necessary information to install and use your purchased products. During the transition from using the old license file activations, some users may need to contact support for assistance.

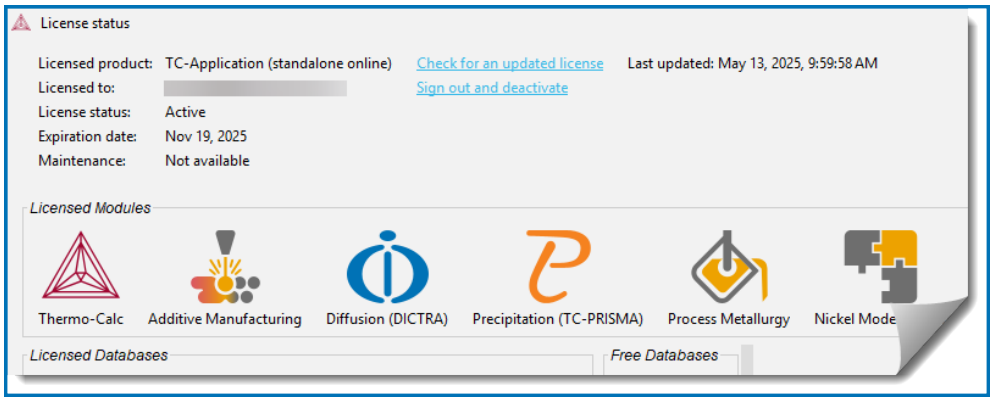
What is Unavailable in the New License System (2026b)

- Floating licenses for TC-Python and TC-Toolbox for MATLAB®
- Free Educational Package installations
- On Premise License Server installations

Viewing Product License Information

After you have installed Thermo-Calc and activated your license by entering your user credentials, you can view the license information by selecting **Help** → **Show License Info**.

In the **License status** window, it is an overview of your license as well as where you can check for updates, sign out or deactivate the license, and review its status and when it expires. If you have a Maintenance & Support Subscription (M&SS) the date of expiration is also displayed.



Checking for License Updates

After you have installed Thermo-Calc and activated your license by entering your user credentials, you can remotely check to see if your product license is up-to-date.

> Internet access is required. If you have chosen to use an offline license activation, this option is not available. Access to this update service is one reason the online activation type is recommended.

1. Open Thermo-Calc.
2. Select **Help** → **Show License Info**.
3. In the **License status** window, click **Check for an updated license**.
4. The program synchronizes with the license software management database and updates the licenses accordingly.

> When you update to a new version of Thermo-Calc, you may also need to update your license if you have added additional modules or databases.

TC-Python Additional License Activation Steps

When you also have a license for TC-Python, there are additional steps required to complete the activation. This is covered in the sections:

- TC-Python: Configuring a License
- TC-Python: Setting Environment Variables

TC-Toolbox Additional License Activation Steps

When you also have a license for TC-Toolbox for MATLAB®, there are additional steps required to complete the activation. This is covered in the section:

- TC-Toolbox: Configuring a License

Reminder that TC-Toolbox is not available with macOS or Linux installations.

Learn More

With respect to downloading and installing the software, there are subtle differences based on operating system (Windows, macOS, or Linux). One benefit of the new user credentials license activation type is that its use is independent of OS and the activation steps are the same across platforms.

Although many steps are the same, separate instructions are available for all the OS and for custom single user installations: Windows® User Credentials Installations, macOS® User Credentials Installations, or Linux User Credentials Installations. There are also instructions for Custom User Credentials Installations.

Visit our website to watch the installation video showing how to install with user credentials (in both online and offline mode), which will replace the license files. The video library also includes the installation videos using the old method (license files) and other installations such as for TC-Python.

Windows® User Credentials Installations

This section is applicable to:

- Operating system: Windows
- Installation type: Single User (SUNLL) or Floating Network Licenses (NWL)
- License activation type: User credentials (online and offline)
- Upgrading to a new version of Thermo-Calc (M&SS maintenance plan only)

Step 1: Download Thermo-Calc Software

Administrative rights can sometimes be required to complete this installation. An email from Thermo-Calc Software (or from someone in your organization) includes the links and information you need to access and activate the current version of the software you want to download.

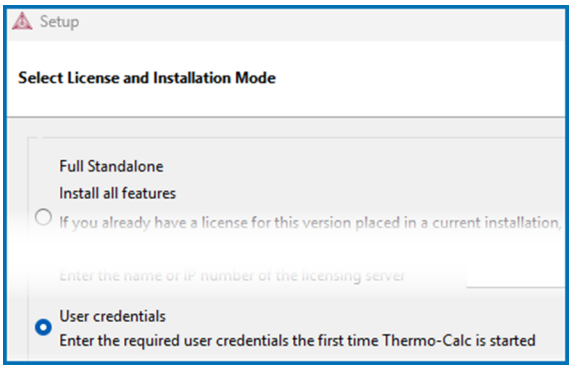
1. Click the link from the email and the first page of the **Download Center** opens. Under the **Windows** section, select the OS version. Click **Go to download page**.
2. In the **Sign in to access this site** window, enter the **Username** and **Password** (found in the email) and click **Sign in**.

3. On the **Download Center** page under **Software**, click the **.exe** link to download the file for the current software version for your operating system (e.g. 2026b).

Step 2: Install Thermo-Calc Software

1. Once the download is complete, navigate to the folder where you downloaded the software. Double-click the downloaded program file (the suffix is based on the operating system). Remember that administrative rights are needed, so when you are prompted for that user name and password, enter those credentials here, not the ones sent to you from Thermo-Calc.
2. Click **Yes** to continue.
3. On the **Setup - Thermo-Calc 2026b** window click **Next**.
4. On the **License Agreement** window click to accept the license agreement. Click **Next**.

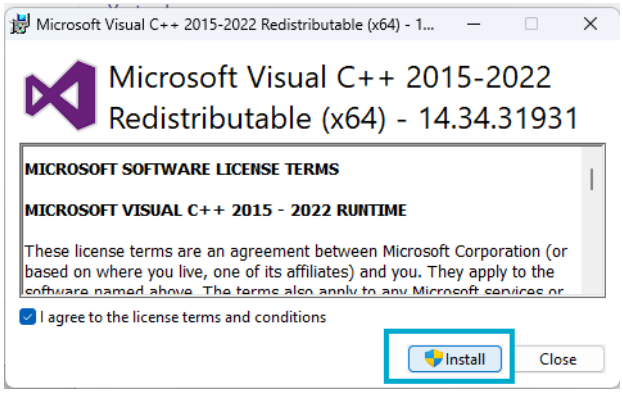
5. In the **Select License and Installation Mode** window click **User credentials** and then click **Next**.



6. TC-Python is automatically installed when the **User credentials** option is chosen. The **Install TC-Python** page is a reminder for users of TC-Python that additional installation and license credential procedures are needed after Thermo-Calc is installed. Read the separate installation instructions (also included in the full installation guide) for more information if applicable. Click **Next**.
7. In the **Ready to Install** window click **Next**. The software continues installing.
8. At the end of installation, click **Finish**. Once this is done, open Thermo-Calc either from the shortcut on your desktop or from the menu.

Error Messages

If you encounter errors about missing files (e.g. MSVCP or VCRUNTIME DLL) at any time during installation process or while trying to use the software, it is probably because you need to install Microsoft Visual C++ Redistributable.



If this is the case, it is recommended that you search for *install Microsoft Visual C++ Redistributable* and visit the Microsoft page to learn more and download the program.

To install the program, you need administrator access to your computer. Once you have installed the program, you can continue with Thermo-Calc.

Step 3: Activate the License

If your work environment does not allow an Internet connection to activate the license, as a last resort you can use the option **Create offline activation file**. Overall it is best to use the **Activate online** option as this provides more flexibility and future benefits including being able to easily update your license. See the last section for details.

1. Open Thermo-Calc. The first window includes highlights from the current release. Click **Close**.
2. In the **License status** window, enter the **User** and **Password** provided to you.

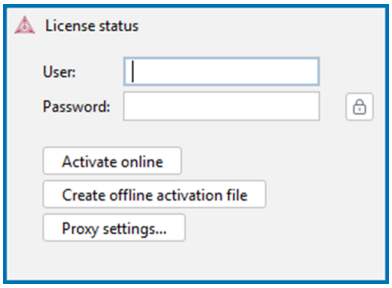
   Your license user credentials are sent to you in an email from Thermo-Calc or a representative. This is different from the Download Center login details. If you have not received the information, first ask the main Thermo-Calc contact in your organization. Otherwise, contact Support for clarification.

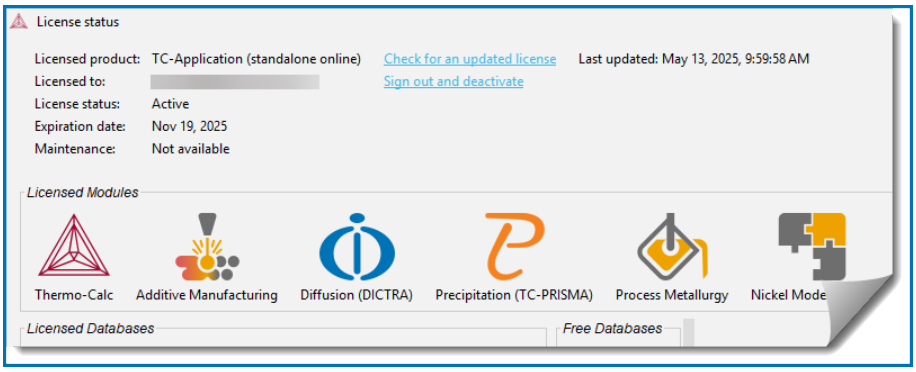
3. If you use a proxy server, click **Proxy settings**. Click **Use proxy** and enter your information. Click **OK**.

4. Click **Activate online**.

> If the fields become empty when you click **Activate online**, this means the activation did NOT work. See the troubleshooting section for details about next steps When Activate Online Does Not Work.

5. Once it is activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.





> At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

Step 4: Optional Offline License Activations

Offline activations are only available for single user (SUNLL) licenses and should only be used as a last resort, i.e. if there is no option provided by your organization to achieve online activation. The computer only needs to be connected to a network during the license activation, not when working with the software.

Offline activations can be an alternative for users who are in a highly secure environment that does not allow Internet connections.

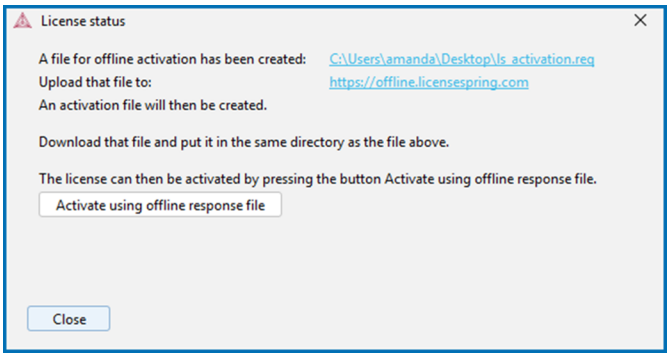
In general it is highly recommended to use the **Online activation** option as this provides more flexibility including faster and easier license updates, i.e. for offline activations license updates require repeating the full offline activation procedure.

You will need access to the Internet to complete the activation. You can do this either by:

- Accessing the Internet temporarily from the computer you will use Thermo-Calc on, or
- Activating the license on another computer then transferring the license to the computer you will use Thermo-Calc on.

These instructions are a continuation from previous steps and assume you have already installed Thermo-Calc and entered your user credentials.

1. Click **Create offline activation file**. The **License status** window opens with instructions you can refer to.



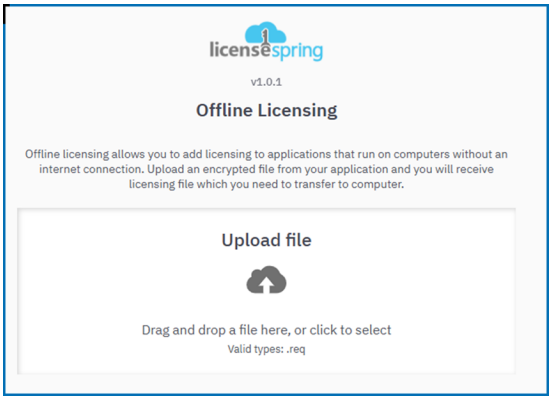
2. A local file to use for the offline activation is created and the link to where it is downloaded to your computer is provided. The file is named `ls_activation.req`. Click the link to go to this location on your computer.

> If you have downloaded the file to a computer that does not have Internet access, then copy this file to one that does and continue the process. Later you will copy the generated offline license back to the computer where Thermo-Calc is installed.

3. On the computer that has Internet access, go to the URL shown on the **License status** window: https://offline.licensespring.com.

4. Navigate to the `ls_activation.req` file on your computer and drag and drop it into the center of the window. The program generates another file and downloads it to your computer. This file is named `ls_activation.lic`.

> As soon as the `ls_activation.req` file is uploaded the license is considered by the software to be activated.



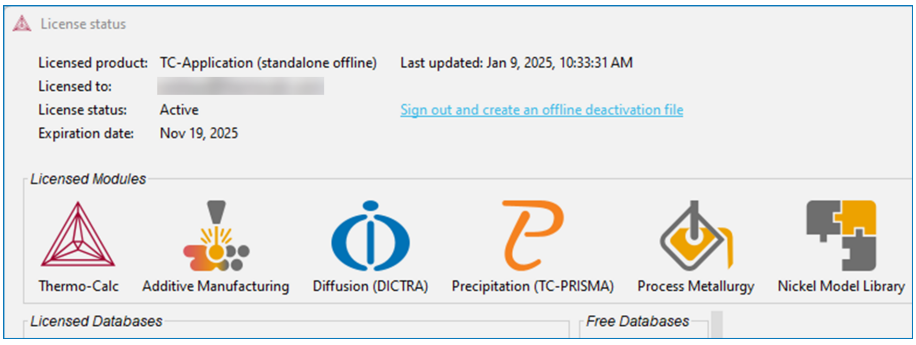
> If at this point you want to switch to an online activation instead (recommended), you can delete the `ls_activation.req` file from the computer location to end the offline activation process.

5. Navigate to the downloaded `ls_activation.lic` file. If needed, this is when you copy this file back to the computer where Thermo-Calc is installed. In both cases the new file should be copied back to the same folder where the original file `ls_activation.req` is located.

6. Once the two files are in the same folder, you are ready to generate an offline license.

7. Go to the **License status** window and click **Activate using offline response file**.

   Once activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.



8. You do not need to keep the files you downloaded. Return to where these files are downloaded and delete them.

At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

Learn More

There are two *license activation types* available with 2026b: (1) **User credentials**, which are entered after installation and managed via an online portal or (2) where a **license file** is installed directly on the computer or a licensing server. Many users have already started using the *user credentials* activation type and all users will eventually be migrated to the new system.

For instructions about other operating systems, network installations, or installing an SDK (e.g. TC-Python or TC-Toolbox for MATLAB®) search the *Thermo-Calc Installation Guide*, which is also available on our website. You can also review the Licensing Options included on our website.

Visit our website to watch the installation video showing how to install with user credentials (in both online and offline mode), which will replace the license files. The video library also includes the installation videos using the old method (license files) and other installations such as for TC-Python.

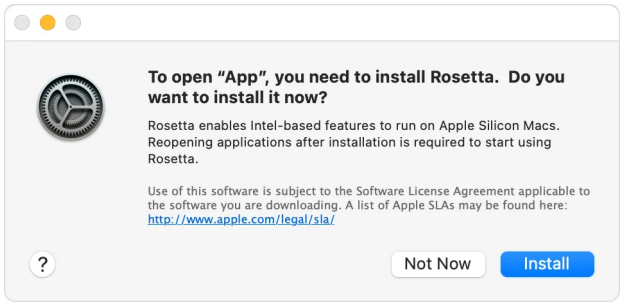
macOS® User Credentials Installations

This section is applicable to:

- Operating system: macOS
- Installation type: Single User (SUNLL) or Floating Network Licenses (NWL)
- License activation type: User credentials (online and offline)
- Upgrading to a new version of Thermo-Calc (maintenance plan only)

Step 1: Install Required macOS Software

To install and run Thermo-Calc on a Mac computer with an ARM processor, Rosetta first needs to be installed. If prompted, install as per macOS instructions.



Step 2: Download Thermo-Calc Software

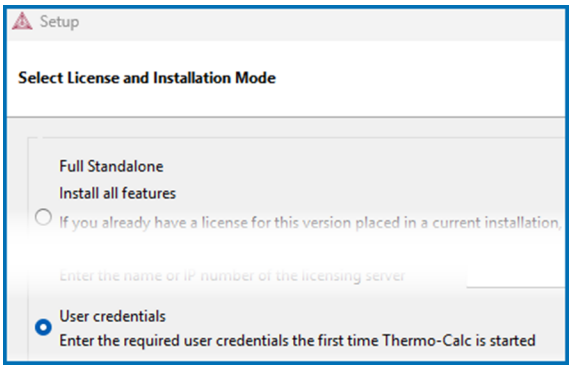
Administrative rights are required to complete this installation. An email from Thermo-Calc Software (or from someone in your organization) includes the links and information you need to access and activate the current version of the software you want to download.

1. Click the link from the email and the first page of the **Download Center** opens. Under the **macOS** section, select the OS version. Click **Go to download page**.
2. In the **Sign in to access this site** window, enter the **Username** and **Password** (found in the email) and click **Sign in**.
3. On the **Download Center** page under **Software**, click the **.zip** link to download the file for the current software version for your operating system (e.g. 2026b).

Step 3: Install Thermo-Calc Software

1. Once the download is complete, navigate to the folder where you downloaded the software. Double-click the downloaded program file (the suffix is based on the operating system). Remember that administrative rights are needed, so when you are prompted for that user name and password, enter those credentials here, not the ones sent to you from Thermo-Calc.
2. Click **Yes** to continue.
3. On the **Setup - Thermo-Calc 2026b** window click **Next**.
4. On the **License Agreement** window click to accept the license agreement. Click **Next**.

5. In the **Select License and Installation Mode** window click **User credentials** and then click **Next**.



6. TC-Python is automatically installed when the **User credentials** option is chosen. The **Install TC-Python** page is a reminder for users of TC-Python that additional installation and license credential procedures are needed after Thermo-Calc is installed. Read the separate installation instructions (also included in the full installation guide) for more information if applicable. Click **Next**.
7. In the **Ready to Install** window click **Next**. The software continues installing.
8. At the end of installation, click **Finish**. Once this is done, open Thermo-Calc either from the shortcut on your desktop or from the menu.

Step 4: Activate the License

If your work environment does not allow an Internet connection to activate the license, as a last resort you can use the option **Create offline activation file**. Overall it is best to use the **Activate online** option as this provides more flexibility and future benefits including being able to easily update your license. See the last section for details.

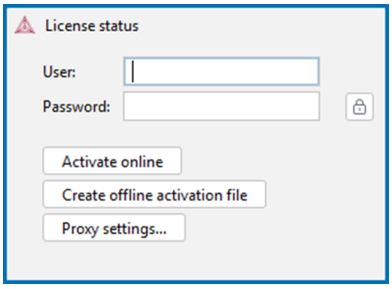
1. Open Thermo-Calc. The first window includes highlights from the current release. Click **Close**.
2. In the **License status** window, enter the **User** and **Password** provided to you.

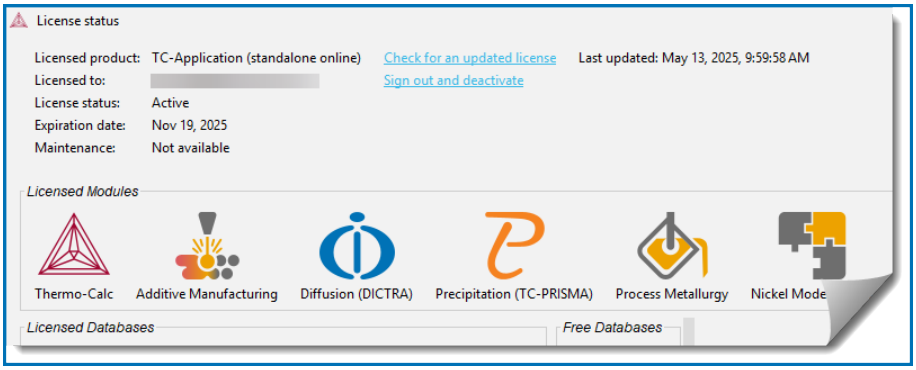
> Your license user credentials are sent to you in an email from Thermo-Calc or a representative. This is different from the Download Center login details. If you have not received the information, first ask the main Thermo-Calc contact in your organization. Otherwise, contact Support for clarification.

3. If you use a proxy server, click **Proxy settings**. Click **Use proxy** and enter your information. Click **OK**.
4. Click **Activate online**.

> If the fields become empty when you click **Activate online**, this means the activation did NOT work. See the troubleshooting section for details about next steps When Activate Online Does Not Work.

5. Once it is activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.





At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

Step 5: Optional Offline License Activations

Offline activations are only available for single user (SUNLL) licenses and should only be used as a last resort, i.e. if there is no option provided by your organization to achieve online activation. The computer only needs to be connected to a network during the license activation, not when working with the software.

Offline activations can be an alternative for users who are in a highly secure environment that does not allow Internet connections.

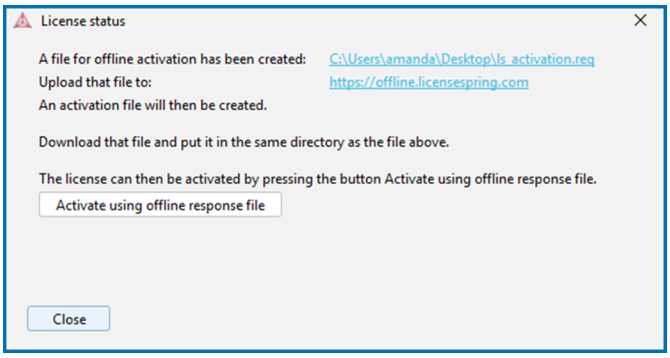
In general it is highly recommended to use the **Online activation** option as this provides more flexibility including faster and easier license updates, i.e. for offline activations license updates require repeating the full offline activation procedure.

You will need access to the Internet to complete the activation. You can do this either by:

- Accessing the Internet temporarily from the computer you will use Thermo-Calc on, or
- Activating the license on another computer then transferring the license to the computer you will use Thermo-Calc on.

These instructions are a continuation from previous steps and assume you have already installed Thermo-Calc and entered your user credentials.

1. Click **Create offline activation file**. The **License status** window opens with instructions you can refer to.



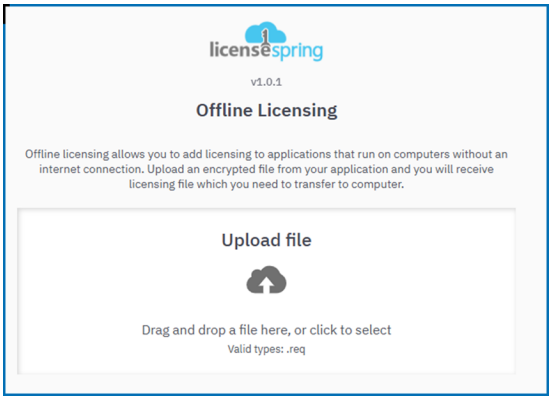
2. A local file to use for the offline activation is created and the link to where it is downloaded to your computer is provided. The file is named `ls_activation.req`. Click the link to go to this location on your computer.

If you have downloaded the file to a computer that does not have Internet access, then copy this file to one that does and continue the process. Later you will copy the generated offline license back to the computer where Thermo-Calc is installed.

3. On the computer that has Internet access, go to the URL shown on the **License status** window: https://offline.licensespring.com.

4. Navigate to the `ls_activation.req` file on your computer and drag and drop it into the center of the window. The program generates another file and downloads it to your computer. This file is named `ls_activation.lic`.

> As soon as the `ls_activation.req` file is uploaded the license is considered by the software to be activated.



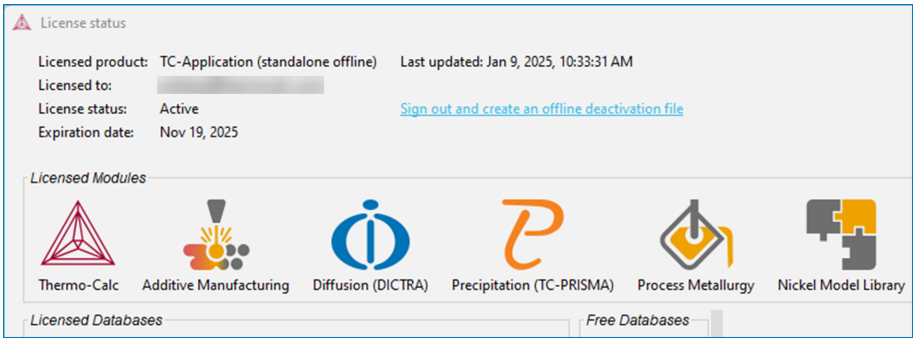
> If at this point you want to switch to an online activation instead (recommended), you can delete the `ls_activation.req` file from the computer location to end the offline activation process.

5. Navigate to the downloaded `ls_activation.lic` file. If needed, this is when you copy this file back to the computer where Thermo-Calc is installed. In both cases the new file should be copied back to the same folder where the original file `ls_activation.req` is located.

6. Once the two files are in the same folder, you are ready to generate an offline license.

7. Go to the **License status** window and click **Activate using offline response file**.

   Once activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.



8. You do not need to keep the files you downloaded. Return to where these files are downloaded and delete them.

At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

Learn More

There are two *license activation types* available with 2026b: (1) **User credentials**, which are entered after installation and managed via an online portal or (2) where a **license file** is installed directly on the computer or a licensing server. Many users have already started using the *user credentials* activation type and all users will eventually be migrated to the new system.

For instructions about other operating systems, network installations, or installing an SDK (e.g. TC-Python or TC-Toolbox for MATLAB®) search the *Thermo-Calc Installation Guide*, which is also available on our website. You can also review the Licensing Options included on our website.

Visit our website to watch the installation video showing how to install with user credentials (in both online and offline mode), which will replace the license files. The video library also includes the installation videos using the old method (license files) and other installations such as for TC-Python.

Linux User Credentials Installations

This section is applicable to:

- Operating system: Linux
- Installation type: Single User (SUNLL) or Floating Network Licenses (NWL)
- License activation type: User credentials (online and offline)
- Upgrading to a new version of Thermo-Calc (maintenance plan only)

Step 1: Download Thermo-Calc Software

Administrative rights are required to complete this installation. An email from Thermo-Calc Software (or from someone in your organization) includes the links and information you need to access and activate the current version of the software you want to download.

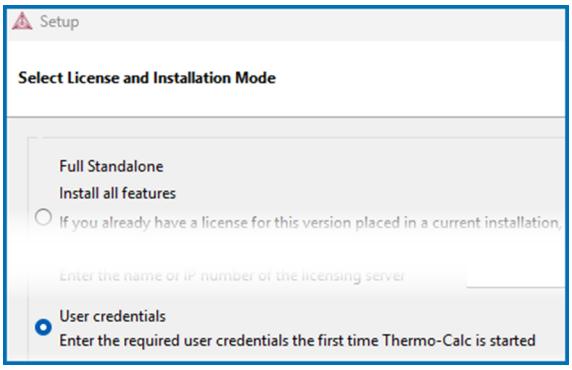
1. Click the link from the email and the first page of the **Download Center** opens. Under the **Linux** section, select the OS version. Click **Go to download page**.
2. In the **Sign in to access this site** window, enter the **Username** and **Password** (found in the email) and click **Sign in**.

3. On the **Download Center** page under **Software**, click the **.run** link to download the file for the current software version for your operating system (e.g. 2026b).

Step 2: Install Thermo-Calc Software

1. Once the download is complete, navigate to the folder where you downloaded the software. Double-click the downloaded program file (the suffix is based on the operating system). Remember that administrative rights are needed, so when you are prompted for that user name and password, enter those credentials here, not the ones sent to you from Thermo-Calc.
2. Click **Yes** to continue.
3. On the **Setup - Thermo-Calc 2026b** window click **Next**.
4. On the **License Agreement** window click to accept the license agreement. Click **Next**.

5. In the **Select License and Installation Mode** window click **User credentials** and then click **Next**.



6. TC-Python is automatically installed when the **User credentials** option is chosen. The **Install TC-Python** page is a reminder for users of TC-Python that additional installation and license credential procedures are needed after Thermo-Calc is installed. Read the separate installation instructions (also included in the full installation guide) for more information if applicable. Click **Next**.
7. In the **Ready to Install** window click **Next**. The software continues installing.
8. At the end of installation, click **Finish**. Once this is done, open Thermo-Calc either from the shortcut on your desktop or from the menu.

Step 3: Activate the License

If your work environment does not allow an Internet connection to activate the license, as a last resort you can use the option **Create offline activation file**. Overall it is best to use the **Activate online** option as this provides more flexibility and future benefits including being able to easily update your license. See the last section for details.

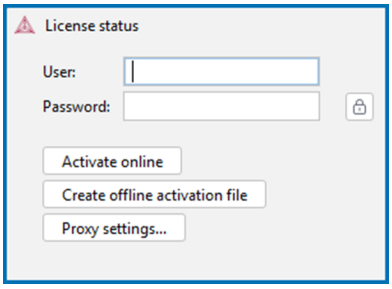
1. Open Thermo-Calc. The first window includes highlights from the current release. Click **Close**.
2. In the **License status** window, enter the **User** and **Password** provided to you.

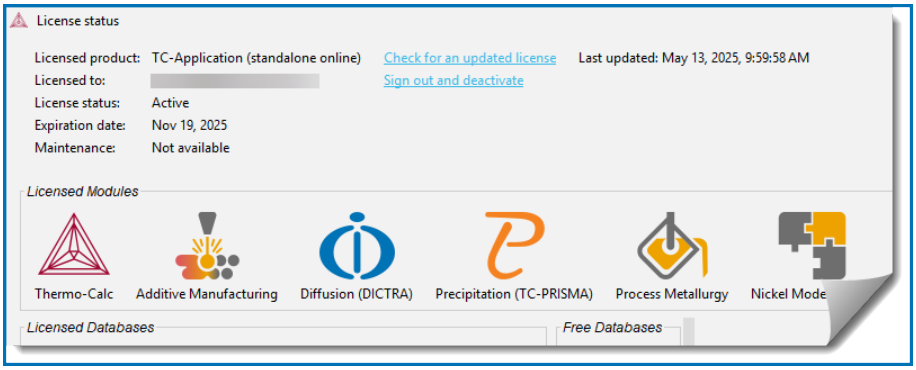
> Your license user credentials are sent to you in an email from Thermo-Calc or a representative. This is different from the Download Center login details. If you have not received the information, first ask the main Thermo-Calc contact in your organization. Otherwise, contact Support for clarification.

3. If you use a proxy server, click **Proxy settings**. Click **Use proxy** and enter your information. Click **OK**.
4. Click **Activate online**.

> If the fields become empty when you click **Activate online**, this means the activation did NOT work. See the troubleshooting section for details about next steps When Activate Online Does Not Work.

5. Once it is activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.





At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

Step 4: Optional Offline License Activations

Offline activations are only available for single user (SUNLL) licenses and should only be used as a last resort, i.e. if there is no option provided by your organization to achieve online activation. The computer only needs to be connected to a network during the license activation, not when working with the software.

Offline activations can be an alternative for users who are in a highly secure environment that does not allow Internet connections.

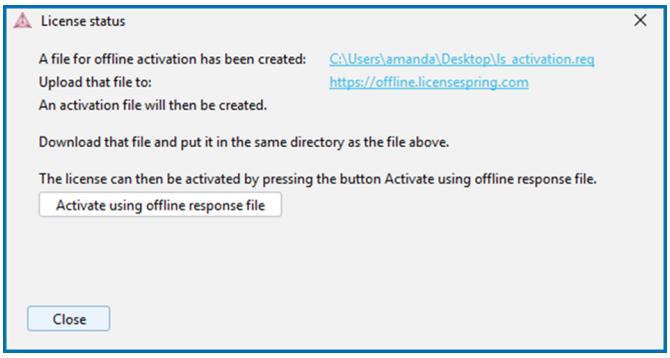
In general it is highly recommended to use the **Online activation** option as this provides more flexibility including faster and easier license updates, i.e. for offline activations license updates require repeating the full offline activation procedure.

You will need access to the Internet to complete the activation. You can do this either by:

- Accessing the Internet temporarily from the computer you will use Thermo-Calc on, or
- Activating the license on another computer then transferring the license to the computer you will use Thermo-Calc on.

These instructions are a continuation from previous steps and assume you have already installed Thermo-Calc and entered your user credentials.

1. Click **Create offline activation file**. The **License status** window opens with instructions you can refer to.



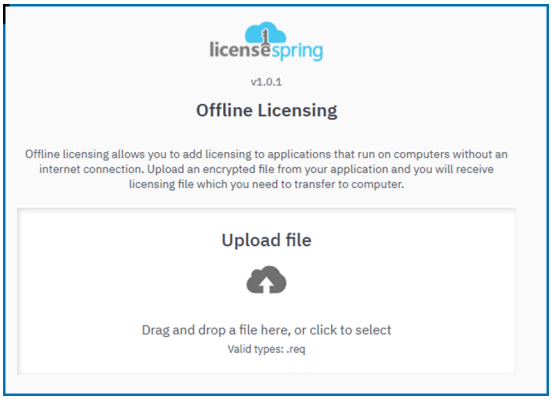
2. A local file to use for the offline activation is created and the link to where it is downloaded to your computer is provided. The file is named `ls_activation.req`. Click the link to go to this location on your computer.

If you have downloaded the file to a computer that does not have Internet access, then copy this file to one that does and continue the process. Later you will copy the generated offline license back to the computer where Thermo-Calc is installed.

3. On the computer that has Internet access, go to the URL shown on the **License status** window: https://offline.licensespring.com.

4. Navigate to the `ls_activation.req` file on your computer and drag and drop it into the center of the window. The program generates another file and downloads it to your computer. This file is named `ls_activation.lic`.

> As soon as the `ls_activation.req` file is uploaded the license is considered by the software to be activated.



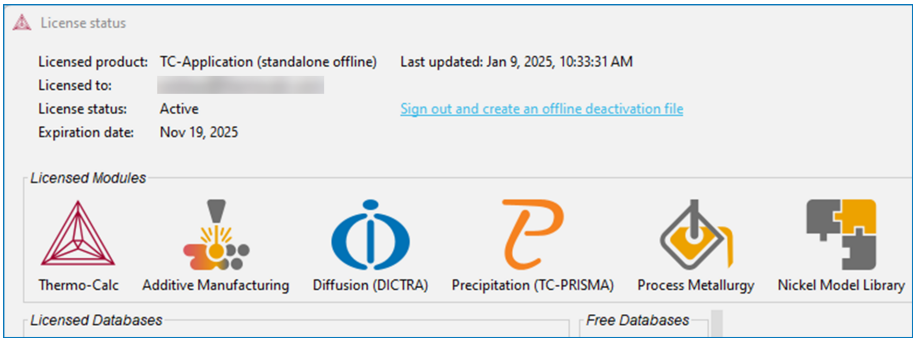
> If at this point you want to switch to an online activation instead (recommended), you can delete the `ls_activation.req` file from the computer location to end the offline activation process.

5. Navigate to the downloaded `ls_activation.lic` file. If needed, this is when you copy this file back to the computer where Thermo-Calc is installed. In both cases the new file should be copied back to the same folder where the original file `ls_activation.req` is located.

6. Once the two files are in the same folder, you are ready to generate an offline license.

7. Go to the **License status** window and click **Activate using offline response file**.

   Once activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.



8. You do not need to keep the files you downloaded. Return to where these files are downloaded and delete them.

At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

There are two *license activation types* available with 2026b: (1) **User credentials**, which are entered after installation and managed via an online portal or (2) where a **license file** is installed directly on the computer or a licensing server. Many users have already started using the *user credentials* activation type and all users will eventually be migrated to the new system.

For instructions about other operating systems, network installations, or installing an SDK (e.g. TC-Python or TC-Toolbox for MATLAB®) search the *Thermo-Calc Installation Guide*, which is also available on our website. You can also review the Licensing Options included on our website.

Visit our website to watch the installation video showing how to install with user credentials (in both online and offline mode), which will replace the license files. The video library also includes the installation videos using the old method (license files) and other installations such as for TC-Python.

Custom User Credentials Installations

Use the **Custom** option to have more control over what component features to include or exclude, for example, to exclude an SDK.

This section is applicable to:

- Operating systems: Windows, macOS, or Linux
- Installation type: Single User (SUNLL) or Floating Network Licenses (NWL)
- License activation type: User credentials (online and offline)
- Upgrading to a new version of Thermo-Calc (maintenance plan only)

Step 1: Download Thermo-Calc Software

This section uses Windows as an example, but download the applicable OS for use.

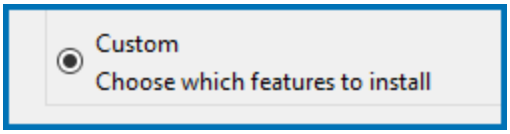
Administrative rights can sometimes be required to complete this installation. An email from Thermo-Calc Software (or from someone in your organization) includes the links and information you need to access and activate the current version of the software you want to download.

1. Click the link from the email and the first page of the **Download Center** opens. Under the **Windows** section, select the OS version. Click **Go to download page**.
2. In the **Sign in to access this site** window, enter the **Username** and **Password** (found in the email) and click **Sign in**.

3. On the **Download Center** page under **Software**, click the **.exe** link to download the file for the current software version for your operating system (e.g. 2026b).

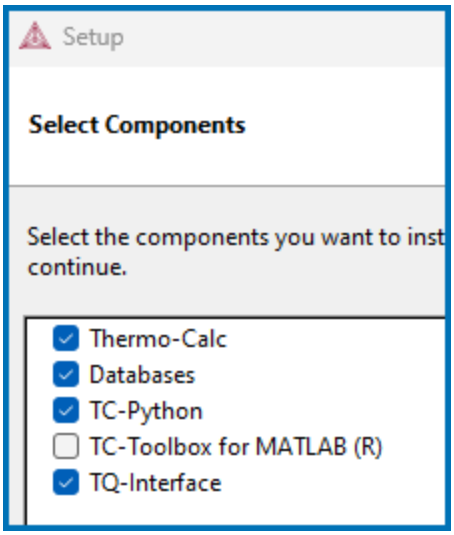
Step 2: Select the Components to Install

1. Once the download is complete, navigate to the folder where you downloaded the software. Double-click the downloaded program file (the suffix is based on the operating system). Remember that administrative rights are needed for Windows and macOS, so when you are prompted for that user name and password, enter those credentials here, not the ones sent to you from Thermo-Calc.
2. Click **Yes** to continue.
3. On the **Setup - Thermo-Calc 2026b** window click **Next**.
4. On the **License Agreement** window click to accept the license agreement. Click **Next**.
5. In the **Select License and Installation Mode** window click **Custom**. Click **Next**.



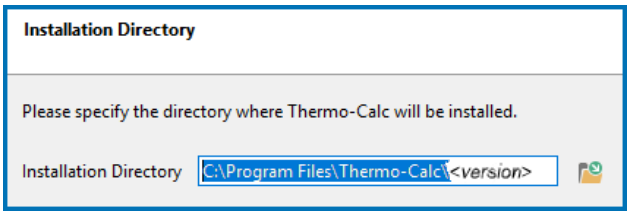
6. On the **Specify Configuration** window the **Create Shortcut on Desktop** checkbox is selected by default. Click **Next**.

7. In the **Select Components** window, click to select or deselect the checkboxes as needed. Click **Next**.

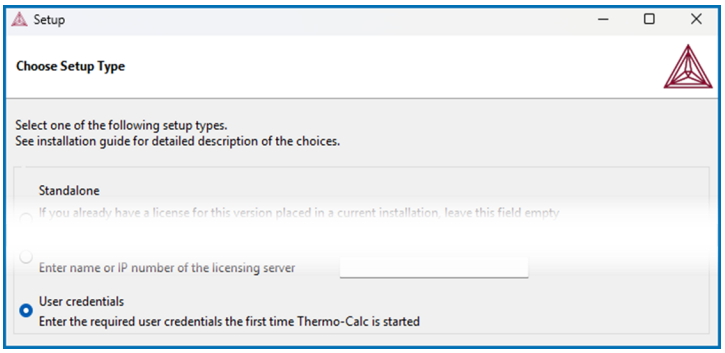


Step 3: Finish Installing Thermo-Calc

1. In the **Installation Directory** window, either accept the default path or enter a path to where you want to install the software. Click the file button to **Browse for Folder** and navigate to another directory.



2. In the **Choose Setup Type** window, click **User credentials**.



3. TC-Python is automatically installed when the **User credentials** option is chosen. The **Install TC-Python** page is a reminder for users of TC-Python that additional installation and license credential procedures are needed after Thermo-Calc is installed. Read the separate installation instructions (also included in the full installation guide) for more information if applicable. Click **Next**.
4. In the **Ready to Install** window click **Next**.
5. Click **Finish** and start using Thermo-Calc. For Linux users, log out and log back in to finish the installation.

For macOS installations and if you have previous Thermo-Calc installations: When you launch Thermo-Calc with the new or updated version, the splash screen hides the **Import User Settings** dialog box. In order to proceed you need to click the splash screen and then click **Yes** or **No** in the dialog box.

Step 4: Activate the License

If your work environment does not allow an Internet connection to activate the license, as a last resort you can use the option **Create offline activation file**. Overall it is best to use the **Activate online** option as this provides more flexibility and future benefits including being able to easily update your license. See the last section for details.

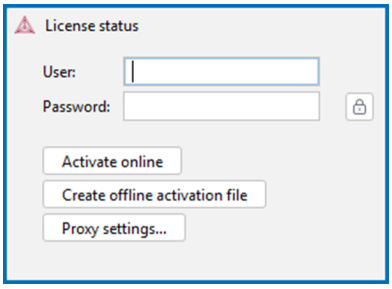
1. Open Thermo-Calc. The first window includes highlights from the current release. Click **Close**.
2. In the **License status** window, enter the **User** and **Password** provided to you.

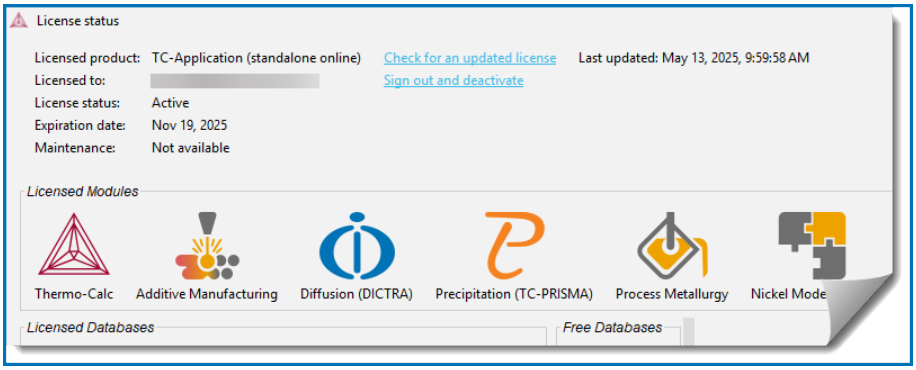
> Your license user credentials are sent to you in an email from Thermo-Calc or a representative. This is different from the Download Center login details. If you have not received the information, first ask the main Thermo-Calc contact in your organization. Otherwise, contact Support for clarification.

3. If you use a proxy server, click **Proxy settings**. Click **Use proxy** and enter your information. Click **OK**.
4. Click **Activate online**.

> If the fields become empty when you click **Activate online**, this means the activation did NOT work. See the troubleshooting section for details about next steps When Activate Online Does Not Work.

5. Once it is activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.





At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

Step 5: Optional Offline License Activations

Offline activations are only available for single user (SUNLL) licenses and should only be used as a last resort, i.e. if there is no option provided by your organization to achieve online activation. The computer only needs to be connected to a network during the license activation, not when working with the software.

Offline activations can be an alternative for users who are in a highly secure environment that does not allow Internet connections.

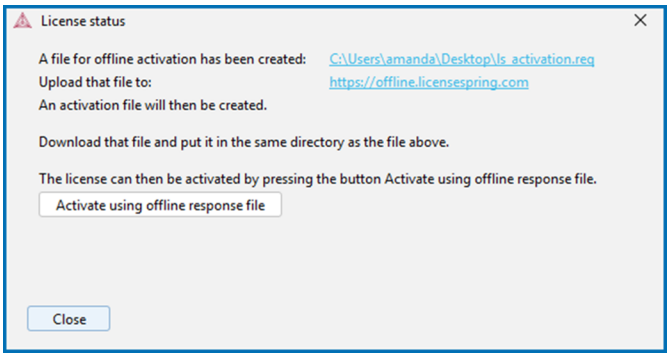
In general it is highly recommended to use the **Online activation** option as this provides more flexibility including faster and easier license updates, i.e. for offline activations license updates require repeating the full offline activation procedure.

You will need access to the Internet to complete the activation. You can do this either by:

- Accessing the Internet temporarily from the computer you will use Thermo-Calc on, or
- Activating the license on another computer then transferring the license to the computer you will use Thermo-Calc on.

These instructions are a continuation from previous steps and assume you have already installed Thermo-Calc and entered your user credentials.

1. Click **Create offline activation file**. The **License status** window opens with instructions you can refer to.



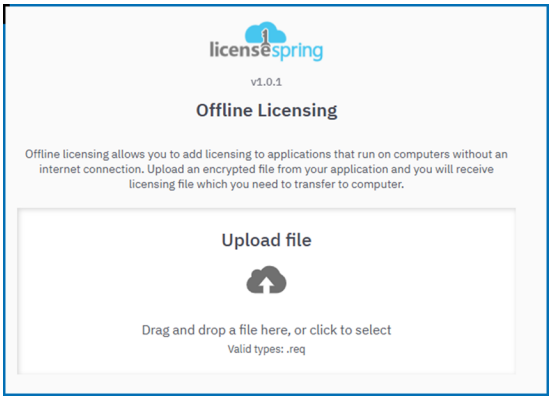
2. A local file to use for the offline activation is created and the link to where it is downloaded to your computer is provided. The file is named `ls_activation.req`. Click the link to go to this location on your computer.

If you have downloaded the file to a computer that does not have Internet access, then copy this file to one that does and continue the process. Later you will copy the generated offline license back to the computer where Thermo-Calc is installed.

3. On the computer that has Internet access, go to the URL shown on the **License status** window: https://offline.licensespring.com.

4. Navigate to the `ls_activation.req` file on your computer and drag and drop it into the center of the window. The program generates another file and downloads it to your computer. This file is named `ls_activation.lic`.

> As soon as the `ls_activation.req` file is uploaded the license is considered by the software to be activated.



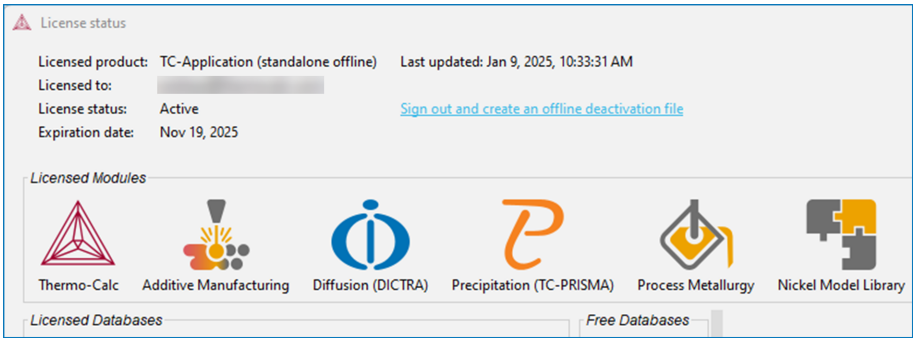
> If at this point you want to switch to an online activation instead (recommended), you can delete the `ls_activation.req` file from the computer location to end the offline activation process.

5. Navigate to the downloaded `ls_activation.lic` file. If needed, this is when you copy this file back to the computer where Thermo-Calc is installed. In both cases the new file should be copied back to the same folder where the original file `ls_activation.req` is located.

6. Once the two files are in the same folder, you are ready to generate an offline license.

7. Go to the **License status** window and click **Activate using offline response file**.

   Once activated you will see the **License status** window with a list of the products you have access to. Click **Close** and start using Thermo-Calc.



8. You do not need to keep the files you downloaded. Return to where these files are downloaded and delete them.

At any time you can view the product license information by selecting **Help → Show License Info** from the menu in Thermo-Calc.

About the Thermo-Calc Installed Components and Add New Components to an Existing Installation

Unattended or Silent Network Installations (User Credentials)

Sometimes it is convenient to install Thermo-Calc network clients without providing user input after the installation is initiated (an unattended network installation), i.e. a *silent installation*. This is available for Windows and Linux operating systems.

Step 1: Create an Option File in a Text Editor to Enter the Options

Below is a example for installation when you have a license activation type **user credentials**:

```
installation_mode=custom
setup_type=licenseSpring
```

Step 2: Go to the Directory Where the Installation File is Saved

Thermo-Calc can only be installed in unattended mode from the command line prompt.

Start the installation in unattended mode using the option file created with this command:

- Windows: `<installationfile>.exe --mode unattended --optionfile <path\optionfile>`
- Linux: `<installationfile>.run --mode unattended --optionfile <path/optionfile>`

To see other options when you start the Thermo-Calc installation program from the command line prompt, run this command:

- Windows: `<installationfile>.exe --help`
- Linux: `<installationfile>.run --help`

Step 3: Activate the User Credentials Type of License

1. In the installation folder these files are found based on OS:
    - Windows: `License-manager.bat`
    - Linux: `License-manager.sh`

2. From the command line prompt, run the command once for every product you want to activate:
    - Windows: `License-manager.bat <product> activate <user><password>`
    - Linux: `License-manager.sh <product> activate <user><password>`

<product> can be TC-Application, TC-Python, or TC-Toolbox. *<user>* and *<password>* are the user credentials provided by email from Thermo-Calc or a representative.

The license manager can be used for activation, updating, and so forth. Run the command `License-manager.bat --help` and it shows the available options.

Deactivating Online or Offline Licenses

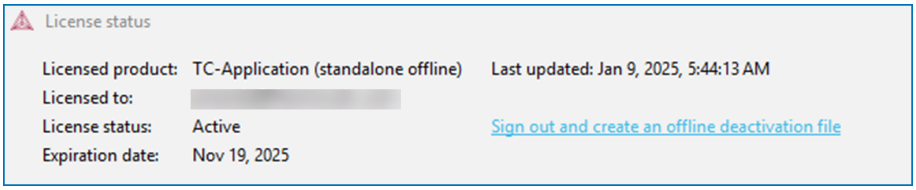
In this section is information about deactivating online and offline licenses.

Deactivating an Online License

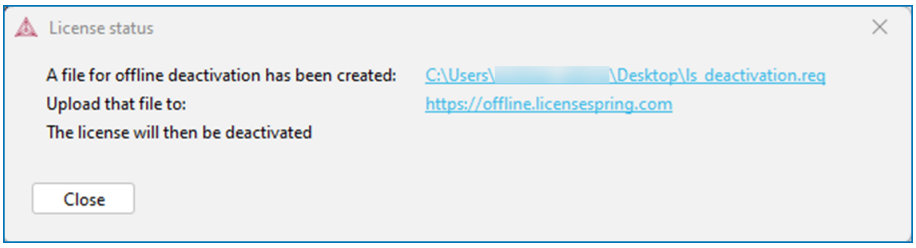
1. Open Thermo-Calc.
2. Select **Help** → **Show License Info**.
3. In the **License status** window, click **Sign out and deactivate**.
4. The login window opens where you enter the user credentials and the license is deactivated.

Deactivating an Offline License

1. Open Thermo-Calc.
2. Select **Help** → **Show License Info**.
3. In the **License status** window, click **Sign out and use an offline deactivation file**.

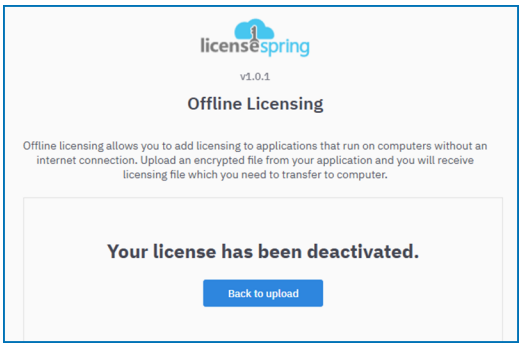


4. A local file to use for the offline deactivation is created and the link to where it is downloaded to your computer is provided. The file is named `ls_deactivation.req`. Click the link to go to this location on your computer.



> Since you have downloaded the file to a computer that does not have Internet access, then either temporarily access the Internet, or copy the file to one where you can continue the process.

5. On the computer that has Internet access, go to the URL shown on the **License status** window: https://offline.licensespring.com.
6. Navigate to the `ls_deactivation.req` file on your computer and drag and drop it into the center of the window. The Offline Licensing window confirms that the license is deactivated.



7. You do not need to keep the file you downloaded. Return to where the deactivation file was downloaded or saved and delete it.

Troubleshoot User Credential License Activations

This section is specific to troubleshoot some common problems with the *user credentials* license activation option.

When Activate Online Does Not Work

If the fields become empty (i.e. go blank) when you click **Activate Online**, this means that the final step of the license activation has failed. You need to contact support to troubleshoot further.

1. Close the license activation window.
2. Go to the bottom left corner of Thermo-Calc and click to open the **Event Log** window.
3. Copy all the red error messages and send these to your local support contact should you have one. Otherwise copy and paste these into an email and send to support@thermocalc.com.

Firewall or Anti-virus Issues

If you have trouble with a local or non-local firewall or anti-virus software blocking Thermo-Calc from accessing LicenseSpring API, then try this solution.

Make an exception allowing Thermo-Calc to connect to the following IP addresses through TCP ports 443 and 80:

- 34.250.134.210
- 34.251.49.36
- 52.18.228.254
- 54.78.102.217

Proxy Service or SSL Certification Issues

If you see this error

```
ERROR LicenseManager: . Thrown at:
com.licensespring.internal.services.LicenseSpringApiRetryer:tryCauseMessage:LineNo:
96 PKIX path
```

then it is either because you are behind a proxy server OR the SSL certification has failed.

For both of these types of issues you typically need to contact your organization's IT department for assistance.

- A proxy service is used for an Internet connection, which blocks the connection. Use the **Proxy Settings** option available on the license activation window, or contact your proxy service provider to make an exception.
- For SSL certification: The Let's Encrypt root public CA should be installed (ISRG Root X1). This is included in all supported OS, but can be missing in the organization's security service.

Other Common Errors

Some general troubleshooting suggestions are included in this section.

Problem	*Suggested Solution*
The incorrect password is entered	There can be issues when you copy and paste passwords from other sources. Check that no extra spaces were accidentally copied at the beginning or end of a password, and that all of the string is included in the selection.
Offline activation procedure was initiated but not completed, thus blocking the final activation.	It is recommended that where possible an online activation is used instead. First try to fix this issue by deleting the `ls_activation.req` file on your computer as described in the step for Offline Activation described for your specific OS. In other cases, once an offline activation is attempted, and if it does not work, the license can still be registered by the license software as being activated, thus blocking the final activation. Contact support@thermocalc.com to reset the license.

Learn More

All users are being migrated to this new *user credentials* license activation type. For this type of activation, the information is managed via an online portal system as well as accessible from within Thermo-Calc. Customers are being contacted directly by email to provide the necessary information to install and use your purchased products. During the transition from using the old license file activations, some users may need to contact support for assistance.

Default Installation Directories

The default directories where the software and its components are installed, including where the license file is stored, vary by platform and user type.

If you want to select specific components to install or if you want to install the software in a non-default installation directory, then do a **custom** installation (Windows and Linux only). In the table, *<user>* stands for the user name and *<version>* for the version of Thermo-Calc, for example 2026b.

Installation Default Directory: Windows

As of Thermo-Calc 2026a, Thermo-Calc can be installed without requiring administration rights for most Windows users. This changes the file paths to where certain items are located.

Windows User Type	*Default Directory*
No Admin Rights needed (Per-user installation)	Thermo-Calc can be installed without admin rights. However, the program is then only available to that specific user profile. The installation directory defaults to: `C:\Users\<username>\AppData\Local\Programs\Thermo-Calc\2026b` The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click **View > Show > Hidden Items**. For more control, you can also make changes to more than one folder via the **Folder Options > View > Advanced Settings** window then select **Show hidden files, folders, and drives**. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.
Administrator (Machine-wide installation)	If an administrator installs Thermo-Calc (even though Admin rights are not needed) the standard file path is below but this can vary based on your specific IT practices. `C:\Program Files\Thermo-Calc\2026b` In some cases when an interim software update is installed there is also a backup folder created in this folder. For details, see Updating the Software for Interim Releases.
Public Documents vs Documents Paths depend on system set up i.e. if you use Microsoft 365 OneDrive	It is recommended that you work with the files that are copied to the *user* Documents folder as described below. ***Public Documents Folder for Original Installation*** The default folder installation for documents, materials files, examples, and other items that can require additional licenses are installed under **Public Documents** for ALL USERS ON THE SAME MACHINE.

Windows User Type	*Default Directory*

	The **Public Documents** folder always contains the *original* set of contents as per the installation. For example,
	`C:\Users\Public\Documents\Thermo-Calc\2026b`
	
	Documents Folder - Copy of Original
	
	After installing Thermo-Calc, and when you first open the program, all files and folders from **Public Documents** are copied to the user's **Documents** folder. This local copy is associated to the user login and permissions are restricted to the user and administrators.
	
	For example, common locations can be:
	`C:\Users\<username>\AppData\Thermo-Calc\2026b`
	`C:\Users\<username>\Documents\Thermo-Calc\2026b`
	
	 If you are using MS365 and OneDrive, the Documents folder could be mapped there, e.g. OneDrive\<*username*>\Documents\Thermo-Calc\2026b.

Server network	This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a. License software installations on a server network (the License Manager software) `C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager\WinNT\`

Installation Default Directory: macOS

macOS User Type	*Default Directory*

Administrator (user name and password required)	The Thermo-Calc program is installed in the **Applications** folder:
	`Thermo-Calc-2026b.app and uninstall-Thermo-Calc-2026b.app`
	The documents, materials, examples, and other folders that sometimes require additional licenses are installed here:
	`/Users/Shared/Thermo-Calc/2026b`
	In some cases when an interim software update is installed there is also a backup folder created in this folder. For details, see Updating the Software for Interim Releases.
	To go to this folder, in Finder, from the **Go** main menu select **Go to folder**. Enter the above file path and click **Go**.

Installation Default Directory: Linux

Linux User Type	*Default Directory*
Non root user	The Thermo-Calc program including the documents, materials, examples, and other folders that sometimes require additional licenses are installed here: `/home/<user>/Thermo-Calc/2026b`
Root user	The Thermo-Calc program including the documents, materials, examples, and other folders that sometimes require additional licenses are installed here: `/opt/Thermo-Calc/2026b` In some cases when an interim software update is installed there is also a backup folder created in this folder. For details, see Updating the Software for Interim Releases.
License software installations on a server network (the License Server software)	This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a. If you are doing a network installation then these files are available as a tar-file from the Thermo-Calc website. Contact Support for more information. In the downloaded tar-file, there is a **restart_lserv** script file, which can be used as a template for creating a script that starts up the License Server.

Installation Default Directory: Databases, Database Checker, and TDB Editor

The standard Thermo-Calc databases and the database initialization file `tc_initd.tdb` are located in a subfolder to the Thermo-Calc installation. For example, in a Windows Standalone installation, you can find these in a folder called **data**.

Installation File Paths

The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements.

After installation, you can go to **Tools > Options > Database directory** to confirm the file path, which can be useful for troubleshooting purposes.

Single Users (Local, Non-Admin Installation)

```
C:\Users\<username>\AppData\Local\Programs\Thermo-Calc\2026b\data.
```

The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click **View > Show > Hidden Items**. For more control, you can also make changes to more than one folder via the **Folder Options > View > Advanced Settings** window then select **Show hidden files, folders, and drives**. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.

All Users (Admin)

```
C:\Program Files\Thermo-Calc\2026b\data
```

Common Phase Names

In some database folders, there is a *Common Phase Name* file, which is used to include common phase names in plotting (when applicable). This file can also be used as a guide to create your own user-defined file.

Search the Help (press F1) for *Working with Common Phase Names* to learn how to add your own and where this is found.

Database Checker

The Thermo-Calc software package includes a program to check that the syntax of unencrypted database files is correct. The program applies the syntax rules set out in the *Database Manager User Guide* and reports errors and issues warnings. This program is intended for advanced users who develop and manage databases.

Thermo-Calc accepts some deviations from these syntax rules. Although warnings can be ignored, errors must be corrected. Reported errors must be corrected in the TDB file before the database can be loaded by the application. Sometimes the warnings can also reveal the need for additional corrections as shown in the example below.

For example, a warning is generated if a phase name is detected that is also an abbreviation of another phase name in the database. Although allowed, it is not recommended as this can (in some cases) lead to unexpected results because abbreviations are also used when entering commands in the Console and included in macro files. The following shows why in this case an abbreviation is not recommended.

Imagine that a macro file uses the abbreviation `ABC` to refer to a phase in a database that is named `ABCDE`. As long as there is no other phase in the database with the same exact name or initial abbreviation, it works. But if a new phase is added to the database and is actually named `ABC` then the macro can in error refer to the wrong phase. The macro still runs but now refers to the phase `ABC` instead of `ABCDE` because `ABC` is an exact match, *which takes precedence over abbreviations*. The Database Checker displays a warning because this situation can only occur when one phase name is an abbreviation of another.

With respect to using this tool, the executable `DatabaseChecker` file is found in the Thermo-Calc home directory.

The program can also be launched by selecting **Tools** → **Database Checker** from the main menu in Thermo-Calc.

TDB Editor

The TDB Editor is an editing tool for those who develop their own custom databases for use with Thermo-Calc or other applications. The tool speeds up the database editing process by providing immediate feedback through syntax coloring, syntax checking, and by allowing formatting and easy navigation to items of interest in the TDB file.

During installation, the `tdb-language-support.vsix` file is installed in the Thermo-Calc home directory.

In order to access the most-up-to-date version of the TDB editing functionality, it must be reinstalled every time a *new* version of Thermo-Calc is installed.

For information about installing the TDB Editor, which is separate from the main installation and can be done later, see the *Database Manager's User Guide* contained in the *Thermo-Calc Documentation Set* or press F1 in Thermo-Calc and search the help.

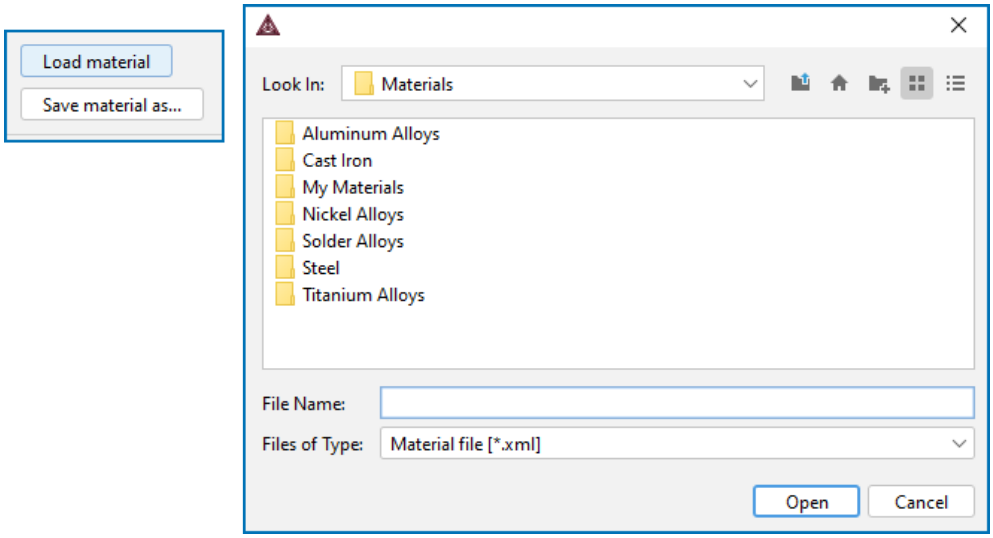
Installation Default Directory: Materials

When you are working with the System Definer or Material to Material Calculator you can open the default **Materials** folder included with your installation.

At the bottom of the window under **Material**, click **Load material** to navigate to a material file.

There is a separate folder for materials saved using the Process Metallurgy Calculator. See Installation Default Directory: Process Metallurgy Materials.

For the Additive Manufacturing (AM) Module, the Material Properties library is managed by the software.



The default directory where these material files are stored is based on operating system:

Operating System	*Materials Installation Directory*
Windows	The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements. ***Single user (Local, Non-Admin Installation)***

Operating System	*Materials Installation Directory*

	`C:\Users\<username>\AppData\Local\Programs\Thermo-Calc\2026b\Materials`
	
	The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click **View > Show > Hidden Items**. For more control, you can also make changes to more than one folder via the **Folder Options > View > Advanced Settings** window then select **Show hidden files, folders, and drives**. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.
	
	All Users (Admin)
	
	`C:\Users\<username>\Documents\Thermo-Calc\2026b\Materials`

Linux	On Linux all user files are installed where the program is installed. If installed as root the default is: `/opt/Thermo-Calc/2026b/Materials`
macOS	`/Users/Shared/Thermo-Calc/2026b/Materials`

Installation Default Directory: Process Metallurgy Materials

With the Process Metallurgy Calculator you can save materials to work with again. This is the default folder where these are stored based on your operating system:

Operating System	*Process Metallurgy Materials Installation Directory*

Windows	The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements.
	
	Single User (Local, Non-Admin Installation)
	
	`C:\Users\<username>\AppData\Thermo-Calc\2026b\ProcessMetallurgyMaterials`
	
	 If you are using MS365 and OneDrive, the Documents folder could be mapped there, e.g. OneDrive*<username>*\Documents\Thermo-Calc\2026b.
	
	 The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click **View > Show > Hidden Items**. For more control, you can also make changes to more than one folder via the **Folder Options > View > Advanced Settings** window then select **Show hidden files, folders, and drives**. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.
	
	All Users (Admin)
	
	`C:\Users\<username>\Documents\Thermo-Calc\2026b\ProcessMetallurgyMaterials`

Linux	On Linux all user files are installed where the program is installed. If installed as root the default is: `/opt/Thermo-Calc/2026b/ProcessMetallurgyMaterials`
macOS	`/Users/Shared/Thermo-Calc/2026b/ProcessMetallurgyMaterials`

Installation Default Directory: Custom Property Models

All Property Models (whether these are predefined or custom models) must be located in a subdirectory of the Property Model directory. You can go to the **Options** window then on the **General** tab the **Model directory** field displays the default directory.

To open the **Options** window:

- Windows: Select **Tools** → **Options**.
- Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on the keyboard.

Predefined models included with the Property Model Calculator are installed in the locations below based on your operating system. If you create your own models using TC-Python, this is the default directory where these are saved.

Operating System	*Property Model Installation Directory*

Windows	The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements.
	
	Single User (Local, Non-Admin installation)
	
	`C:\Users\<username>\AppData\Local\Programs\Thermo-Calc\2026b\PropertyModels`
	
	All Users (Admin installation)
	
	`C:\Program Files/Thermo-Calc/2026b\PropertyModels`

Linux	On Linux all user files are installed where the program is installed. If installed as root the default is:
	
	`/opt/Thermo-Calc/2026b/PropertyModels`
	
	or:
	
	`/home/<username>/Thermo-Calc/2026b/PropertyModels`

macOS	`/Applications/Thermo-Calc-2026b.app/Contents/Resources/PropertyModels`

License File and License Server Installations

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

About License Keys and Files

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

To run Thermo-Calc and its components you need a valid license key for each product. The license keys are included in the license file emailed to you by Thermo-Calc Software.

You can copy the license file to the applicable computer(s) before or after installing the software—the license file itself is not required during the installation process. However, it is required to make calculations in Thermo-Calc.

Request a License File from Thermo-Calc Software

First Steps of Installation

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

This section reviews some of the things you need to do before installing the Thermo-Calc software.

- Learn about the different default directories where the software and license files are installed.
- For network installations, collect subnet information.
- Make sure the person installing the software has administrator rights for Windows and macOS.
- For macOS, install XQuartz and make sure the security preferences are set correctly.
- For a Linux Cent OS 7 installation, also install gtk2 before you run the installation script.

```
yum install gtk2
```

Should I get my license file before or after software installation? The Thermo-Calc license file itself is not required during the installation process. However, it is required to make calculations in Thermo-Calc. The license file has details about your computer(s) that in some cases cannot be determined accurately until *after* installation (especially for a network installation). For most users it is recommended you request the file before you start installing.

You do not need a license file if you are provided with user credentials to activate your license. See About User Credentials License Activations and proceed to the relevant installation instructions.

Installation Default Directories and the License File

You do not need a license file if you are provided with user credentials to activate your license. See About User Credentials License Activations and proceed to the relevant installation instructions.

The default directories where the software and its components are installed, including where the license file is stored, vary by platform and user type.

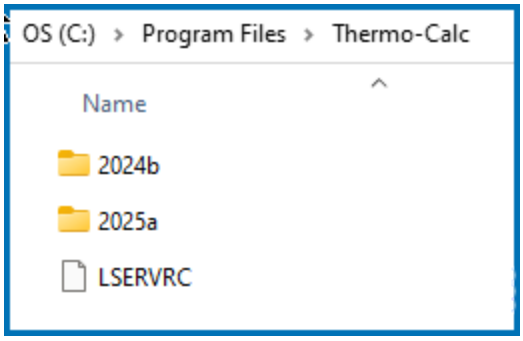
If you want to select specific components to install or if you want to install the software in a non-default installation directory, then do a **custom** installation (Windows and Linux only). In the table, *<user>* stands for the user name and *<version>* for the version of Thermo-Calc, for example 2026b.

License File Installation Location for All Operating Systems

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The Thermo-Calc license file is installed outside of the installation program folder. If you have more than one version of Thermo-Calc installed then there are additional folders by version number with only one license file.

For macOS the license file is put in `/Users/Shared/Thermo-Calc`. The example below is for a Standalone Windows installation.



Learn More

See the following for more information:

- Installation Default Directory: Windows
- Installation Default Directory: macOS
- Installation Default Directory: Linux
- Installation Default Directory: Databases, Database Checker, and TDB Editor
- Installation Default Directory: Materials
- Installation Default Directory: Process Metallurgy Materials
- Installation Default Directory: Custom Property Models
- Installation Default Directories: TC-Python and Bundled Python Interpreter
- Installation Default Directory: TC-Toolbox Examples and Diagnostic Script

Standalone Installations (License File)

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

You can either do a full or a custom standalone installation. The license type is called a Single-User Node-Locked License (SUNLL).

Standalone Installations (SUNLL)

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The standalone installation is used with the Single-User Node-Locked License (SUNLL). The Thermo-Calc software and a Thermo-Calc license file are installed on a standalone computer. You can do a full (all operating systems) or a custom installation (Windows and Linux only).

To get started, go to (1) First Steps of Installation and then (2) Standalone Installations (License File).

Full Standalone Installations

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The following describes a full standalone installation. These steps assume you have completed the section First Steps of Installation.

Step 1: Request your License File from Thermo-Calc Software

Upgrading to a new version of Thermo-Calc: Skip this section if you are upgrading to a new version of Thermo-Calc (and you have a maintenance plan), or you have already been provided with the license file.

For license file activations, follow the instructions for your operating system in the section Request a License File from Thermo-Calc Software. Also note that the license file name must be the same as the existing file name to ensure there are no errors during the update.

You do not need a license file if you are provided with user credentials to activate your license. See About User Credentials License Activations and proceed to the relevant installation instructions.

Step 2: Download your Thermo-Calc Installation Software

Administrative rights are required for Windows and macOS to complete this installation. The email from Thermo-Calc Software (or from someone in your organization) includes the links and information you need to access the current version of the software you want to download.

1. Click the link from the email and the first page of the **Download Center** opens. Under the applicable operating system section (Windows, macOS, or Linux), select the OS version. Click **Go to download page**.
2. In the **Sign in to access this site** window, enter the **Username** and **Password** (found in the email) and click **Sign in**.
3. On the **Download Center** page under **Software**, click the relevant link for your operating system to download the file for the current software version (2026b).

Step 3: Run the Applicable Installation File for your Operating System

1. Navigate to the folder for your operating system and click the link to download the software package, then go to the folder where you downloaded it.

Windows

Double-click the **.exe** file to launch the **Setup** program.

macOS

Double-click the downloaded file then follow the instructions.

For macOS and when you first run the installer, you may see a message that *Thermo-Calc-osx-<version> can't be opened because Apple cannot check it for malicious software*. If this happens, select **Show in Finder**. Then, in the opened **Finder** window right-click the downloaded file `Thermo-Calc-osx-<version>` and select **Open**.

Linux

To start the Setup Wizard in a Terminal window, enter these commands in the directory where the installation file is saved:

```
> chmod +x linux-installation-x64-2026b.run
> ./linux-installation-x64-2026b.run
```

If you are an openSUSE root user, see Linux Installation Notes for some information about your installation.

2. On the **Setup** window click **Next**.
3. On the **License Agreement** window click the button to accept the license agreement then click **Next**.

Step 4: Select the License and Installation Mode and Install the Software

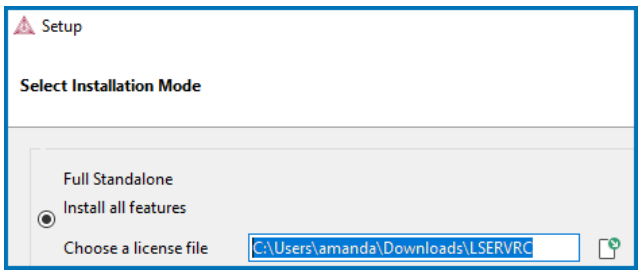
About the Thermo-Calc Installed Components

1. In the **Select License and Installation Mode** window click **Full Standalone: Install all features**.

   If you want to exclude a component (e.g. an SDK), then use the **Custom** option. See Custom Standalone Installations (License File). For TC-Toolbox for MATLAB®, also see Installing TC-Toolbox with the Custom Option.

   If you also have a license for TC-Python, it is installed when the **Full Standalone** or **Full Network Client** option is chosen, but there are additional steps required as described separately for this SDK.

2. For a **Full Standalone** installation, in the **Choose a license file** field either enter the file path or click the file button to navigate to where you saved the license file emailed to you from Thermo-Calc Software.



The license file is called **lservrc**. Click **Next**. To prevent errors, leave this field blank if you did not get a license file yet. If you did not get your license file see Request a License File from Thermo-Calc Software.

TC-Python is installed for all users even if you do not have a license. The **Install TC-Python** window is a reminder that additional installation procedures are required after Thermo-Calc is installed. See the *TC-Python Installation Guide*.

3. In the **Ready to Install** window click **Next**. Click **Finish** and start using Thermo-Calc.

Learn More

For Linux users, log out and log back in to finish the installation.

For macOS installations and if you have previous Thermo-Calc installations: When you launch Thermo-Calc with the new or updated version, the splash screen hides the **Import User Settings** dialog box. In order to proceed you need to click the splash screen and then click **Yes** or **No** in the dialog box.

Windows® Standalone (License File) Installations

There are two *license activation types* available with 2026b: (1) **User credentials**, which are entered after installation and managed via an online portal or (2) where a **license file** is installed directly on the computer or a licensing server. Many users have already started using the *user credentials* activation type and all users will eventually be migrated to the new system.

This section is applicable to:

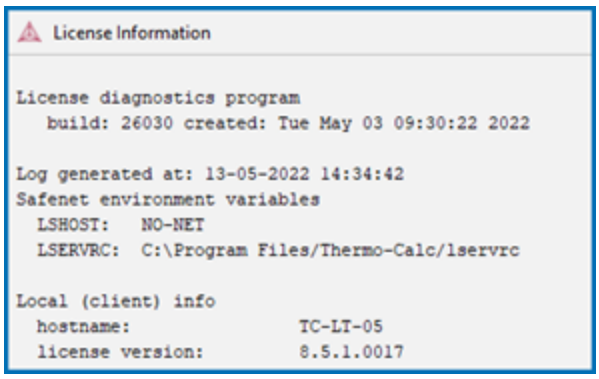
- Operating system: Windows
- Installation type: Full Standalone (SUNLL)
- License activation type: License file where the software and the license file are installed together on one computer.
- Upgrading to a new standalone version of Thermo-Calc (maintenance plan only)

Step 1: Request a License File

Upgrading to a new version of Thermo-Calc: Skip this section if you are upgrading to a new version of Thermo-Calc (and you have a maintenance plan), or you have already been provided with the license file.

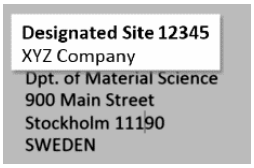
1. Your license information is sent to you in an email from Thermo-Calc or a representative. When you are sent a *license file*, save it to your computer to use during software installation. You may also need to provide some information that is accessed from Thermo-Calc.

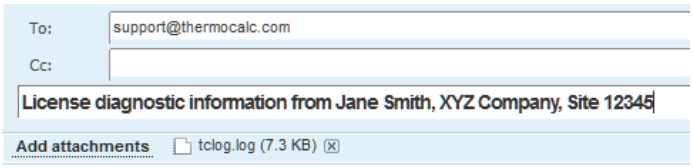
   Select **Help → Show License Info**.



2. Copy the information from the **License Information** window. A lot of information may be shown below the initial screen, so make sure you scroll down to the end when you select and copy the window's contents. (Alternatively, you can copy the same information from the console by using the SYS module command DISPLAY_LICENSE_INFO.)
3. Send an email to support@thermocalc.com. Make sure to include the following in the subject line:

   License diagnostic information from <Name> where Name is replaced with your **name**, the **organization name** and the **Site Number**. *You can find the five-digit site number on an invoice or any correspondence from Thermo-Calc Software.*





4. A representative from Thermo-Calc Software replies to the email and attaches your license file(s).
5. Save the license file(s) to your computer or network.

Step 2: Download Thermo-Calc Software

Administrative rights can sometimes be required to complete this installation. An email from Thermo-Calc Software (or from someone in your organization) includes the links and information you need to access and activate the current version of the software you want to download.

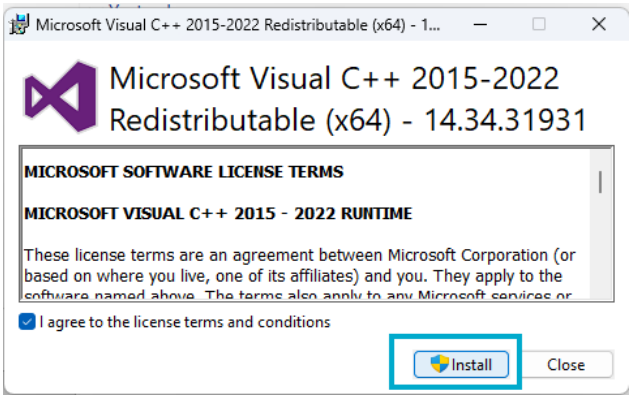
1. Click the link from the email and the first page of the **Download Center** opens. Under the **Windows** section, select the OS version. Click **Go to download page**.
2. In the **Sign in to access this site** window, enter the **Username** and **Password** (found in the email) and click **Sign in**.
3. On the **Download Center** page under **Software**, click the **.exe** link to download the file for the current software version for your operating system (e.g. 2026b).

Step 3: Install Thermo-Calc Software

1. Navigate to the folder where you downloaded the software. Double-click the **.exe** program. If you are prompted for admin user name and password, enter these credentials here. Click **Yes** to continue.
2. On the **Setup - Thermo-Calc 2026b** window click **Next**.
3. On the **License Agreement** window click to accept the license agreement. Click **Next**.

Error Messages

If you encounter errors about missing files (e.g. MSVCP or VCRUNTIME DLL) at any time during installation process or while trying to use the software, it is probably because you need to install Microsoft Visual C++ Redistributable.



If this is the case, it is recommended that you search for *install Microsoft Visual C++ Redistributable* and visit the Microsoft page to learn more and download the program.

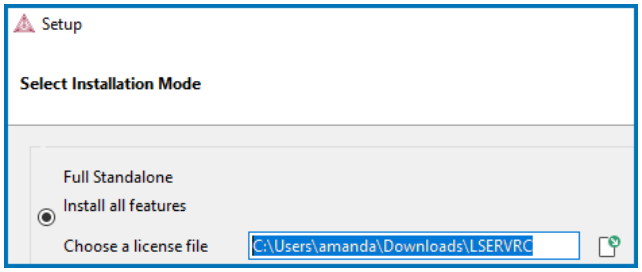
To install the program, you need administrator access to your computer. Once you have installed the program, you can continue with Thermo-Calc.

Step 4: Select License and Installation Mode

1. In the **Select License and Installation Mode** window click **Full Standalone: Install all features**.

   If you also have a license for TC-Python, it is installed when the **Full Standalone** or **Full Network Client** option is chosen, but there are additional steps required as described separately for this SDK.

2. For a **Full Standalone** installation, in the **Choose a license file** field either enter the file path or click the file button to navigate to where you saved the license file emailed to you from Thermo-Calc Software.



The license file is called **lservrc**. Click **Next**. To prevent errors, leave this field blank if you did not get a license file yet.

TC-Python is installed for all users even if you do not have a license. The **Install TC-Python** window is a reminder that additional installation procedures are required after Thermo-Calc is installed. See the *TC-Python Installation Guide*.

3. In the **Ready to Install** window click **Next**. Click **Finish** and start using Thermo-Calc.

macOS® Standalone (License File) Installations

There are two *license activation types* available with 2026b: (1) **User credentials**, which are entered after installation and managed via an online portal or (2) where a **license file** is installed directly on the computer or a licensing server. Many users have already started using the *user credentials* activation type and all users will eventually be migrated to the new system.

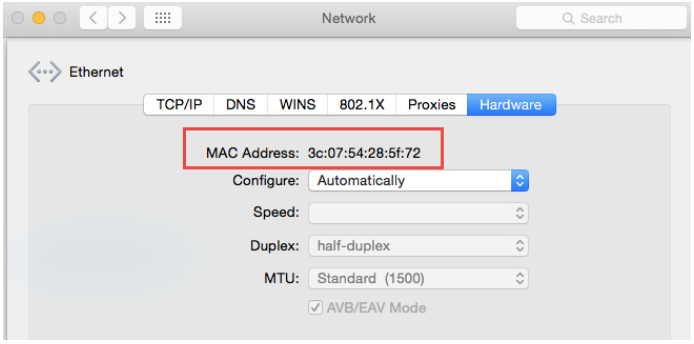
This section is applicable to:

- Operating system: macOS
- Installation type: Full Standalone (SUNLL)
- License activation type: License file where the software and the license file are installed together on one computer.
- Upgrading to a new standalone version of Thermo-Calc (maintenance plan only)

Step 1: Request a License File

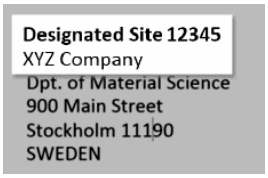
Upgrading to a new version of Thermo-Calc: Skip this section if you are upgrading to a new version of Thermo-Calc (and you have a maintenance plan), or you have already been provided with the license file.

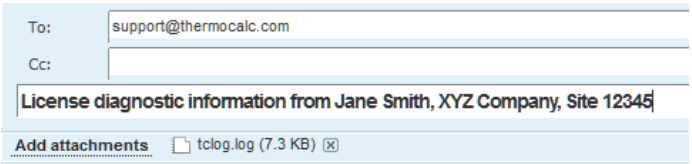
1. From the Apple main menu, select **System Preferences**.
2. Click **Network**.
3. In the left column select **Ethernet** or **Built-in Ethernet** (do not select a WiFi connection as a local static MAC address is required).
4. Click **Advanced → Hardware**. The **Network** window shows you the **MAC Address**. For example, the MAC address (the host ID) might be **3c:07:54:28:5f:72**.



5. Send an email to support@thermocalc.com and copy and paste the MAC address into the body of the email. Make sure to include the following in the subject line:

   License diagnostic information from <Name> where Name is replaced with your **name**, the **organisation name** and the **Site Number**. *You can find the five-digit site number on an invoice or any correspondence from Thermo-Calc Software.*

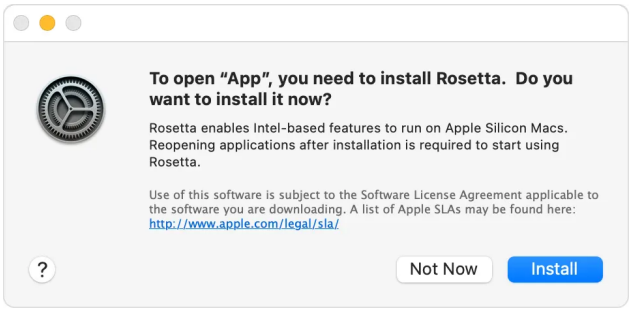




6. A representative from Thermo-Calc Software replies to the email address provided and attaches your license file or files.
7. Save your license file to your computer or network.

Step 2: Install Required macOS Software

To install and run Thermo-Calc on a Mac computer with an ARM processor, Rosetta first needs to be installed. If prompted, install as per macOS instructions.



Step 3: Download Thermo-Calc Software

Administrative rights are required to complete this installation. An email from Thermo-Calc Software (or from someone in your organization) includes the links and information you need to access and activate the current version of the software you want to download.

1. Click the link from the email and the first page of the **Download Center** opens. Under the **macOS** section, select the OS version. Click **Go to download page**.
2. In the **Sign in to access this site** window, enter the **Username** and **Password** (found in the email) and click **Sign in**.
3. On the **Download Center** page under **Software**, click the **.zip** link to download the file for the current software version for your operating system (e.g. 2026b).

Step 4: Install Thermo-Calc Software

For macOS and when you first run the installer, you may see a message that *Thermo-Calc-osx-<version> can't be opened because Apple cannot check it for malicious software*. If this happens, select **Show in Finder**. Then, in the opened **Finder** window right-click the downloaded file `Thermo-Calc-osx-<version>` and select **Open**.

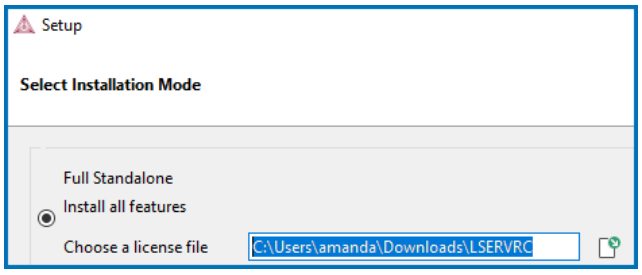
1. Navigate to the folder where you downloaded the software. Double-click the **.zip** program. Remember that administrative rights are needed, so when you are prompted for that user name and password, enter these credentials here. Click **Yes** to continue.
2. On the **Setup - Thermo-Calc 2026b** window click **Next**.
3. On the **License Agreement** window click to accept the license agreement. Click **Next**.

Step 5: Select License and Installation Mode

1. In the **Select License and Installation Mode** window click **Full Standalone: Install all features**.

   If you also have a license for TC-Python, it is installed when the **Full Standalone** or **Full Network Client** option is chosen, but there are additional steps required as described separately for this SDK.

2. For a **Full Standalone** installation, in the **Choose a license file** field either enter the file path or click the file button to navigate to where you saved the license file emailed to you from Thermo-Calc Software.



The license file is called **lservrc**. Click **Next**. To prevent errors, leave this field blank if you did not get a license file yet.

TC-Python is installed for all users even if you do not have a license. The **Install TC-Python** window is a reminder that additional installation procedures are required after Thermo-Calc is installed. See the *TC-Python Installation Guide*.

3. In the **Ready to Install** window click **Next**. Click **Finish** and start using Thermo-Calc.

Import User Settings

For macOS installations and if you have previous Thermo-Calc installations: When you launch Thermo-Calc with the new or updated version, the splash screen hides the **Import User Settings** dialog box. In order to proceed you need to click the splash screen and then click **Yes** or **No** in the dialog box.

Custom Standalone Installations (License File)

Use the **Custom** option to have more control over what component features to include or exclude, for example, to exclude an SDK.

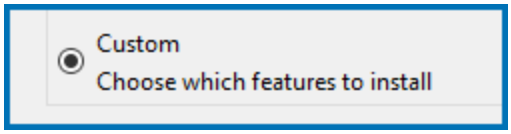
This topic describes how to do a custom installation on a standalone computer for either a Windows or Linux operating system. These steps assume you have completed these sections:

- First Steps of Installation
- Steps 1 to 3 of a Full Standalone Installations where you request your license file, download the software and then have started to set up the program up to the **Select Installation Mode** window.

Step 1: Choose the Components to Install

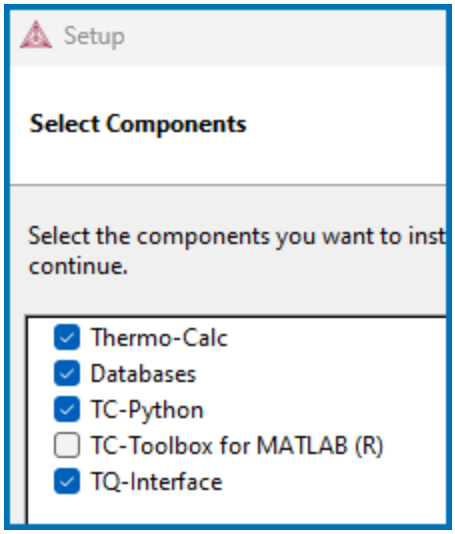
About the Thermo-Calc Installed Components

1. In the **Select License and Installation Mode** window click **Custom**. Click **Next**.



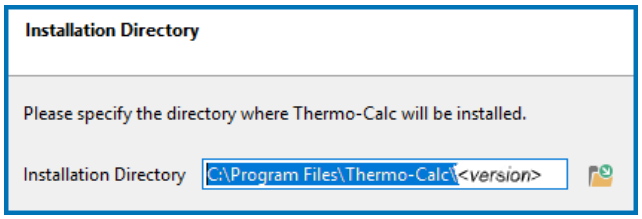
2. On the **Specify Configuration** window the **Create Shortcut on Desktop** checkbox is selected by default. Click **Next**.

3. In the **Select Components** window, click to select or deselect the checkboxes as needed. Click **Next**.



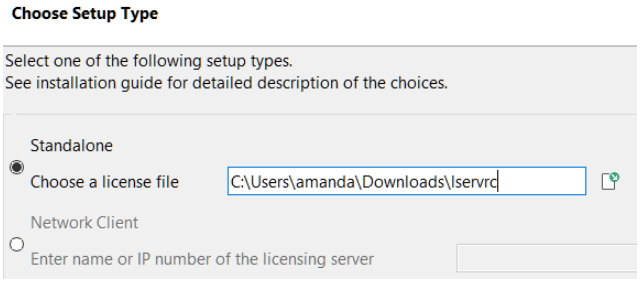
Step 2: Set the Installation Directory and Choose the License File

1. In the **Installation Directory** window, either accept the default path or enter a path to where you want to install the software (see Installation Default Directories and the License File). Click the file button to **Browse for Folder** and navigate to another directory.



> To prevent errors, leave this field blank if you do not have a license file yet.

2. In the **Choose Setup Type** window, click **Standalone**.



3. In the **Choose a license file** field enter the path to your license file (called **lservrc**) or click the file button to navigate to a location on the computer and open the file.
4. TC-Python is automatically installed when the **User credentials** option is chosen. The **Install TC-Python** page is a reminder for users of TC-Python that additional installation and license credential procedures are needed after Thermo-Calc is installed. Read the separate installation instructions (also included in the full installation guide) for more information if applicable. Click **Next**.

Step 3: Install the Software and Start Using Thermo-Calc

1. In the **Ready to Install** window click **Next**.

   See the separate instructions for TC-Toolbox for MATLAB®.

2. Click **Finish** and start using Thermo-Calc. For Linux users, log out and log back in to finish the installation.

For macOS installations and if you have previous Thermo-Calc installations: When you launch Thermo-Calc with the new or updated version, the splash screen hides the **Import User Settings** dialog box. In order to proceed you need to click the splash screen and then click **Yes** or **No** in the dialog box.

If you did not get your license file see Request a License File from Thermo-Calc Software.

Network Client Installations (License Files)

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

This installation type is available for all operating systems, however for macOS the License Server must be run on a Windows or Linux computer. It is applicable to the consolidated and distributed network types of installations as well as for the licensing installation on a server network.

Subnet Information for Network Licenses

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

This is related to Full Network Client Installations.

For network licenses, the subnet information is also required. Ask your network administrator for the *network address for the subnet*. Additional requirements are included elsewhere for network installations.

- Subnets should be in the format aaa.bbb.ccc*** (for example: 192.168.29.0/24 or 192.168.29.*
- When installing on Sentinel RMS License Server version 9.7, a maximum of seven (7) subnets are permitted.

An alternative way to get this information is to run the command:

- *Windows:* `ipconfig /all`
- *macOS/Linux*: `ip a`

Multi-User Network Installations (NWL)

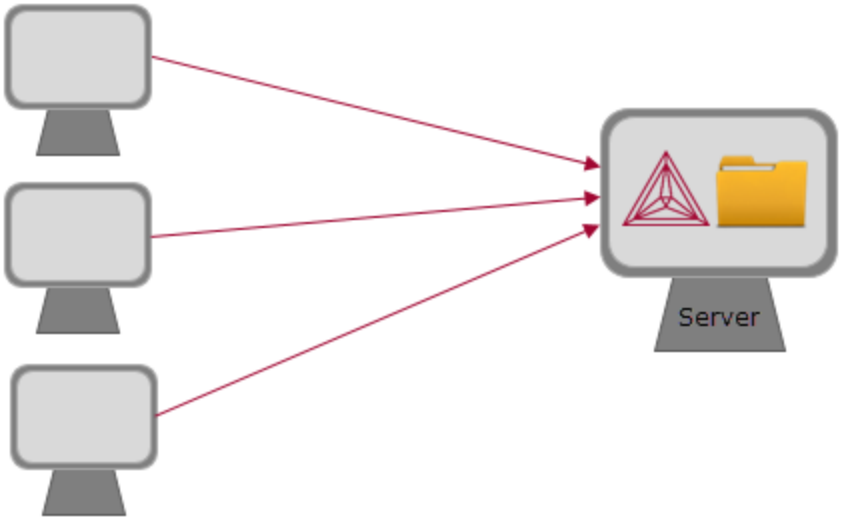
This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

There are different types of multi-user network installations: consolidated, distributed, and where the licensing software is installed on a computer network. There is also a subtype of installation called thin client, which is a step done with the consolidated and distributed network installations.

Thin client installations: A thin client installation is where the Thermo-Calc software is installed on a computer server but is run from a client computer. The licensing software can be installed on the computer server (a consolidated network) or on a different computer (a distributed network). This type of installation is available for Windows and Linux operating systems. The client computer must have the Thermo-Calc software installed. This type of installation mainly sets environmental variables and paths on the client computer.

Consolidated Network Installations

The consolidated network installation is used with a Network License (NWL) and it is available for Windows and Linux operating systems.

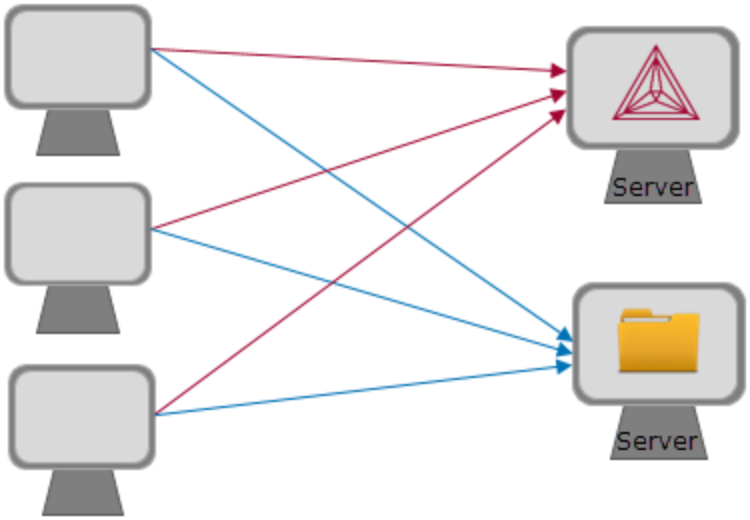


The Thermo-Calc software and the license management program are installed on the same server where the license file is also copied. A thin client installation allows all computers (the clients) in the server network to access both the software and the licensing on the same computer server.

To get started, go to (1) First Steps of Installation and then (2) Network Client Installations (License Files).

Distributed Network Installations

The distributed network installation is used with a Network License (NWL) and is available for Windows and Linux operating systems.

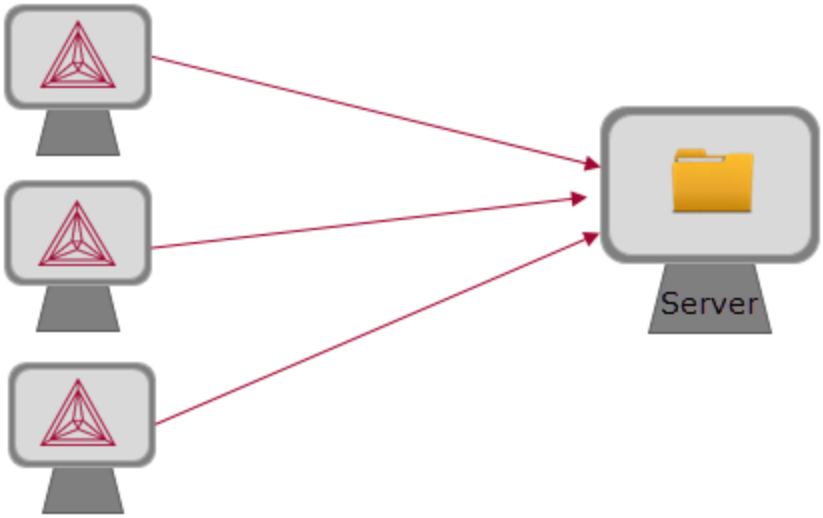


The Thermo-Calc software is installed on one computer server in a network and the licensing software is installed on a different computer server where the license file is also copied. A thin client installation allows all computers (the clients) in the server network to access both the software and the licensing on the two computer servers.

To get started, go to (1) First Steps of Installation and then (2) Network Client Installations (License Files).

License Installations on a Server Network

When a license file is installed on a server network, it is used with a Network License (NWL). It is available for all platforms. However, for macOS the server containing the licensing software must be set up on Windows or Linux.



The licensing software is installed on a computer server where the license file is also copied. The Thermo-Calc software is installed on every computer in the network that needs it.

To get started, go to (1) First Steps of Installation and then (2) Network Client Installations (License Files).

Full Network Client Installations

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The following outlines how to do a full network client installation.

Step 1: Install the Sentinel RMS Management License Software

Follow the instructions for your operating system:

Windows

- Windows: About Installing the License Manager
- Windows: Installing the Sentinel RMS License Manager

Linux

- Linux: About Installing the License Server
- Linux: Installing the Sentinel RMS License Server

Step 2: Complete Steps 1 to 3 of a Full Standalone Installation

These steps assume you have completed the instructions for Full Standalone Installations to download and run the software up to the **Select Installation Mode** window. It is up to you whether you get the computer information for the license files before or after installing the software.

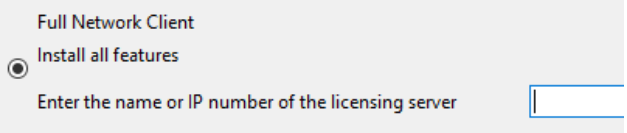
Step 3: Choose the Installation Type and Enter the Computer Server Details

About the Thermo-Calc Installed Components

1. In the **Select Installation Mode** window click **Full Network Client** to **Install all features**.

> If you want to exclude a component (perhaps one of the SDKs), then use the **Custom** option and see Custom Network Client Installations.

2. In the field, enter the name or IP number of the computer where the licensing software is installed. Click **Next**.



3. TC-Python is installed for all users even if you do not have a license. The **Install TC-Python** window is a reminder that additional installation procedures are required after Thermo-Calc is installed. See the *TC-Python Installation Guide* for details.
4. In the **Ready to Install** window click **Next**.
5. When the **Completing the Thermo-Calc Setup Wizard** window opens, click **Finish**. For *Linux* users, log out and log back in to start using Thermo-Calc.

> For macOS installations and if you have previous Thermo-Calc installations: When you launch Thermo-Calc with the new or updated version, the splash screen hides the **Import User Settings** dialog box. In order to proceed you need to click the splash screen and then click **Yes** or **No** in the dialog box.

If you did not get your Thermo-Calc license file see Request a License File from Thermo-Calc Software.

Windows: About Installing the License Manager

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The Sentinel RMS License Manager service supplies the client computers in your network with license tokens when it runs Thermo-Calc software. The Sentinel RMS License Manager software is installed on a computer that acts as a license server in your network. This is related to Full Network Client Installations and administrative rights are required for all steps.

If you have previously installed an older version of Sentinel RMS License Manager, you must first uninstall the old version then **reboot** the server before starting with a new installation.

Learn More

Remember to collect subnet information before beginning. See Subnet Information for Network Licenses.

A network license can only be used on one specific computer that hosts the License Manager. The network license determines which client computers receive license tokens using the IP addresses and IP ranges.

Supported Windows Versions

These Windows operating systems are supported for the installation of Sentinel RMS License Manager. When ready, go to Windows: Installing the Sentinel RMS License Manager.

For macOS, the Sentinel RMS License software is installed on a Windows or Linux computer server where the Thermo-Calc license file must also be located.

Windows 32-bit Operating Systems

- Windows 7
- Windows 8.1
- Windows 10 v1909
- Windows Server 2008

Windows 64-bit Operating Systems

- Windows 7
- Windows 8.1
- Windows 10 v1909
- Windows Server 2008
- Windows Server 2008 R2
- Windows Server 2012
- Windows Server 2012 R2
- Windows Server 2016
- Windows Server 2019

Windows: Installing the Sentinel RMS License Manager

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

First review Windows: About Installing the License Manager. Then if this is a new installation of the Sentinel RMS License Manager, start with Step 2.

Step 1: Uninstall Any Older Versions of Sentinel RMS License Manager

1. With Administrator rights, log onto the server that hosts the Sentinel RMS License Manager.
2. Save a copy of the license file LSERVRC found in the default directory—the license file can be saved as a text file: `C:\Program Files (x86)\Common Files\SafeNetSentinel\Sentinel RMS License Manager\WinNT\`.

   After saving the existing license file and uninstalling the old version of Sentinel RMS, ensure you delete the old license file (LSERVRC) in the above folder. This license is not required anymore.

3. Reboot the computer hosting the Sentinel RMS License Manager.
4. Continue with the installation and use the preselected default settings.

Step 2: Download and Install Thermo-Calc

This step is not required to complete the server installation, however some administrators may want to do it at this point.

1. Download Thermo-Calc.

    - *Web downloads*: For web links sent in an email from Thermo-Calc Software, go to the URL and log in with the information provided to download the software.
    - *DVD installations*: Insert the DVD and follow the instructions.

2. Install Thermo-Calc. For testing purposes, and in order to confirm the installation is working correctly, install the Thermo-Calc software on the same computer as the Sentinel RMS License Manager. If required after testing, Thermo-Calc can always be uninstalled.

Step 3: Install the Sentinel RMS License Manager Software

1. From the download, extract the files `license_server_win_9.7.zip` and `LS_tools_win.zip`.
2. Right-click `setup.exe` and select **Run as Administrator** from the menu.

Step 4: Choose the Installation Directory

1. Click to accept the license agreement.
2. Enter your **User Name** and **Organization** and select to install the License Manager for **All users**.
3. In the **Destination Folder** window click **Next** to accept the suggested destination directory or **Change** to select another directory.

Step 5: Choose the Setup Type and Install the Software

1. In the **Setup Type** window, select **Complete**. Click **Next**.
2. Select the **Unblock the system firewall for the Sentinel RMS License Manager** checkbox.

    Selecting the checkbox is required to run Thermo-Calc.

3. Click **Next** and then **Install**.

4. Click **Finish** to exit the InstallShield Wizard.

Step 6: Install the Thermo-Calc Network License Using WIAdmin

> Only the WIAdmin tool can be used to update the network license used by the License Manager.

1. Save the source file containing the license code. The source file can be kept as a .txt file
2. Go to the previously saved file `LS_tools_win.zip`.
3. Right-click the file `WlmAdmin.exe` and select **Run as Administrator** from the menu.
4. If the license server is not found under subnet servers, go to **Edit → Defined Server List**.
5. Enter the host name or IP address of the license server.
6. Click **Add** and then **OK**.
7. Click **View → Refresh All** to update the list.
8. In the left main window right-click the name of a License Manager.
9. From the menu select **Add Feature → From a File → To Server and its File**.
10. To add the license from a file, select **From a File**. This permanently adds the license code to the License Manager license file as well as to the License Manager memory.
11. In the windows that open, browse to the source file that contains the license code and click **Open**.

Step 7: Install Additional Tool Options

Sentinel RMS License 9.7 Tools

Linux: About Installing the License Server

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The Sentinel RMS License Server service supplies the client computers in your network with license tokens when it runs Thermo-Calc software. The Sentinel RMS License Server software is installed on a computer that acts as a license server in your network. This is related to Full Network Client Installations.

Preparing for Installation

Read and be aware of the following before you begin the section Linux: Installing the Sentinel RMS License Server.

Remember to collect subnet information before beginning. See Subnet Information for Network Licenses.

Uninstall Older Versions of the License Server

- Older versions of the License Server must be stopped by with `lsrvdown` before running the new installation. This is Step 1 in Linux: Installing the Sentinel RMS License Server.
- If you have a license server: Upgrade your license server if the new one is a higher version than the present one. Clients work with newer license servers (managers) but not necessarily with ones older than the client.

Requires Root Access or sudoers List

Root access to your computer is required or you need to be on the `sudoers` list.

Linux 32-bit Installations on a 64-bit OS

To run a license server 32-bit on a Linux 64-bit OS, 32-bit library support is needed.

Thermo-Calc License File

The name of the **license file** must be in lower case letters (**lservrc**) because Linux commands and operations are case-sensitive.

- You need a valid **lservrc** network license file supplied by Thermo-Calc Software (Requesting the License File for Windows or Linux) as well as the actual License Server—a file (program) called **lserv**.
- The Thermo-Calc license file needs to be readable and writable by the license server (license manager).

Differences Between 32- and 64-bit Scripts

Sentinel RMS License Server version 9.7 supports both 32- and 64-bit. However, when writing scripts be aware of script naming and do not mix the scripts.

- All 32-bit scripts are named *<script_name>*, for example `restart_lserv`
- All 64-bit scripts are named *<script_name>64*, for example, `restart_lserv64`

It is not possible to use Linux 32-bit scripts/tools to manage license server 64-bit and vice versa, you cannot use Linux 64-bit scripts/tools to manage license server 32-bit

openSUSE Administration (sudo) Users

Note the following if you are a sudo user (administrator) in openSUSE installing Thermo-Calc using this command:

```
sudo ./Thermo-Calc-linux-<full-version-number>.run
```

When this command is used, you will do a text-based installation instead of having a graphical interface to guide you. The information is the same, just without the user interface.

For example, the *<full-version-number>* is not just 2026b, it is what is found in the **Help → About** window in Thermo-Calc and it changes every release. You can find the current full version number listed on our website.

Supported Linux Operating Systems and Versions

For macOS, the Sentinel RMS License software is installed on a Windows or Linux computer server where the Thermo-Calc license file must also be located.

Both Linux 32-bit and 64-bit operating systems are supported for the installation of Sentinel RMS License Server.

- Red Hat Enterprise Linux (RHEL) 7.x
- Red Hat Enterprise Linux (RHEL) 8.x
- SUSE Linux Enterprise Server (SLES)12.x
- SUSE Linux Enterprise Server (SLES) 15.x
- Debian Linux 9.x
- Debian Linux 10.x
- Ubuntu Linux 16.x (LTS)
- Ubuntu Linux 18.x (LTS)
- Ubuntu Linux 20.x (LTS)
- OpenSUSE Leap 42.x
- OpenSUSE Leap 15.x

Linux: Installing the Sentinel RMS License Server

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

First review Linux: About Installing the License Server. Then if this is a new installation of the Sentinel RMS License Server, start with Step 2.

Sentinel RMS License Server version 9.7 supports both 32- and 64-bit. However, when writing scripts be aware of script naming and do not mix the scripts.

- All 32-bit scripts are named *<script_name>*, for example `restart_lserv`
- All 64-bit scripts are named *<script_name>64*, for example, `restart_lserv64`

It is not possible to use Linux 32-bit scripts/tools to manage license server 64-bit and vice versa, you cannot use Linux 64-bit scripts/tools to manage license server 32-bit

Step 1: Stop Older Versions of the Sentinel RMS License Server

1. To stop an old version of the License Server already running, go to the directory where the old file is found, and enter the commands:

   - 32-bit license server

     ```
     >chmod +x <lsrvdown>
     >./lsrvdown <host_name>
     ```

   - 64-bit license server

     ```
     >chmod +x <lsrvdown64>
     >./lsrvdown64 <host_name>
     ```

2. Edit existing scripts that start the older version of the License Server so that they start the newer version instead.

   For more information about the **lservdown utility**, go to https://docs.sentinel.thalesgroup.com/softwareandservices/rms/

Step 2: Write a Script to Start the License Server

The following is an excerpt from the template script for starting the License Server found in the restart_lserv file.

Replace the paths for LICENSE_SERVER_DIR, LICENSE_FILE_DIR and LOG_DIR to match your system. Save it as a script:

```
# set the directory where the executables are located
LICENSE_SERVER_DIR=/usr/local/Thermo-Calc/2026b/Licensing-files
# set the directory of the license file lservrc
LICENSE_FILE_DIR=/usr/local/Thermo-Calc/2026b/Licensing-files
# set the directory where you wish to save the log-files
LOG_DIR=/tmp
# stop the running server
# (omit this line if calling this script at startup)
$LICENSE_SERVER_DIR/lsrvdown $HOSTNAME
# start the license server
$LICENSE_SERVER_DIR/lserv -s $LICENSE_FILE_DIR/lservrc -l $LOG_DIR/lserv_use.log -f
$LOG_DIR/lserv_err.log
```

Step 3: Confirm the HOSTNAME variable and open the UDP port

The hostname should always correspond to the DNS record verify this by doing the following.

1. Before starting the License Server make sure that the value of the $HOSTNAME variable is correct. This value can be shown by typing the `> nslookup $HOSTNAME` command in the terminal window:

   The value should be the same IP address that is shown when you use the ifconfig command.

2. Open the UDP port 5093 in your firewall. In case you have installed SELinux you might also need to disable it by setting `SELINUX=permissive` in the `/etc/selinux/config` file.

Step 4: Start the License Server

1. To start the License Server, run the script created as root. Enter these commands in the console:

```
> chmod +x <name_of_script_file>
> ./<name_of_script_file>
```

2. If you want the License Server to start when you boot the system, put a copy of the start script under `/etc/rc.d/init.d` and start the script from the file `/etc/rc.d/rc.local`.

Step 5: Install Additional Tool Options

Sentinel RMS License 9.7 Tools

Thin Client Installations

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

This topic describes how you install a thin Thermo-Calc client to run Thermo-Calc from a file server. It is applicable to consolidated and distributed network installations for either a Windows or Linux operating system.

Installation Requirements

- You need access to the directory where Thermo-Calc is installed on the file server.
- You need the IP number or name of the computer where the license file is installed.
- For *Linux* you may have to disable your firewall. If SELinux is installed, try disabling it by setting `SELINUX=permissive` in `/etc/selinux/config`.

Installing a Thin Client on Windows

The following details may also be of use to those installing in a Windows environment.

- Requests license server name or address and sets LSHOST as a user environment variable accordingly.
- Sets TC<*version*>_HOME (where <*version*> is the software version, e.g. TC22A_HOME) as a user environment variable to point to the location from which the thin client installer is running.

The default folders where documents, materials files, examples, and other folders that sometimes require additional licenses are installed under **Public Documents** for ALL USERS. See Installation Default Directory: Windows.

1. Map the file server share as a network drive so that it gets an assigned drive letter (e.g. **E:**).

2. Open the **\Thermo-Calc***<version>*** directory on the file server, where *version* is the current version of the software.

3. Open the directory **Thin-client**. Double-click the `Thermo-Calc-client-windows-<version>.exe` file.

4. Click to accept the terms of the license agreement. Click **Next**.

5. Enter the name or IP number of where the license file and the License Manager software is installed. Click **Next**.

6. By default the **Create Shortcuts on Desktop** checkbox is selected. Click **Next**.

The shortcuts to the program are added to the user's Windows roaming profile as well as placed on the user's Desktop (not the system's).

7. In the **Ready to Install** window, click **Next**.

8. Click **Finish**. To start Thermo-Calc find the program on the server and start it from there.

Installing a Thin Client on Linux

1. Add the following to the `smb.conf` file, where *<user>* is your user name:

```
[public]
path=/home/<user>/Thermo_Calc/2026b
public=yes
writable=yes
comment=smb share
guest OK=yes
force user=<user>
```

2. From the client, mount the directory on the server computer that contains the Thermo-Calc server installation (by default, this directory is called **/Thermo-Calc/2026b**). How the directory is mounted depends on the Linux distribution being used as well as how the Thermo-Calc directory on the server computer is shared. Use the Linux command `mount`. For example:

   ```
   > mkdir public

   > sudo mount -t cifs //ip_number_server_computer/public ./public -o
   user=<user>
   ```

3. Open the mounted directory on your computer, and run `client-install-linux-x64.run` or `client-install-linux-x86.run` in the **/Thin-client** directory.
4. If you do this from the terminal window, use the following to start the installation (assuming that the file server is a 64-bit computer):

   > ./client-install-linux-x64.run

5. Click **Forward** and click to select the license agreement. Click **Forward**.
6. Enter the name or IP number of the License Server. Click **Forward**.
7. If you are installing as a non-root user, by default, the **Create Shortcuts on Desktop** checkbox is selected. Click **Forward**.
8. In the **Ready to Install** window click Forward.
9. Click **Finish**. Log out and log back in to start using Thermo-Calc.

Custom Network Client Installations

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

This installation type is available for all operating systems, however for macOS the License Server must be run on a Windows or Linux computer.The requirements are the same as for a full client installation.

Step 1: Install the Licensing Software

Follow the instructions for your operating system:

- Windows: About Installing the License Manager, or
- Linux: About Installing the License Server

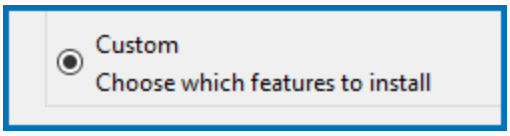
Step 2: Complete Steps 1 to 4 of a Full Standalone Installation

Follow the instructions for Full Standalone Installations to download and run the software. It is up to you whether you get the computer information for the license files before or after installing the software.

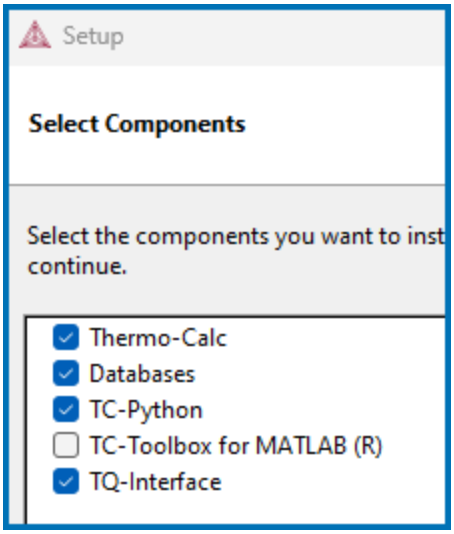
Step 3: Select the Installation Mode and the Components to Include or Exclude

About the Thermo-Calc Installed Components

1. In the **Select License and Installation Mode** window click **Custom**. Click **Next**.

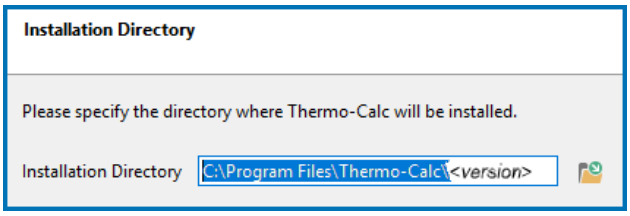


2. On the **Specify Configuration** window the **Create Shortcut on Desktop** checkbox is selected by default. Click **Next**.
3. In the **Select Components** window, click to select or deselect the checkboxes as needed. Click **Next**.



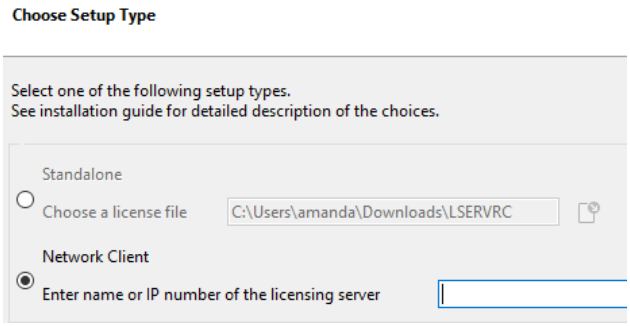
Step 4: Set the Installation Directory and the File Path to the License

1. In the **Installation Directory** window, either accept the default path or enter a path to where you want to install the software (see Installation Default Directories and the License File). Click the file button to **Browse for Folder** and navigate to another directory. Click **Next**.



To prevent errors, leave this field blank if you do not have a license file yet.

2. In the **Choose Setup Type** window, click **Network Client** and enter the name or IP number of the computer where the licensing software is installed. Click **Next**.



If you have selected to install **TC-Python** there is a reminder window that additional installation procedures are required after Thermo-Calc is installed. See the *TC-Python Installation Guide*.

Step 5: Install the Software and Start Using Thermo-Calc

1. In the **Ready to Install** window click **Next**.

   See the separate instructions for TC-Toolbox for MATLAB®.

2. Click **Finish** and start using Thermo-Calc. For Linux users, log out and log back in to finish the installation.

For macOS installations and if you have previous Thermo-Calc installations: When you launch Thermo-Calc with the new or updated version, the splash screen hides the **Import User Settings** dialog box. In order to proceed you need to click the splash screen and then click **Yes** or **No** in the dialog box.

If you did not get your license file see Request a License File from Thermo-Calc Software.

Unattended or Silent Network Client Installations (License File)

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

Terminology note: The use of the term *license server* (lower case letters) is applicable to the option files as described in this section. For the purposes of the step-by-step instructions it is not used to refer to the type of network installation that runs the licensing software.

Sometimes it is convenient to install Thermo-Calc network clients without providing user input after the installation is initiated (an unattended network client installation), i.e. a *silent installation*. This is available for Windows and Linux operating systems.

Make sure you know the name or IP number of the computer where the licensing software and the license file are to be installed.

Step 1: Create an Option File in a Text Editor to Enter the Options

The following is an example of an option file for a custom network client installation, where *<name/IP number>* is the name or IP number of the computer where the license file is installed:

```
installation_mode=custom
setup_type=client
enable-components=thermo,databases,tq,toolbox,tcpython
icons=1
license_server=<name/IP number>
```

Below is a shorter example, specifying that a full Thermo-Calc network client should be installed:

```
installation_mode=full_client
license_server=<name/IP number>
```

Step 2: Go to the Directory Where the Installation File is Saved

Thermo-Calc can only be installed in unattended mode from the command line prompt.

Start the installation in unattended mode using the option file created with this command:

- Windows: `<installationfile>.exe --mode unattended --optionfile <path\optionfile>`
- Linux: `<installationfile>.run --mode unattended --optionfile <path/optionfile>`

To see other options when you start the Thermo-Calc installation program from the command line prompt, run this command:

- Windows: `<installationfile>.exe --help`
- Linux: `<installationfile>.run --help`

Which TC-Python Installation Should I Choose?

A license is required to run TC-Python. Also remember to review the System Requirements page on our website.

This guide helps you to get a working TC-Python API installation. There are these options to install TC-Python.

Install with the Bundled Python Interpreter

This is a straightforward installation where TC-Python is pre-installed together with some popular Python packages.

This is the recommended option for new users to TC-Python who may only want to run the examples. The available pre-installed packages (e.g. numpy, scipy, scikit-learn, pyvista, and matplotlib) can also be sufficient for many advanced users.

Installing TC-Python with a Bundled Python Interpreter

Optional Packages

Install with a Python Interpreter of Your Choice

This installation requires additional steps and is the recommended option for more advanced use and has full flexibility.

Installing TC-Python Into a Python Interpreter of Your Choice.

TC-Python Help and Learning Resources

There are several resources available to help you get working with TC-Python.

Help Options

Once TC-Python is installed, the help is available in different ways.

- When working with TC-Python, and when you are working in an IDE such as Pycharm, there is inline guidance or code completion with interactive suggestions to guide you.
- The latest version of the HTML help is available on our website.
- The same help is available in a standalone PDF, also available on our website.

TC-Python Examples

After you have installed all the necessary items to get up and running then you can look at several included examples. You can use these examples to both learn about the use of TC-Python and as a way to build your own calculation project.

The location of the installed examples is based on the operating system but all are installed in the **SDK → TC-Python → Examples** subfolder.

Installation Default Directories: TC-Python and Bundled Python Interpreter

TC-Python Learning Resources on the Website

There is a variety of resources related to TC-Python that you can access via the dedicated TC-Python help page as well as other useful links highlighted in this section.

TC-Python Help

Navigate to the TC-Python help page, which has links to a variety of items such as:

- The current online Help and its equivalent PDF.
- Download a zip file of the current examples. These examples are already included with your installation; this is an option to download all at once.

- Links to the **Documentation** archive on our website to access older versions of the PDFs or the current version of the installation guide.
- Troubleshooting and diagnostic information.

Training and Other Learning Resources

- Go to our Training Courses page to learn more about your options for Live Online, In-Person, or Customized training.
- Visit the Learning Hub to register to use our online self-paced courses.
- Go to our TC-Python Video Tutorials page to access additional content.
- Scroll to the bottom of the main TC-Python product page to Learn More About TC-Python. Various Publications, Webinars, and other resources are available at the links.

Installing TC-Python with a Bundled Python Interpreter

TC-Python can be installed using a Python interpreter that is bundled to Thermo-Calc. This interpreter has TC-Python pre-installed together with some popular Python packages. This is the recommended option for new users to TC-Python who may only want to run the examples.

The bundled interpreter package is also used to run the Property Models in Thermo-Calc. Do not make changes to interpreter packages or this can stop Thermo-Calc from working correctly. To fix issues caused by changes to an interpreter, completely uninstall Thermo-Calc and start over, either with the bundled interpreter package or using interpreters of your choice.

If you are planning to do more advanced calculations that require other external packages then you may want to follow these instructions instead: Installing TC-Python Into a Python Interpreter of Your Choice

Bundled Python Interpreter Included Packages

The bundled Python 3 interpreter contains the following major packages:

- colour-science
- matplotlib
- numpy
- scikit-learn
- scipy
- pandas
- pyvista
- TC-Python
- tmm

These TC-Python examples require additional packages that are not available in the bundled Python interpreter, and thus cannot be run: `pyex_M_01_Input_from_file.py` and `pyex_M_02_Output_to_file.py`.

If you have recommendations for additional packages to include, send an email to Thermo-Calc Support.

Step 1: Install an IDE (Integrated Development Environment)

Any editor can be used to write the Python code, but an IDE is recommended, e.g. PyCharm. These instructions are based on the use of PyCharm.

Use of an IDE gives you access to code completion, which helps when you use the API as it gives you the available methods on the objects you are working with.

1. Navigate to the PyCharm website: https://www.jetbrains.com/pycharm/download.
2. Click to choose your OS and then click **Download**. You can use the **Community** version of PyCharm.
3. Follow the instructions. It is recommended you keep all the defaults.

For Mac installations, you also need to set some environment variables as described below in macOS: Setting Environment Variables.

Step 2: Configure PyCharm to Use the Bundled Python Interpreter

Open PyCharm and configure the interpreter:

1. Go the menu **File → Settings**.
2. Navigate in the tree to **Project: YourProjectName** and choose **Project Interpreter**.
3. Click on the settings symbol close to the **Project Interpreter** dropdown menu and choose **Add**.

4. Select **System Interpreter** and add the bundled Thermo-Calc Python 3 interpreter. It is located in different places depending on the operating system and on Windows if it is installed for all users or a single user:

Operating System	*Path to the Bundled Python Interpreter*

Windows	The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements.
	
	After installing Thermo-Calc, you can go to **Tools > Options > Property Model Python interpreter** to determine the file path. This can be useful for troubleshooting purposes.
	
	Single User
	
	`C:\Users\`*`UserName`*`\AppData\Local\Programs\Thermo-Calc\2026b\python\python.exe`
	
	The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click **View > Show > Hidden Items**. For more control, you can also make changes to more than one folder via the **Folder Options > View > Advanced Settings** window then select **Show hidden files, folders, and drives**. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.
	
	All Users
	
	`C:\Program Files\Thermo-Calc\2026b\python\python.exe`

Linux	`/home/`*`UserName`*`/Thermo-Calc/2026b/python/bin/python3`
macOS	`/Applications/Thermo-Calc-2026b.app/Contents/Resources/python/bin/python3`

5. Select the interpreter and confirm.

Step 3: Run a TC-Python Example

It is recommended that you open one or more of the included examples to both check that the installation has worked and to start familiarizing yourself with the code.

If you have a license activation type based on **user credentials** you first need to activate your license. See License Activation with User Credentials.

Open the TC-Python Project in PyCharm

When you first open the TC-Python project and examples, it can take a few moments for the Pycharm IDE to index before some of the options are available.

1. Open PyCharm and then choose **File** → **Open**. The first time you open the project you will need to navigate to the path of the TC-Python installation based on your operating system.

Operating System	*Path to the TC-Python Folder*
Windows	`C:\Users\<username>\Documents\Thermo-Calc\2026b\SDK\TC-Python`
Linux	`/home/UserName/Thermo-Calc/2026b/SDK/TC-Python`
macOS	`/Users/Shared/Thermo-Calc/2026b/SDK/TC-Python`

2. Click the **Examples** folder and then click **OK**.
3. From any subfolder:
   - Double-click to open an example file to examine the code.
   - Right-click an example and choose **Run**.

If you are not following the recommended approach and create a *new* project (**File → New Project…**), you need to consider that by default the options to choose the interpreter are hidden within the **Create Project** window. For this, click **Project Interpreter: New Virtual Environment** and in most cases choose your *System Interpreter* containing the Python bundled to Thermo-Calc instead of the default *New Virtual Environment*.

Installing TC-Python Into a Python Interpreter of Your Choice

TC-Python can be installed using a Python interpreter of your choice. This is the recommended option for any more advanced usage and provides full flexibility.

If you are new to TC-Python and want to mainly run the examples, then it is recommended you install the bundled Python interpreter. The available pre-installed packages (e.g. numpy, scipy, scikit-learn, pyvista, and matplotlib) can also be sufficient for many advanced users. See Installing TC-Python with a Bundled Python Interpreter.

Step 1: Install a Python Distribution

If you already have a Python distribution installation, skip this step.

These instructions are based on using the Anaconda platform for the Python distribution.

1. Navigate to the Anaconda website: https://www.anaconda.com/download/.
2. Click to choose your OS (operating system) and then click **Download**. Follow the instructions. It is recommended you keep all the defaults.

Step 2: Install Thermo-Calc and the TC-Python SDK

1. Install Thermo-Calc.
2. When the installation is complete, open the TC-Python folder that includes the *.whl file needed for the next step. There is also an **Examples** folder with Python files you can use in the IDE to understand and work with TC-Python.

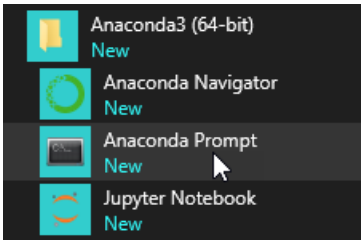
Step 3: Install TC-Python

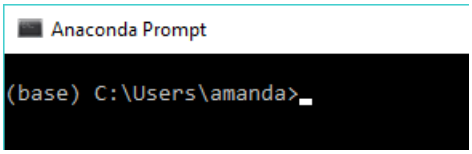
Updating to a Newer Version

On Windows, it is recommended you use the Python distribution prompt (i.e. Anaconda), especially if you have other Python installations.

Do not use Virtual Environments unless you have a good reason to do so. Also see Fixing Potential Issues with the Environment.

1. Open the command line. For example, in Anaconda on a Windows OS, go to **Start → Anaconda → Anaconda Prompt**.





2. At the command line, enter the following. Make sure there are no spaces at the end of the string or in the folder name or it will not run:

```
pip install <path to the TC-Python folder>/TC_Python-<version>-py3-none-any.whl
```

On Linux, and depending on the interpreter, *pip3* is typically used.

Operating System	*Path to the TC-Python Folder*
Windows	`C:\Users\<username>\Documents\Thermo-Calc\2026b\SDK\TC-Python`
Linux	`/home/UserName/Thermo-Calc/2026b/SDK/TC-Python`
macOS	`/Users/Shared/Thermo-Calc/2026b/SDK/TC-Python`

3. Press <Enter>. When the process is completed, there is a confirmation that TC-Python is installed.

> If your computer is located behind a proxy-server, the default pip-command will fail with a network connection error. In that case you need to install the dependency py4j in a special configuration:

```
pip install -proxy user:password@proxy_ip:port py4j jproperties
```

> Go to the TC-Python Help **Troubleshooting** section for detailed information. This can be found on our website or from the installed documentation where you can search for "pip install fails" with “Failed to establish a new network connection” or similar.

Step 4: Install an IDE (Integrated Development Environment)

Any editor can be used to write the Python code, but an IDE is recommended, e.g. PyCharm. These instructions are based on the use of PyCharm.

Use of an IDE gives you access to code completion, which helps when you use the API as it gives you the available methods on the objects you are working with.

1. Navigate to the PyCharm website: https://www.jetbrains.com/pycharm/download.
2. Click to choose your OS and then click **Download**. You can use the **Community** version of PyCharm.
3. Follow the instructions. It is recommended you keep all the defaults.

> For Mac installations, you also need to set some environment variables as described below in macOS: Setting Environment Variables.

Step 5: Open the IDE and Run a TC-Python Example

After you complete all the software installations and set up the pip install path, you are ready to open the IDE to start working with TC-Python.

It is recommended that you open one or more of the included examples to both check that the installation has worked and to start familiarizing yourself with the code.

If you have a license activation type based on **user credentials** you first need to activate your license. See License Activation with User Credentials.

Open the TC-Python Project in PyCharm

When you first open the TC-Python project and examples, it can take a few moments for the Pycharm IDE to index before some of the options are available.

1. Open PyCharm and then choose **File** → **Open**. The first time you open the project you will need to navigate to the path of the TC-Python installation based on your operating system.

Operating System	*Path to the TC-Python Folder*
Windows	`C:\Users\<username>\Documents\Thermo-Calc\2026b\SDK\TC-Python`
Linux	`/home/UserName/Thermo-Calc/2026b/SDK/TC-Python`
macOS	`/Users/Shared/Thermo-Calc/2026b/SDK/TC-Python`

2. Click the **Examples** folder and then click **OK**.
3. From any subfolder:
   - Double-click to open an example file to examine the code.
   - Right-click an example and choose **Run**.

Also see Optional Packages if you are using the Additive Manufacturing Module for simulations.

Installation Default Directories: TC-Python and Bundled Python Interpreter

These are the default paths to the TC-Python folder containing the **Examples** folder and **whl** file. The Bundled Python interpreter is installed in a different location, which is also detailed below based on operating system.

The **Examples > Miscellaneous** folder contains a diagnostic script, called `diagnostics.py`. This is also available for download from our website.

TC-Python

Operating System	*Path to the TC-Python Folder*
Windows	`C:\Users\<username>\Documents\Thermo-Calc\2026b\SDK\TC-Python`
Linux	`/home/UserName/Thermo-Calc/2026b/SDK/TC-Python`
macOS	`/Users/Shared/Thermo-Calc/2026b/SDK/TC-Python`

Bundled Python Interpreter

For a bundled Python interpreter installation, these are the paths to this location based on your operating system.

Operating System	*Path to the Bundled Python Interpreter*
Windows	The file path is based on whether the installation is a single user (no admin required installation) or for all users (e.g. an IT administrator installs the program for you). This can vary based on organizational requirements.

<table>
<tr><th>Operating System</th><th>Path to the Bundled Python Interpreter</th></tr>
<tr><td></td><td>

After installing Thermo-Calc, you can go to Tools > Options > Property Model Python interpreter to determine the file path. This can be useful for troubleshooting purposes.
<h3>Single User</h3>
<code>C:\Users\UserName\AppData\Local\Programs\Thermo-Calc\2026b\python\python.exe</code>

The AppData folders are usually hidden by default. You can view the files in Windows Explorer by enabling the option to show hidden files, e.g. click View > Show > Hidden Items. For more control, you can also make changes to more than one folder via the Folder Options > View > Advanced Settings window then select Show hidden files, folders, and drives. If you need to navigate to the folder location on a regular basis, it can be useful to add a shortcut to your Desktop.
<h3>All Users</h3>
<code>C:\Program Files\Thermo-Calc\2026b\python\python.exe</code>
</td></tr>
<tr><td>Linux</td><td><code>/home/UserName/Thermo-Calc/2026b/python/bin/python3</code></td></tr>
<tr><td>macOS</td><td><code>/Applications/Thermo-Calc-2026b.app/Contents/Resources/python/bin/python3</code></td></tr>
</table>

Optional Packages

Plotting results of Additive Manufacturing simulations requires the package *pyvista*. It is automatically installed if using the option *[am-plotting]* during the installation:

```
pip install <path to the TC-Python folder>/TC_Python-<version>-py3-none-any.
whl[am-plotting]
```

The bundled interpreter contains *pyvista* by default.

TC-Python: Configuring a License

TC-Python requires a license to run. If you do not yet have the information about your license, contact Thermo-Calc Support at support@thermocalc.com.

> If you have no valid license, an exception is thrown that states: `NO LICENSE: No activated license for TC-Python`.

Depending on the type of license, different steps are required to configure TC-Python to use it.

Environment Variables

Some environment variables need to be set. On Windows this is normally done during the installation of Thermo-Calc, but on Linux and macOS this needs to be performed for each used IDE or terminal.

TC-Python: Setting Environment Variables

License Activation with User Credentials

This section is applicable to licenses that are activated after entering user credentials (i.e. user name and password).

> The TC-Python license is a separate license from the Thermo-Calc software license. You need to activate the TC-Python license once on your computer after, or in addition to, activating the Thermo-Calc license.

It is recommended to run the included example to perform the activation and deactivation. By default an online activation is performed, but you can choose other methods, which are both included in the example and described in the API documentation.

- Open and run the example `pyex_M_04_license.py`, which is located in the **Miscellaneous** folder.
- The license activation is completed with the methods in the class `tc_`

`python.license.LicenseManager`.

- Depending on the type of license other methods are available, for example for online and offline activation plus the use of proxy settings are described.

To use the license on a different computer, the license must first be deactivated on the original computer. This is for both online and offline activations.

TC-Python: Setting Environment Variables

macOS and Linux

In order to use TC-Python on macOS and Linux you need to set some environment variables.

```
TC26B_HOME=/Applications/Thermo-Calc-2026b.app/Contents/Resources
```

User Credential License Types

If you have a license based on user credentials:

```
TC_LICENSE_SPRING=y
```

License File Type Activations

If you use a license server:

```
LSHOST=<name-of-the-license-server>
```

If you have a node-locked license:

```
LSHOST=NO-NET
LSERVRC=/Users/Shared/Thermo-Calc/lservrc
```

If running in the terminal these can be set using export `LSHOST=NO-NET`, etc.

PyCharm IDEs

In PyCharm, you can add environment variables in the configurations.

For other operating systems, the configuration can be done in the same way as described below.

1. Select **Run → Edit Configurations** to open the **Run/Debug Configurations** window.
2. Choose **Templates** and then **Python**.
3. Enter the environment variable(s) by clicking the button to the right of the **Environment Variables** text field. Now the environment variables(s) are set for each new configuration by default.

Existing configurations need to be removed and recreated to obtain the environment variables in them.

Updating to a Newer Version

If you are using the bundled Python interpreter automatically installed with Thermo-Calc, these steps are not required.

These steps are required if you have previously followed the instructions in Installing TC-Python Into a Python Interpreter of Your Choice.

When updating to a newer version of Thermo-Calc, you always need to also install the latest version of TC-Python. It is not sufficient to run the installer of Thermo-Calc (except for bundled versions of the Python interpreter).

```
pip install <path to the TC-Python folder>/TC_Python-<version>-py3-none-any.whl
```

In case of problems you may wish to uninstall the previous version of TC-Python in advance:

```
pip uninstall TC-Python
```

```
pip install <path to the TC-Python folder>/TC_Python-<version>-py3-none-any.whl
```

However, this should not normally be required.

On Linux typically *pip3* is used.

You can check the currently installed version of TC-Python by running:

```
pip show TC-Python
```

macOS: Setting Environment Variables

In order to use TC-Python on macOS you need to set some environment variables.

```
TC26B_HOME=/Applications/Thermo-Calc-2026b.app/Contents/Resources
```

User Credentials License Activations

```
TC_LICENSE_SPRING=y
```

License File Type Activations

If you use a license server:

```
LSHOST=<name-of-the-license-server>
```

If you have a node-locked license:

```
LSHOST= NO-NET
LSERVRC=/Users/Shared/Thermo-Calc/lservrc
```

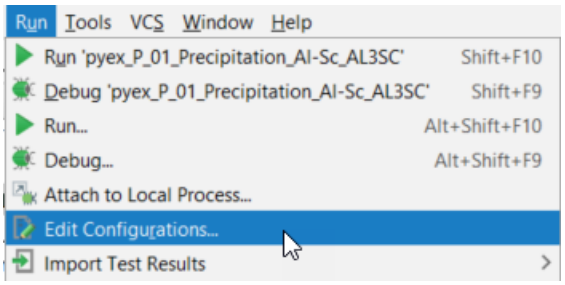
PyCharm IDEs

In PyCharm, you can add environment variables in the configurations.

Select **Run** → **Edit Configurations** to open the **Run/Debug Configurations** window. Enter the environment variable(s) by clicking the button to the right of the **Environment Variables** text field. Now the environment variables(s) will be set for each new configuration by default.

Existing configurations need to be removed and recreated to obtain the environment variables in them.

The same way for configuring the environment variables can be used on other operating systems as if necessary.



Run Tools VCS Window Help
Run 'pyex_P_01_Precipitation_Al-Sc_AL3SC' Shift+F10
Debug 'pyex_P_01_Precipitation_Al-Sc_AL3SC' Shift+F9
Run... Alt+Shift+F10
Debug... Alt+Shift+F9
Attach to Local Process...
Edit Configurations...
Import Test Results

Fixing Potential Issues with the Environment

In most cases you should run TC-Python within your **global** Python 3 interpreter and not use Virtual Environments unless you have a good reason to do so.

If there are problems with the interpreter settings, for example, a common problem when you first use TC-Python is the message *No module named tc_python*, which you can resolve in the **Settings** window as follows:

1. Go the menu **File → Settings**.
2. Navigate in the tree to *<Project.YourProjectName>* and choose **Project Interpreter**.
3. Click on the settings symbol close to the **Project Interpreter** drop-down menu and choose **Add**.
4. Choose **System Interpreter** and add your existing Python 3 interpreter.
5. Select your added interpreter and confirm.

If you are not following the recommended approach and create a *new* project (**File → New Project…**), you need to consider that by default the options to choose the interpreter are hidden within the **Create Project** window. For this, click **Project Interpreter: New Virtual Environment** and in most cases choose your *System Interpreter* containing the Python bundled to Thermo-Calc instead of the default *New Virtual Environment*.

If you really need to use a Virtual Environment, it is recommended you review the hints provided in the **Best Practices** section in the full TC-Python HTML help or PDF.

TC-Python Diagnostic Script

A diagnostic script is available to help you if you have problems running TC-Python.

It is important to run the diagnostic script EXACTLY the same way as you run your TC-Python script (in the same IDE, same project, same Python environment, same Jupyter notebook, etc).

The script automatically prints useful suggestions that, in many cases, will help you to fix the problem yourself. If you are unable to solve the problem, contact us for support.

You can find the script in these locations:

- As an example (`diagnostics.py`) located as described in Installation Default Directories: TC-Python and Bundled Python Interpreter.
- On our website. The script is based on the version of Thermo-Calc installed.
- Details that you can copy are also in the **Troubleshooting** section of the help or PDF guide.

Also refer to the **Best Practices** section in the help or PDF guide to see if there are any other solutions or tips.

About TC-Toolbox for MATLAB®

TC-Toolbox for MATLAB® (TC-Toolbox) provides an interface to the commonly used MATLAB® software for scientific and engineering computing. This software development kit (SDK) is ideal for fast realization of ideas and visualization of results during research and development activities. The TC-Toolbox API includes calculation types available in Thermo-Calc such as single point equilibrium, property (step) and phase (map) diagrams, Scheil solidification simulations, as well as all the general Thermo-Calc Property Models (e.g. yield strength, spinodal, driving force, etc.).

With the addition of licenses for the applicable software and databases, you can further maximize your integration with MATLAB® to include the capabilities of the Steel Model Library Property Models (e.g. bainite, pearlite, etc.), as well as access the range of functionality included with the Diffusion Module (DICTRA) and the Precipitation Module (TC-PRISMA). Generally, all the functionality available in Graphical Mode or via the TC-Python SDK is available.

TC-Toolbox for MATLAB® is available on Windows platforms.

This guide helps you to get a working TC-Toolbox for MATLAB® installation.

A license is required to run TC-Toolbox for MATLAB® and MATLAB® must also be installed on your computer prior to the TC-Toolbox installation. Also remember to review the System Requirements page on our website.

TC-Toolbox Help Resources

There are these locations and formats of the documentation you need related to this SDK.

The help for TC-Toolbox for MATLAB® is available from these locations (1) within the MATLAB® environment—both as help and as part of the tab completion (2) directly on the Thermo-Calc website.

The TC-Toolbox for MATLAB® technical documentation content is available either as interactive help (in HTML format or when in MATLAB® using tab completion or accessed via different menus or key combinations) or as a standalone PDF.

There are these ways to access the content:

- Directly in MATLAB® via the Help menu then under **Supplemental Software** click **TC-Toolbox**. Help is also available when writing code and using the tab completion feature and/or pressing different key combinations as described in the *Best Practices* section of the help.
- From the website: HTML Help or PDF.

The full installation instructions are only included in the Thermo-Calc help (press F1), and in the PDF version of the main installation guide found on the website: Thermo-Calc Installation Guide.

Installation Default Directory: TC-Toolbox Examples and Diagnostic Script

The software component and the examples are installed as described below. The technical help is available after installation is complete or at any time on our website.

This is the default path to the installation folder for the TC-Toolbox component on Windows operating systems. Be aware that the initial installation files and examples are placed in Public\Documents, then after opening Thermo-Calc for the first time, these are copied to the Documents folder for each user.

Review the section Installation Default Directory: Windows, which describes the difference between the original installation location of **Public Documents** and where, after opening Thermo-Calc for the first time, items are copied into a local user **Documents** folder.

Examples (including Diagnostic Script) Installation Location

There are included examples with all TC-Toolbox installations. These are generally the same as the examples included with TC-Python although with a different suffix (`matex`) and prefix (`*.m` or `*.mlx`) in the file name. Not all examples included with TC-Python are available for this SDK.

The TC-Toolbox diagnostic script is also available from our website.

Both the installation files AND the examples are installed in the following folders.

The default Windows folders where the TC-Toolbox examples are installed starts with the original installation placing these under **Public Documents** for ALL USERS.

For a local user, and after Thermo-Calc is opened for the first time, these files are copied to the user's **Documents** folder where this local copy is associated to the user login. The Public **Documents** folder always contains the original set of contents as per the installation.

```
C:\Users\Public\Public Documents\Thermo-Calc\<version>\SDK\TC-Toolbox-
MATLAB
```

After installing Thermo-Calc, and when you first open the program, the set of folders containing the examples is copied from the source Public\Documents location into a user Documents folder:

```
C:\Users\<user>\Documents\Thermo-Calc\<version>\SDK\TC-Toolbox-
MATLAB\Examples
```

It is recommended that you work with the files that are copied to the user folder.

Installing TC-Toolbox

There are automatic or manual installation instructions for TC-Toolbox for MATLAB®.

Automatic Installation of TC-Toolbox

When the following conditions are met, Thermo-Calc automatically installs the TC-Toolbox for MATLAB® component on your computer.

1. MATLAB® is already installed.
2. There is only one Windows user on the computer where TC-Toolbox is being installed.

Then follow the regular installation instructions for Thermo-Calc, choosing whether you use a Standalone or Network installation. If required also see Testing a TC-Toolbox Installation.

A reminder regarding the license. Although you do not need to have a license file during the installation process (it can be added after the fact), you do need to have purchased a license for TC-Toolbox for MATLAB® to run the program within MATLAB®.

Manual Installation of TC-Toolbox

The installation is not automatic if:

- There are multiple Windows users on the same machine, or
- The installer cannot find the directory path to the MATLAB installation.

Multiple Windows Users on Same Machine

If there are multiple windows users on the same machine, then the following manual steps are done at the end of the automatic installation.

1. A message at the end of the Thermo-Calc installation process displays with instructions.
2. An Explorer window automatically opens to the `C:\Users\Public\Documents\Thermo-Calc\2026b\SDK\TC-Toolbox-MATLAB` folder.

3. Double-click the `InstallTCToolboxMATLAB.cmd` file to finalize the process. This briefly launches MATLAB® and installs TC-Toolbox. If required see Testing a TC-Toolbox Installation.

Installer Cannot Find the MATLAB® Installation Directory

If the Thermo-Calc installer cannot find the MATLAB® installation directory,

1. Start the version of MATLAB® that you want to install TC-Toolbox in.
2. Open and run the MATLAB® script included with your installation of Thermo-Calc.

   `C:\Users\<username>\Documents\Thermo-Calc\2026b\SDK\TC-Toolbox-MATLAB\setupTCToolbox.m`

You can also follow the instructions for Installing TC-Toolbox with the Custom Option.

TC-Toolbox: Configuring a License

TC-Toolbox requires a license to run. If you do not yet have the information about your license, contact Thermo-Calc Support at support@thermocalc.com.

Depending on the type of license, an additional step is required to configure TC-Toolbox for MATLAB® to use it.

License Activation

This section is applicable to licenses that are activated after entering user credentials (i.e. user name and password).

> The TC-Toolbox for MATLAB® license is a separate license from the Thermo-Calc software license. You need to activate the TC-Toolbox license once on your computer after, or in addition to, activating the Thermo-Calc license.

It is recommended to run the included example to perform the activation and deactivation. By default an online activation is performed, but you can choose other methods, which are both included in the example and described in the API documentation.

- Open and run the example `matex_M_04_license.m`, which is located in the **Miscellaneous** folder.
- The license activation is completed with the methods in the class `tc_toolbox.LicenseManager`.
- Depending on the type of license other methods are available, for example for online and offline activation plus the use of proxy settings are described.

> To use the license on a different computer, the license must first be deactivated on the original computer. This is for both online and offline activations.

Installing TC-Toolbox with the Custom Option

MATLAB® must be installed before you install TC-Toolbox.

As described in Installing TC-Toolbox, if MATLAB® is already installed, then Thermo-Calc automatically installs the files you need either using the *Full Standalone* or *Full Network Client* installation where you **install all features**. Otherwise you need to use the **Custom** installation.

The following generally describes the **Custom** option for either a Standalone or Network installation. Use the **Custom** option if MATLAB® is installed but the Thermo-Calc installer is not finding the directory path so you need to enter the path manually.

Some steps are described in more detail in other parts of this guide.

Step 1: Request your License File from Thermo-Calc Software

A reminder regarding the license. Although you do not need to have a license file during the installation process (it can be added after the fact), you do need to have purchased a license for TC-Toolbox for MATLAB® to run the program within MATLAB®.

Step 2: Download your Thermo-Calc Installation Software and Install MATLAB®

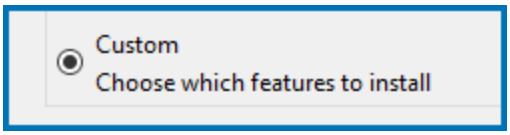
1. Download Thermo-Calc from the Download Center as per the instructions and login credentials received.
2. Install the MATLAB software.

Step 3: Run the Thermo-Calc Installation File as an Administrator

1. Locate the Thermo-Calc installation file on your computer. Right-click the **.exe** file and choose **Run as administrator** to launch the **Setup** program.
2. Accept the **License Agreement** and click **Next**.

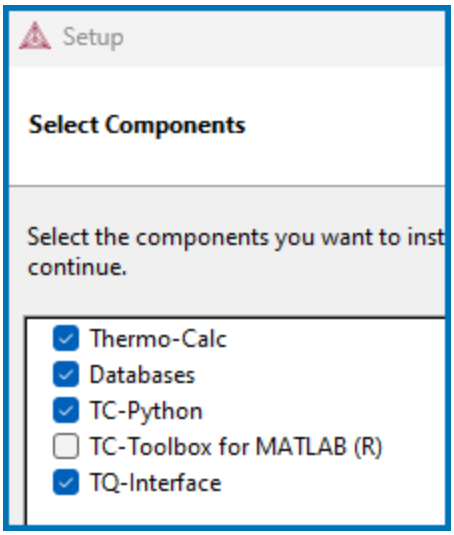
Step 4: Select the Custom Installation Type

1. In the **Select Installation Mode** window click **Custom**. Click **Next**.



2. On the **Specify Configuration** window the **Create Shortcut on Desktop** checkbox is selected by default. Click **Next**.

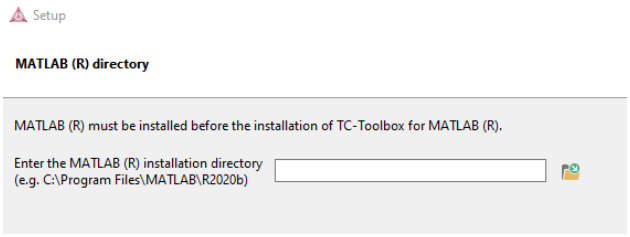
3. In the **Select Components** window, click to select the **TC-Toolbox for MATLAB** checkbox.



> Remember, you must have MATLAB® already installed and may need to know the file path to the MATLAB® folder. If the **TC-Toolbox for MATLAB** checkbox is NOT selected, this confirms that the Thermo-Calc installer did NOT locate the MATLAB® installation (or it is not installed yet).

4. Click **Next**.

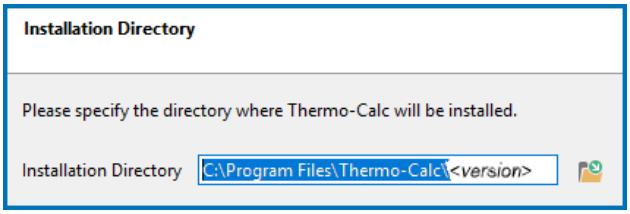
5. If you selected the **TC-Toolbox for MATLAB** checkbox, the **MATLAB directory** window opens.



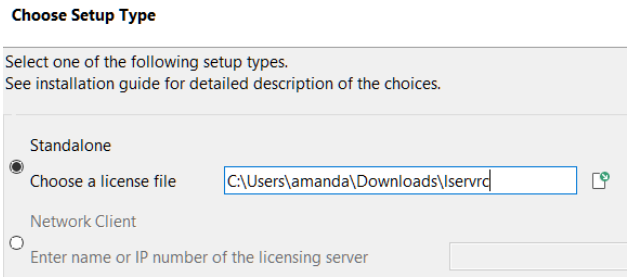
- If MATLAB® is already installed but the Thermo-Calc installer could not find the path, then enter the file path to the MATLAB® installation directory or click the file button to **Browse for Folder** and navigate to the directory. Click **Next**.
- If MATLAB® is NOT installed, click **Cancel** to exit the Thermo-Calc installer program. Once MATLAB® is installed you can return to this process.

Step 5: Set the Thermo-Calc Installation Directory and Choose the Setup Type

1. In the **Installation Directory** window, either accept the default path or enter a path to where you want to install the Thermo-Calc software. Click the file button to **Browse for Folder** and navigate to another directory.



2. In the **Choose Setup Type** window, click **Standalone** or **Network Client**.



- For a Standalone installation: In the **Choose a license file** field enter the path to your license file (called **lservrc**).

- For a Network installation: Enter the details as required into the **Enter the name or IP number of the licensing server** field. Click **Next**.

> If the **TC-Python** checkbox is also selected to be installed (which it is by default), the **Install TC-Python** window is a reminder that additional installation procedures are required after Thermo-Calc is installed.

Step 6: Install and Start Using Thermo-Calc as an Add-on in MATLAB®

1. In the **Ready to Install** window click **Next**.

> If MATLAB® is not installed (and you selected the TC-Toolbox checkbox) a message displays to confirm that TC-Toolbox will not be installed until you complete the MATLAB® installation. If MATLAB is installed, click **Back** to confirm that the installation path is correct, otherwise **Cancel** this Thermo-Calc installation, install MATLAB and start again.

2. Click **Finish**.

Step 7: Test the Installation

Testing a TC-Toolbox Installation

Testing a TC-Toolbox Installation

Generally you can check the installation by first looking in the **Home** tab to see if the program is in the menu. Then try running the diagnostic script or another example.

To check the installation, in MATLAB®, from the **Add-Ons** menu, select **Manage Add-Ons**. If TC-Toolbox is in the **Add-Ons** list it is likely it installed correctly but it is recommended you run the diagnostic script or another example to confirm.

See Installation Default Directory: TC-Toolbox Examples and Diagnostic Script for details about where to find the installed script and examples. Also see TC-Toolbox Installation Troubleshooting for additional suggestions.

The TC-Toolbox diagnostic script is also available from our website.

TC-Toolbox Installation Troubleshooting

Below are some suggestions to help troubleshoot a TC-Toolbox for MATLAB® installation.

Use the Diagnostic Script

A diagnostic script is available as an installed example or via the website to help you if you have problems running TC-Toolbox.

> It is important to run this script EXACTLY the same way as you run your MATLAB® script.

The script automatically prints useful suggestions that, in many cases, will help you to fix the problem yourself. If you are unable to solve the problem, contact us for support.

You can find the script in these locations:

- As an example (`diagnostics.m`) located as described in Installation Default Directory: TC-Toolbox Examples and Diagnostic Script.
- On our website. The script is based on the version of Thermo-Calc installed. If downloading from the website, it is named for example, `tc-toolbox-diagnostic-script-2026b.m`.
- Details that you can copy are also in the **Troubleshooting** section of the help or PDF guide.

> Also refer to the **Best Practices** section in the help or PDF guide to see if there are any other solutions or tips.

MATLAB® Installation Directory Not Found

For Windows installations of the TC-Toolbox for MATLAB® component, you may get an error message or window asking for the MATLAB® installation directory path.

The most common reason for this is that MATLAB® is not installed. If this is the case, exit the Thermo-Calc installation, install MATLAB® and then run the Thermo-Calc installation program again.

If MATLAB® is installed and Thermo-Calc just did not find the file path during the installation setup process, then enter the path in the field when prompted.

Determining the Licensing Software Version (Network Installs)

Sometimes you may need to know the version of License Manager (Windows) or License Server (Linux) software being used. This can be useful while troubleshooting network installations.

- On *Windows* open a command prompt and go to the directory where `lservnt.exe` is found. For example:

  ```
  >C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager\WinNT
  ```

  Type the command `>lservnt.exe -help` and the version is displayed.

- On *Linux* open a Terminal window and go to the directory where the `lserv script` is saved. For example:

  ```
  >cd opt/Thermo-Calc/<version>/Licensing-files
  ```

  Type the command `>./lserv -help` and the version is displayed.

Silent Installations

Administrative rights are required to install the Thermo-Calc software package. If you or your IT department are having problems silently installing TC-Toolbox over a network, perhaps to multiple computers, you need to run a file that is available after Thermo-Calc is installed.

1. Install Thermo-Calc as usual (requires administrative rights).

2. After Thermo-Calc is installed, navigate to this folder:

   ```
   C:\Users\Public\Documents\Thermo-Calc\<2026b>\SDK\TC-Toolbox-MATLAB\.
   ```

3. Double-click the `InstallTCToolboxMATLAB.cmd` file to run it

The `InstallTCToolboxMATLAB.cmd` file must be run by the user who is going to use TC-Toolbox for MATLAB®, i.e. anyone with admin rights can install Thermo-Calc, but for TC-Toolbox, the user must be logged in to run this file.

Uninstalling TC-Toolbox for MATLAB®

Uninstallation requires that the user is logged in with administrator rights and Thermo-Calc is installed for this same user. Then the uninstallation is automatically completed as part of the uninstallation of Thermo-Calc. Otherwise a manual step is required.

To uninstall TC-Toolbox (when not automatically uninstalled):

1. Start MATLAB®.
2. In the **Home** tab from the **Add-Ons** menu, select **Manage Add-Ons**.
3. Right-click **TC-Toolbox** and choose **Uninstall**.

Step 3: Option to Save Backup User Created Files *3425*

Uninstalling Thermo-Calc **3430**

Windows 11 ..... *3430*

macOS *3430*

Linux *3431*

Add New Components to an Existing Installation

If you want to add new components to an existing Thermo-Calc installation (for example, you purchased a license for TC-Toolbox for MATLAB®), run the installation again.

Custom User Credentials Installations and Custom Standalone Installations (License File)

1. For macOS you need to have administrative level rights before running the file. For Windows, as of 2026a, most users do not need administrative rights and can double-click the executable Thermo-Calc installation **.exe** file to launch the **Setup** program.

   Linux OS: If Thermo-Calc was not installed by root the first time, then administrative rights are not required.

2. Click **Next**. Click to accept the license agreement.
3. Select the additional component(s) to install.
4. Click **Next** to start the installation, which adds the new component(s).

Use the **Uninstall** program to *remove* components. See Uninstalling Thermo-Calc or Uninstalling TC-Toolbox for MATLAB®.

Updating the Software for Interim Releases

The full version of Thermo-Calc software is released twice a year. The software releases are named after the year of the release followed by an “a” for the first release of the year or a “b” for the second release of the year. For example, this release is 2026b.

Occasionally after a full release, an interim release version, an update, is required to fix a serious bug or to address an external issue that occurred after the full release. Software licenses come with a free 12 month Maintenance & Support Subscription, starting from the time of purchase, and this includes these software updates.

Go to our website to confirm the current distributed software version and determine if there are updates, or to learn more about Maintenance and Support options.

Step 1: Check for a Software Update

You can set your software to automatically check for updates upon start up.

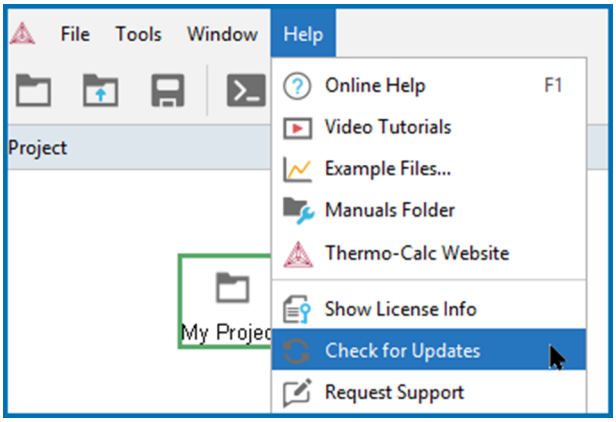
- From within the software on the **Options** window, **General** tab, set **Check update interval** to **On start up**.

  To open the **Options** window:

  - Windows: Select **Tools** → **Options**.
  - Mac: Select **Thermo-Calc** *<version>* → **Preferences** or **Settings** or press <⌘> on

the keyboard.

- If you do not have Automatic Updates on you can go to **Help →** **Check for Updates**.



Step 2: Follow the Installation Instructions for the Applicable OS

After the software has checked for updates and determined there is one, the applicable installation file for your operating system is downloaded. Then follow the instructions provided in the Installation Guide for the specific operating system and license type.

> For an update to the software, no additional license files or user credentials are required.

Step 3: Option to Save Backup User Created Files

> There are significant operating system differences regarding what backup files are saved if you are installing an update on Windows versus macOS or Linux.

During the installation process, several default folders are added to your system that include documentation, materials, and example files. This is the same for all operating systems. During an update, Thermo-Calc runs a check of these default folders to determine if there are changed or new user files that are saved in these folders. For example, you might have saved a

completely new project `*.tcu` file into the Examples folder, or after running one of the included examples such as *T_06_Serial_Equilibrium_Calculators.tcu*, the default file is changed and now includes results.

On Windows operating systems, Thermo-Calc gives you the opportunity after the installation to specifically save a backup of these user created or modified files to your Documents folder when you open Thermo-Calc for the first time after the update.

However, for macOS and Linux operating systems, the behavior is different due to limitations enabling the identification of changes to some files.

Operating System	*When Does Backup Occur?*	*What Files are Copied?*
Windows	After installation, when you open the software for the first time	Documents, Materials, and/or Examples files are copied when you choose **Yes** at the prompt (see the Windows section for details).
macOS	During installation	There is an option during the installation process to save a backup copy of the Examples folder even if no changes are made to files (see the macOS or Linux sections for details). Materials and Documents folders are not automatically copied even if there are file changes or additions. However, you can always manually back up these folders (see the macOS or Linux sections for details).
Linux		

Windows

First complete the installation update. Then when you open Thermo-Calc for the first time, and if Thermo-Calc identifies that there are changed files, you are prompted with a **Software Update - Action Required** window that identifies the folders where the applicable files are changed or added.

These file types are not kept, i.e. these are excluded: dll, exe, lib, mltbx, pdf, whl, html, and htm.

Click **Yes** to save a backup of these changed files or **No** to continue opening Thermo-Calc as normal where the default set of folders are copied from the source `Public Documents` location into a user `Documents` folder.

If you choose to save a backup of the files, the new backup folder is added to this same location, for example:

```
C:\Users\<username>\AppData\Thermo-Calc\2026b_backup
```

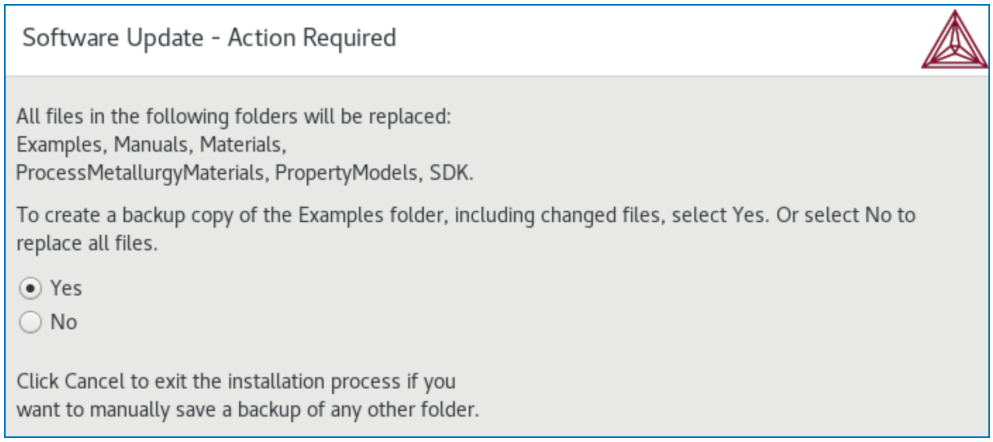
```
C:\Users\<username>\Documents\Thermo-Calc\2026b_backup
```

Installation Default Directory: Windows

macOS

During the installation process you are prompted with a **Software Update - Action Required** window.

This window always displays whether there are changes or additions to the folders or not.



The Materials and Documentation folders do not automatically have a backup saved. If you think there are user files you want to keep it is recommended that you click **Cancel** at this prompt to exit the installer, then manually copy the folders to another location. Then start the installation update process again.

To create a backup copy of the `Examples` folder, including changed files (i.e. all files are copied, not just the changed or new ones). Options at this prompt are to click:

- **Yes** to create the backup.
- **No** to replace all files.
- **Cancel** to exit the installation process, i.e. to manually save a backup of any other folder.

The default backup folder containing a full copy of all the contents of the `Examples` folder is saved to this location, for example:

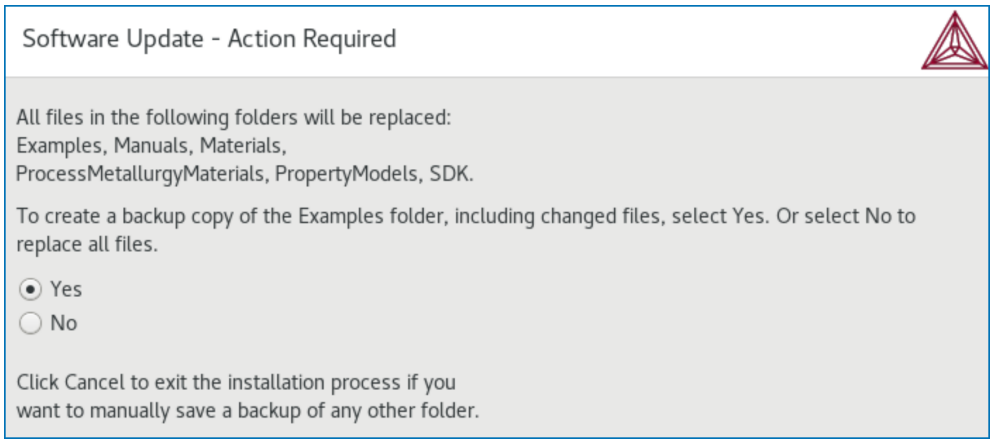
```
/Users/Shared/Thermo-Calc/2026b/Examples_backup
```

Installation Default Directory: macOS

Linux

During the installation process you are prompted with a **Software Update - Action Required** window.

This window always displays whether there are changes or additions to the folders or not.



The Materials and Documentation folders do not automatically have a backup saved. If you think there are user files you want to keep it is recommended that you click **Cancel** at this prompt to exit the installer, then manually copy the folders to another location. Then start the installation update process again.

To create a backup copy of the `Examples` folder, including changed files (i.e. all files are copied, not just the changed or new ones). Options at this prompt are to click:

- **Yes** to create the backup.
- **No** to replace all files.
- **Cancel** to exit the installation process, i.e. to manually save a backup of any other folder.

The default backup folder containing a full copy of all the contents of the `Examples` folder for Linux depends if you are a root super user requiring administrative privileges or a common user.

For example, for a common user:

```
/home/<user>/Thermo-Calc/2026b/Examples_backup
```

For example, for a root user:

```
/opt/Thermo-Calc/2026b/Examples_backup
```

Installation Default Directory: Linux

Uninstalling Thermo-Calc

Uninstalling TC-Toolbox for MATLAB®

Windows 11

1. From **Start**, go to **Settings → Apps → Installed Apps**.
2. In the list of programs, locate the version of Thermo-Calc you want to uninstall. Click the three dots to the right of the row.
3. Select **Uninstall**. Select **Uninstall** a second time.
4. If required, enter your admin level user credentials.
5. In the **Setup** window, **Uninstallation Mode** dialog box, choose to uninstall the **Entire application** or **Individual components**. Follow the instructions to finish.

You can also directly launch the Thermo-Calc uninstaller program:

1. Navigate to where the Thermo-Calc program is installed, i.e in the **Program Files** folder.
2. Locate the uninstaller program, named `Thermo-Calc-<version>-uninstaller.exe`.
3. Double-click and enter your admin level user credentials as required.
4. In the **Setup** window, **Uninstallation Mode** dialog box, choose to uninstall the **Entire application** or **Individual components**. Follow the instructions to finish.

macOS

Deleting the program from the Applications folder does not remove the program from your operating system. Run the **Thermo-Calc-***<version>***-uninstaller** program located in the Applications folder.

1. Go to the **Applications** folder and double click the file that starts with **Thermo-Calc-***<version>***-uninstaller**. Enter the administrator's user name and password.
2. Click **Yes** to choose **Entire application** or select individual components. Otherwise click **No** to quit.
3. The **Uninstalling Thermo-Calc** window shows the progress. Click **OK** when prompted.

Linux

1. To start the uninstallation procedure, in the Thermo-Calc installation directory use the command
   `./Thermo-Calc-2026b-uninstaller.run`

   For *Thin Client* installations, use the command

   `./Thermo-Calc-client-2026b-uninstaller.run`

2. To remove the whole application, including all its components, select **Entire application** and click **Forward**, or to remove specific components, select **Individual components** and click **Forward**.

If you intend to reinstall Thermo-Calc 2026b it is important to (1) Restart the computer before you reinstall the software and (2) remove the environmental variable TC26B_HOME.

Request License Files

Request a License File from Thermo-Calc Software **3433**

Getting License Information for License File Activations Using Thermo-Calc **3434**

Requesting the License File for Windows or Linux **3435**

Requesting the License File for macOS **3437**

Request a License File from Thermo-Calc Software

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The following explains how to retrieve the necessary diagnostic and network adaptor information about your computer and then send an email to Thermo-Calc Software to get your license file(s) containing the license key(s).

To set up the correct licensing:

1. Make a note of your company or organization's *site number*. You can find the site number on an invoice or any correspondence from Thermo-Calc Software.
2. Retrieve your computer diagnostic and network adapter information.
3. Email Thermo-Calc Software with this information.
4. A Thermo-Calc Software representative emails you the license file. Save the license file **lservrc** (there is no file suffix) to a location where you can easily access it later.

Thermo-Calc Support Center on our website

Getting License Information for License File Activations Using Thermo-Calc

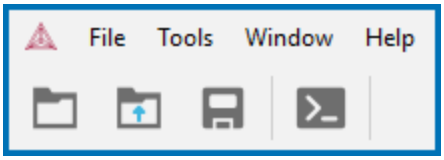
This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

Viewing and using the license information is based on the license activation type. When you have a license file activation type, you may need to copy information to provide to Thermo-Calc.

In Graphical Mode, and if you have already installed Thermo-Calc, you can view the license information by selecting **Help** → **Show License Info**.

In Console Mode you can run the SYS module command DISPLAY_LICENSE_INFO.

1. Open Thermo-Calc.
2. Click the **Switch to Console Mode** button .



3. At the SYS: prompt, enter DISPLAY_LICENSE_INFO.You can output the information to a FILE or to the SCREEN.

```
SYS:DISPLAY_LICENSE_INFO
OUTPUT TO SCREEN OR FILE /SCREEN/:SCREEN
```

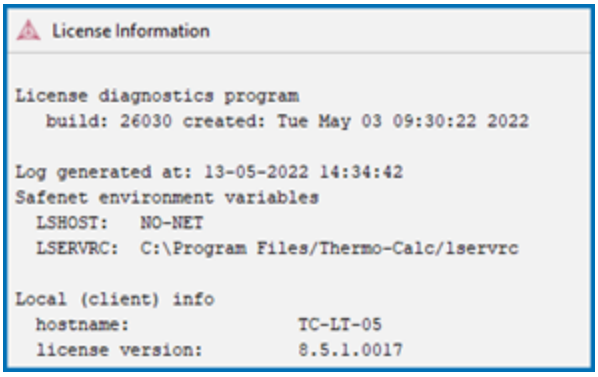
4. For both options, the information is displayed on screen. Copy the section containing the **Ethernet** and **IP address**. You can save it to a text file or paste it directly into an email. If you choose FILE as the output, then you can attach the file to an email.

Requesting the License File for Windows or Linux

Upgrading to a new version of Thermo-Calc: Skip this section if you are upgrading to a new version of Thermo-Calc (and you have a maintenance plan), or you have already been provided with the license file.

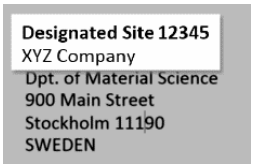
1. Your license information is sent to you in an email from Thermo-Calc or a representative. When you are sent a *license file*, save it to your computer to use during software installation. You may also need to provide some information that is accessed from Thermo-Calc.

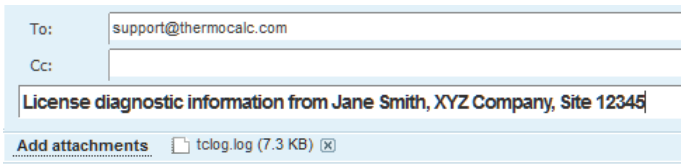
   Select **Help → Show License Info**.



2. Copy the information from the **License Information** window. A lot of information may be shown below the initial screen, so make sure you scroll down to the end when you select and copy the window's contents. (Alternatively, you can copy the same information from the console by using the SYS module command DISPLAY_LICENSE_INFO.)
3. Send an email to support@thermocalc.com. Make sure to include the following in the subject line:

   License diagnostic information from <Name> where Name is replaced with your **name**, the **organization name** and the **Site Number**. *You can find the five-digit site number on an invoice or any correspondence from Thermo-Calc Software.*



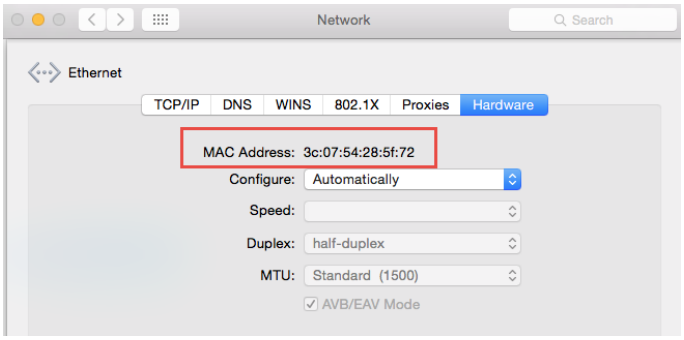


4. A representative from Thermo-Calc Software replies to the email and attaches your license file(s).
5. Save the license file(s) to your computer or network.

Requesting the License File for macOS

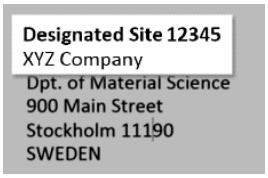
Upgrading to a new version of Thermo-Calc: Skip this section if you are upgrading to a new version of Thermo-Calc (and you have a maintenance plan), or you have already been provided with the license file.

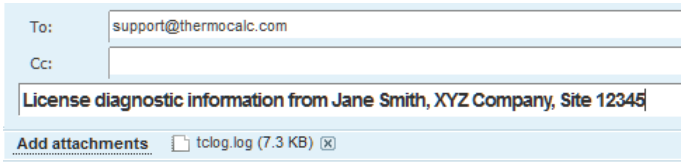
1. From the Apple main menu, select **System Preferences**.
2. Click **Network**.
3. In the left column select **Ethernet** or **Built-in Ethernet** (do not select a WiFi connection as a local static MAC address is required).
4. Click **Advanced → Hardware**. The **Network** window shows you the **MAC Address**. For example, the MAC address (the host ID) might be **3c:07:54:28:5f:72**.



5. Send an email to support@thermocalc.com and copy and paste the MAC address into the body of the email. Make sure to include the following in the subject line:

   License diagnostic information from <Name> where Name is replaced with your **name**, the **organisation name** and the **Site Number**. *You can find the five-digit site number on an invoice or any correspondence from Thermo-Calc Software.*





6. A representative from Thermo-Calc Software replies to the email address provided and attaches your license file or files.
7. Save your license file to your computer or network.

Troubleshooting and Miscellaneous

There are diagnostic scripts available for TC-Python and TC-Toolbox for MATLAB® (these are included as examples in the Miscellaneous folder). These scripts are also available on our website.

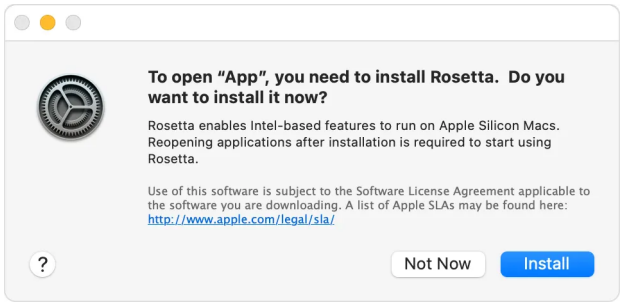
macOS Installation Notes

How to Restart After an Installation

In some types of installations (e.g. a network installation), you may have to restart your Mac to use Thermo-Calc for the first time.

Rosetta is Required when there is an ARM Processor

To install and run Thermo-Calc on a Mac computer with an ARM processor, Rosetta first needs to be installed. If prompted, install as per macOS instructions.



How to Enable the Security Settings

1. From the Apple main menu, select **System Preferences**.
2. Click **Security and Privacy**.
3. Click **General**. At the bottom of the **Security & Privacy** window, click the lock icon to make changes. Enter the administrator password as required.
4. If you have already tried to launch the Thermo-Calc installer, you can click **Open Anyway** to proceed. Otherwise, under **Allow apps downloaded from:** click **Anywhere** and then **Allow from Anywhere**.
5. Continue with the applicable installation type (standalone or network).

Remember to reset your security after installing Thermo-Calc.

Linux Installation Notes

The following are details you need to know regarding your Linux installation as well as how to open Thermo-Calc.

openSUSE Administration (sudo) Users

Note the following if you are a sudo user (administrator) in openSUSE installing Thermo-Calc using this command:

```
sudo ./Thermo-Calc-linux-<full-version-number>.run
```

When this command is used, you will do a text-based installation instead of having a graphical interface to guide you. The information is the same, just without the user interface.

For example, the *<full-version-number>* is not just 2026b, it is what is found in the **Help → About** window in Thermo-Calc and it changes every release. You can find the current full version number listed on our website.

Opening Thermo-Calc in Linux

To open Thermo-Calc double-click the **Thermo-Calc-2026b** application or from the Thermo-Calc installation directory enter `$ ./Thermo-Calc-2026b.sh` in the terminal.

License File Activation Type Errors

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

Determining the Current License File Directory Path

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

This topic explains how to find out where your license file is installed, either by default or if a different directory was chosen for previously installed versions. For new installations, where you may not have had a license file when you installed Thermo-Calc, you can also use these instructions to determine the correct file path.

From within Thermo-Calc

If you have already installed Thermo-Calc, you can view the path to the license file in the GUI. Select **Help → Show License Info**.

In Console Mode you can run the SYS module command DISPLAY_LICENSE_INFO.

Windows Standalone Installations

How do I add or update a standalone (SUNLL) license on a Windows computer where Thermo-Calc is already installed?

1. Unpack the .zip file that contains your standalone license and save the LSERVRC file on your computer. Find out where to place the new license file by opening a Command Prompt Window (cmd.exe) and type in the command line:

   ```
   >set LSERVRC
   ```

2. Press `Enter`. The output from the command is the path to the license file (including the name of the license file). For example: if the output is

   ```
   LSERVRC=C:\Users\<user>\Documents\Thermo-Calc\lservrc
   ```

   then the new license file should be placed in `C:\Program Files\Thermo-Calc\2026b\`

Linux Standalone Installations

How do I add or update a standalone (SUNLL) license on a Linux computer where Thermo-Calc is already installed?

Find out where to place the new license file by opening a Terminal window and type in the command line:

```
echo $LSERVRC
```

Windows Network Installations

How do I add or update a network license on Windows?

Only the WlAdmin tool can be used to update the network license used by the License Manager. See Step 6: Install the Thermo-Calc Network License Using WIAdmin.

Linux Network Installations

How do I add or update a network license on Linux?

Replace your current license file with the new license file. The license file is located in the same directory as the license server.

Specifying a New Server Name or IP Number

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

The Thermo-Calc Setup wizard does not warn you if the name or IP number entered to the server (with the license management software) is incorrect.

If the name or IP number is not set at all, or if it is set to an empty string, then when you start Thermo-Calc the following message displays: *Warning Environment variable "LSHOST" is not set. Software will not function properly*.

Windows

This section explains how to specify or change the name or IP number of the server where the License Manager is installed and for a consolidated network client installation.

To install a license for an existing Thermo-Calc program, follow these steps:

1. Close all running Thermo-Calc programs.
2. Open a command line window.
3. Specify the name or IP number of the licensing software server. Type:

   ```
   set LSHOST=<name/IP number>
   ```

   To display the current name or IP number, type:

   ```
   set LSHOST
   ```

macOS

Permanently set the environmental variable LSHOST to specify a new licensing server name or IP number. Refer to the file `/Applications/Thermo-Calc-2026b.app/Contents/Info.plist`.

In this file, you can manually set the TC26B_HOME variable, which specifies the home directory of the Thermo-Calc program. See the `Info.plist` file for an example.

Linux

You can set or change the name or IP number of the license server at a later time by setting the environmental variable “LSHOST” to this name or number.

Firewalls

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

Windows

For a Windows License Manager installation you may have to change the system firewall settings to allow the License Manager to communicate with the computers running the client applications. Go to the Windows Firewall settings window to see if there are any problems. If prompted, select Unblock the system firewall for the Sentinel RMS License Manager and click Next.

Linux

For a Linux License Server installation you need to open the UDP port 5093 in your firewall. In case you have installed SELinux you might also need to disable it by setting SELINUX=permissive in the /etc/selinux/config file.

Client/Server Mismatch

This section is applicable to installations involving a **license file** activation type. This licensing method is gradually being replaced by the **user credentials** activation type starting with Thermo-Calc 2025a.

For some network installations there can be a naming mismatch that causes errors. The server (where the license management software is installed) gets information from its DNS servers that an IP address (aaa.bbb.ccc) belongs to a computer (Computer A). But the client computer identifies itself as having a different IP address (aaa.bbb.ccc.eee) for the same computer (Computer A).

Even if the IP address of the client computer belongs to a subnet range listed in the license file, there is a problem with accessing the license file because the computer name does not match the information.

You may need your organisation's network administrator to assist with this issue.

How to Check

Compare computer names on the client computer and server

1. On the client computer, start a command prompt **cmd.exe** and type `ipconfig /all`. Press `Enter`. A variety of data is displayed on screen. Write down the following information for later comparison:
    - Hostname
    - DNS Suffix
    - Current IPv 4 Address
2. In the command window, type `nslookup` *<client_computer_name>,* where *client_computer_name* is the actual name of the client. Press `Enter`.

    This shows what information is saved on the DNS Servers used by the client computer. This information should match what is shown in the output from the first step.

3. On the server that holds the license management software, open a command prompt and run the command line: `nslookup client_computer_name`. The output lists the information for this server.

   Does it match the information given by the command ipconfig /all on the client computer? If not try the following.

Try these options to correct the issue

1. If the client computer has a dynamic (DHCP) IP address, either change it to a static one or make a reservation on the DHCP Server so that the computer always get the same IP address.
2. Update the records on the DNS Servers used by both the client computer and the server computer.

You can also configure the computer names and IP addresses in the local Hostfile of the client and server:

1. On the client computer, make a backup copy of the file C:\Windows\System32\drivers\etc\hosts.
2. Open the original in a simple text editor.
3. Add a new line which contains the IP and name of the server, for example: 192.168.29.27 license_server.thermocalc.se.
4. Save the changes.
5. On the server, make a backup copy of the file /etc/hosts.
6. Open the original in a simple text editor.
7. Add a new line which contains the IP and name of the client, for example: 192.168.29.47 Computer_A.thermocalc.se.
8. Save the changes.
9. In the host file, there is an example of how the operating system (Windows or Linux) wants the line in the hosts file to look like.

macOS Installations: Running the License Initialization Script

As part of the Standalone installation of Thermo-Calc, the Setup runs a license initialization script. If this part of the installation process did not complete properly for a standalone installation, you must manually run the license initialization script. You need the administrator username and password for these steps.

How to Run the Script

For this script to successfully initialize the license, the license file must be called **lservrc** and be located in the folder:

```
/Users/Shared/Thermo-Calc
```

Installation Default Directory: macOS

1. Open a terminal window. The **Terminal** application is in the */Applications/Utilities* folder.
2. At the prompt, enter this command:

   ```
   $ sudo /Applications/Thermo-Calc-
   2026b.app/Contents/Resources/license-initialization-macOS-x86_
   64.sh
   ```

   If you are not already logged in as an administrator, you probably cannot run the `sudo` command. If this is the case, then you can use the `su` command in the terminal window to login as an administrator. Contact your local system administrator for help.

3. Enter the administrator password and press `Enter`.
4. When you restart your computer and run the license initialization script, you are ready to start using Thermo-Calc.

> If you did not install a license file during this procedure, you can still start Thermo-Calc although you will get the **No license file found** message.

Linux Installations: Running the License Initialization Script

As part of a Standalone installation of Thermo-Calc, the Setup runs a license initialization script. If you get a warning message during the standalone installation `Unable to run post-installation script`, run the license initialization script as root after the installation, then you need to manually run the script as root.

openSUSE Administration (sudo) Users

Note the following if you are a sudo user (administrator) in openSUSE installing Thermo-Calc using this command:

```
sudo ./Thermo-Calc-linux-<full-version-number>.run
```

When this command is used, you will do a text-based installation instead of having a graphical interface to guide you. The information is the same, just without the user interface.

For example, the *<full-version-number>* is not just 2026b, it is what is found in the **Help → About** window in Thermo-Calc and it changes every release. You can find the current full version number listed on our website.

How to Run the Script

For this script to successfully initialize the license, the license file must be called **lservrc** and be located in the directory where you have installed Thermo-Calc.

Installation Default Directory: Linux

1. In the console, go to the Thermo-Calc installation directory.
   - The license file is put in `/home/<user>/Thermo-Calc` if you are installing as a non-root user, where `<user>` is your user name.
   - If you are installing as root, then this directory is `opt/Thermo-Calc/`.
2. Enter this command:

```
$ sudo sh license-initialization-linux.sh
```

If you are not able to execute the `sudo` command because you are not on the sudoers list, you must log in as a root user with the command `su`, and then use `sh` to run the license initialization script. For example, on a 64-bit computer, enter the following:

```
$ sh license-initialization-linux.sh
```

3. Log out of Thermo-Calc and then log back in to save these changes.

Sentinel RMS License 9.7 Tools

These tools relate to Network Client installations of the Sentinel RMS License software.

GetHostID: Get HostID/Mac Address

GetHostID is a tool that retrieves the HostID/Mac address from the computer hosting the license server and saves it to a text file.

For Linux the output file is called `gethostid.log`. For Windows it is called `TC_Hostid.txt`.

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager (Windows) or Server (Linux), version 9.7.
- The tool is applicable to Windows and Linux (32-bit and 64-bit) operating systems. See Windows: Installing the Sentinel RMS License Manager or Linux: Installing the Sentinel RMS License Server.

Windows

1. Extract `getHostID_win.zip`.
2. Right-click `getHostID_win.bat` and select **Run as Administrator** from the menu.

   The output is saved in a file: `TC_Hostid.txt` located in the same folder as `getHostID_win.bat`.

Linux 32-bit

1. Extract `gethostid.tar`.
2. Run the command: `>./gethostid`.

   The output is saved in a file: `gethostid.log` located in the same directory as `gethostid`.

Linux 64-bit

1. Extract `gethostid64.tar`.
2. Run the command: `>./gethostid64`.

   The output is saved in a file: `gethostid.log` located in the same directory as `gethostid64`.

lsmon: Monitor License Manager Transactions

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager (Windows) or Server (Linux), version 9.7.

- The tool is applicable to Windows and Linux (32-bit and 64-bit) operating systems. See Windows: Installing the Sentinel RMS License Manager or Linux: Installing the Sentinel RMS License Server.

Platforms

Windows, Linux 32-bit, Linux 64-bit

The tool retrieves information about all features currently licensed by the Sentinel RMS License Manager, licenses, and clients.

On UNIX computers, you can use "Poll-interval-in-seconds" to specify that lsmon should keep monitoring and reporting usage activity instead of displaying information once and stopping. If specified, lsmon waits for that many seconds between re-polls of the License Manager.

lsmon monitors all licensed applications supported by a License Manager. If the License Manager supports licensed applications from multiple vendors, then all licenses for all vendors are displayed.

- On Windows, use `lsmon` *[Server-host]*
- On Linux 32-bit, use `lsmon` *[Poll-interval_in_seconds] [Server-host]*
- On Linux 64-bit, use `lsmon64` *[Poll-interval_in_seconds] [Server-host]*

OPTIONS

- *Poll-interval_in_seconds*: Enable periodic update at indicated rate. This option is supported on UNIX only).
- *Server-host*: The name of the computer on which the License Manager is running. If Server-host is omitted, lsmon will attempt to talk to the Sentinel RMS License Manager on the computer indicated in the LSHOST environment variable or in the LSHOST (or lshost) file. If the variable or the file does not exist, then it will attempt to contact a License Manager using the broadcast mechanism. If lsmon fails to find a Sentinel RMS License Manager, it will display an error message and exit.

lspool: Maintain Redundant License Manager Pool

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager (Windows) or Server (Linux), version 9.7.

- The tool is applicable to Windows and Linux (32-bit and 64-bit) operating systems. See Windows: Installing the Sentinel RMS License Manager or Linux: Installing the Sentinel RMS License Server.

lspool is a redundant License Manager administration utility (command-line) for Windows and UNIX.

OPTIONS

- `h` Displays a list of lspool usage options.
- `a` *<license manager>* Adds the License Manager to the redundant License Manager pool. Specify the hostname or IP address of the License Manager system. Modifies the redundant license file.. On Windows, dynamic addition of License Manager in an existing redundant pool is not supported.
- `d` *<license manager>* Deletes the License Manager from the redundant License Manager pool. Specify the hostname or IP address of the License Manager system. Modifies the redundant license file. On Windows, dynamic deletion of License Manager in an existing redundant pool is not supported.
- `l` Displays the host name of the leader redundant License Manager.
- `p` Displays the list of License Managers in the redundant License Manager pool.
- `g` *< feature> <version>* Displays the license token distribution criteria for the specified feature/version. If the version is not specified, it must be replaced with empty quotation marks: " ".
- `L` *<event> <OFF|ON>* Disables/enables logging for an event. The events you select will be logged into the License Manager trace log file (only if error logging is enabled).

LSPOOL - L OPTIONS

Events that can be logged using the -L option are given below. The following events are temporarily logged (except 1) and need to be set each time the License Manager is restarted.

- `0` Logs all events.
- `1` Logs when the License Manager is up. On by default. 2 Logs election of the leader License Manager.

- 3 Logs the two-way redundant License Manager heartbeat:> Leader License Manager periodically logs the update status received from all its followers

  > Follower License Manager periodically logs the update about the contact established with the current leader License Manager

- 5 Logs the usage information event, shared by the leader, regarding the number of tokens issued. 7 Logs the license token distribution information synchronization event.
- 9 Logs when the License Manager is down.
- 11 Logs addition of a license into the file or memory. Also logs deletion of a license from the memory.

lsrvdown: Shut Down the License Manager

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager (Windows) or Server (Linux), version 9.7.

- The tool is applicable to Windows and Linux (32-bit and 64-bit) operating systems. See Windows: Installing the Sentinel RMS License Manager or Linux: Installing the Sentinel RMS License Server.

lsrvdown utility is used to shut down the named License Manager.

Platforms

Windows, Linux 32-bit, Linux 64-bit

- On Windows and Linux 32-bit use `lsrvdown host-name`
- On Linux 64-bit use `lsrvdown64 host-name`

lsrvdown can be run from the operating system command prompt by an administrative user on a client or License Manager computer.

- On UNIX, only the user logged in as “root” can use lsrvdown.
- On Windows, any user with administrative privileges may use lsrvdown unless the License Manager was started by a user logged in as Administrator, in which case only Administrator can shut the License Manager down. The computer on which you are running lsrvdown must be in the same network domain as the License Manager computer.

The same user must install the Sentinel RMS License Manager and also run this utility.

lswhere: Display a List of License Managers

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager (Windows) or Server (Linux), version 9.7.

- The tool is applicable to Windows and Linux (32-bit and 64-bit) operating systems. See Windows: Installing the Sentinel RMS License Manager or Linux: Installing the Sentinel RMS License Server.

Platforms

Windows, Linux 32-bit, Linux 64-bit

lswhere command displays the network names of the computers running the License Manager. By default, lswhere displays for each License Manager the address of the computer on which that License Manager is running as well as its host name.

lswhere can be run on Windows and UNIX. lswhere should be run from the operating system command prompt by an administrator or application user on a standalone, client, or License Manager computer.

lswhere should be run in the following format:

- Windows and Linux 32-bit: `lswhere` *[option]*
- Linux 64-bit: `lswhere64` *[option]*

OPTIONS

- `d` Displays details on the License Managers found on the network.
- `r` Displays only the IP addresses of the License Managers found on the network (resolves the host names). lswhere can also be run without specifying any command line options.

WlmAdmin Administrative Tool

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager for Windows, version 9.7.
- The tool is applicable to Windows operating systems. See Windows: Installing the Sentinel RMS License Manager.

WlmAdmin performs a variety of administrative functions for the license management activities. It displays elaborate information that includes the License Manager information, feature information, and license and client information.

Platform

Windows

WlmAdmin can administer a remote Linux license server.

WlmAdmin Functions

- Provides information on the License Managers.
- Details on licenses and clients using them in the network. For example, the administrator can see which users have acquired that license and who are in a queue waiting for the license.

If you are using redundant License Managers, you can use WlmAdmin as an informational tool to:

- Add or delete a redundant License Manager from the redundant License Manager file.
- Display a list of all License Managers in the redundant License Manager pool and display the name of the License Manager leader.
- Display the distribution criteria for specific licenses (only high assurance model is allowed, where the reigning leader server keeps all the license tokens).

View License Manager Information

- Click the name of a License Manager in the left-hand pane of the main window. In the right-hand pane of the display, you see the IP address of the computer containing the License Manager and its host name.

Add or Remove a License Manager from the Defined Server List

- To add a License Manager: Right-click the name of a License Manager in the list of Subnet Servers. From the menu select **Add to Defined List**.
- To remove a License Manager: Right-click the name of a License Manager in the list of Defined Servers. From the menu select **Remove from Defined List**.

Add a License Code to the License Manager from a File

1. Right-click the name of a License Manager in the left-hand pane of the main window.
2. From the menu select **Add Feature > From a File > To Server and its File**.
3. To add the license from a file, select **From a File**. This permanently adds the license code to the License Manager license file as well as to the License Manager memory.
4. In the new windows, browse to the source file that contains the license code and click **Open**.
5. Select the license code file.

Delete Old License Features from the License Manager

1. Right-click the file `WlmAdmin.exe` and select **Run as Administrator**.

   If the license server is not found under subnet servers, go to **Edit > Defined Server List**.

2. Enter the host name or IP address of the license server.
3. Click **Add** and **OK**.
4. Click **View > Refresh All** to update the list.
5. Right-click the name of a License Manager in the left-hand pane of the main window.
6. From the menu select **Remove all Features**

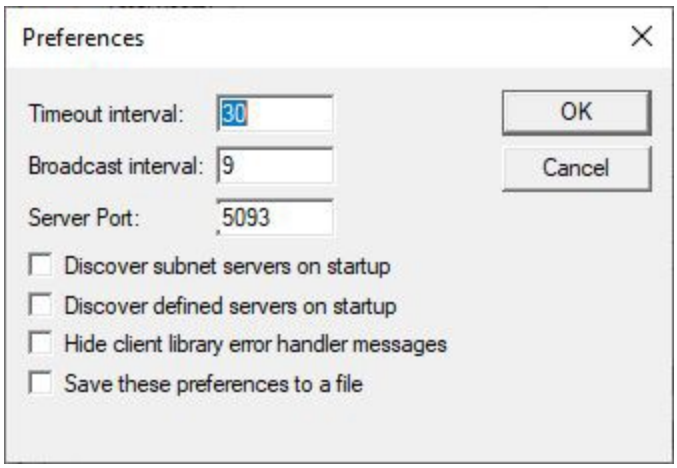
Shut Down a License Manager

- Right-click the name of a License Manager in the left-hand pane of the main window. From the menu select **Shutdown Server**.

Setting WlmAdmin Preferences

WlmAdmin allows you to choose what to display when it starts.

From the **Edit** menu, select the **Preferences** command to view WlmAdmin Preferences:



- **Timeout Interval**: The number of seconds after which WlmAdmin will stop trying to contact a License Manager. If you have a large network or a slow one, you might want to increase this number if you find WlmAdmin has difficulty retrieving information from License Managers.
- **Broadcast Interval**: Specify the number of seconds between broadcasts to the network to discover License Managers.
- **Server Port**: To set any custom port (other than the default port 5093) on which the RMS License Manager is running.

  Set this port number before you add that License Manager in the list of defined servers.

- **Discover subnet servers on startup**: To automatically discover and display the License Managers on your subnet.

- **Discover defined servers on startup**: To always show the License Managers you have defined.

- **Show client library error handler messages**: To pass license management error messages from Sentinel RMS to WlmAdmin.

- **Save these preferences to a file**: To save your choices.

Sldemo: Show Basic API Functions

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager for Windows, version 9.7.
- The tool is applicable to Windows operating systems. See Windows: Installing the Sentinel RMS License Manager.

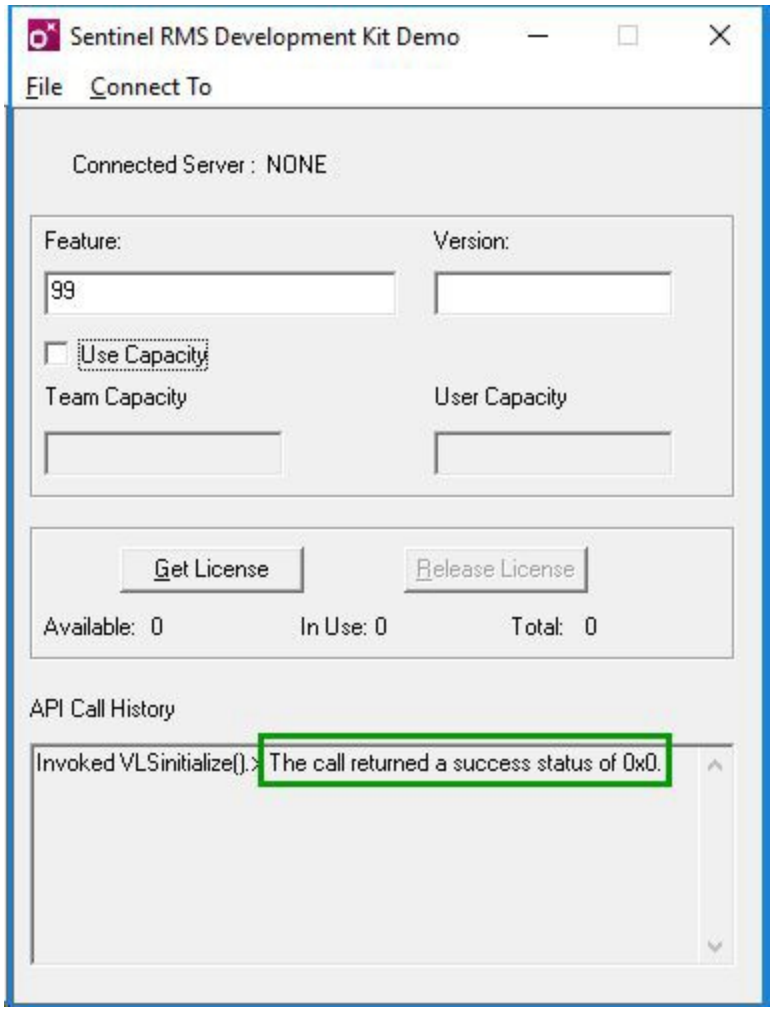
slmdemo is a Windows-based graphical sample program to show basic API functions. Evaluate it using the steps described here to understand the basic API calls and test the connectivity between client and license server

slmdemo can be used to test the connectivity to a remote Linux license server

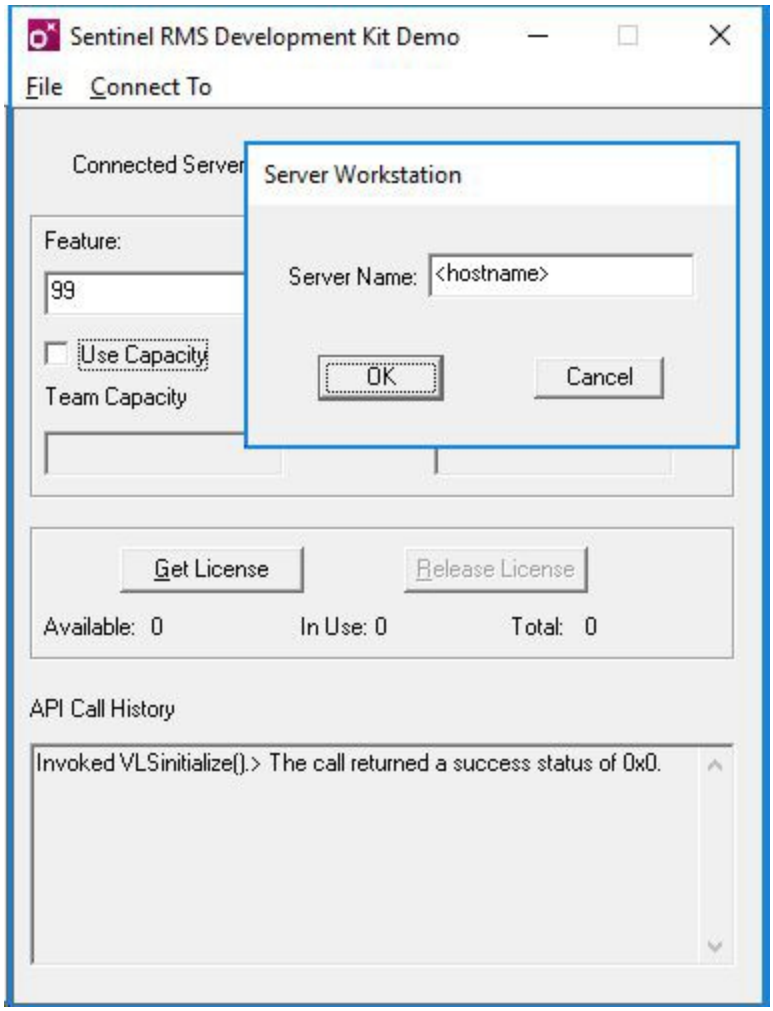
Platform

Windows

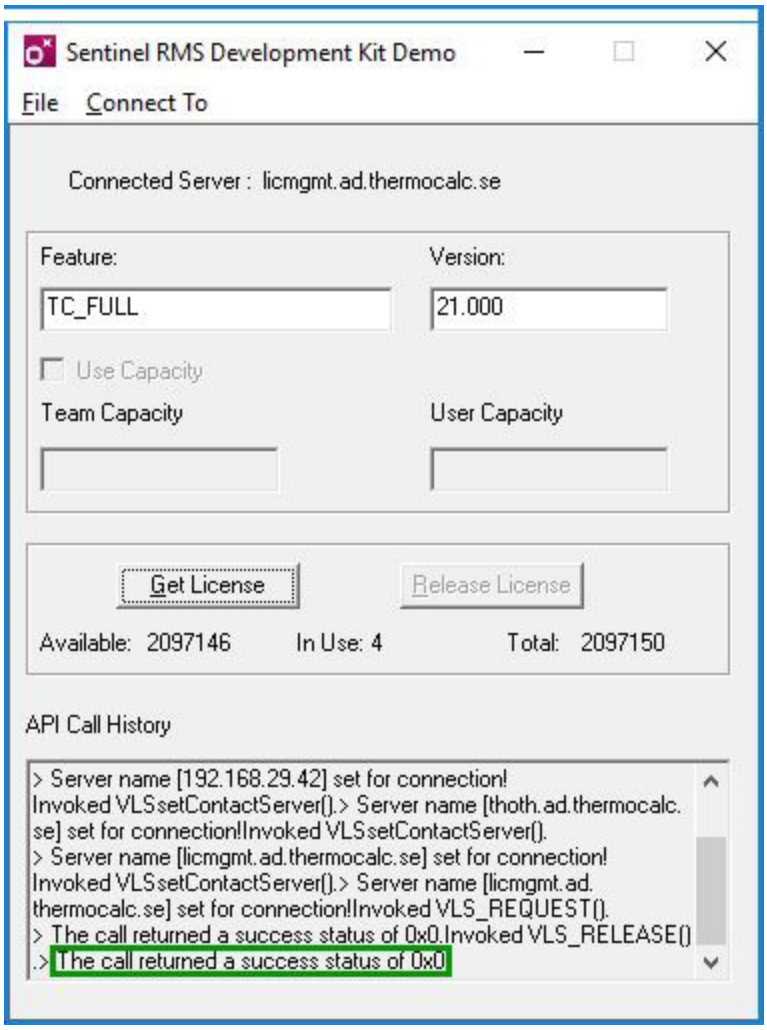
Right-click on the executable and select **Run as administrator**. slmdemo calls the VLSinitialize API when the application is invoked successfully.



Set the contact server (License Manager) under the **Connect To > Server** menu option. Enter a `hostname` , which is the hostname or IP address of the License Server.



Click **OK** and enter in the field one of the license features available in the network license file. Where *Feature* is the name of the feature ex. **TC_FULL** and *Version* is the license version in the NWL (Network) license. Click **Get License**. The message `The call returned a success status of 0x0` means that the connection client <> license server works.



To save the log, click **File > Save log**.

Wechoid: Get a Computer Locking Code

- This is related to the Full Network Client Installations using the Sentinel RMS License Manager for Windows, version 9.7.

- The tool is applicable to Windows operating systems. See Windows: Installing the Sentinel RMS License Manager.

Before your software vendor creates a license code with any computer restrictions, you must get the locking code for your computer with the Wechoid program. Your software vendor will tell you which computers you must run Wechoid on. The Wechoid utility outputs either one or two hexadecimal locking codes depending upon how your software vendor has configured it. You will send all locking information to your software vendor. Your software vendor will use this information, which is specific to your computers, to generate new license codes.

Platform

Windows

When launched, the utility shows the available lock criteria (a checkmark is added next to each) and the values. Click to clear (uncheck) all checkboxes except for **Ethernet Address**.

Software Development Kits (SDKs)

The Software Development Kits (SDKs) are available for users who wish to use the power and flexibility of Thermo-Calc in their own application programs. SDKs are add-on features that allow users to call Thermo-Calc functions and access the thermodynamic and mobility databases directly from within your own software codes or other software programs.

Each SDK incorporates an application programming interface (API), a programmer's guide, and a collection of examples to help users get started.

The following SDKs are briefly described as there is extensive information available in separate help content:

- TC-Python
- TC-Toolbox for MATLAB®

The *TQ-Interface Application Programmer's Guide* is fully included here and also available as a separate guide on the website.

TC-Python

TC-Python is a Python™ language-based SDK available with Thermo-Calc which allows for easy and flexible coupling of Thermo-Calc calculations with other software programs. It was built in the popular language Python™ to give Thermo-Calc users access to many other programs, such as numerical packages like NumPy, SciPy, and TensorFlow, which can now be used in combination with our calculations. It can also be used from within Jupyter notebooks or comparable interactive Python™ consoles.

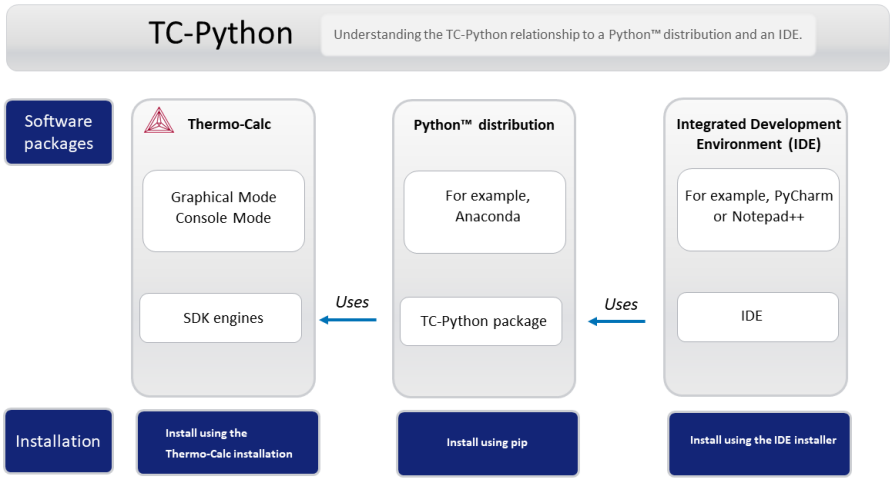
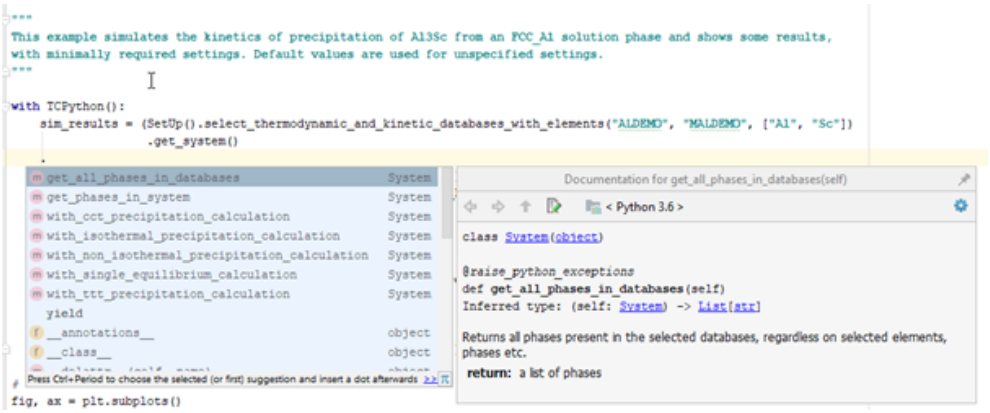
Introduction to TC-Python API

TC-Python is available with all operating systems supported by Thermo-Calc (Windows, macOS, and Linux) and examples are included with this API to help you learn about using the Python scripts as well as can be used as the basis for your own projects.



The design of the API (and using intelligent code completion with some IDEs such as Microsoft's Intellisense®) guides you through the process of setting up the simulation, where good default values are used. This minimizes the occurrence of errors and makes it an easy option even for those who do not have experience working with APIs.



An example of the PyCharm IDE using the intelligent code completion and its associated documentation that describes the classes and methods.

Some key features of TC-Python include:

- TC-Python is based on the Python™ programming language and uses intelligent code completion to help you more easily navigate through the available classes and methods.
- Python™ is a widely used language in science community but is also used for web applications and other things. For someone experience or just starting out as a programmer.
- This API is an integral part of the Integrated Computational Materials Engineering (ICME) framework, where you can couple it in a very open way. For example, you can use numerical packages like NumPy and SciPy in combination with our calculations as well as more easily do parallel computations.
- As an object-oriented approach, this makes it easier to reuse information (classes/methods) and more quickly run your calculations when you need to change the compositions.
- TC-Python can be used to develop custom Property Models for the Property Model Calculator. User-developed Property Models allow you to customize Thermo-Calc to meet your modeling needs.

TC-Python Help and Learning Resources

There are several resources available to help you get working with TC-Python.

Help Options

Once TC-Python is installed, the help is available in different ways.

- When working with TC-Python, and when you are working in an IDE such as Pycharm, there is inline guidance or code completion with interactive suggestions to guide you.
- The latest version of the HTML help is available on our website.
- The same help is available in a standalone PDF, also available on our website.

TC-Python Examples

After you have installed all the necessary items to get up and running then you can look at several included examples. You can use these examples to both learn about the use of TC-Python and as a way to build your own calculation project.

The location of the installed examples is based on the operating system but all are installed in the **SDK → TC-Python → Examples** subfolder.

Installation Default Directories: TC-Python and Bundled Python Interpreter

TC-Python Learning Resources on the Website

There is a variety of resources related to TC-Python that you can access via the dedicated TC-Python help page as well as other useful links highlighted in this section.

TC-Python Help

Navigate to the TC-Python help page, which has links to a variety of items such as:

- The current online Help and its equivalent PDF.
- Download a zip file of the current examples. These examples are already included with your installation; this is an option to download all at once.

- Links to the **Documentation** archive on our website to access older versions of the PDFs or the current version of the installation guide.
- Troubleshooting and diagnostic information.

Training and Other Learning Resources

- Go to our Training Courses page to learn more about your options for Live Online, In-Person, or Customized training.
- Visit the Learning Hub to register to use our online self-paced courses.
- Go to our TC-Python Video Tutorials page to access additional content.
- Scroll to the bottom of the main TC-Python product page to Learn More About TC-Python. Various Publications, Webinars, and other resources are available at the links.

TC-Python Examples

These SDK examples are not directly accessible from the Thermo-Calc menu.

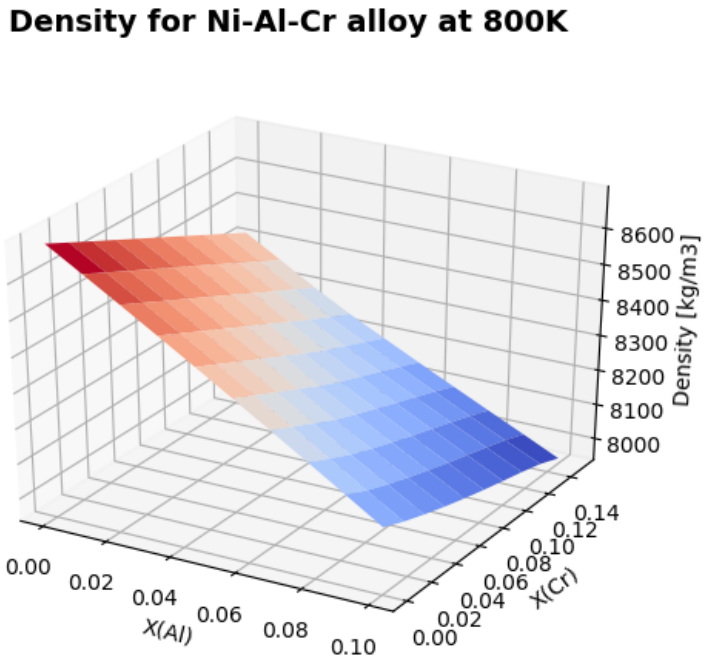
- Material to Material Calculator Examples

General Examples

T_01: Single Point Equilibrium of a Ternary System

File name: `pyex_T_01_Single-point_equilibrium_looping_and_3d_plotting.py`

This example shows how you create a single equilibrium calculation from a ternary system, loop it while changing Al and Cr concentration, then calculate density and plot the result as a 3D surface.



Plot showing the density for Ni-Al-Cr alloy at 800 K.

T_02: Single Equilibrium Calculation of Solidus and Liquidus Temperature

File name: `pyex_T_02_Single_equilibrium_solidus_and_liquidus_temperature.py`

This example shows how to create a single equilibrium calculation from a ternary system and configure it to calculate the solidus and liquidus temperature using fixed phase conditions for the liquid phase. There can be multiple solutions to a fixed phase condition and it is good practice to perform a regular equilibrium calculation close to where the phase transition is. This example starts with an equilibrium calculation at 1700 K in order to get good start values.

The result from this example is output to the log window.

```
Liquidus temperature: 1715.05 K
Amount of FCC_A1#1 = 0.000
Amount of LIQUID#1 = 1.000
06:40:40,737 [Thread-1]  INFO CalculationEngine:   Normal POLY minimization, not global

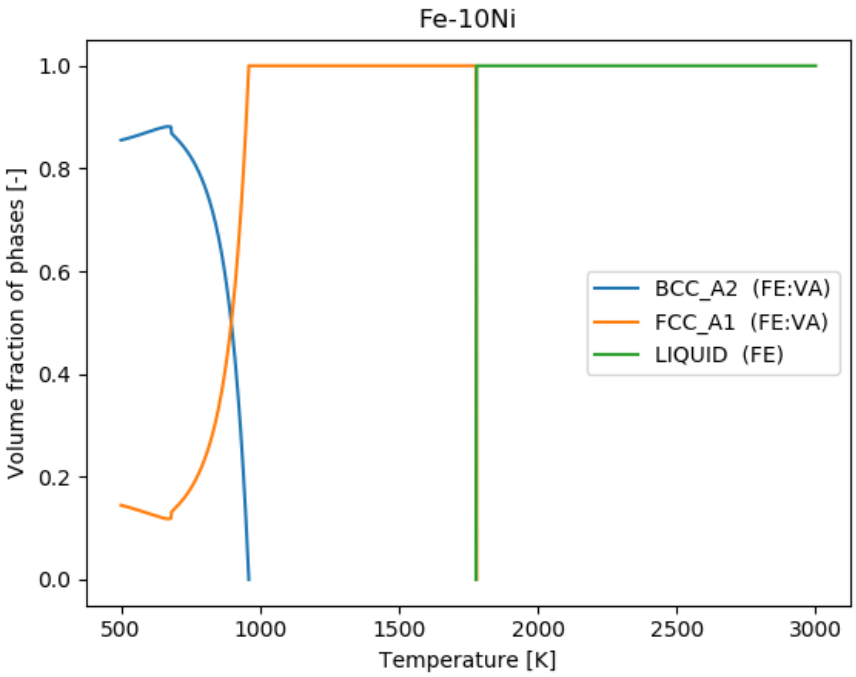
Solidus temperature: 1598.13 K
Amount of FCC_A1#1 = 1.000
Amount of LIQUID#1 = 0.000
```

T_08: Create a Property (Step) Diagram

File name: `pyex_T_08_Property_diagram.py`

This example shows how to create a property (step) diagram using TC-Python.

The alloy system Fe-Ni is used as an example.

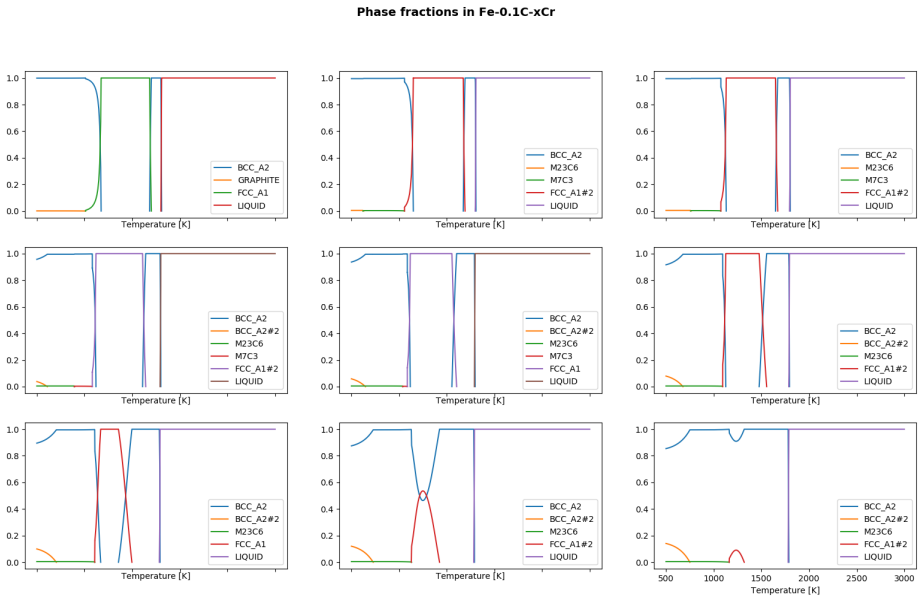


T_09: Run Multiple Property (Step) Diagram Calculations in Parallel

File name: `pyex_T_09_Property_diagram_loop_parallel.py`

This example shows how to run multiple property (step) diagram calculations in parallel. TC-Python supports parallel computation only by using multi-processing.

The alloy system Fe-C-Cr is used as an example.

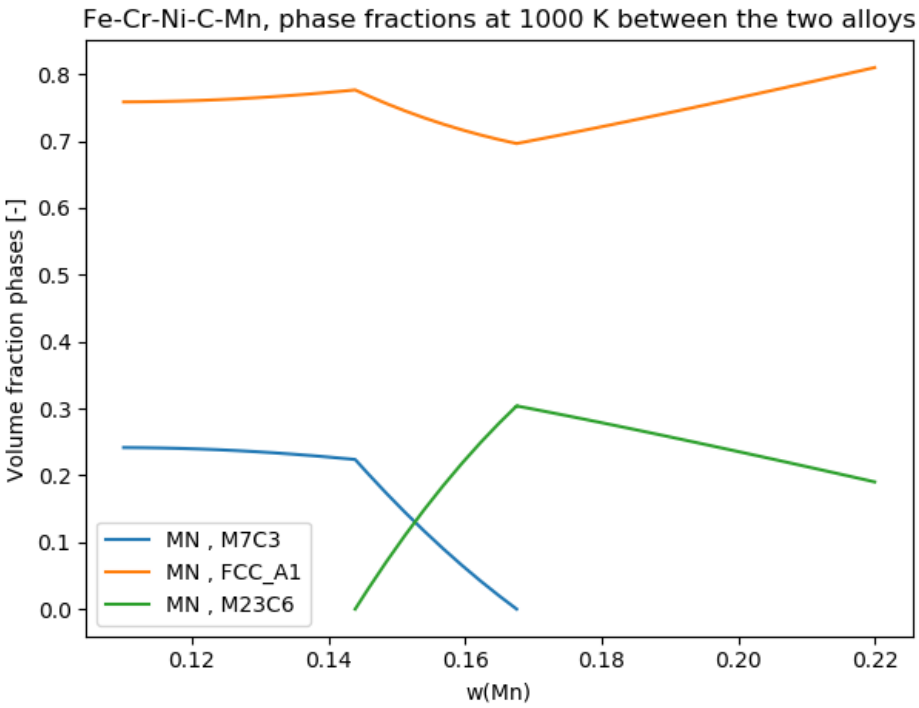


Plot results after running multiple property (step) diagrams for an Fe-C-Cr alloy.

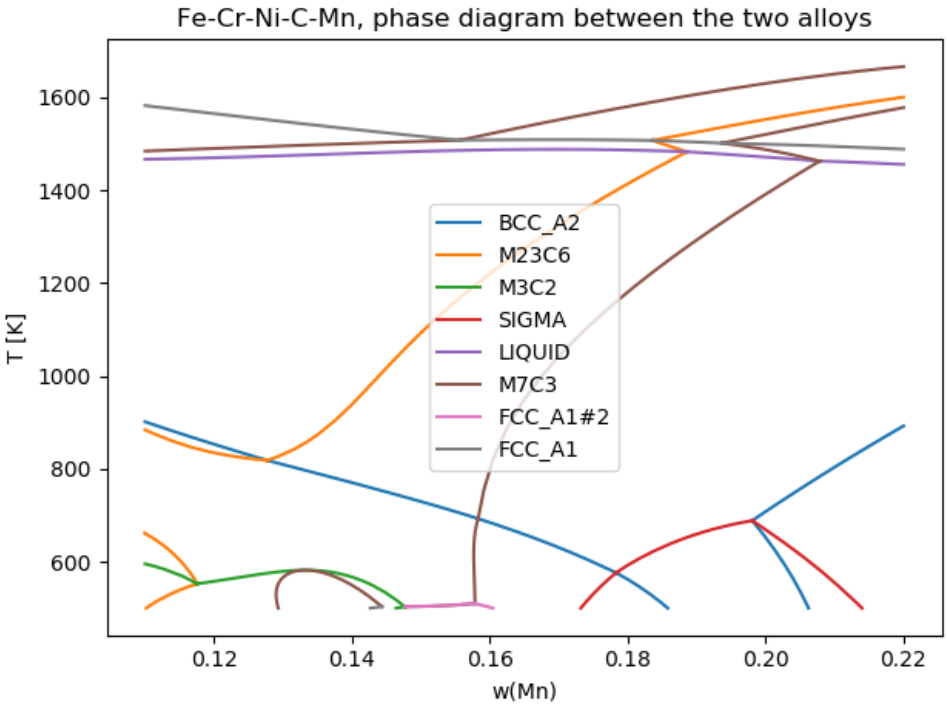
T_10: Create Property Diagrams

File name: `pyex_T_10_Property_diagram_alloy_A_to_alloy_B.py`

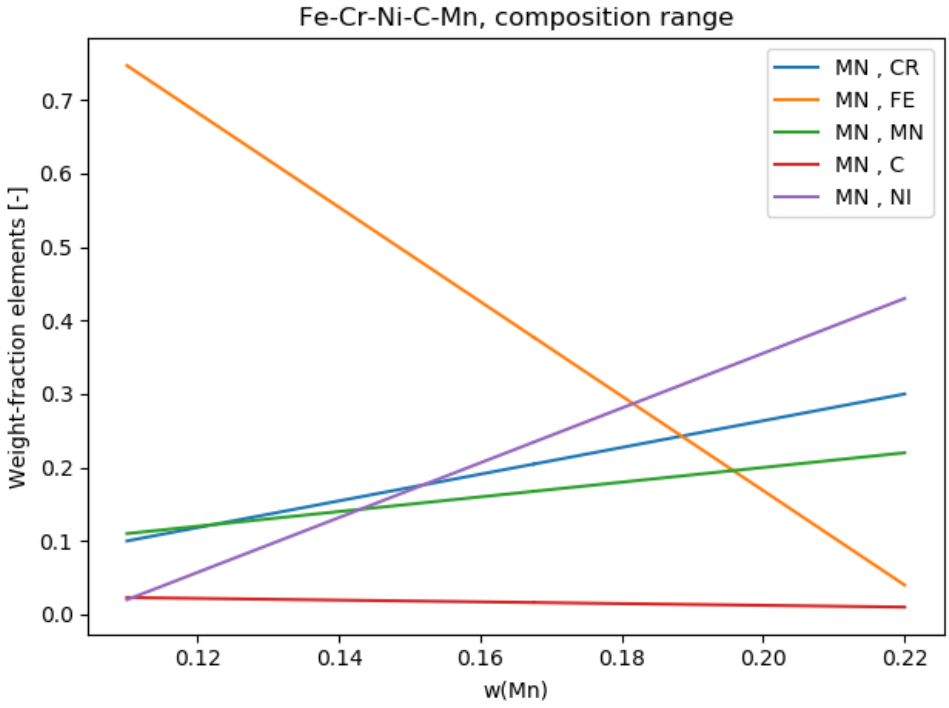
This example shows how to perform step calculations to create property diagrams. The plot results for this example show a section between two materials when moving from one material composition to another. On the left side of the diagram it is one alloy and on the right side it is another alloy.



A property (step) diagram showing how phase fraction varies in the section.



A phase diagram for the same section as the property diagram but with the temperature on the y-axis.



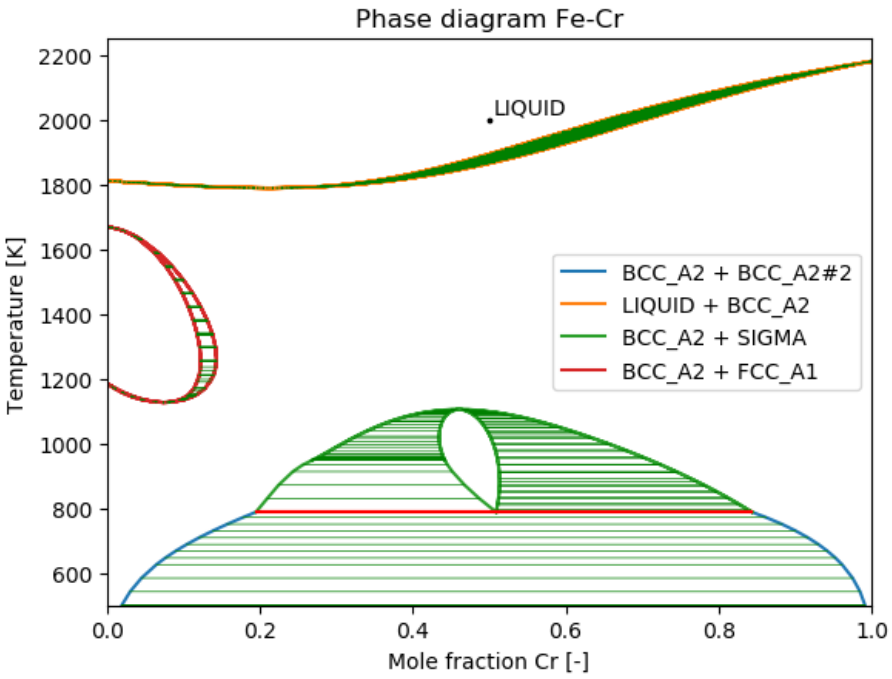
In this plot, the compositions vary linearly along the section.

T_11: Calculate and Plot a Phase Diagram

File name: `pyex_T_11_Phase_diagram.py`

This example shows how to calculate and plot a phase diagram.

The system Fe-Cr is used as an example.



The phase diagram for Fe-Cr.

T_12: Export Phase Diagram Data to a CSV File

File name: `pyex_T_12_Phase_diagram_export_to_csv_file.py`

Exports the line data of a phase diagram into a CSV-file that can be imported into other plotting software for creating customized plots for example. It is easy to adapt the code to generate a different format of the CSV-file or to use a completely different output file format.

See CSV Files for the location.

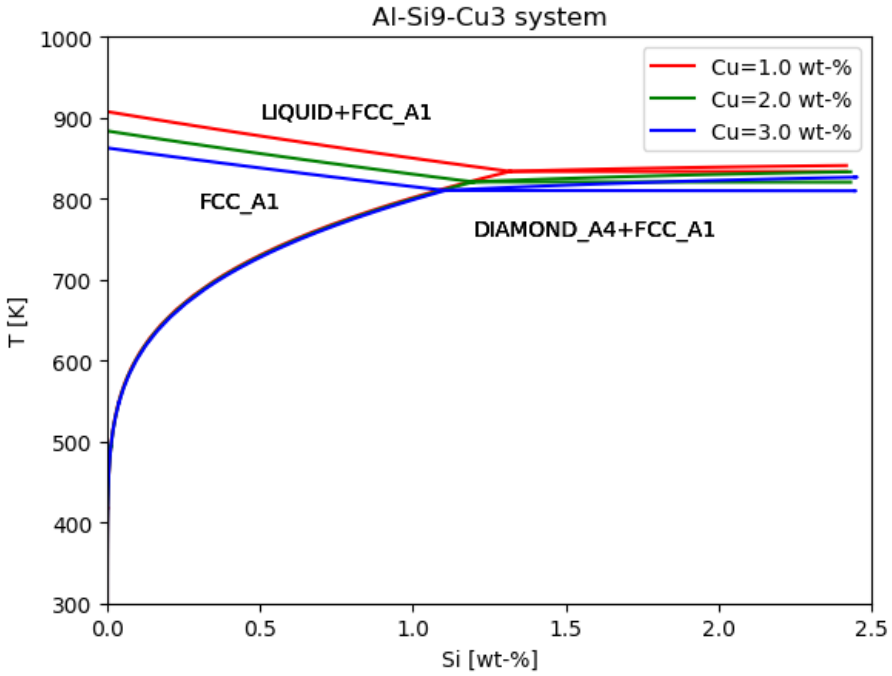
The system Fe-C-Cr is used as an example.

T_13: Calculate a Single Phase FCC_A1 Region Shift

File name: `pyex_T_13_Phase_diagram_single_phase_region_shift_Al_Si_Cu.py`

Calculates and plots the single phase FCC_A1 region of Al-Si-Cu alloys and compares them for different Cu-contents.

For simplicity only FCC_A1 and DIAMOND_A4 are enabled as solid phases.



The plot results for the single phase FCC_A1 region of Al-Si-Cu alloys compared to Cu at 1, 2, and 3 wt %.

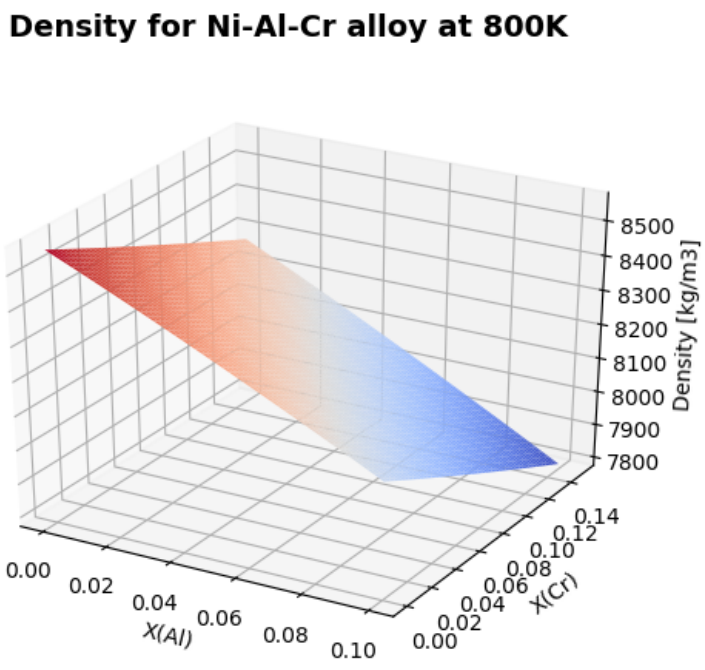
T_14: Create a Batch Equilibria from a Ternary System

File name: `pyex_T_14_Batch_equilibria.py`

This example shows how you create a batch equilibrium calculation from a ternary system, loop it while changing Al and Cr concentration, then calculate the density and plot the result as a 3D surface.

This is almost the same example as `pyex_T_01_Single_equilibrium_looping_and_3d_plotting.py`, but instead of 100 equilibria it calculates 10000 but only for BCC_A2.

It is much more efficient, since it is using `BatchEquilibriumCalculation` and not `SingleEquilibriumCalculation`. `BatchEquilibriumCalculation` has improved performance when calculating a large number of equilibria when each individual calculations is quick. E.g. when evaluating single phase properties for thousands of compositions.

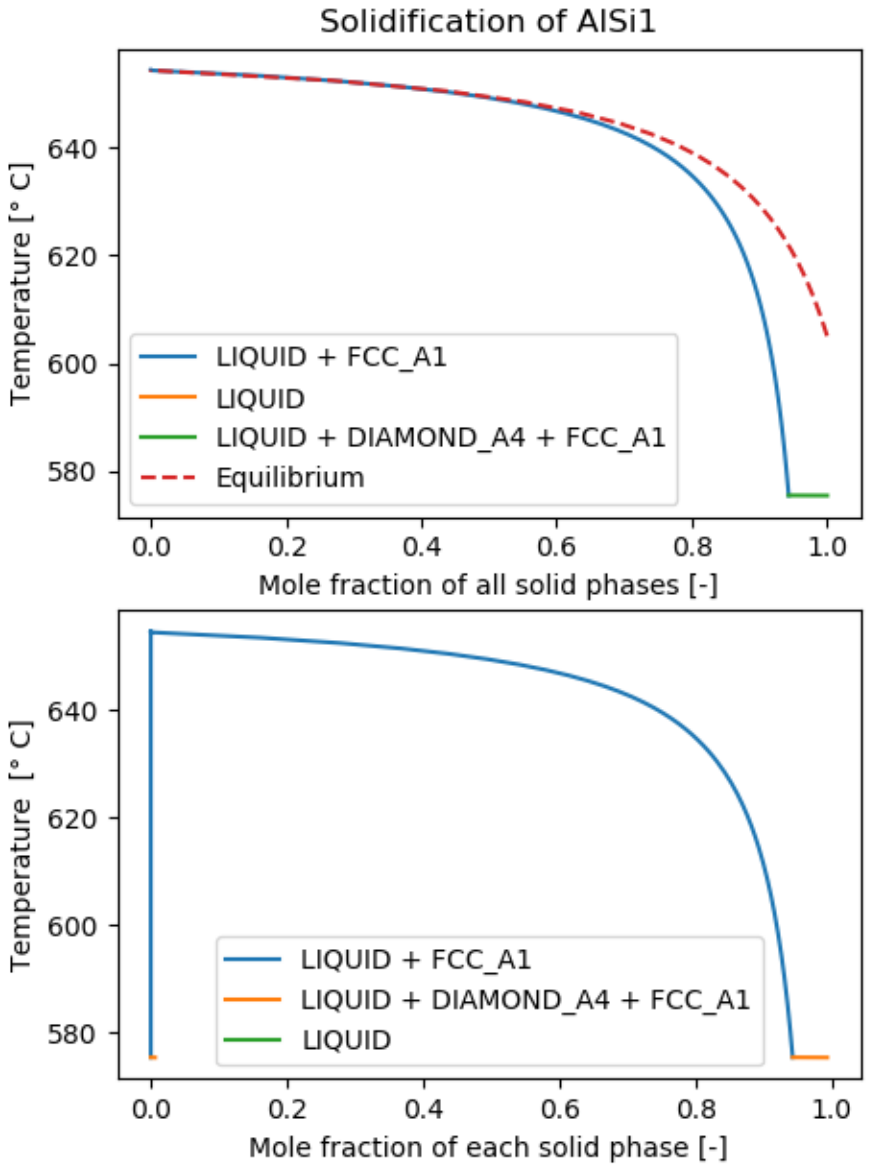


Scheil Examples

T_03: Scheil Mole Fraction of a Solid

File name: `pyex_T_03_Scheil_mole_fraction_of_solid.py`

Shows the basic usage of Scheil calculations in TC-Python and mixing them with equilibrium calculations.



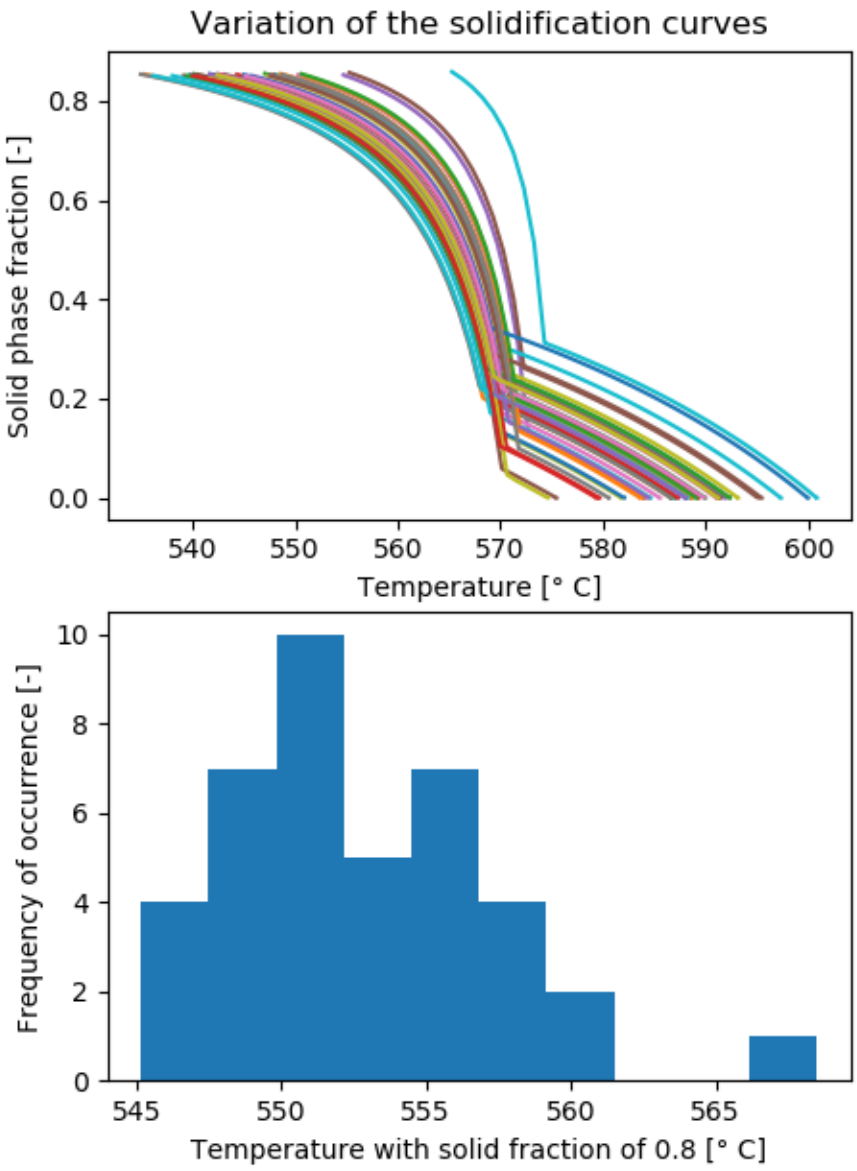
Plot results showing Solidification of $AlSi_1$ (top) and mole fraction of all solid phases (bottom).

T_04: Scheil Composition Distribution

File name: `pyex_T_04_Scheil_composition_distribution_Al_Si_Cu_Mg.py`

Calculates the variation of the 80% solid temperature using Scheil solidification for random compositions within a specification range.

The alloy system Al-Si-Cu is used as an example.



Plot results showing variation of the solidification curves (top) and how temperature varies by frequency (bottom).

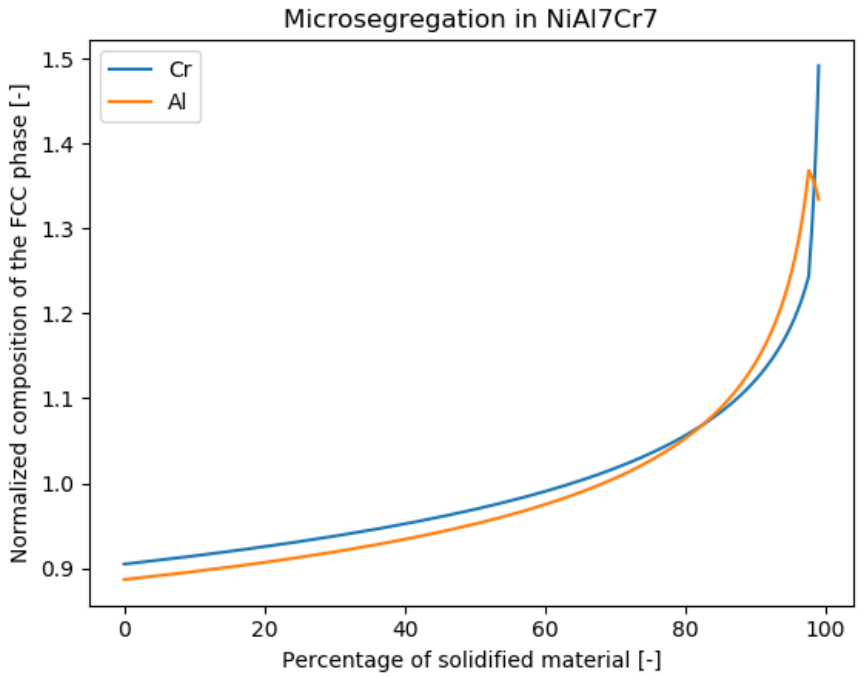
T_05: Scheil Composition Profiles in a Solidified Ni-based Superalloy

File name: `pyex_T_05_Scheil_composition_profiles_Ni_base.py`

Calculates the microsegregation profile in a solidified Ni-based superalloy using the Scheil-method.

The plot is normalized relative to the nominal composition and shows the composition of the matrix phase (FCC).

A model alloy in the system Ni-Al-Cr is used as an example.

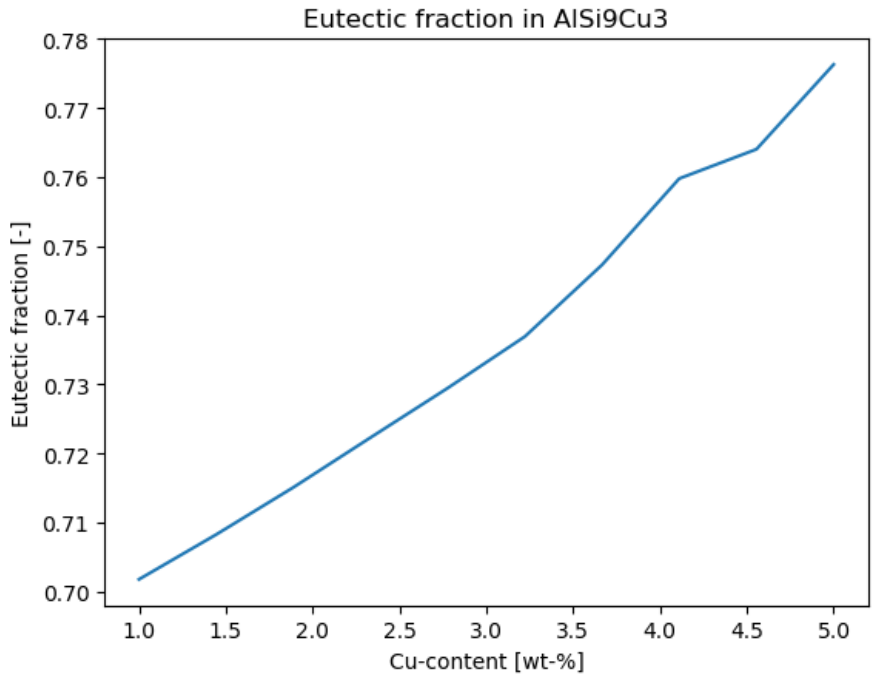


T_06: Scheil Calculation of an Eutectic Fraction

File name: `pyex_T_06_Scheil_eutectic_fraction_Al_Si_Cu.py`

Calculates the eutectic fraction using Scheil-solidification for varied alloying element content.

The alloy system Al-Si-Cu is used as an example.



Plot result showing Eutectic fraction in $Al_5Si_9Cu_3$.

T_07: Scheil Solidification Simulation - Export to CSV

File name: `pyex_T_07_Scheil_latent_heat_for_solidification_simulations.py`

Calculates the characteristic properties of the solidification of a range of alloys using Scheil-solidification and saves the data into a CSV-file (named `Al_Si_Cu_scheil_solidification.csv`) that can be imported by other software.

See CSV Files for the location.

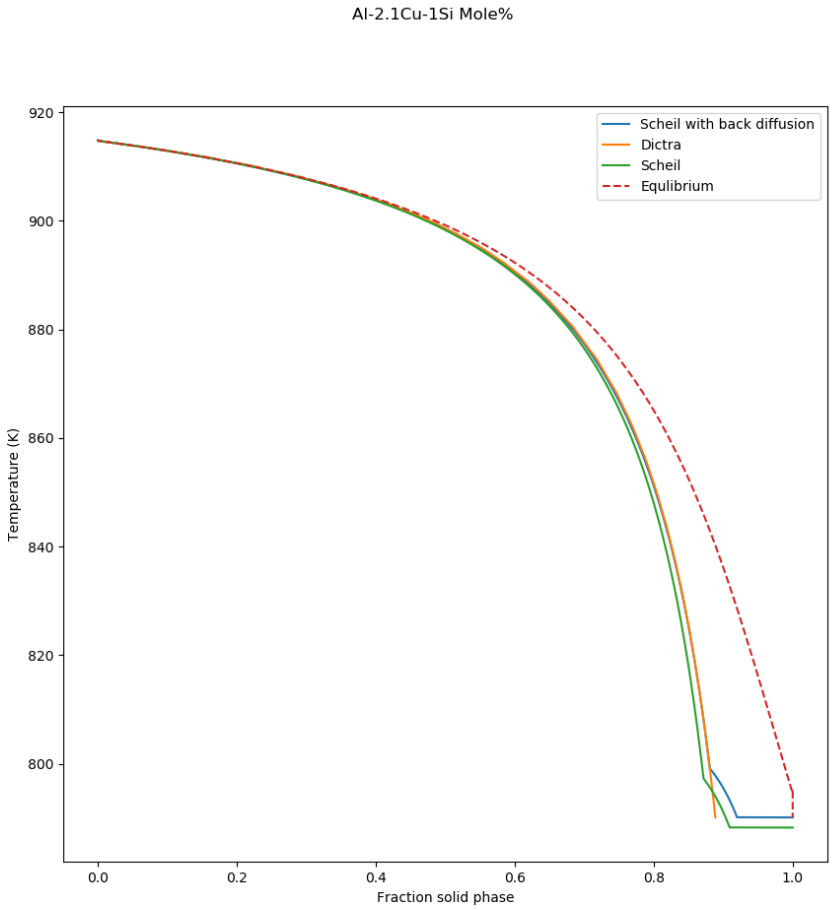
Such data is typically used as an input into other simulation software, e.g. for casting simulation.

The alloy system Al-Si-Cu is used as an example.

T_15: Calculate Solidification using Scheil with Back Diffusion

File name: `pyex_T_15_Scheil_back_diffusion.py`

Calculates solidification using Scheil with back diffusion in the primary phase, and compares the result to other calculation types.



Plot result of a Scheil with back diffusion calculation in the primary phase compared to three other calculation types (Diffusion Module (DICTRA), Scheil, and equilibrium).

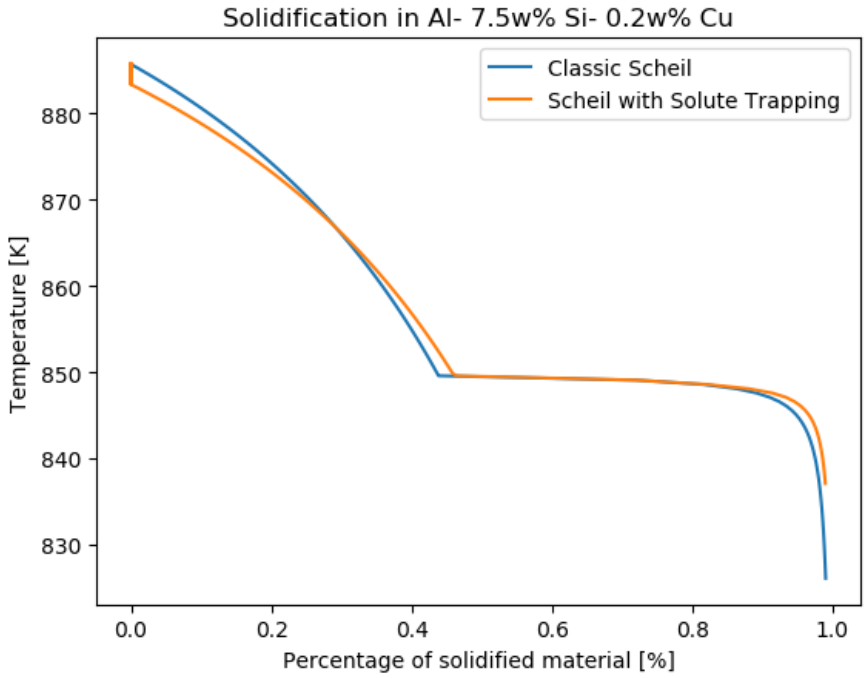
T_16: Calculate Solidification using Scheil with Solute Trapping

Calculates the solidification with and without Solute Trapping.

Then compare the solidification in the two cases by plotting temperature vs. mole fraction of solid phase. The alloy system Al-Si-Cu is used as an example.

File name: `pyex_T_16_Scheil_Solute_Trapping_Al_Si_Cu.py`

Graphical Mode example T_13: Scheil Solidification with Solute Trapping.



The effect of Scheil solidification with solute trapping of a Al-7.5Si-0.2Cu alloy compared to a classic Scheil calculation.

Material to Material Calculator Examples

T_17: Material to Material - Single Fraction of B

Calculates the phases occurring for a material mixture, in this case for a mixture of a martensitic stainless steel with Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `pyex_T_17_Material_to_Material_single_fraction_of_B.py`

The result from this example is output to the log window.

```
Stable phases at 650 °C, 40 wt-% Alloy 800: ['FCC_A1#1', 'SIGMA#1']
Molar fractions:
FCC_A1#1=93.2%
SIGMA#1=6.8%
```

T_18: Material to Material - Step Along Fraction of B

Calculates the phases occurring during a gradual transition between two materials, in this case from a martensitic stainless steel to Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `pyex_T_18_Material_to_Material_step_along_fraction_of_B.py`

T_19: Material to Material - Step Along Temperature

Calculates the phases occurring for a material mixture with varying temperature, in this case for a mixture of a martensitic stainless steel with Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `pyex_T_19_Material_to_Material_step_along_temperature.py`

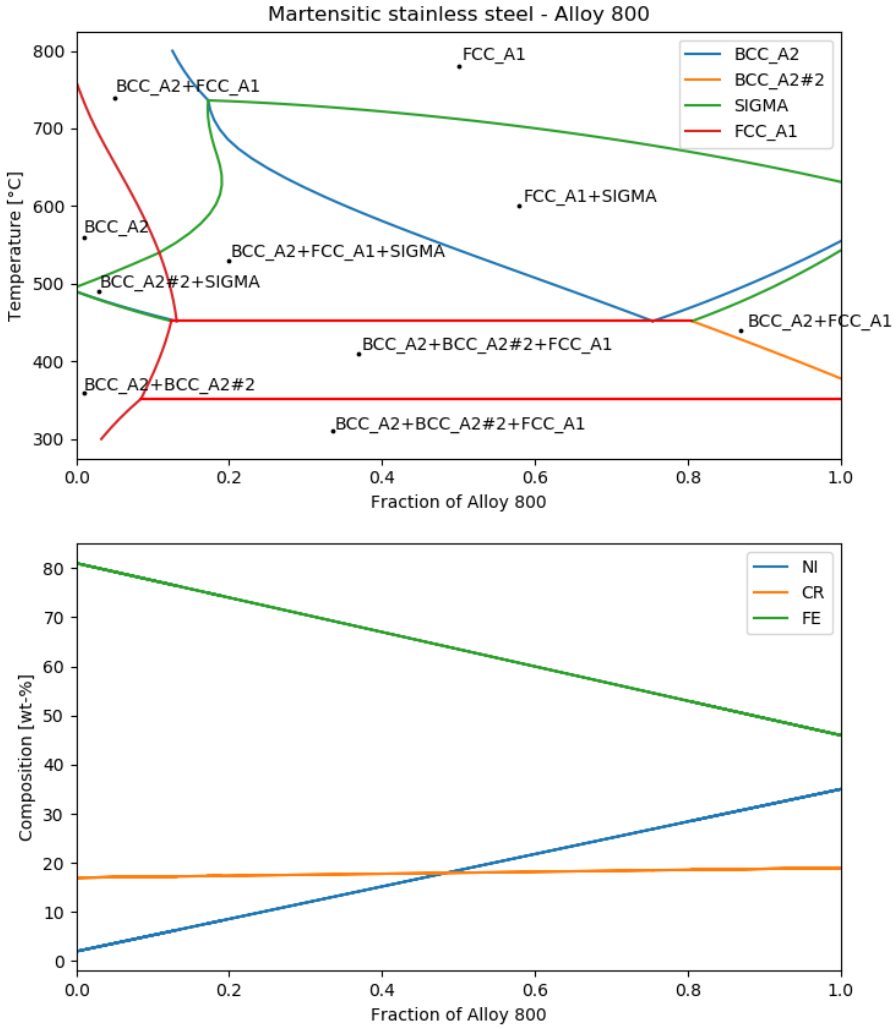
T_20: Material to Material - Phase Diagram

Calculates a "phase diagram" for a material mixture, in this case for a mixture of a martensitic stainless steel with Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `pyex_T_20_Material_to_Material_phase_diagram.py`



TC-Python Property Model Examples

Read more on our website about Property Models, including information about the material specific Model Libraries (i.e steel, nickel, titanium, etc.), as well as how to create your own custom models in TC-Python. If you are in Thermo-Calc, press F1 to search the help.

PM_01: Calculating Interfacial Energy with a Property Model

File name: `pyex_PM_01_Property_model_interfacial_energy.py`

This example shows how to run a (Jython) property model from TC-Python to calculate the interfacial energy. The Thermo-Calc Property Model uses a broken-bond approach. Any other pre-installed or user-defined Property Model created in Thermo-Calc can be loaded and used in the same way as in this example.

The details of a property model (arguments, result quantities, and so forth) are defined in the Thermo-Calc Property Model and are not known to TC-Python in advance. Therefore, when using the TC-Python property models, the workflow differs compared to other TC-Python modules. The available arguments need to be queried by using the respective `` `get_...()` `` – method. This requires some interactive development style until a first working version of the code is set up.

When TC-Python refers to the term "arguments", in the Property Model Development Framework it refers to "UI Panel Components". This refers to the same elements of the property model but differ in the same because TC-Python does not have a user interface (UI).

```
Available result quantities: {'interfacialEnergy'}
Description of 'interfacialEnergy': Interfacial energy [J/m**2]
Interfacial energy at 800 °C: 21.34875704825066 mJ/m**2
```

Output after calculating interfacial energy with a Property Model.

PM_02: Property Model Parameter Fitting

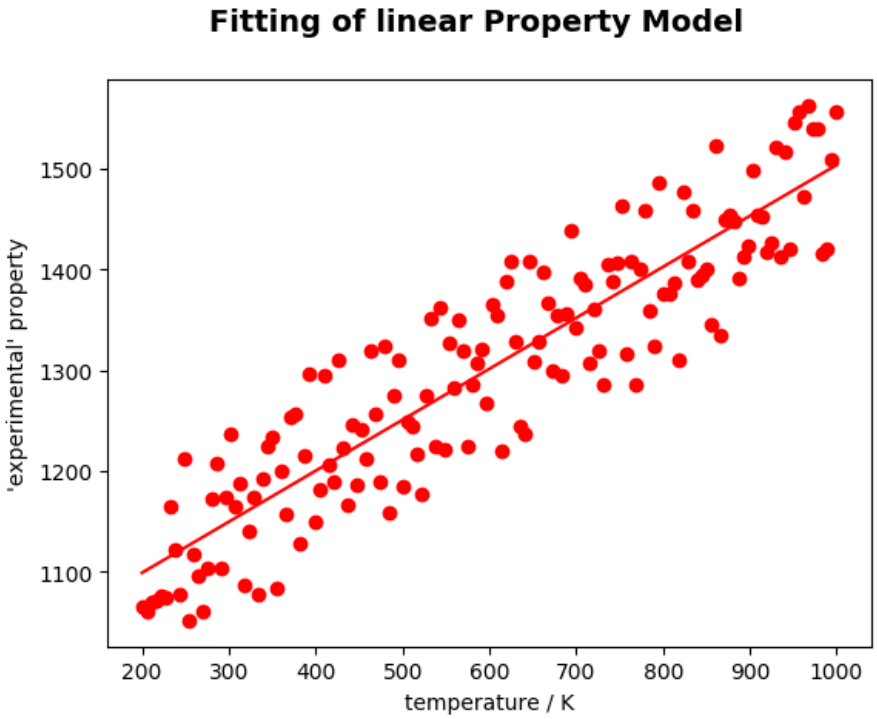
File name: `pyex_PM_02_Property_model_parameter_fitting.py`

This example shows how to optimize the parameters of a (Jython) property model. Typically this approach is used in order to fit a property model to experimental data. That can be useful for any application where no analytical correlation between the input parameters (composition, temperature and other parameters) and the material property can be established.

Examples might be solid solution strength models or martensite temperature models where the transformation barrier is modeled.

For the purpose of this example, the linear fitting to noisy data is shown.

A 'model parameter' is a value that can be changed from the outside of the model in the way demonstrated here. Internally it can be represented in any way; the only requirement is that the property model implements the 'Python Property Model Development Framework' interface methods `:func:`provide_model_parameters()`` and `:func:`set_model_parameter()``.



Fitting of a linear Property Model.

PM_03: Example Script to Develop and Run Your Own Property Model

File name: `pyex_PM_03_Property_model_self_developed_model.py`

This example shows how to develop and run your own Property Model. An example model is provided in the folder `property_models/FreezeInEquilibriumPython`. It is a simplified version of the FreezeInEquilibrium model that is installed with Thermo-Calc. Run this script to use the example model.

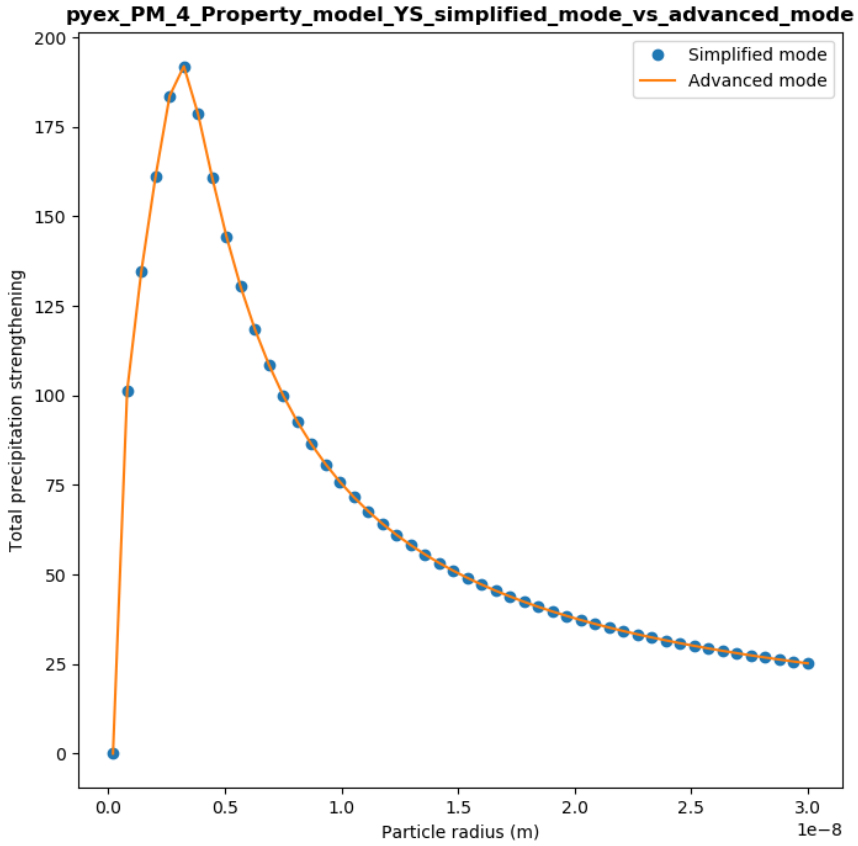
Any changes made to the main model file (`FreezeInEquilibriumPythonModel.py`), takes effect the next time you run this script.

PM_04: Yield Strength Simplified Mode vs Advanced Mode

File name: `pyex_PM_04_Property_model_YS_simplified_mode_vs_advanced_mode.py`

This example shows how to call the Yield Strength model using the Simplified and Advanced modes.

It is based on the Graphical Mode example "PM_G_04_Yield_Strength", which is included with the Thermo-Calc installation.



Comparing the total precipitation strengthening to particle radius for the Advanced and Simplified modes used with the Yield Strength Property Model.

PM_05: Property Model Equilibrium with Freeze-in Temperature

File name: `pyex_PM_05_Property_model_equilibrium_with_freeze_in_temperature.py`

This example demonstrates how to call the Freeze-in Temperature Equilibrium Property Model using TC-Python.

This example is not available with TC-Toolbox for MATLAB®.

The Freeze-in Temperature Equilibrium Property Model calculates the equilibrium material state at the specified "freeze-in" temperature, and evaluates material properties at the specified system temperature. The assumption used for this model is that diffusion and phase transformations are negligible for a material when below the freeze-in temperature and therefore, the material state is kept constant for system temperatures below the freeze-in temperature.

> The TCS Al-based Alloys Database (TCAL) is used in this example. A valid license for version 7 (TCAL7) or newer is required to run the example.

If you do not have a license, it is suggested that you change the variable tdb to ALDEMO or other thermodynamic database of interest, and modify the `dependent_element` and key-value pairs in the `'composition' dict()` to be compatible with the selected database.

This example also demonstrates how to collect and plot all output results of any Property Model using a dictionary. For additional information on this Property Model, in Thermo-Calc press F1 and search the help.

pyex_PM_06: Yield Strength with Multiple Precipitates

File name: `pyex_PM_06_yield_strength_with_multiple_precipitates.py`

This example shows how to invoke dynamic arguments (equivalent to clicking the add (+) button in the GUI) for a Property Model field that supports this. One common example is adding multiple precipitates to a yield strength calculation.

> The TCS Al-based Alloys Database (TCAL) is used in this example. A valid license for version 7 (TCAL7) or newer is required to run the example.

pyex_PM_07: Nickel Coarsening Property Model

File name: `pyex_PM_07_Property_model_Coarsening_Ni.py`

This example demonstrates how to use the Coarsening-Ni Property Model using TC-Python. In this example, a commercial alloy, UNS N07718 is used as the baseline composition, while Aluminum (Al) and Niobium (Nb) concentration is varied.

For this example, the coarsening rate coefficient of gamma double prime (BCT_D022) in a gamma (FCC_L12) matrix is calculated. The Coarsening Property Model calculates the coarsening rate coefficient of one or several precipitate phases in a matrix phase, assuming spherical geometry of the precipitating phase(s).

This example also shows how to plot the results of a Property Model calculation using a contour plot with Matplotlib.

To run this example requires a license for the TCS Ni-based Superalloys Database (TCNI) version 12 (TCNI12) or newer and the TCS Ni-alloys Mobility Database (MOBNI) version 6 (MOBNI6) or newer.

pyex_PM_08: Multiple Calculations Using CSV Data

File name: `pyex_PM_08_Property_model_multiple_calculations_using_data_from_CSV.py`

This example demonstrates how to perform multiple calculations using data from a .csv file. In this example, a .csv file containing composition information is used to set composition of each calculation.

For this example, two calculations are run for each composition in the .csv file.

- Calculation 1 ('calc1'): Coarsening-Ni Property Model, which calculates coarsening rate coefficients
- Calculation 2 ('calc2'): Single equilibrium calculation, which calculates volume fractions and molar volumes.

For both calculations, gamma double prime (BCT_D022) in a gamma (FCC_L12) matrix is considered. After all calculations are complete, the results are added to the initial dataframe of compositions. The Coarsening Property Model calculates the coarsening rate coefficient of one or several precipitate phases in a matrix phase, assuming spherical geometry of the precipitating phase(s).

This example also shows one way to handle compositions which do not have data for all elements(i.e., zeros or blanks in the data), which can cause calculation errors if not accounted for.

To run this example requires a license for the TCS Ni-based Superalloys Database (TCNI) version 12 (TCNI12) or newer and the TCS Ni-alloys Mobility Database (MOBNI) version 6 (MOBNI6) or newer.

TC-Python Additive Manufacturing Examples

You do not need an Additive Manufacturing license to use most of these examples. However, a TC-Python license is needed.

To run more complex AM calculations, you need an Additive Manufacturing (AM) Module license.

pyex_AM_01: Transient Simulation of a Single Track

File name: `pyex_AM_01_Transient_DE_No_Marangoni.py`

Also see the Graphical Mode example that this is based on: AM_01: Transient Simulation of a Single Track.

The transient model solves for the heat equation in the entire 3D domain, including the melt pool, and is therefore, computationally expensive to solve. The fluid flow inside the melt pool due to the Marangoni effect is not included in this example. The double ellipsoidal, or the so-called Goldak heat source model, is used to predict melt pool size and temperature distribution during single track scanning. The parameters for the double ellipsoidal heat source are computed using optimization in a steady-state case for the given process parameters (power and scanning speed) and the melt pool size reported in the paper by Grange et al. [2021Gra].

Reference

[2021Gra] D. Grange, A. Queva, G. Guillemot, M. Bellet, J.-D. Bartout, C. Colin, Effect of processing parameters during the laser beam melting of Inconel 738: Comparison between simulated and experimental melt pool shape. J. Mater. Process. Technol. 289, 116897 (2021).

pyex_AM_02: Transient and Steady-state Simulations of a Single Track

File name: `pyex_AM_02_Transient_SS_DE.py`

Also see the Graphical Mode example that this is based on:AM_02: Transient and Steady-state Simulations of a Single Track.

In this example a steady state and a single track simulation (with heat source from steady-state) are performed for Inconel 738LC.

The Transient with heat source from Steady-state model exploits the assumption that the melt pool size and temperature distribution reaches a steady-state almost instantly and thus first solves for a Steady-state case with the given process parameters. The result from the Steady-state in the form of temperature distribution in the melt pool is then mapped as a heat source in the transient simulation. This novel approach is much faster and efficient than the approach used in example pyex_AM_01 where the heat equation is solved in the entire 3D domain.

pyex_AM_03: Steady-state Simulations

File name: `pyex_AM_03_Steady.py`

Also see the Graphical Mode example that this is based on:AM_03: Steady-state Simulations.

In this example steady-state simulations are performed for IN625 with different conditions, i.e.

- without fluid flow in the melt pool,
- with fluid flow in the melt pool due to Marangoni effect,
- and using separate material properties for the powder.

and then the results are compared to demonstrate the effects of fluid flow and separate material properties for the powder on the temperature distribution as well as on the shape of the melt pool. For the first two simulations, the same material properties are used for both powder and solid substrate while for the third simulation no fluid flow is included in the melt pool.

pyex_AM_04: Scheil Transient Steady-state

File name: `pyex_AM_04_Scheil_TransientSS.py`

Also see the Graphical Mode example that this is based on: AM_04: Scheil Transient Steady-state.

In this example, three different simulations are performed:

- Steady-state
- Transient Single track
- Transient Multilayer

Both Transient_Single track and Transient_Multilayer use Transient with heat source from Steady-state model to compute time-dependent temperature distribution in the given geometry. The primary difference between this example and the previous examples (pyex_AM_01 to pyex_AM_03) is that, in this case, the material properties data is retrieved from the Scheil Calculator whereas in the previous examples the material properties are taken from the preinstalled material library.

Furthermore, this example simulates scanning of two layers of powder where the second layer is spread on the top of the first layer when scanning of the first layer is completed.

pyex_AM_05: Keyhole Example - Printability Map

File name: `pyex_AM_05_Printability_map.py`

Also includes a CSV file, pyex_AM_05_melt_pool_experiments.csv

This example requires an Additive Manufacturing (AM) Module license.

In this example a calibrated double ellipsoidal heat source is used to perform batch steady-state AM calculations for all the experimental variations of power and scan speed in the single track experiments.

A printability map is then produced using simple functions for the defects keyholing, balling, and lack of fusion. All defect functions are based on the melt pool dimensions (width, depth and length).

The Graphical Mode examples, AM_06a: Calibrating a Heat Source for a 316L Steel and AM_06b: Using the Calibrated Heat Source for a 316L Steel are similar to this version.

pyex_AM_06: Keyhole and Gaussian Heat Source

File name: `pyex_AM_06_Keyhole.py`

The Graphical Mode examples, AM_06a: Calibrating a Heat Source for a 316L Steel and AM_06b: Using the Calibrated Heat Source for a 316L Steel are similar to this version.

In this example a steady state with Gaussian heat source and keyhole model is demonstrated. The parameters for the Gaussian heat source are computed using optimization in a steady-state case for the given process parameters (power and scanning speed) and the melt pool size reported in the paper by Hu et al. [2019Hu].

Reference

[2019Hu] Z. Hu, B. Nagarajan, X. Song, R. Huang, W. Zhai, J. Wei, Formation of SS316L Single Tracks in Micro Selective Laser Melting: Surface, Geometry, and Defects. Adv. Mater. Sci. Eng. 2019, Article ID 9451406, 1–9 (2019).

pyex_AM_07: Laser Scanning Strategy and Probe Positioning

File name: `pyex_AM_07_Laser_Strategy_Probe_Position.py`

The Graphical Mode example AM_12: Using AM Calculator Probe Data with the Precipitation Module (TC-PRISMA) is similar to this.

This example shows how to visualize and assess the laser strategy, and use this information to guide probe placement. There is a `ScanningPath` class which stores the information about the laser scanning path for each layer. The example plots the laser strategy with a figure created for each layer. A line-scan of probes is created that is positioned on a laser as it passes the closest to the center. It starts and ends at the midpoint with the neighboring laser passes. The location of the probes are shown on the plots.

pyex_AM_08: CET Property Model with Thermal Gradients and Solidification Rates

File name: `pyex_AM_08_CET_IN718.py`

The Graphical Mode example AM_10: CET Transition in an IN718 Alloy is similar to this.

In this example the thermal gradients and solidification rates are calculated after a AM steady state simulation for the alloy IN718. The Property Model Columnar-to-Equiaxed-Transition (CET) is used to calculate the transition limits for the same alloy and range of thermal gradients and solidification rates.

The results from the two calculations are overlaid in a 2d plot showing that most solidification conditions are for columnar growth. The thermal gradients and solidification rates are visualized in 3d plots.

pyex_AM_09: Using the Core-ring Beam Shape

File name: `pyex_AM_09_CoreRing_BeamShape.py`

Also see the Graphical Mode example that this is based on: AM_13: Using the Core-ring Beam Shape

In this example a batch of steady state calculations are run using the Core-Ring heat source model. The heat source parameters for the Core-ring heat source as well as the processing parameters [power and speed] are taken from Holla et al. [2024Hol]. In the end, the predicted melt pool width and depth are compared to the experimental data.

Reference

[2024Hol] V. Holla, J. Grünewald, P. Kopp, P. M. Praegla, C. Meier, K. Wudy, S. Kollmannsberger, Validity of Thermal Simulation Models for Different Laser Beam Shapes in Bead-on-Plate Melting. Integr. Mater. Manuf. Innov. 13, 969–985 (2024).

pyex_AM_10: Using the Top-hat Beam Shape

File name: `pyex_AM_10_TopHat_BeamShape.py`

Also see the Graphical Mode example that this is based on: AM_14: Using the Top-hat Beam Shape

In this example a batch of steady state calculations are run using the Top-hat heat source model. The heat source parameters for the Top-hat heat source as well as the processing parameters [power and speed] are taken from Sow et al. [2020Sow]. The beam radius of the top-hat beam is adjusted to match the laser distribution of the large multimode laser spot (Fig. 2 in [2020Sow]). In the end, the predicted melt pool width and depth are compared to the experimental data.

Reference

pyex_AM_11: Multiple Process

File name: `pyex_AM_11_Multiple_process.py`

This example demonstrates how to efficiently run multiple additive manufacturing (AM) simulations in parallel using TC-Python with Python's multiprocessing capabilities. The code implements a systematic approach to handle multiple simulations with different process parameters (power and scanning speed).

pyex_AM_12: Electron Beam Melting in an IN718 Alloy

File name: `pyex_AM_12_Electron_Beam_Melting_IN718.py`

In this example a batch of steady-state calculations are run using the Electron Beam heat source model. The experimental data as well as the process conditions are taken from [2019Din]. The steady-state calculations represent single bead experiments where electron beam was used to scan an IN718 base plate at 1025 °C. In the end, the predicted melt pool width and depth are compared to the experimental data.

Also see the Graphical Mode example that this is based on: AM_15: Electron Beam Melting in an IN718 Alloy.

Reference

[2019Din] X. Ding, Y. Koizumi, D. Wei, and A. Chiba, “Effect of process parameters on melt pool geometry and microstructure development for electron beam melting of IN718: A systematic single bead analysis study,” Addit. Manuf., vol. 26, pp. 215–226, Mar. 2019.

pyex_AM_13: Composition Change Due to Evaporation

File name: `pyex_AM_13_Composition_change.py`

Also see the Graphical Mode example that this is based on: AM_16: Composition Change Due to Evaporation.

TC-Python Diffusion Examples

You do not need a Diffusion Module (DICTRA) license to use these examples, which use up to three components and this is available for all users with a Thermo-Calc license.

To run more complex diffusion calculations, you need a Diffusion Module license.

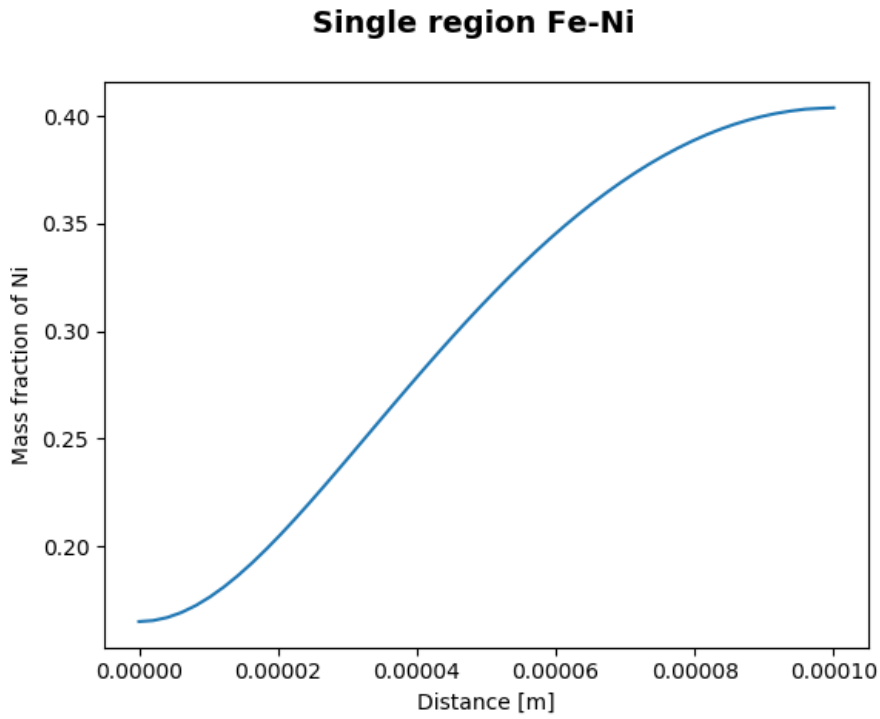
D_01: Diffusion within a Single Phase Austenitic Region of an Fe-Ni Alloy

File name: `pyex_D_01_Diffusion_Single_Phase.py`

This example simulates diffusion within a single phase austenitic region of an Fe-Ni alloy. The initial condition is a linear gradient from 10 wt-% - 50 wt-% Ni at 1400 K.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_01: Homogenization of a Binary Fe-Ni Alloy.



Single phase austenitic region of an Fe-Ni alloy.

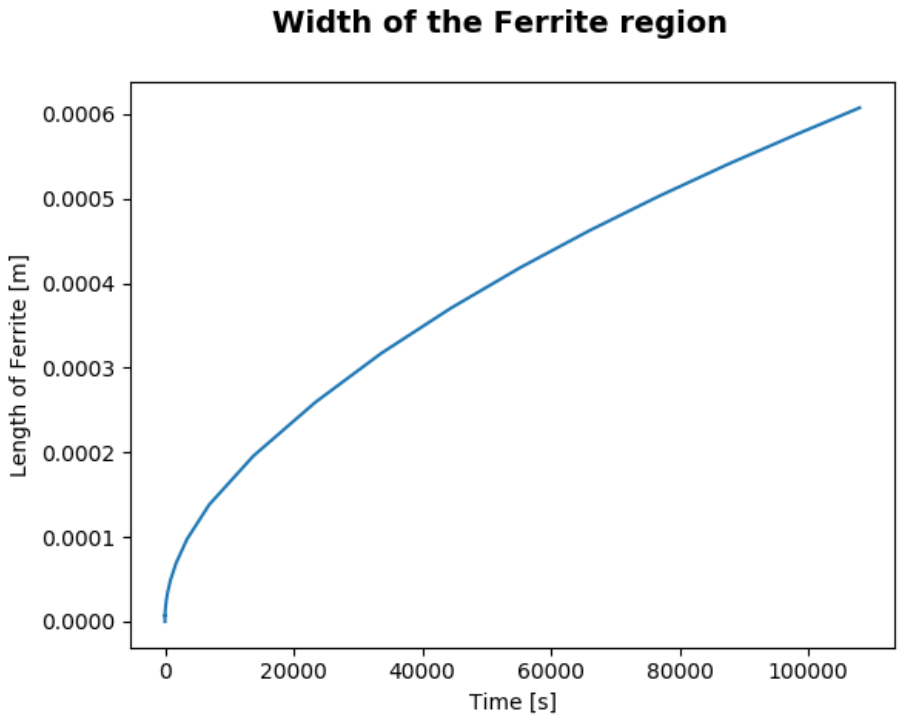
D_02: Diffusion with a Moving Boundary Between a Ferrite and Austenite Region

File name: `pyex_D_02_Diffusion_Moving_Boundary.py`

This example simulates diffusion including a moving boundary between a ferrite and austenite region in an Fe-C steel. Initially the C-concentration is constant in each region, with a step at the boundary. All units are in wt-%.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_02: Ferrite (bcc)/Austenite(fcc) Transformation in a Binary Fe-C Alloy.



Plot result showing the width of a ferrite region for an Fe-C steel.

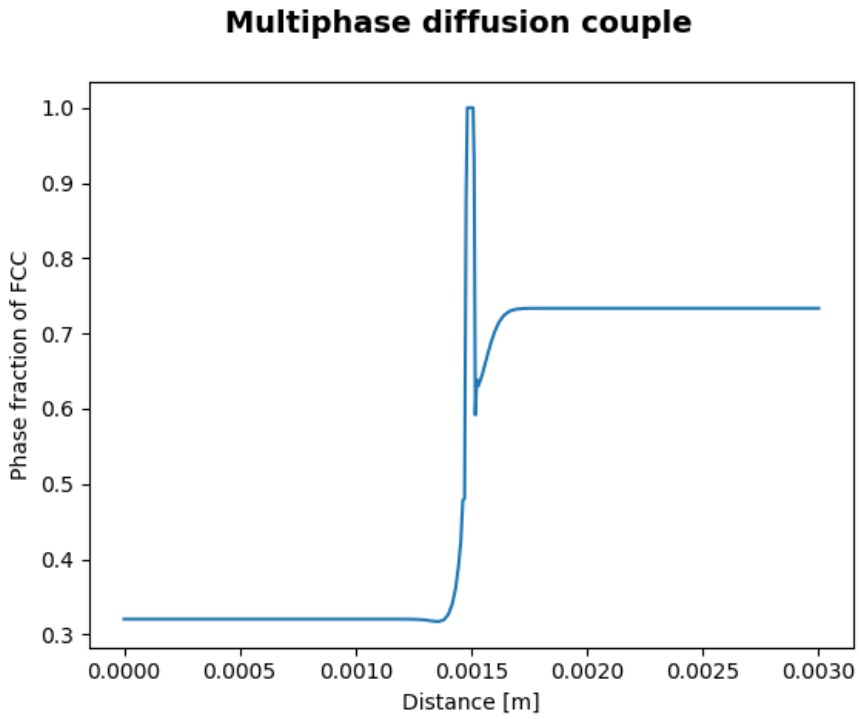
D_03: Diffusion in a Single Region with Multiple Phases

File name: `pyex_D_03_Diffusion_Multiphase.py`

This example simulates diffusion in a single region having multiple phases. Initially a step concentration profile is defined within the single region. Due to the multiple phases, the default `AutomaticSolver` uses the `homogenization mode`.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_03: Evolution of an Fe-Cr-Ni Diffusion Couple.



Plot result of diffusion in a single region having multiple phases.

D_04: Diffusion with an Inactive Phase Forming in the Presence of a Driving Force

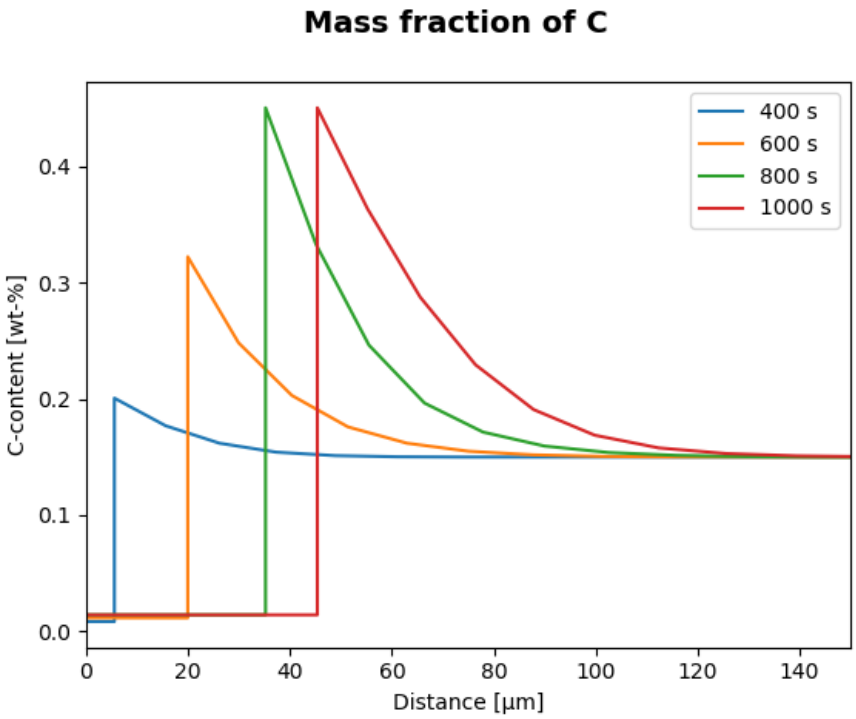
File name: `pyex_D_04_Diffusion_Fe-C_Moving_Boundary_Austenite_to_Ferrite.py`

This example simulates a moving boundary problem that is initially a one-phase austenite region. Due to the available driving force, a new ferrite region is starting to grow at the left interface of the austenite region.

Initially a constant concentration profile is defined within the single-phase region.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_04: Fe-C Moving Boundary - Austenite to Ferrite.



Plot result showing the mass fraction of C.

D_05: Moving Boundary Diffusion Couple for an Fe-Ni-Cr Alloy

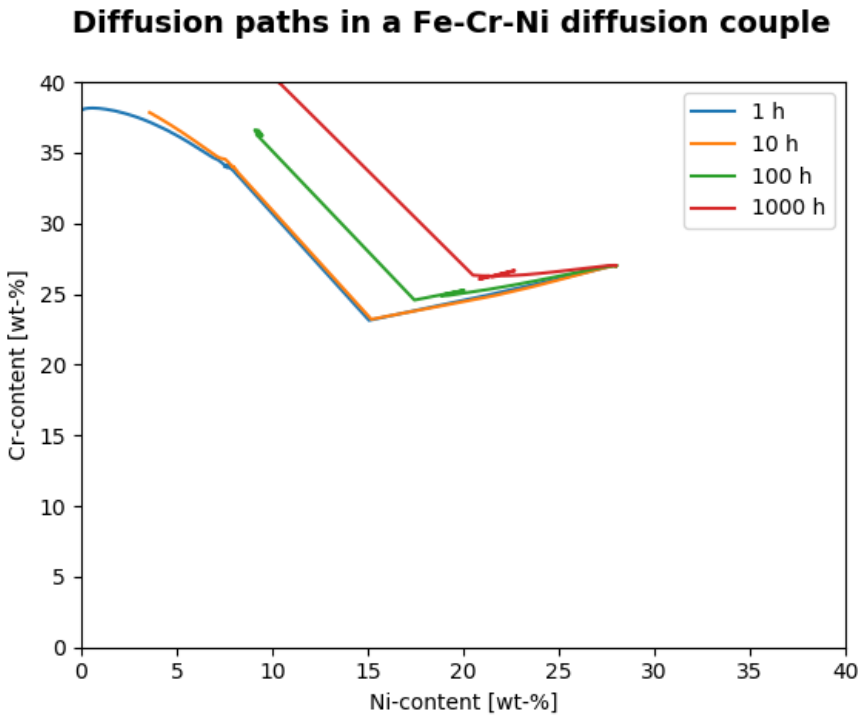
File name: `pyex_D_05_Diffusion_Fe_Ni_Cr_Moving_Boundary_Diffusion_Couple.py`

This example simulates the diffusion paths in a moving boundary problem between two multiphase regions. Due to the multiple phases, the default `AutomaticSolver` uses the `homogenization mode`.

Initially there is a concentration profile with a step between the regions.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_05: γ/α/γ Diffusion Couple of Fe-Ni-Cr alloys.



Plot result showing diffusion paths in an Fe-Cr-Ni diffusion couple.

D_06: Deriving Diffusion Coefficients from Experiment

File name: `pyex_D_06_Deriving_Diffusion_Coefficients_From_Experiment.py`

This example demonstrates the direct optimization of mobility database parameters by fitting to experimentally measured composition profiles. A manual determination of the interdiffusion coefficients (for example using the Boltzmann-Matano method) is not required. Additionally, no derivatives of the experimental curve is required as this is difficult for scattered data.

> This example takes several minutes to calculate. The results are updated continually. The plot examples shown are the final iterations.

D_07: Homogenization of a Scheil Profile

File name: `pyex_D_07_Homogenization_Of_Scheil_Profile.py`

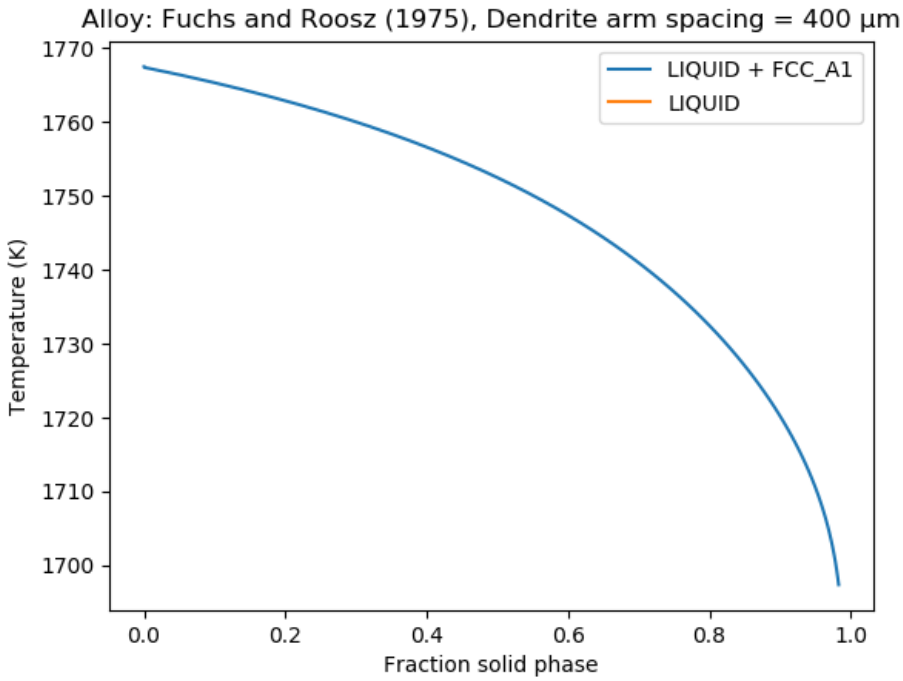
This example models the homogenization of a cast Ni-Cr steel and compares predictions with the experimental data collated by Fuchs and Roósz [1975Fuc].

As a first step, the microsegregation after solidification is simulated using a Scheil-calculation, then as a second step the homogenization is simulated using a diffusion simulation.

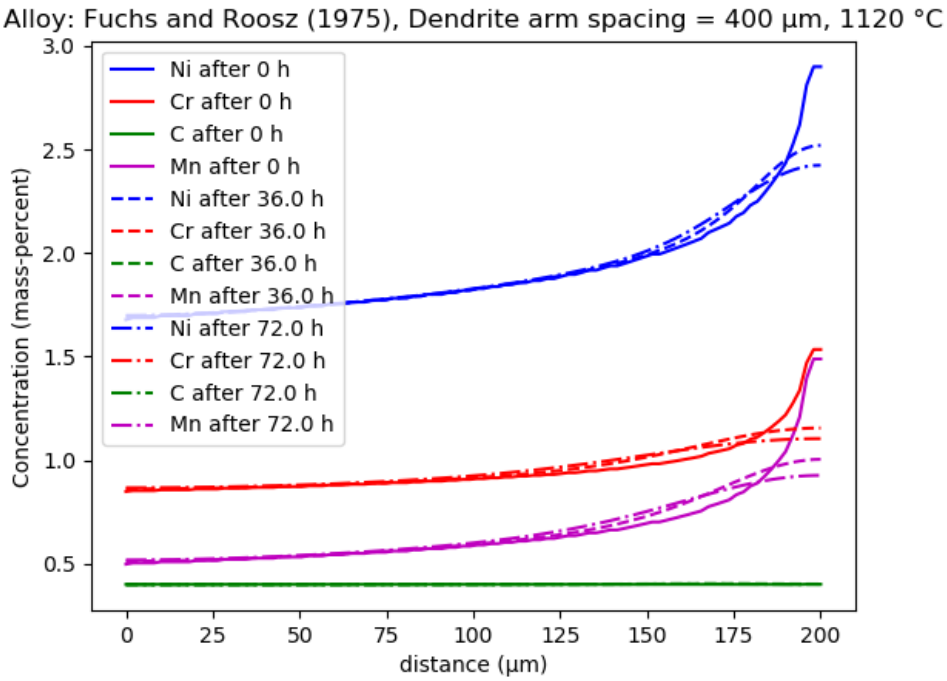
The conditions studied have a dendritic half spacing of 200 µm and are heat treated at 1120 °C.

The data has been de-normalized to allow comparison using weight percent composition values. The composition of the steel is 0.4C, 0.65Mn, 0.35Si, 0.015S, 0.01P, 1.9Ni, 0.95Cr and 0.3 Mo (wt.%). The diffusion of Cr and Ni are modelled using a simplified chemistry of 0.4C, 0.65Mn, 1.9Ni, and 0.95Cr using the FEDEMO thermodynamic and MFEDEMO mobility databases.

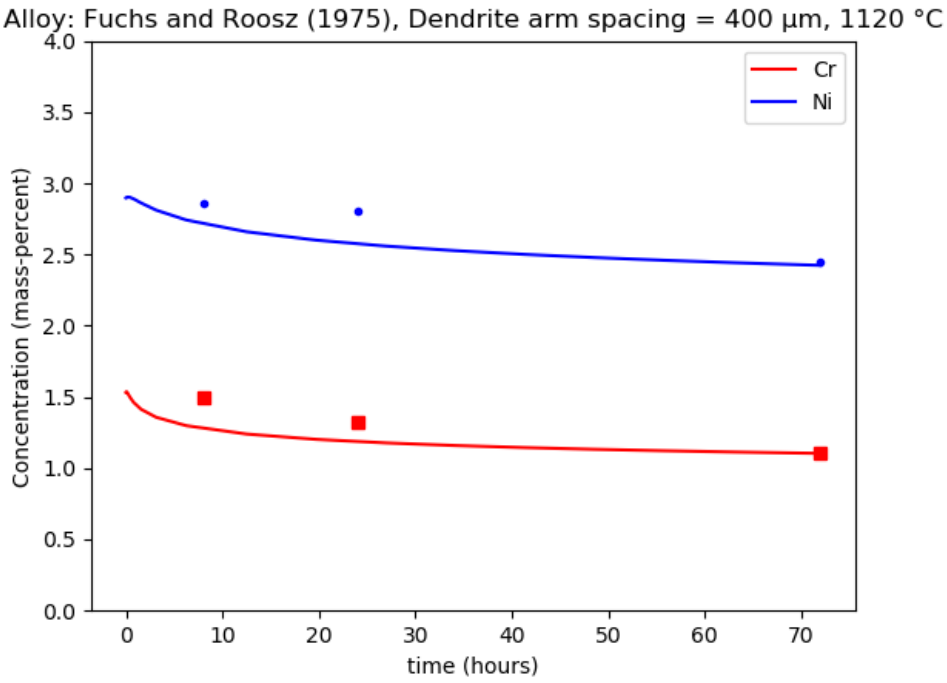
Also see the Graphical Mode example that this is based on: D_10: Iron (Fe) Homogenization in Scheil.



Scheil solidification simulation for alloy 319.2. The plot shows "Fraction of solid phase" as a function of Temperature. The resulting microsegregation is used as an input for homogenization simulation below and is seen at time=0 in the next plot.



A homogenization treatment is simulated using diffusion simulation for Alloy 319.2 with a secondary arm spacing of 400 µm. Results are shown for times 0, 4, and 8 hours.



A homogenization treatment is simulated using a diffusion simulation for Alloy 319.2 with a secondary arm spacing of 400 µm. The plot shows the concentration of Cr and Ni at the interdendritic region.

TC-Python Precipitation Examples

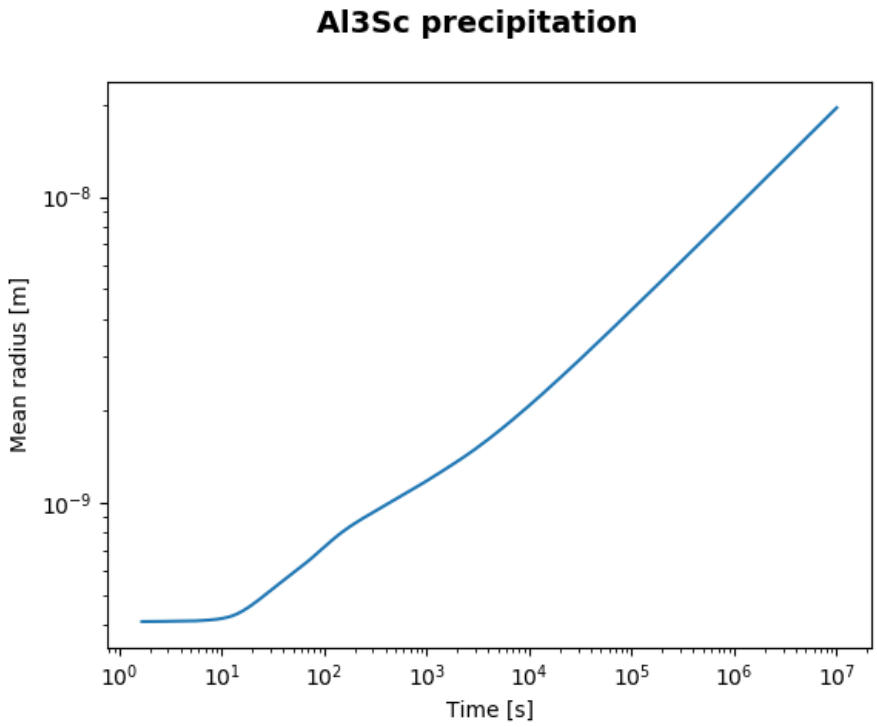
You do not need a Precipitation Module (TC-PRISMA) license to use these examples, which use up to three components and this is available for all users with a Thermo-Calc license.

To run more complex precipitation calculations, you need a Precipitation Module license.

P_01: Precipitation of Al3Sc from FCC_A1

File name: `pyex_P_01_Precipitation_Al-Sc_AL3SC.py`

This example simulates the kinetics of precipitation of Al_3Sc from an FCC_A1 solution phase and shows some results, with minimally required settings. Default values are used for unspecified settings.



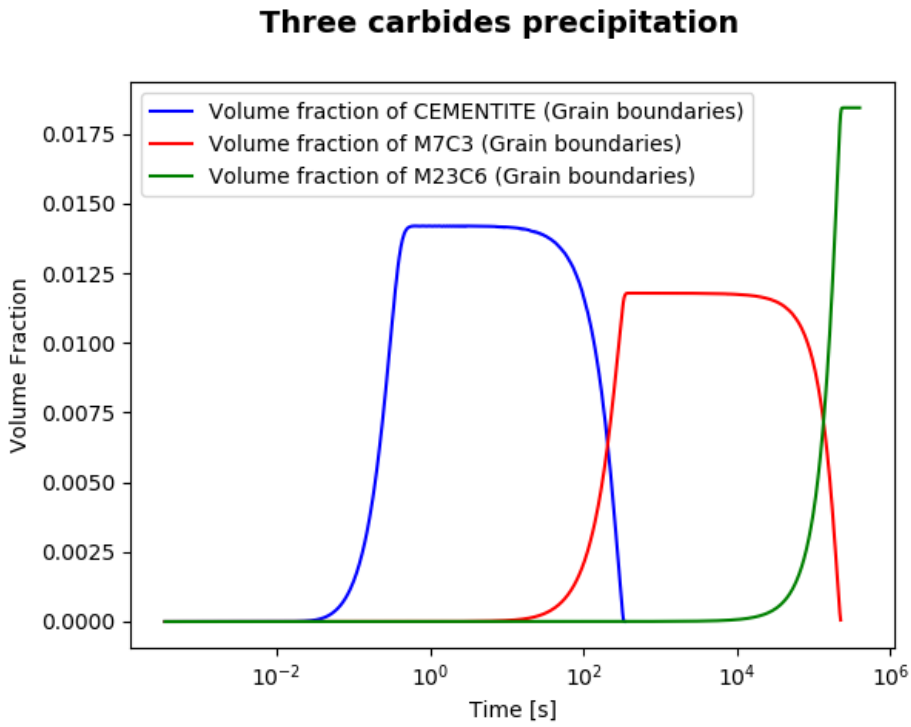
Plot results for the kinetics of precipitation of Al_3Sc from an FCC_A1 solution phase.

P_02: Precipitation of Stable and Metastable Carbides from the Ferrite Phase

File name: `pyex_P_02_Precipitation_Fe-C-Cr_Cementite-M7C3-M23C6.py`

Also see the Graphical Mode example that this is based on: P_02: Stable and Metastable Carbides - Isothermal

This example simulates the kinetics of precipitation of both stable and metastable carbides from the ferrite phase. It demonstrates that metastable carbides (cementite, M7C3) may first emerge and then disappear and the stable phase (M23C6) prevails.



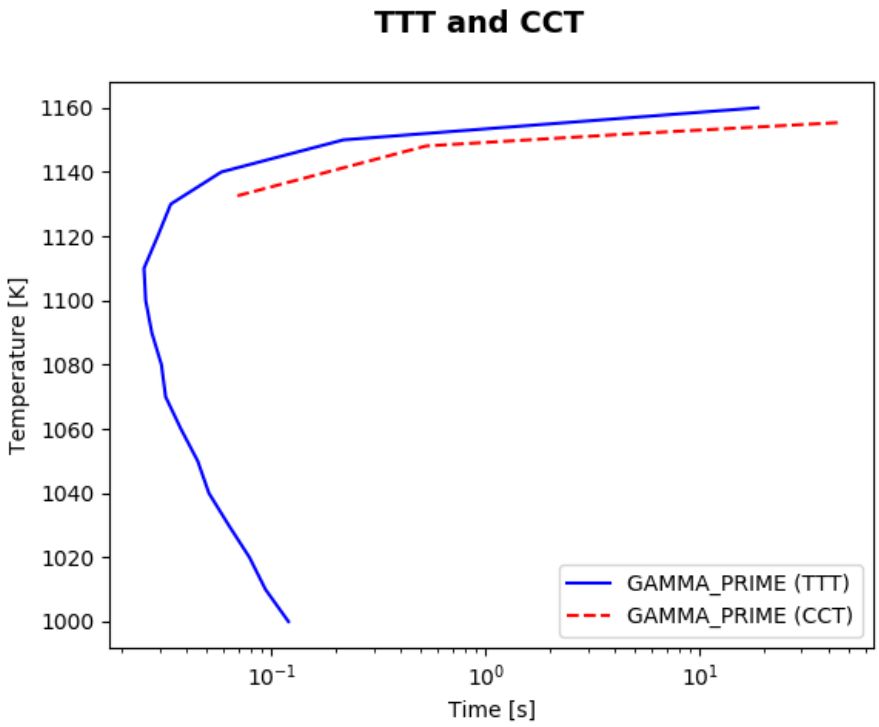
Plot result of volume fraction changes of Cementite, M7C3, and M23C6 phases.

P_03: Precipitation of Ni-Al-Cr

File name: `pyex_P_03_Precipitation_Ni-Al-Cr_TTT_CCT_Gamma-Gamma_prime.py`

This example simulates the precipitation of gamma-prime phase from gamma phase in a Ni-Al-Cr alloy. It demonstrates how to run TTT (temperature-time-transformation) and CCT (continuous-cooling-transformation) diagrams. It also shows (1) how to set up objects (the system, precipitate phase, and matrix phase) and then reuse them, and (2) how to set an alias for the precipitate phase.

This example takes several minutes to calculate. The results are updated continually. The plot examples shown are the final iterations.



Plot result of TTT (blue solid) and CCT (red dashed) curves of GAMMA_PRIME phase.

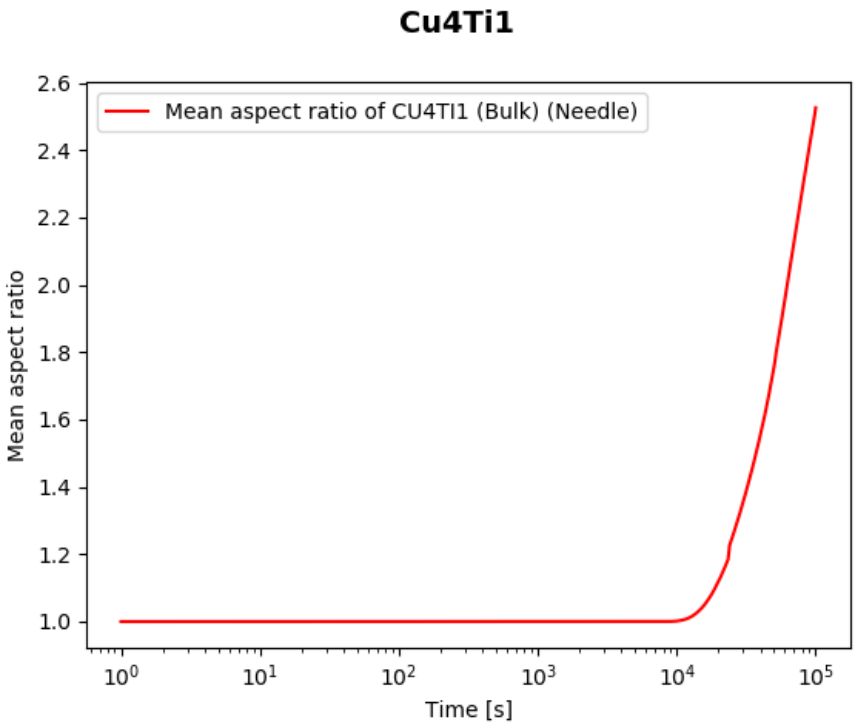
P_04: Precipitation of a Cu-Ti Binary Alloy

File name: `pyex_P_04_Precipitation_Cu-Ti_CU4TI1_Sphere_Needle.py`

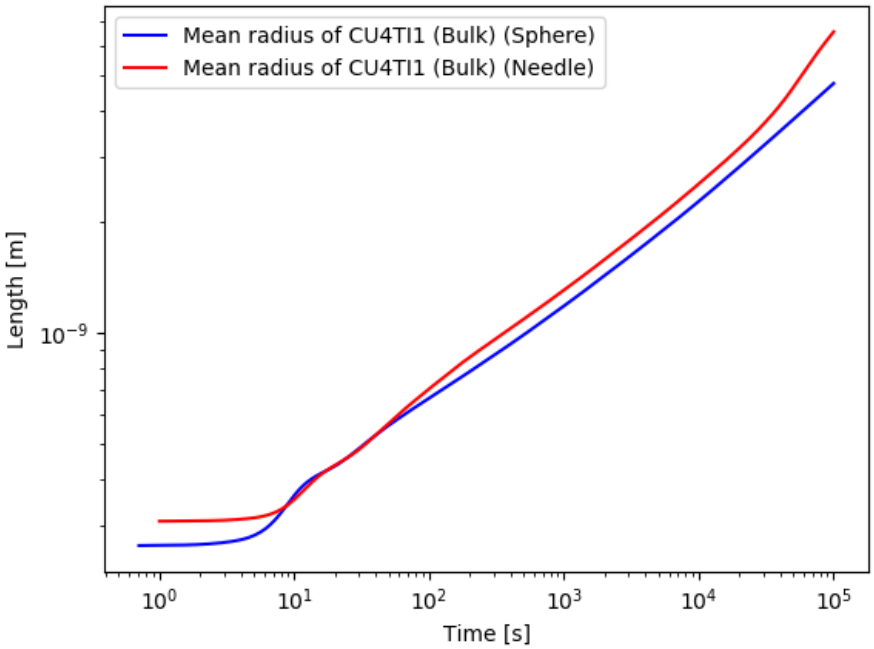
Also see the Graphical Mode example that this is based on: P_08: Precipitation of Cu-Ti CU4TI with Assumptions of Sphere and Needle Morphologies

In this isothermal calculation example, the precipitation of the Cu4Ti phase in a Cu-Ti binary alloy is calculated. To make a comparison, two separate simulations are performed: (1) one assuming spherical morphology without elastic strain energy, and (2) one assuming needle morphology whose shape, determined by competition between interfacial energy and elastic strain energy, is changed during the simulation.

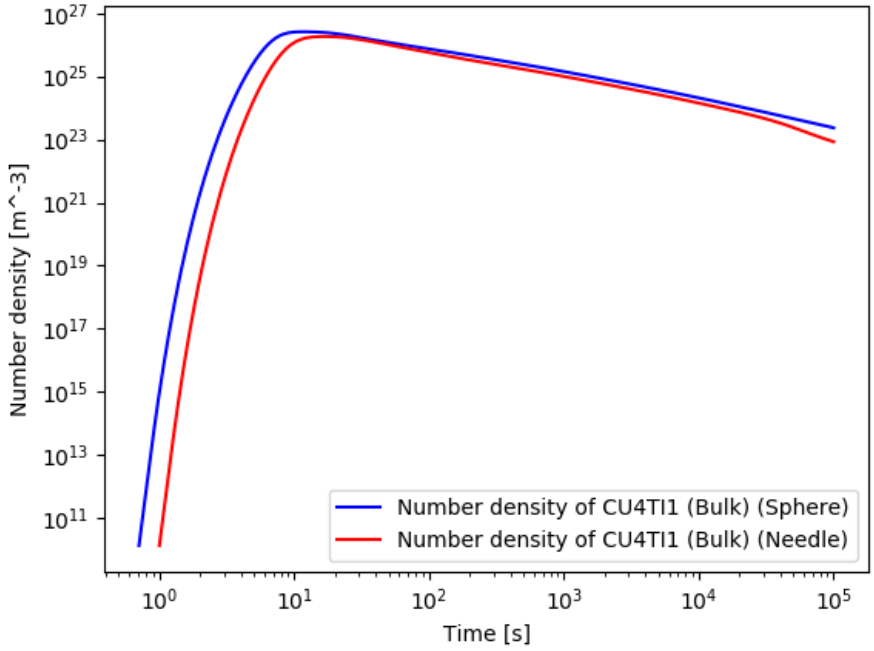
This example takes several minutes to calculate. The results are updated continually. The plot examples shown are the final iterations.



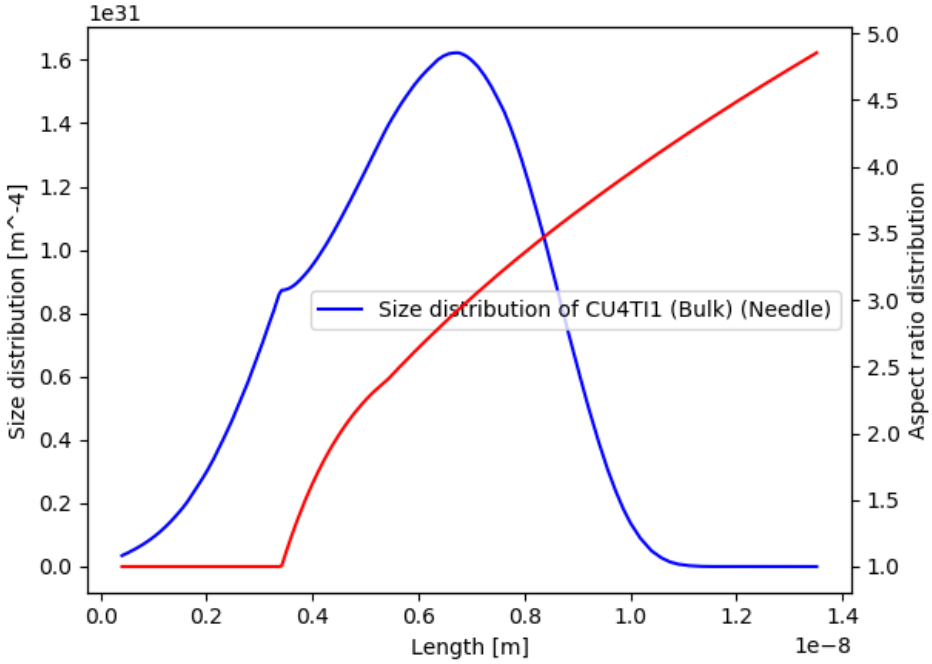
Plot result of the mean aspect ratio of Cu_4Ti_1 with a needle morphology.



Plot result of the mean radius of Cu_4Ti_1 comparing the sphere and needle morphologies.



Plot result of the number density of Cu_4Ti_1 comparing the sphere and needle morphologies.

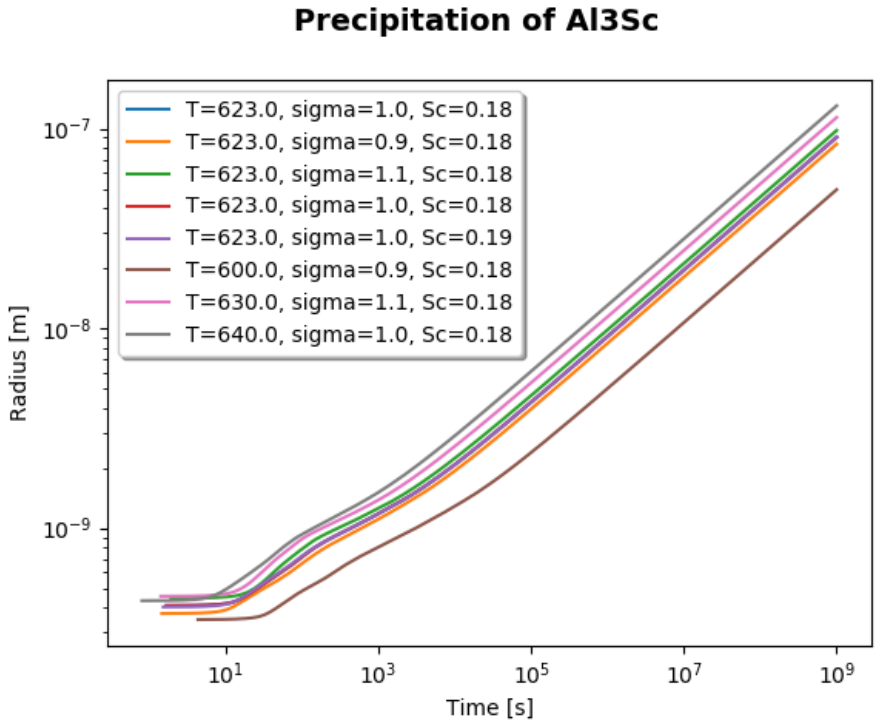


Plot result of the size distribution of Cu_4Ti_1 with a needle morphology.

P_05: Precipitation of Al-Sc in a Multiprocess

File name: `pyex_P_05_Precipitation_Al-Sc_AL3SC_Multiprocess.py`

This example shows how to set up multiple precipitation calculations with different parameter settings and send them to four processors for concurrent execution.



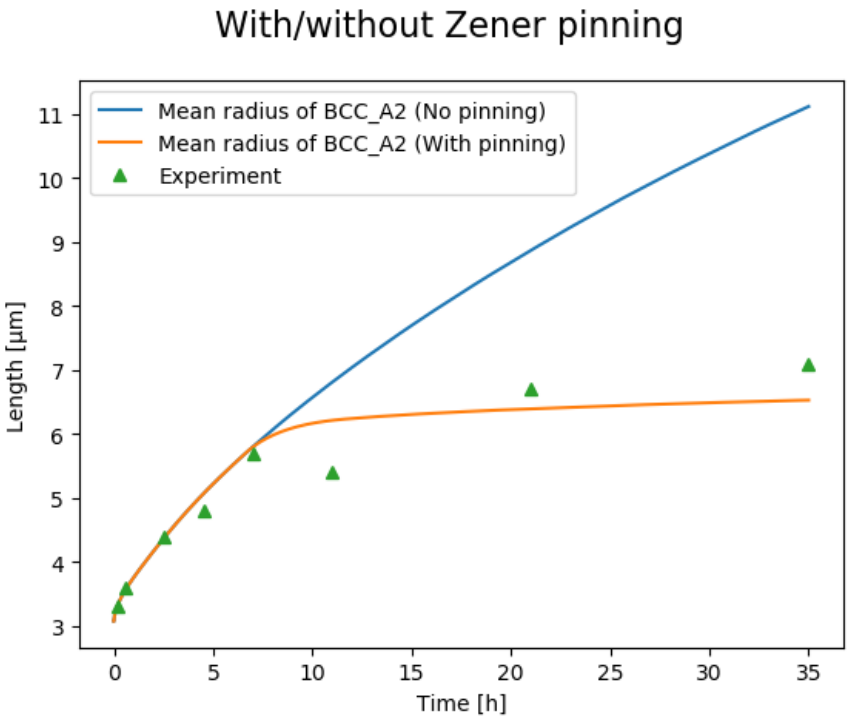
Plot result of mean radius change of Al_3Sc phase simulated with different temperatures (T), interfacial energy values (sigma), and alloy compositions (Sc).

P_06: Grain Growth and the Zener Pinning Effect

File name: `pyex_P_06_Precipitation_Fe_C_zenner_pinning.py`

Also see the Graphical Mode example that this is based on: P_14: Grain Growth and the Zener Pinning Effect

This example simulates the kinetics of precipitation of CEMENTITE from a BCC_A2 solution phase and shows the grain growth results for two cases: with and without Zener pinning. A log normal distribution is applied for the matrix grain size.



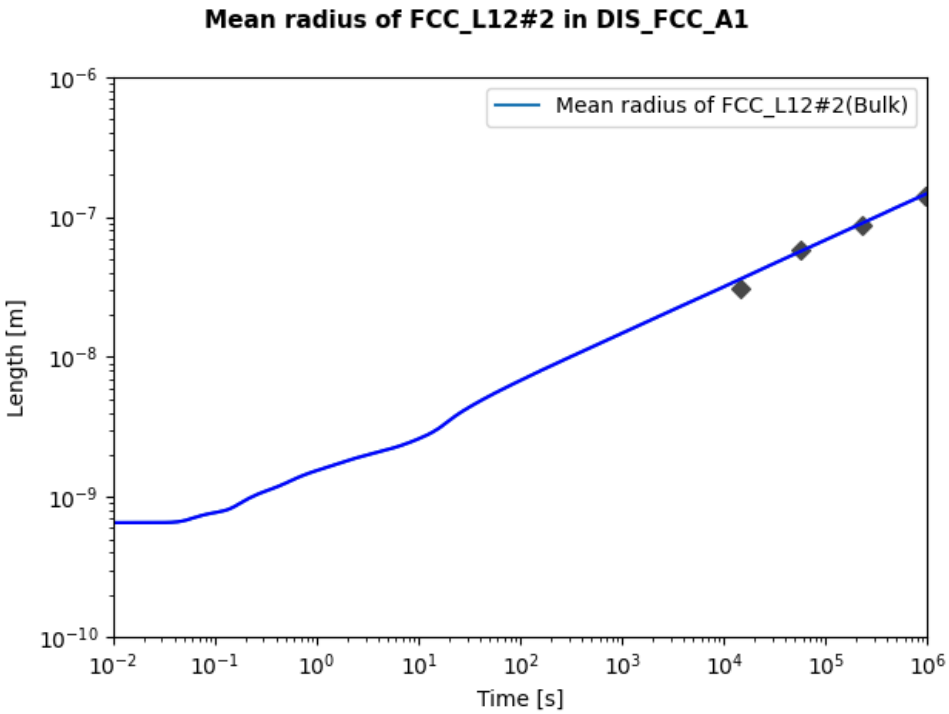
Plot result of ferrite grain size changes comparing simulations without pinning effect of cementite (blue curve), with pinning effect (orange curve), and experimental data (green triangles).

P_07: Precipitation NiAlCr Isothermal

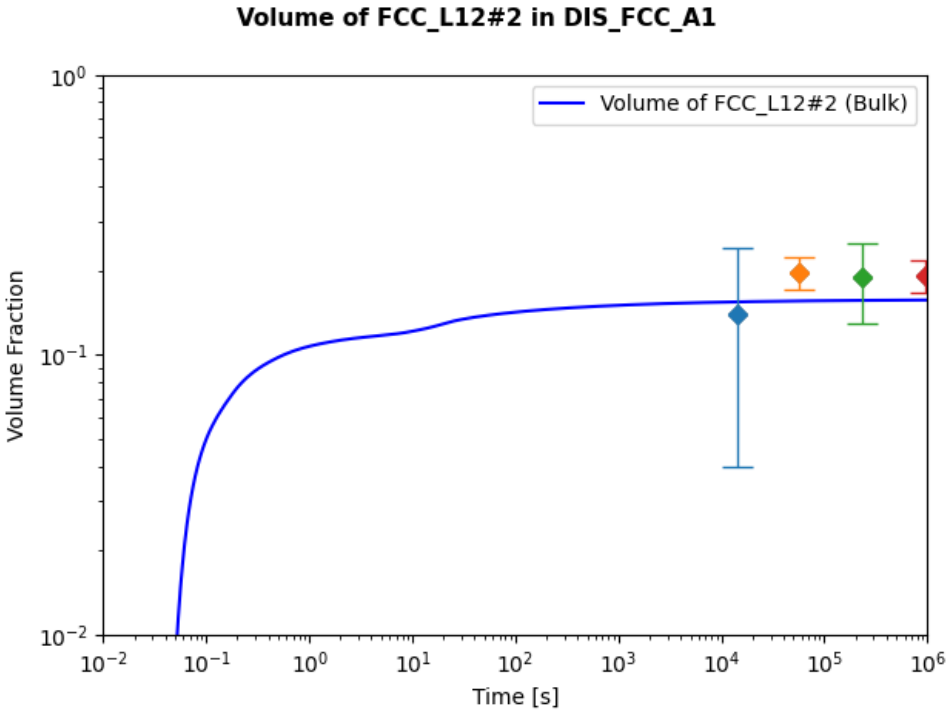
File name: `pyex_P_07_Precipitation_Ni_Al_Cr_Isothermal_Gamma_Gamma.py`

Also see the Graphical Mode example that this is based on: P_05: Precipitation of γ' in Ni Superalloys - Isothermal

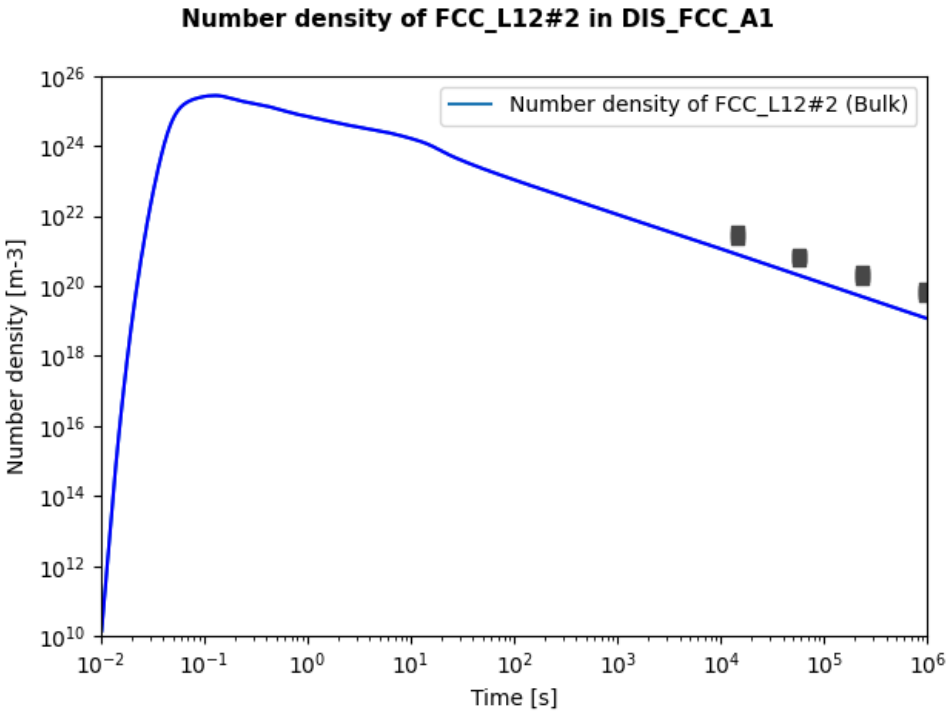
This example simulates the kinetics of precipitation of gamma prime (γ') phase from gamma (γ) phase. The simulation results can be compared with experimental data collected from Sudbrack et al. [2008Sud].



This plot shows the results of an isothermal calculation to plot the mean radius of the cementite phase.



This plot shows the results of an isothermal calculation to plot the volume fraction of the cementite phase.



This plot shows the results of an isothermal calculation to plot the number density of the cementite phase.

P_09: Precipitation AlSc Sphere and Cuboid Morphology

File name: `pyex_P_09_Precipitation_Al_Sc_Sphere_Cuboid.py`

Also see the Graphical Mode example that this is based on: P_09: Precipitation of Al-Sc AL3SC with Assumption of Sphere and Cuboid Morphologies

In this isothermal calculation example, the simulation of Al3Sc phase precipitation in an Al-Sc binary alloy is carried out. Two calculations are conducted: one assumes a spherical morphology without elastic strain energy, while the other assumes a cuboid shape determined by the interplay between interfacial energy and elastic strain energy. The simulation results are then compared with experimental data collected from studies by Marquis and Seidman [2001Mar] and Novotny and Ardell [2001Nov].

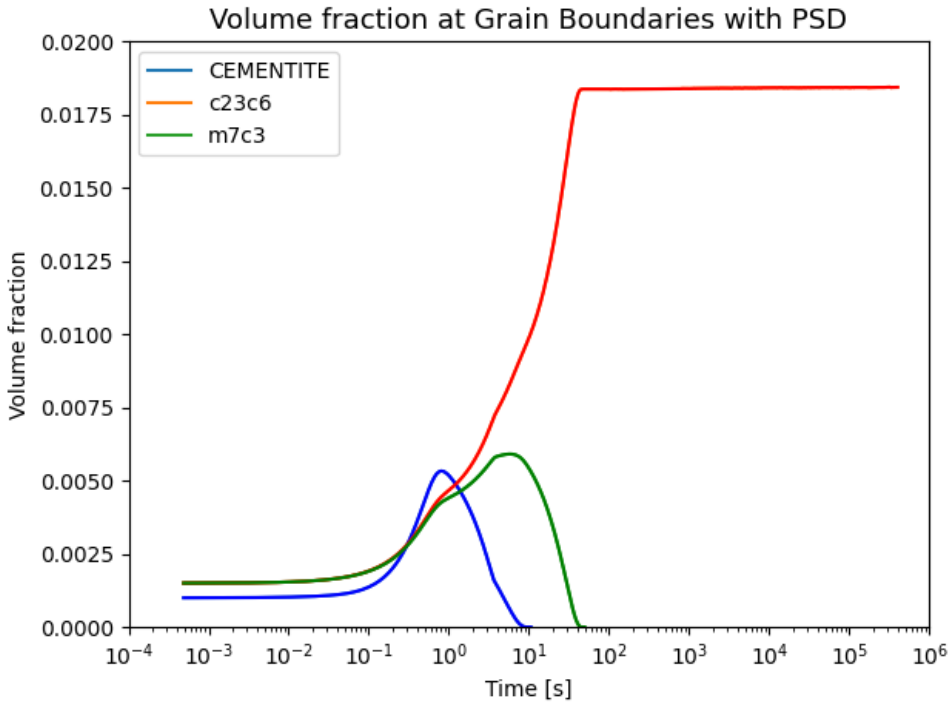
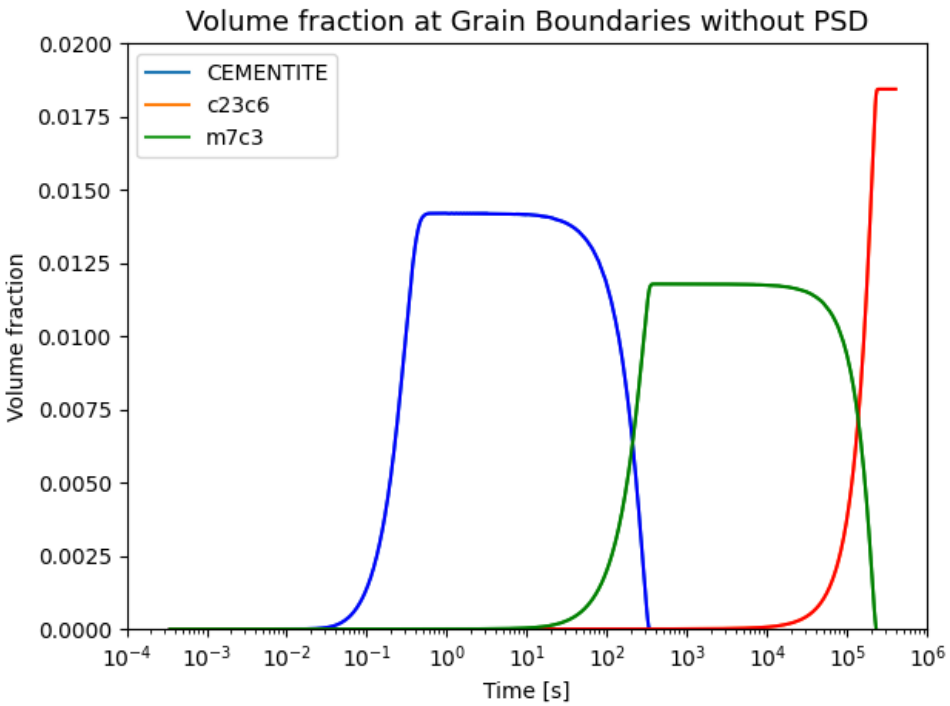
P_10: Precipitation Initial PSD FeCrC

File name: `pyex_P_10_Precipitation_Intitial_PSD_FeCrC.py`

Also see the Graphical Mode example that this is based on: P_10: Initial Particle Size Distribution of Fe-Cr-C

In this example, the effect of the initial particle size distribution (PSD) on overall precipitation kinetics is demonstrated. Two Precipitation Calculators are utilized to simulate and compare carbide precipitations in a Fe-0.1C-12Cr alloy within a ferritic BCC_A2 matrix. Competitive precipitations involving three carbides, CEMENTITE, M23C6, and M7C3, are analyzed, and the precipitation kinetics are compared in terms of the presence or absence of the initial particle size distribution.





P_11: Interfacial Energy

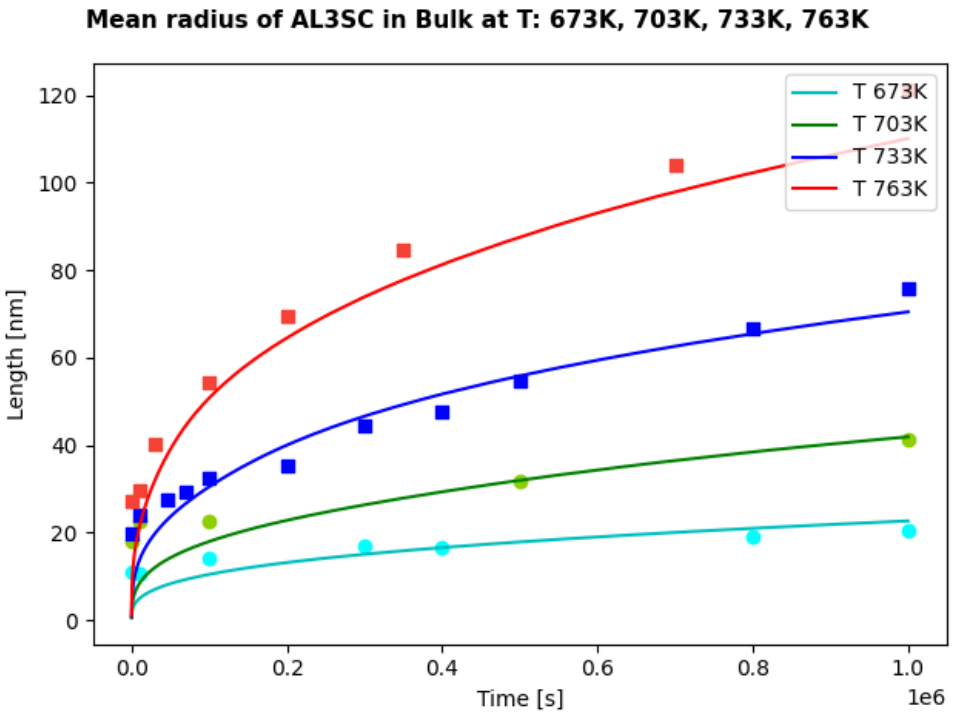
File name: `pyex_P_11_Interfacial_Energy.py`

Also see the Graphical Mode example that this is based on: P_11: Interfacial Energy Function

At four temperature points (673 K, 703 K, 733 K, and 763 K), this isothermal calculation employs four Precipitation Calculators, each 30 K apart. It aims to investigate the mean radius of an Al-0.12Sc system with an FCC_A1 matrix phase and AL3SC precipitate phase featuring bulk nucleation sites.

Notably, the user defines the interfacial energy function, utilizing an error function for a smooth transition of interfacial energy, transitioning from 0.065 J/m^2 to 0.085 J/m^2 based on particle radii, distinguishing between values below and above 1e-8m and 5e-8m, respectively.

A dataset based on Iwamura and Miura [2004Iwa] data is compared with the calculated results.



The results of an isothermal calculation to examine the mean radius of an Al-0.12Sc system with experimental data.

P_13: Precipitation FeCCr Paraequilibrium Precipitation of Cementite

File name: `pyex_P_13_Precipitation_Fe_C_Cr_Paraequilibrium_Precipitation_of_Cementite.py`

Also see the Graphical Mode example that this is based on: P_13: Paraequilibrium Precipitation of Cementite Fe-C-Cr

In this example, the precipitation of cementite during tempering of a Fe-Cr-C steel is simulated considering two interface conditions: one is the usual ortho-equilibrium condition; the other is the paraequilibrium condition. The simulation results are compared with the experimental data from Sakuma et al. [1980Sak].

Reference

[1980Sak] T. Sakuma, N. Watanabe, T. Nishizawa, The Effect of Alloying Element on the Coarsening Behavior of Cementite Particles in Ferrite. Trans. Japan Inst. Met. 21, 159–168 (1980).

P_15: FeCMn PE and OE Precipitation of Cementite

File name: `pyex_P_15_Fe_C_Mn_PE_OE_Precipitation_of_Cementite.py`

Also see the Graphical Mode example that this is based on: P_15: Smooth Transition from Paraequilibrium to Ortho-equilibrium

In this example, the precipitation of cementite during tempering of an Fe-Mn-C steel is simulated considering three interface conditions: the usual ortho-equilibrium (OE) condition; paraequilibrium (PE) condition; and a smooth transition from paraequilibrium to ortho-equilibrium condition (PE-OE). The simulation results are compared with the experimental data from Miyamoto et al. [2007Miy].

Reference

[2007Miy] G. Miyamoto, J. Oh, K. Hono, T. Furuhara, T. Maki, Effect of partitioning of Mn and Si on the growth kinetics of cementite in tempered Fe–0.6 mass% C martensite. Acta Mater. 55, 5027–5038 (2007).

pyex_P_16 Precipitation for a Ni-Al-Cr Stereology

File name: `P_16_Precipitation_Ni_Al_Cr_Stereology.py`

The isothermal coarsening kinetics of γ' precipitates in a Ni-Al-Cr alloy is modeled. The experimental data is from [2008Sud], which investigates isothermal coarsening kinetics at a temperature of 873 K for up to 264 h. It is assumed that there are no precipitates in solution at the beginning of the isothermal heat treatment.

Also see the Graphical Mode example that this is based on: P_16 Isothermal Coarsening and a 3D to 2D Stereological Conversion .

Reference

[2008Sud] C. K. Sudbrack, T. D. Ziebell, R. D. Noebe, D. N. Seidman, Effects of a tungsten addition on the morphological evolution, spatial correlations and temporal evolution of a model Ni–Al–Cr superalloy. Acta Mater. 56, 448–463 (2008).

pyex_P_17 Precipitate Upon Precipitate

File name: `pyex_P_17_Precipitation_Upon_Precipitate.py`

This example demonstrates the ability to model precipitate phases acting as a nucleation site. A particle phase acting as a nucleation site is referred to as an *inoculant*. The example simulates the nucleation of β'' (BETA_DPRIME), and its transition into β' (BETA_PRIME) in an Al-Mg-Si alloy, comparing results to the experimental data of Myhr et al. [2001Myh].

The heat treatment is isothermal at 185 °C for 300 hours. The β'' phase is assumed to be spherical, and the β' phase is approximated as needles.

Also see the Graphical Mode example that this is based on: P_17 Precipitate Upon Precipitate and Nucleation Sites

To run the example requires licenses to both the thermodynamic and mobility databases: TCS Al-based Alloys Database (TCAL) and TCS Al-alloys Mobility Database (MOBAL).

Reference

[2001Myh] O. Myhr, Ø. Grong, S. J. Andersen, Modelling of the age hardening behaviour of Al–Mg–Si alloys. Acta Mater. 49, 65–75 (2001).

TC-Python Process Metallurgy Examples

You can find several learning resources on the Process Metallurgy page of our website (or in Thermo-Calc, go to **Help → Thermo-Calc website**). You can also subscribe to the Thermo-Calc newsletter to be kept up-to-date about upcoming releases, training, examples, videos and much more.

To use the Process Metallurgy Module with TC-Python requires a full license to Thermo-Calc 2022b or newer, a valid MS&S subscription, a license to the TCS Metal Oxide Solutions Database (TCOX8 or newer), plus a license to TC-Python.

PMET_01: Single Adiabatic Equilibrium

This example shows how to create a basic adiabatic equilibrium calculation for a process metallurgical problem. The equilibrium between a steel and slag melt and oxygen is calculated.

File name: `pyex_PMET_01_Single_adiabatic_equilibrium.py` and the OXDEMO database is used.

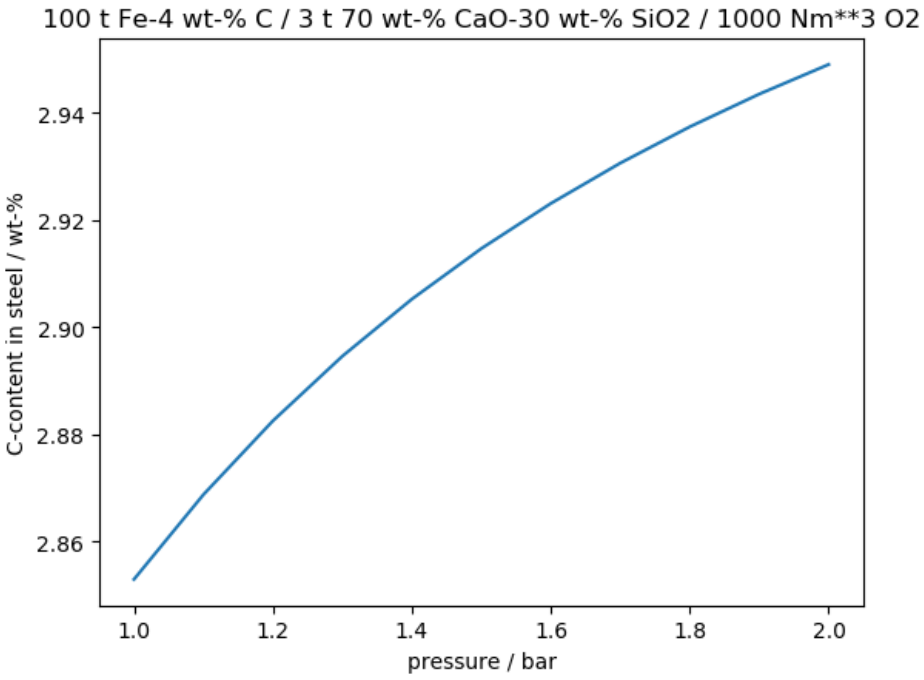
This example has some text output for the calculation result:

```
Stable phases: {'GAS#1', 'IONIC_LIQ#2', 'IONIC_LIQ#1', 'HATRURITE#1'}
Temperature: 1758.4 °C Slag phases: {'IONIC_LIQ#2', 'HATRURITE#1'}
Composition of the overall slag:
Al2O3 = 9.41 mol-%
C = 0.42 mol-%
CaO = 70.43 mol-%
Fe2O3 = 0.00 mol-%
FeO = 0.01 mol-%
SiO2 = 19.73 mol-%
```

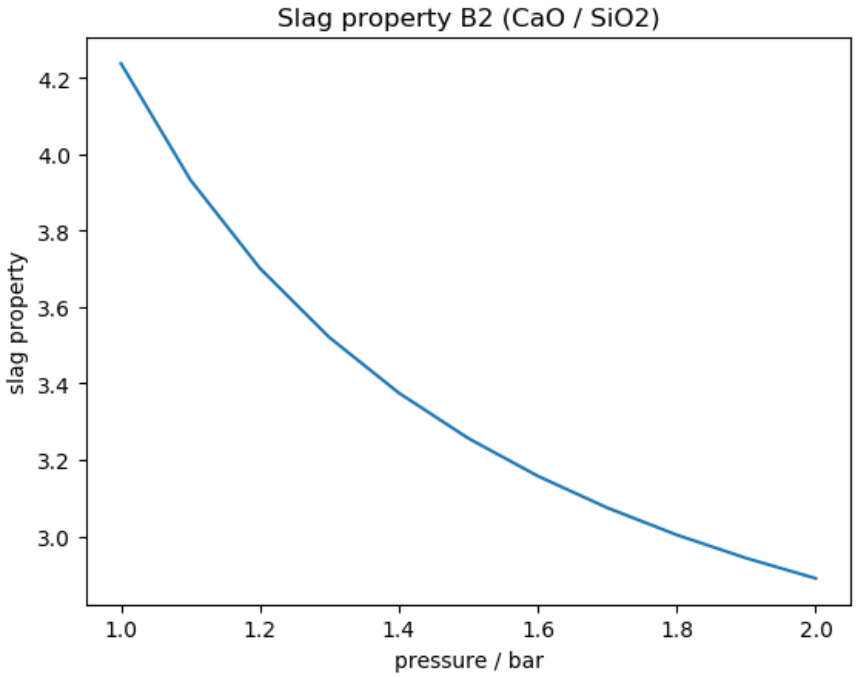
PMET_02: Stepping Adiabatic Equilibrium

This example shows how to create adiabatic equilibrium calculations for varied pressure. The equilibrium between a steel and slag melt and oxygen is calculated.

File name: `pyex_PMET_02_Stepping_adiabatic_equilibrium.py` and the OXDEMO database is used.



The equilibrium carbon content in the steel melt in dependency of the pressure equilibrium between a steel and slag melt and oxygen for a single calculation.



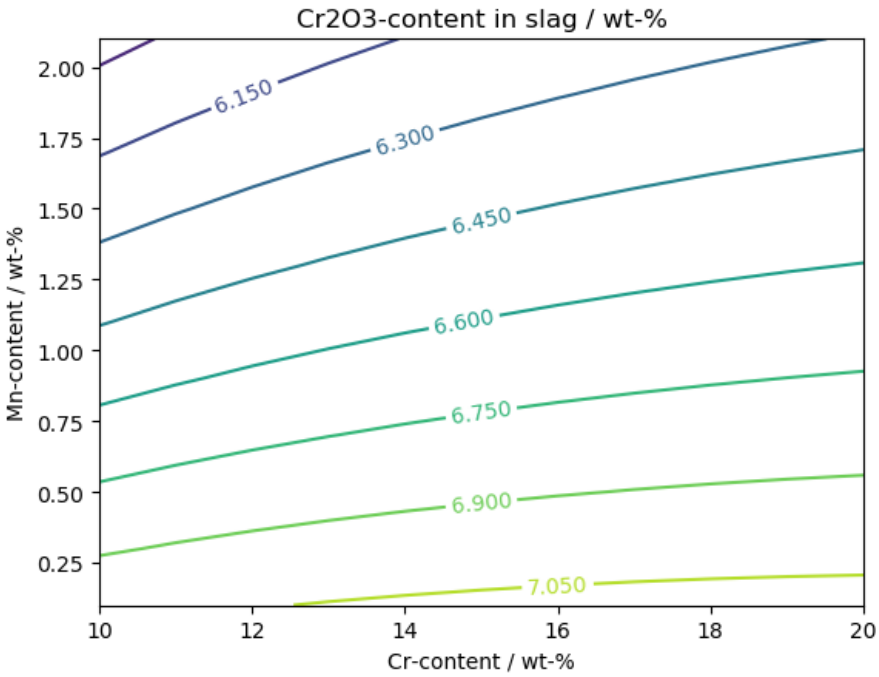
The slag property B2 (CaO/SiO) in dependency of the pressure.

PMET_03: Mapping Isothermal Equilibrium

This example shows how to create isothermal equilibrium calculations with varied composition of two steel components.

File name: `pyex_PMET_03_Mapping_isothermal_equilibrium.py`.

To run this example requires TCOX9 and higher.

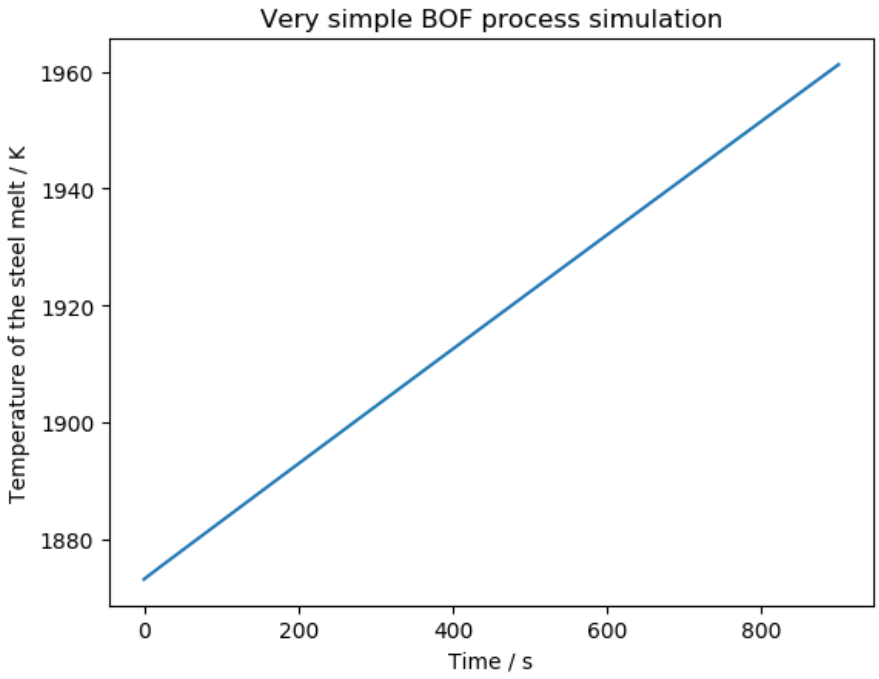


The equilibrium content of Cr2O3 in the slag in dependency of the Cr and Mn content in the steel.

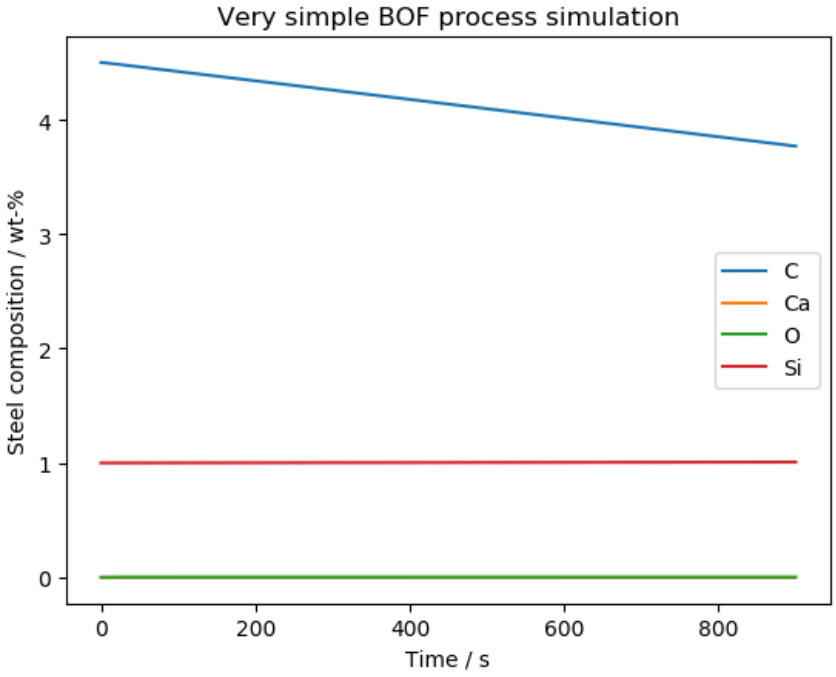
PMET_04: Simple Process Simulation

This example shows how a very simplified process simulation of a basic oxygen furnace (BOF) converter can be set up.

File name: `pyex_PMET_04_Simple_process_simulation.py` and the OXDEMO database is used.



Temperature of the steel melt vs time.



Steel composition vs time.

PMET_05: VOD Process Simulation

This is example shows how a Vacuum Oxygen Decarburization (VOD) refining process could be modeled. It is inspired by the work of Ding et al. [2000Din] and the validation data is derived from the paper.

File name: `pyex_PMET_05_VOD_process_simulation.py`

To run this example requires TCOX9 and higher. Slight model adjustments might be required based on the version.

This example is based on the Graphical Mode example, PMET_07: Vacuum Oxygen Decarburization Kinetics, which is also an application example showcased on our website.

This model shows several features of process simulations, such as:

- time-dependent mass transfer coefficients
- time-dependent pressure
- inclusion flotation
- cooling due to heat losses
- heat transfer between the zones
- control of degassing

This example takes several minutes to calculate. The results are updated continually. The plot examples shown are the final iterations.

For this specific example, several plots are generated. There are slight differences compared to the application example on the website. For general background theory and an overview of how the example is set up and to interpret the results, it is recommended to read the PDF, also available on the website.

Reference

[2000Din] R. Ding, B. Blanpain, P. T. Jones, P. Wollants, Modeling of the vacuum oxygen decarburization refining process. Metall. Mater. Trans. B. 31, 197–206 (2000).

TC-Python Miscellaneous Examples

See CSV Files for the location.

Diagnostics Script

Run this script when troubleshooting TC-Python:

File name: `diagnostics.py`

Run this script EXACTLY the same way as you run your TC-Python script. i.e. In the same IDE, same project, same Python environment, same Jupyter notebook etc.

M_01: Reading a Time-Temperature Profile from a CSV File

This example shows how to read a time-temperature profile from a CSV file and running a precipitation calculation with it. The easiest CSV file is simply a comma-separated text-file as shown in the present example.

File name: `pyex_M_01_Input_from_file.py`

M_02: Property Diagram Exported to Various File Formats

This example shows how to create a property (step) diagram using TC-Python.

The alloy system Fe-Ni is used as an example.

The result is then saved in different file formats:

- JSON
- XML
- CSV
- TXT
- HDF5

File name: `pyex_M_02_Output_to_file.py`

M_03: Best practices to run TC-Python calculations in Juypter Lab / Notebooks

This example shows how you create a single equilibrium calculation from a ternary system, loop it\n", while changing Al and Cr concentration, then calculate the density and plot the result as a 3D surface.

File name: `pyex_M_03_jupyter_lab_best_practices.ipynb`

M_04: Working with the User Credentials License

> The TC-Python license is a separate license from the Thermo-Calc software license. You need to activate the TC-Python license once on your computer after, or in addition to, activating the Thermo-Calc license.

It is recommended to run the included example to perform the activation and deactivation. By default an online activation is performed, but you can choose other methods, which are both included in the example and described in the API documentation.

- Open and run the example `pyex_M_04_license.py`, which is located in the **Miscellaneous** folder.
- The license activation is completed with the methods in the class `tc_python.license.LicenseManager`.
- Depending on the type of license other methods are available, for example for online and offline activation plus the use of proxy settings are described.

> To use the license on a different computer, the license must first be deactivated on the original computer. This is for both online and offline activations.

This example shows a variety of ways to manage licenses that are activated or deactivated with user credentials. Described are the online and offline methods plus the use of proxy settings.

The general details cover these topics.

- Printing information about the currently activated license.
    - For any activation type, i.e. online, offline, or proxy settings.
- Online license activation for computers with Internet access using user credentials.
    - This requires a valid *username* and *password* that is provided by email and originates from a Thermo-Calc representative.
- Offline license activations for computers without Internet access. Learn how to:
    - Create an offline activation file in the supplied directory.
    - Activate an offline license using the offline activation file. See `create_offline_activation_file()` in the API documentation.
- Proxy settings. Learn how to use proxy settings for the LicenseManager.
    - This function shows the `proxy_settings_set` method to configure proxy settings when working with the license.
- Update the current license to its latest state. **This is only available for online activations.**
    - This task is used to refresh the license information and ensure it is up-to-date.
- Deactivate an active license.
    - Typically done when a license is no longer needed on a specific computer or you want to activate it on a different computer.
    - For offline licenses it creates an offline deactivation file, which is then used to deactivate the license on a computer that does not have Internet access.

TC-Toolbox for MATLAB®

TC-Toolbox for MATLAB® provides an interface to the commonly-used MATLAB® software for scientific and engineering computing. This kit is ideal for fast realization of ideas and visualization of results during research and development activities. The API offers the same functionality as our TC-Python API, but is well suited for users who already have a license for MATLAB®, want to connect to other programs offered by MATLAB®, or are familiar with the MATLAB® programming language.

TC-Toolbox for MATLAB® is currently only available on Windows platforms.

TC-Toolbox Process Metallurgy Examples 3576

TC-Toolbox Miscellaneous Examples 3579

About TC-Toolbox for MATLAB®

TC-Toolbox for MATLAB® (TC-Toolbox) provides an interface to the commonly used MATLAB® software for scientific and engineering computing. This software development kit (SDK) is ideal for fast realization of ideas and visualization of results during research and development activities. The TC-Toolbox API includes calculation types available in Thermo-Calc such as single point equilibrium, property (step) and phase (map) diagrams, Scheil solidification simulations, as well as all the general Thermo-Calc Property Models (e.g. yield strength, spinodal, driving force, etc.).

With the addition of licenses for the applicable software and databases, you can further maximize your integration with MATLAB® to include the capabilities of the Steel Model Library Property Models (e.g. bainite, pearlite, etc.), as well as access the range of functionality included with the Diffusion Module (DICTRA) and the Precipitation Module (TC-PRISMA). Generally, all the functionality available in Graphical Mode or via the TC-Python SDK is available.

TC-Toolbox for MATLAB® is available on Windows platforms.

TC-Toolbox Help Resources

There are these locations and formats of the documentation you need related to this SDK.

The help for TC-Toolbox for MATLAB® is available from these locations (1) within the MATLAB® environment—both as help and as part of the tab completion (2) directly on the Thermo-Calc website.

The TC-Toolbox for MATLAB® technical documentation content is available either as interactive help (in HTML format or when in MATLAB® using tab completion or accessed via different menus or key combinations) or as a standalone PDF.

There are these ways to access the content:

- Directly in MATLAB® via the Help menu then under **Supplemental Software** click **TC-Toolbox**. Help is also available when writing code and using the tab completion feature and/or pressing different key combinations as described in the *Best Practices* section of the help.
- From the website: HTML Help or PDF.

The full installation instructions are only included in the Thermo-Calc help (press F1), and in the PDF version of the main installation guide found on the website: Thermo-Calc Installation Guide.

TC-Toolbox for MATLAB® Examples

These SDK examples are not directly accessible from the Thermo-Calc menu.

About the TC-Toolbox for MATLAB Examples

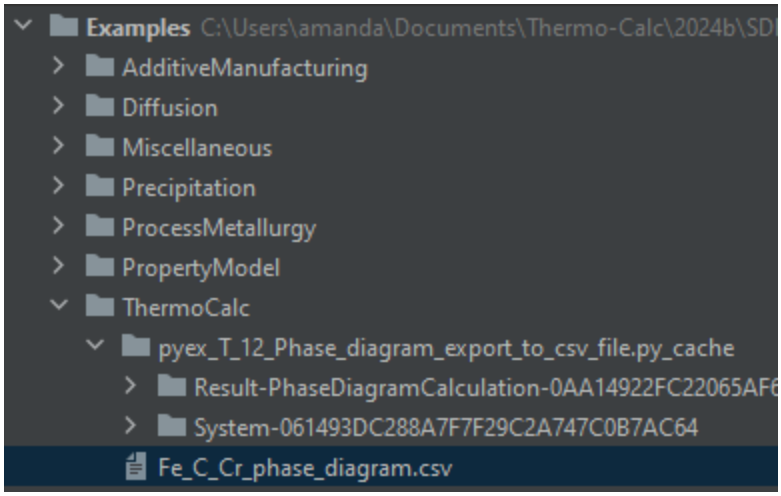
The examples are installed in the **SDK → TC-Toolbox** folder.

These SDK examples are not directly accessible from the Thermo-Calc menu.

Installation Default Directory: TC-Toolbox Examples and Diagnostic Script

CSV Files

When exporting to a CSV file, it is saved in the same location as the example files and based on your OS. Depending on the IDE you are using, you can also access it from the same location as the example files, e.g. in this example the **Project** window.



TC-Toolbox Thermo-Calc Examples

General Examples

T_01: Single Point Equilibrium of a Ternary System

File name: `matex_T_01_Single-point_equilibrium_looping_and_3d_plotting.mlx`

The file type suffix `mlx` demonstrates using Live Scripts, not regular scripts.

This example shows how you create a single equilibrium calculation from a ternary system, loop it while changing Al and Cr concentration, then calculate density and plot the result as a 3D surface.

Using a Live Script provides function hints, i.e. direct description of the method parameters. T

T_02: Single Equilibrium Calculation of Solidus and Liquidus Temperature

File name: `matex_T_02_Single_equilibrium_solidus_and_liquidus_temperature.m`

This example shows how to create a single equilibrium calculation from a ternary system and configure it to calculate the solidus and liquidus temperature using fixed phase conditions for the liquid phase. There can be multiple solutions to a fixed phase condition and it is good practice to perform a regular equilibrium calculation close to where the phase transition is. This example starts with an equilibrium calculation at 1700 K in order to get good start values.

T_08: Create a Property (Step) Diagram

File name: `matex_T_08_Property_diagram.m`

This example shows how to create a property (step) diagram using TC-Python.

The alloy system Fe-Ni is used as an example.

T_09: Run Multiple Property (Step) Diagram Calculations in Parallel

File name: `matex_T_09_Property_diagram_loop_parallel.mlx`

The file type suffix `mlx` demonstrates using Live Scripts, not regular scripts.

This example shows how to run multiple property (step) diagram calculations in parallel. Note that only multi-processing and not multi-threading can be used.

This example requires the Parallel Computing Toolbox of MATLAB®.

The alloy system Fe-C-Cr is used as an example.

T_10: Create Property Diagrams

File name: `matex_T_10_Property_diagram_alloy_A_to_alloy_B.m`

This example shows how to perform step calculations for a multi-material system. Such a calculation is not possible using the Thermo-Calc Graphical User Interface.

T_11: Calculate and Plot a Phase Diagram

File name: `matex_T_11_Phase_diagram.m`

This example shows how to calculate and plot a phase diagram.

The system Fe-Cr is used as an example.

T_12: Export Phase Diagram Data to a CSV File

File name: `matex_T_12_Phase_diagram_export_to_csv_file.m`

Exports the line data of a phase diagram into a CSV-file that can be imported into other plotting software for creating customized plots for example. It is easy to adapt the code to generate a different format of the CSV-file or to use a completely different output file format.

The system Fe-C-Cr is used as an example.

T_13: Calculate a Single Phase FCC_A1 Region Shift

File name: `matex_T_13_Phase_diagram_single_phase_region_shift_Al_Si_Cu.m`

Calculates and plots the single phase FCC_A1 region of Al-Si-Cu alloys and compares them for different Cu-contents.

For simplicity only FCC_A1 and DIAMOND_A4 are enabled as solid phases.

T_14: Create a Batch Equilibria from a Ternary System

File name: `matex_T_14_Batch_equilibria.mlx`

The file type suffix `mlx` demonstrates using Live Scripts, not regular scripts.

This example shows how you create a batch equilibrium calculation from a ternary system, loop it while changing Al and Cr concentration, then calculate the density and plot the result as a 3D surface.

This is almost the same example as `matex_T_01_Single_equilibrium_looping_and_3d_plotting.mlx`, but instead of 100 equilibria it calculates 10000 but only for BCC_A2.

It is much more efficient, since it is using `BatchEquilibriumCalculation` and not `SingleEquilibriumCalculation`. `BatchEquilibriumCalculation` has improved performance when calculating a large number of equilibria when each individual calculations is quick. E.g. when evaluating single phase properties for thousands of compositions.

Scheil Examples

T_03: Scheil Mole Fraction of a Solid

File name: `matex_T_03_Scheil_mole_fraction_of_solid.m`

Shows the basic usage of Scheil calculations and mixing them with equilibrium calculations.

T_04: Scheil Composition Distribution

File name: `matex_T_04_Scheil_composition_distribution_Al_Si_Cu_Mg.m`

Calculates the variation of the 80% solid temperature using Scheil solidification for random compositions within a specification range.

The alloy system Al-Si-Cu is used as an example.

T_05: Scheil Composition Profiles in a Solidified Ni-based Superalloy

File name: `matex_T_05_Scheil_composition_profiles_Ni_base.m`

Calculates the microsegregation profile in a solidified Ni-based superalloy using the Scheil-method.

The plot is normalized relative to the nominal composition and shows the composition of the matrix phase (FCC).

A model alloy in the system Ni-Al-Cr is used as an example.

T_06: Scheil Calculation of an Eutectic Fraction

File name: `matex_T_06_Scheil_eutectic_fraction_Al_Si_Cu.mlx`

The file type suffix `mlx` demonstrates using Live Scripts, not regular scripts.

Calculates the eutectic fraction using Scheil-solidification for varied alloying element content.

The alloy system Al-Si-Cu is used as an example.

T_07: Scheil Solidification Simulation - Export to CSV

File name: `matex_T_07_Scheil_latent_heat_for_solidification_simulations.mlx`

The file type suffix `mlx` demonstrates using Live Scripts, not regular scripts.

Calculates the characteristic properties of the solidification of a range of alloys using Scheil-solidification and saves the data into a CSV-file (named `Al_Si_Cu_scheil_solidification.csv`) that can be imported by other software.

Such data is typically used as an input into other simulation software, e.g. for casting simulation.

The alloy system Al-Si-Cu is used as an example.

T_15: Calculate Solidification using Scheil with Back Diffusion

File name: `matex_T_15_Scheil_back_diffusion.m`

Calculates solidification using Scheil with back diffusion in the primary phase, and compares the result to other calculation types.

T_16: Calculate Solidification using Scheil with Solute Trapping

Calculates the solidification with and without Solute Trapping.

Then compare the solidification in the two cases by plotting temperature vs. mole fraction of solid phase. The alloy system Al-Si-Cu is used as an example.

File name: `matex_T_16_Scheil_Solute_Trapping_Al_Si_Cu.m`

Graphical Mode example T_13: Scheil Solidification with Solute Trapping.

Material to Material Calculator Examples

T_17: Material to Material - Single Fraction of B

Calculates the phases occurring for a material mixture, in this case for a mixture of a martensitic stainless steel with Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `matex_T_17_Material_to_Material_single_fraction_of_B.m`

T_18: Material to Material - Step Along Fraction of B

Calculates the phases occurring during a gradual transition between two materials, in this case from a martensitic stainless steel to Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `matex_T_18_Material_to_Material_step_along_fraction_of_B.m`

T_19: Material to Material - Step Along Temperature

Calculates the phases occurring for a material mixture with varying temperature, in this case for a mixture of a martensitic stainless steel with Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `matex_T_19_Material_to_Material_step_along_temperature.m`

T_20: Material to Material - Phase Diagram

Calculates a "phase diagram" for a material mixture, in this case for a mixture of a martensitic stainless steel with Alloy 800.

This type of calculation is for example useful for understanding effects when welding dissimilar materials - without the need to perform diffusion calculations.

File name: `matex_T_20_Material_to_Material_phase_diagram.m`

TC-Toolbox Property Model Examples

Read more on our website about Property Models, including information about the material specific Model Libraries (i.e steel, nickel, titanium, etc.), as well as how to create your own custom models in TC-Python. If you are in Thermo-Calc, press F1 to search the help.

PM_01: Calculating Interfacial Energy with a Property Model

File name: `matex_PM_01_Property_model_interfacial_energy.m`

This example shows how to run a property model to calculate the interfacial energy. The Thermo-Calc Property Model uses a broken-bond approach. Any other pre-installed or user-defined Property Model created in Thermo-Calc can be loaded and used in the same way as in this example.

This example shows how to run a property model from TC-Python to calculate the interfacial energy. The Thermo-Calc Property Model uses a broken-bond approach. Any other pre-installed or user-defined Property Model created in Thermo-Calc can be loaded and used in the same way as in this example.

The details of a property model (arguments, result quantities, and so forth) are defined in the Thermo-Calc Property Model and are not known to TC-Toolbox in advance. Therefore, when using property models, the workflow differs compared to other TC-Toolbox modules. The available arguments need to be queried by using the respective `get_...()`- method. This requires some interactive development style until a first working version of the code is set up.

PM_02: Property Model Parameter Fitting

File name: `matex_PM_2_Property_model_parameter_fitting.mlx`

The file type suffix `mlx` demonstrates using Live Scripts, not regular scripts.

This example shows how to optimize the parameters of a property model. Typically this approach is used in order to fit a property model to experimental data. That can be useful for any application where no analytical correlation between the input parameters (composition, temperature and other parameters) and the material property can be established.

Examples might be solid solution strength models or martensite temperature models where the transformation barrier is modeled.

For the purpose of this example, the linear fitting to noisy data is shown.

A 'model parameter' is a value that can be changed from the outside of the model in the way demonstrated here. Internally it can be represented in any way; the only requirement is that the property model implements the 'Python Property Model Development Framework' interface methods `:func:`provide_model_parameters()`` and `:func:`set_model_parameter()``.

PM_03: Yield Strength Simplified Mode vs Advanced Mode

File name: `matex_PM_4_Property_model_YS_simplified_mode_vs_advanced_mode.m`

This example shows how to call the Yield Strength model using the Simplified and Advanced modes.

It is based on the Graphical Mode example "PM_G_04_Yield_Strength", which is included with the Thermo-Calc installation.

The details of a property model (arguments, result quantities, and so forth) are defined in the Thermo-Calc Property Model and are not known to TC-Toolbox in advance. Therefore, when using property models, the workflow differs compared to other TC-Toolbox modules. The available arguments need to be queried by using the respective `get_...()`- method. This requires some interactive development style until a first working version of the code is set up.

TC-Toolbox Diffusion Examples

You do not need a Diffusion Module (DICTRA) license to use these examples, which use up to three components and this is available for all users with a Thermo-Calc license.

To run more complex diffusion calculations, you need a Diffusion Module license.

D_01: Diffusion within a Single Phase Austenitic Region of an Fe-Ni Alloy

File name: `matex_D_01_Diffusion_Single_Phase.m`

This example simulates diffusion within a single phase austenitic region of an Fe-Ni alloy. The initial condition is a linear gradient from 10 wt-% - 50 wt-% Ni at 1400 K.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_01: Homogenization of a Binary Fe-Ni Alloy.

D_02: Diffusion with a Moving Boundary Between a Ferrite and Austenite Region

File name: `matex_D_02_Diffusion_Moving_Boundary.m`

This example simulates diffusion including a moving boundary between a ferrite and austenite region in an Fe-C steel. Initially the C-concentration is constant in each region, with a step at the boundary. All units are in wt-%.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_02: Ferrite (bcc)/Austenite(fcc) Transformation in a Binary Fe-C Alloy.

D_03: Diffusion in a Single Region with Multiple Phases

File name: `matex_D_03_Diffusion_Multiphase.m`

This example simulates diffusion in a single region having multiple phases. Initially a step concentration profile is defined within the single region. Due to the multiple phases, the default `AutomaticSolver` uses the `homogenization mode`.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_03: Evolution of an Fe-Cr-Ni Diffusion Couple.

D_04: Diffusion with an Inactive Phase Forming in the Presence of a Driving Force

File name: `matex_D_04_Diffusion_Fe-C_Moving_Boundary_Austenite_to_Ferrite.m`

This example simulates a moving boundary problem that is initially a one-phase austenite region. Due to the available driving force, a new ferrite region is starting to grow at the left interface of the austenite region.

Initially a constant concentration profile is defined within the single-phase region.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_04: Fe-C Moving Boundary - Austenite to Ferrite.

D_05: Moving Boundary Diffusion Couple for an Fe-Ni-Cr Alloy

File name: `matex_D_05_Diffusion_Fe_Ni_Cr_Moving_Boundary_Diffusion_Couple.m`

This example simulates the diffusion paths in a moving boundary problem between two multiphase regions. Due to the multiple phases, the default `AutomaticSolver` uses the `homogenization mode`.

Initially there is a concentration profile with a step between the regions.

The example uses a minimum number of required settings. Default values are used for any unspecified settings.

Also see the Graphical Mode example that this is based on: D_05: γ/α/γ Diffusion Couple of Fe-Ni-Cr alloys.

D_06: Deriving Diffusion Coefficients from Experiment

File name: `matex_D_06_Deriving_Diffusion_Coefficients_From_Experiment.m`

This example demonstrates the direct optimization of mobility database parameters by fitting to experimentally measured composition profiles. A manual determination of the interdiffusion coefficients (for example using the Boltzmann-Matano method) is not required. Additionally, no derivatives of the experimental curve is required as this is difficult for scattered data.

This example has set the maximum number of iterations to 10 in order to keep runtime low.

The results are updated continually and the plot example shown is the final iteration.

References

The example uses data from:

[2010Liu] Y. Q. Liu, D. J. Ma, and Y. Du, “Thermodynamic modeling of the germanium–nickel system,” J. Alloys Compd., vol. 491, no. 1–2, pp. 63–71, Feb. 2010.

[2011Ret] R. Rettig, S. Steuer, and R. F. Singer, “Diffusion of Germanium in Binary and Multicomponent Nickel Alloys,” J. Phase Equilibria Diffus., vol. 32, no. 3, pp. 198–205, Jun. 2011.

D_07: Homogenization of a Scheil Profile

File name: `matex_D_07_Homogenization_Of_Scheil_Profile.m`

This example models the homogenization of a cast Ni-Cr steel and compares predictions with the experimental data collated by Fuchs and Roósz [1975Fuc].

As a first step, the microsegregation after solidification is simulated using a Scheil-calculation, then as a second step the homogenization is simulated using a diffusion simulation.

The conditions studied have a dendritic half spacing of 200 µm and are heat treated at 1120 °C.

The data has been de-normalized to allow comparison using weight percent composition values. The composition of the steel is 0.4C, 0.65Mn, 0.35Si, 0.015S, 0.01P, 1.9Ni, 0.95Cr and 0.3 Mo (wt.%). The diffusion of Cr and Ni are modelled using a simplified chemistry of 0.4C, 0.65Mn, 1.9Ni, and 0.95Cr using the FEDEMO thermodynamic and MFEDEMO mobility databases.

Also see the Graphical Mode example that this is based on: D_10: Iron (Fe) Homogenization in Scheil.

Reference

[1975Fuc] E. G. Fuchs, A. Roósz, Homogenization of Iron-Base Cast Alloys. Met. Sci. 9, 111–118 (1975).

D_08: Diffusion Carburization of Multiphase with Boost and Diffusion

Carburization of an alloy in a two-step procedure with different boundary conditions in each step.

File name: `matex_D_08_Diffusion_Carburization_Multiphase_Boost_And_Diffusion.mlx`.

The file type suffix `mlx` demonstrates using Live Scripts, not regular scripts.

This example requires licenses for TCS Steel and Fe-alloys Database (TCFE) and TCS Steels/Fe-Alloys Mobility Database (MOBFE).

As a first step, the carburization is simulated using a activity-flux boundary condition, then as a second step the homogenization is simulated using a diffusion simulation with closed boundaries.

Reference

Experimental data from:

[2005Tur] T. Turpin, J. Dulcy, and M. Gantois, “Carbon diffusion and phase transformations during gas carburizing of high-alloyed stainless steels: Experimental study and theoretical modeling,” Metall. Mater. Trans. A, vol. 36, no. 10, pp. 2751–2760, Oct. 2005.

TC-Toolbox Precipitation Examples

You do not need a Precipitation Module (TC-PRISMA) license to use these examples, which use up to three components and this is available for all users with a Thermo-Calc license.

To run more complex precipitation calculations, you need a Precipitation Module license.

P_01: Precipitation of Al3Sc from FCC_A1

File name: `matex_P_01_Precipitation_Al-Sc_AL3SC.m`

This example simulates the kinetics of precipitation of Al_3Sc from an FCC_A1 solution phase and shows some results, with minimally required settings. Default values are used for unspecified settings.

P_02: Precipitation of Stable and Metastable Carbides from the Ferrite Phase

File name: `matex_P_02_Precipitation_Fe-C-Cr_Cementite-M7C3-M23C6.m`

Also see the Graphical Mode example that this is based on: P_02: Stable and Metastable Carbides - Isothermal

This example simulates the kinetics of precipitation of both stable and metastable carbides from the ferrite phase. It demonstrates that metastable carbides (cementite, M7C3) may first emerge and then disappear and the stable phase (M23C6) prevails.

P_03: Precipitation of Ni-Al-Cr

File name: `matex_P_03_Precipitation_Ni-Al-Cr_TTT_CCT_Gamma-Gamma_prime.m`

This example simulates the precipitation of gamma-prime phase from gamma phase in a Ni-Al-Cr alloy. It demonstrates how to run TTT (temperature-time-transformation) and CCT (continuous-cooling-transformation) diagrams. It also shows (1) how to set up objects (the system, precipitate phase, and matrix phase) and then reuse them, and (2) how to set an alias for the precipitate phase.

P_04: Precipitation of a Cu-Ti Binary Alloy

File name: `matex_P_04_Precipitation_Cu-Ti_CU4TI1_Sphere_Needle.m`

Also see the Graphical Mode example that this is based on: P_08: Precipitation of Cu-Ti CU4TI with Assumptions of Sphere and Needle Morphologies

In this isothermal calculation example, the precipitation of the Cu4Ti phase in a Cu-Ti binary alloy is calculated. To make a comparison, two separate simulations are performed: (1) one assuming spherical morphology without elastic strain energy, and (2) one assuming needle morphology whose shape, determined by competition between interfacial energy and elastic strain energy, is changed during the simulation.

P_05: Grain Growth and the Zener Pinning Effect

File name: `matex_P_05_Precipitation_Fe_C_zenner_pinning.m`

Also see the Graphical Mode example that this is based on: P_14: Grain Growth and the Zener Pinning Effect

This example simulates the kinetics of precipitation of CEMENTITE from a BCC_A2 solution phase and shows the grain growth results for two cases: with and without Zener pinning. A log normal distribution is applied for the matrix grain size.

TC-Toolbox Process Metallurgy Examples

You can find several learning resources on the Process Metallurgy page of our website (or in Thermo-Calc, go to **Help → Thermo-Calc website**). You can also subscribe to the Thermo-Calc newsletter to be kept up-to-date about upcoming releases, training, examples, videos and much more.

PMET_01: Single Adiabatic Equilibrium

This example shows how to create a basic adiabatic equilibrium calculation for a process metallurgical problem. The equilibrium between a steel and slag melt and oxygen is calculated.

File name: `matex_PMET_01_Single_adiabatic_equilibrium.m` and the OXDEMO database is used.

This example has some text output for the calculation result:

```
Stable phases: {'GAS#1', 'IONIC_LIQ#2', 'IONIC_LIQ#1', 'HATRURITE#1'}
Temperature: 1758.4 °C Slag phases: {'IONIC_LIQ#2', 'HATRURITE#1'}
Composition of the overall slag:
Al2O3 = 9.41 mol-%
C = 0.42 mol-%
CaO = 70.43 mol-%
Fe2O3 = 0.00 mol-%
FeO = 0.01 mol-%
SiO2 = 19.73 mol-%
```

PMET_02: Stepping Adiabatic Equilibrium

This example shows how to create adiabatic equilibrium calculations for varied pressure. The equilibrium between a steel and slag melt and oxygen is calculated.

File name: `matex_PMET_02_Stepping_adiabatic_equilibrium.m` and the OXDEMO database is used.

PMET_03: Mapping Isothermal Equilibrium

This example shows how to create isothermal equilibrium calculations with varied composition of two steel components.

File name: `matex_PMET_03_Mapping_isothermal_equilibrium.m`.

To run this example requires TCOX9 and higher.

PMET_04: Simple Process Simulation

This example shows how a very simplified process simulation of a basic oxygen furnace (BOF) converter can be set up.

File name: `matex_PMET_04_Simple_process_simulation.m` and the OXDEMO database is used.

PMET_05: VOD Process Simulation

This is example shows how a Vacuum Oxygen Decarburization (VOD) refining process could be modeled. It is inspired by the work of Ding et al. [2000Din] and the validation data is derived from the paper.

File name: `matex_PMET_05_VOD_process_simulation.m`

To run this example requires TCOX9 and higher. Slight model adjustments might be required based on the version.

This example is based on the Graphical Mode example, PMET_07: Vacuum Oxygen Decarburization Kinetics, which is also an application example showcased on our website.

This model shows several features of process simulations, such as:

- time-dependent mass transfer coefficients
- time-dependent pressure
- inclusion flotation
- cooling due to heat losses
- heat transfer between the zones
- control of degassing

This example takes several minutes to calculate. The results are updated continually. The plot examples shown are the final iterations.

For this specific example, several plots are generated. There are slight differences compared to the application example on the website. For general background theory and an overview of how the example is set up and to interpret the results, it is recommended to read the PDF, also available on the website.

Reference

[2000Din] R. Ding, B. Blanpain, P. T. Jones, P. Wollants, Modeling of the vacuum oxygen decarburization refining process. Metall. Mater. Trans. B. 31, 197–206 (2000).

TC-Toolbox Miscellaneous Examples

Diagnostics Script

Run this script when troubleshooting TC-Toolbox.

> Run this script EXACTLY the same way as you run your MATLAB script.

File name: `diagnostics.m`

M_01: Reading a Time-Temperature Profile from a CSV File

This example shows how to read a time-temperature profile from a CSV file and running a precipitation calculation with it. The easiest CSV file is simply a comma-separated text-file as shown in the present example.

File name: `matex_M_01_Input_from_file.m`

M_02: Property Diagram Exported to Various File Formats

This example shows how to create a property (step) diagram using TC-Toobox.

The alloy system Fe-Ni is used as an example.

The result is then saved in different file formats:

- JSON
- XML
- CSV
- TXT
- HDF5

File name: `matex_M_02_Output_to_file.m`

M_03: Comparison of Legacy vs New TC-Toolbox

Performance comparison for looping single equilibrium calculations using the legacy version of TC-Toolbox versus the new TC-Toolbox and a batch equilibrium calculation.

File name: `matex_M_03_Benchmark_toolboxes.m`

M_04: Working with the User Credentials License

The TC-Toolbox for MATLAB® license is a separate license from the Thermo-Calc software license. You need to activate the TC-Toolbox license once on your computer after, or in addition to, activating the Thermo-Calc license.

It is recommended to run the included example to perform the activation and deactivation. By default an online activation is performed, but you can choose other methods, which are both included in the example and described in the API documentation.

- Open and run the example `matex_M_04_license.m`, which is located in the **Miscellaneous** folder.
- The license activation is completed with the methods in the class `tc_toolbox.LicenseManager`.
- Depending on the type of license other methods are available, for example for online and offline activation plus the use of proxy settings are described.

To use the license on a different computer, the license must first be deactivated on the original computer. This is for both online and offline activations.

This example shows a variety of ways to manage licenses that are activated or deactivated with user credentials. Described are the online and offline methods plus the use of proxy settings.

The general details cover these topics.

- Printing information about the currently activated license.
    - For any activation type, i.e. online, offline, or proxy settings.
- Online license activation for computers with Internet access using user credentials.
    - This requires a valid *username* and *password* that is provided by email and originates from a Thermo-Calc representative.
- Offline license activations for computers without Internet access. Learn how to:
    - Create an offline activation file in the supplied directory.
    - Activate an offline license using the offline activation file. See `create_offline_activation_file()` in the API documentation.
- Proxy settings. Learn how to use proxy settings for the LicenseManager.
    - This function shows the `proxy_settings_set` method to configure proxy settings when working with the license.
- Update the current license to its latest state. **This is only available for online activations.**
    - This task is used to refresh the license information and ensure it is up-to-date.
- Deactivate an active license.
    - Typically done when a license is no longer needed on a specific computer or you want to activate it on a different computer.
    - For offline licenses it creates an offline deactivation file, which is then used to deactivate the license on a computer that does not have Internet access.

TQ-Interface

TQ-Interface is designed for time-critical, computationally intensive application software that is most likely but not necessarily written in Fortran. It constitutes a collection of Fortran subroutines and functions supplied in the form of a DLL (Dynamically Linked Library). There are also C functions matching all the Fortran subroutines in order to facilitate users who wish to program in languages other than Fortran.

TQ-Interface is successfully used in the MICRESS™ software package (developed by ACCESS e.v., in Aachen, Germany), for simulation of microstructural evolution in multicomponent alloys using a phase-field approach.

TQ-Interface is only available on Windows and Linux platforms.

The *TQ-Interface Application Programmer's Guide* is fully included here and also available as a separate guide on the website.

The TQ-Interface

Topics to Explore >

Introduction to the TQ-Interface **3589**

The Subroutines and Functions **3591**

Introduction to the TQ-Interface

TQ-Interface is designed for time-critical, computationally intensive application software that is most likely but not necessarily written in Fortran. It constitutes a collection of Fortran subroutines and functions supplied in the form of a DLL (*Dynamically Linked Library*). There are also C functions matching all the Fortran subroutines in order to facilitate users who wish to program in languages other than Fortran.

TQ-Interface is an application programming interface (API) for Thermo-Calc, a general software package for multicomponent phase equilibrium calculations. TQ-Interface is for application programmers to write programs using the Thermo-Calc kernel. With this programming interface, it is easy to make Thermo-Calc an integral part of application programs such as those for process simulation, microstructure evolution modeling and materials property prediction.

The thermodynamic properties and phase equilibrium data that can be obtained by using the TQ-Interface include Gibbs energy, enthalpy, entropy, heat capacity, first and second derivatives of Gibbs energy with respect to composition, chemical potential, phase amount, phase composition, partition coefficients, liquidus or solidus points, invariant temperature, heat of reaction, adiabatic combustion temperature, and volume, etc.

Through appending the mobility databases into the workspace, you can also obtain assessed mobility or diffusivity data via the TQ-Interface. The TQ-Interface can also be used to predict metastable or non-equilibrium states by changing the status of the phases under consideration.

The TQ-Interface is available for both Windows and Linux platforms. The use of DLLs means there is no need to recompile existing application programs when a new version of TQ-Interface is released.

TQ-Interface is successfully used in the MICRESS™ software package (developed by ACCESS e.V., in Aachen, Germany), for simulation of microstructural evolution in multicomponent alloys using a phase-field approach.

The SDK is written in FORTRAN. The Subroutines and Functions topic outlines categories of what is available.

The computer language to implement application programs is not restricted to FORTRAN, for example a GUI application written in C++ can realize its various functionalities by using TQ-Interface subroutines with the appropriate calling conventions. See Programming Languages.

Watch a webinar about Coupling TQ-Interface with Precipitation Models for Gas Turbine Applications. Also read more about all the available SDKs on our website.

The Subroutines and Functions

The FORTRAN subroutines and functions available in the TQ-Interface can be classified into categories based on purpose:

1. Initialization Subroutines. For example, initializing the workspace, reading the thermodynamic data files, setting default units for thermodynamic quantities, selecting the input and output options, changing the program input and output units
2. System Data Manipulation Subroutines. For example, identifying system components, phases, and constituents, redefining the system components, changing the status of components and phases or the system reference state.
3. Condition, Stream and Segment Subroutines. For example, defining conditions for an equilibrium calculation, setting conditions for a thermodynamic equilibrium calculation, and setting a new equilibrium segment.
4. Calculations and Results Subroutines. For example, calculate equilibriums, get molar Gibbs energy values, and calculate interfacial energy between a matrix phase and a precipitate phase.
5. Miscellaneous Subroutines. For example, reinitiate the calculation workspace, set error codes and messages, or set equilibrium calculation options.

Essentially, only subroutines 1, 3, and 4 are required to use the TQ- Interface. In the simplest case, only one or two subroutines are needed from each category.

Additional subroutines are grouped as follows:

- Extra Subroutines–Phase Properties. For example, get Gibbs energy of a phase, mobility of a species in a phase, or check if mobility data for a phase is available.
- Database Subroutines For example, get lists of database names, reject a selected element and get data from the selected database.
- Adaptive Interpolation Schemes. For example, define a function or state variable to be interpolated and get statistics on the usage of the interpolation scheme.
- Composition Set Reordering Routines . For example, initialize IWSR workspace and set ideal composition in a phase.

Installing and Using the TQ-Interface

If you have not used Thermo-Calc before, start with the Basic Concepts. Several simple application examples are given in the installed SDK folder.

If you are an experienced Thermo-Calc user you can start by copying a suitable example. You make it work for problems by changing, adding or deleting some callings to TQ-Interface subroutines and functions.

It is strongly recommended that at least one or two examples should be compiled and linked (and tested) to make sure the linked executables can be run successfully.

Installing the TQ-Interface and Examples

The TQ-Interface requires an additional license key, which is purchased along with the Thermo-Calc software/database package. For both Windows and Linux platforms, the TQ-Interface is supplied as a dynamically linked library (DLL).

Installed Example Default File Paths

All the examples in this document are included in the SDK installation directory. For example, for a network installation on Windows, common locations can be:

`C:\Users\<username>\AppData\Thermo-Calc\2026b\SDK\TQ\<Windows>`

`C:\Users\<username>\Documents\Thermo-Calc\2026b\SDK\TQ\<Windows>`

If you are using MS365 and OneDrive, the Documents folder could be mapped there, e.g. OneDrive\<*username*>\Documents\Thermo-Calc\2026b.

Installation Default Directory: Windows and Installation Default Directory: Linux in the help or *Thermo-Calc Installation Guide*.

TQ-Interface Examples

Example Name	*Description*
TQEX01	This sample program shows how to retrieve data from a Thermo-Calc data file, then defines a set of conditions for a single equilibrium calculation, gets the equilibrium phases and their amounts and compositions. The method of calculating the liquidus and solidus temperature is also demonstrated.
TQEX02	This sample program calculates the To line for the fcc and bcc phase in the Fe-C system.
TQEX03	This sample program simulates the non-equilibrium solidification under the Scheil-Guilliver condition.
TQEX04	This sample program simulates the non-equilibrium solidification under the Scheil-Guilliver condition.

Example Name	*Description*
TQEX05	This example demonstrates how to use stream calculation to get the enthalpy of a reaction, i.e., the enthalpy difference between the reaction products at one temperature and the reactants at another temperature. By setting the enthalpy of reaction to zero, the adiabatic temperature can be easily calculated.
TQEX06	This example demonstrates how to use stream calculation to obtain the chill factors in the steelmaking industry.[1]O.Kubaschewski and C.B. Alock, Metallurgical Thermochemistry, 1979, Page 211.
TQEX07	This sample program calculates the A3 temperature of a steel and determines the influence of each alloying element on this temperature. It demonstrates that some very special quantities, such as the composition derivative of temperature, can be obtained easily via the TQ interface.
TQEX08	This sample program displays the diffusion matrix in a multicomponent system.
TQEX09	This sample program show how to retrieve Gibbs energy, Gibbs energy derivatives and mobilities.
TQEX10	This sample program is the same as Example 9 except that it demonstrates how to convert mole fractions to site fractions and first derivatives of Gm w.r.t. site fractions to that w.r.t. mole fractions.
TQEX11	This sample program shows how to get information about the paraequilibrium transformation from FCC to BCC in a steel.
TQEX12	This sample program demonstrates how to use subroutines getting system data from a database and how to restart new calculation on a different system in the same application program.
TQEX13	This sample program demonstrates that the number of phases can increase due to the use of global mininization for equilibrium calculation during which additional composition set(s) can be added automatically if a miscibility gap is detected.
TQEX14	This sample program show how to use the functionality for setting how different composition sets should correspond to different compositions. For example, that in the Ni-Al system the composition set fcc_l12#1 should correspond to gamma and fcc_l12#2 to gamma-prime.
TQEX15	TQ library example to illustrate the use the adaptive interpolation scheme. This example calculates the liquidus temperature in a part of the C-CR-FE system and displays a selection of the results.
	The MPI examples only show how the TQ-Interface can be used in applications together with MPI. Thermo-Calc Software AB or Thermo-Calc Software, Inc. is not available to answer support questions related to MPI.
MPExample1	This is an MPI (Message Passing Interface) example that calculates the Gibbs energy for a composition grid C with a density of "npoints" at 1273K in the Mn-Ni-Fe system.

Example Name	*Description*
MPExample2	This is an MPI (Message Passing Interface) example where a set of equilibrium calculations are distributed over all processes. Then the Gibbs energy of the system is retrieved and collected in a single vector in the master process.

Naming Conventions for Routines

The topic names in this guide are the same as the FORTRAN routine names. Also included in each topic are details for both the FORTRAN and C programming languages. For each section where there is a table, this is how you distinguish between the two programming languages.

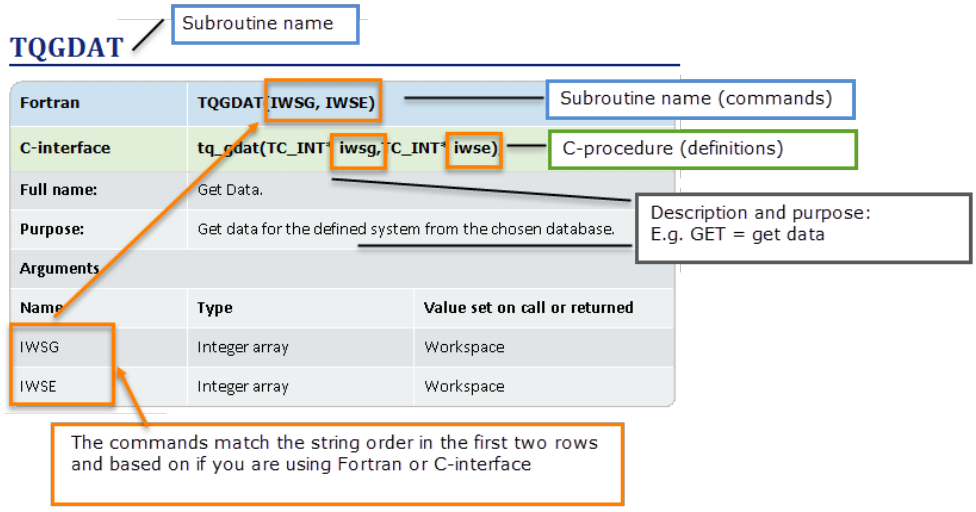
Programming Languages

Naming Conventions Based on Programming Language

Note the following conventions to distinguish between the programming languages.

- Routines starting with **TQ**XXX, for example, *TQGDAT*, are in the Fortran interface
- Routines starting with **tq_**xxxx, for example *tq_gdat*, are in the C-interface.
- In Fortran, all routines are subroutines and do not return any values except where explicitly declared as functions.
- All the C procedures are declared as void and do not return any values except where explicitly otherwise declared.

An example of how to read the subroutine definitions.



Programming Languages

You can program your TQ-library with the FORTRAN or C programming languages.

FORTRAN

No special consideration is needed when interfacing the TQ-library with a program written in FORTRAN; the main core of the TQ-library is written in FORTRAN. By default all parameters are passed to routines by reference, except for strings, which are passed by descriptor.

C-Interface

The C-interface acts as a translation layer in between the calling C-program and the underlying FORTRAN TQ-library.

For a C-interface, the default parameter passing mechanism is by *value* and not by reference. Some decisions must be made as to how parameters, which are updated in the TQ-Interface, are then passed into the library. For example:

- The *C procedures* are defined in the file **tqroot.h** which should be included in the procedures using the library calls in C.
- The **tqroot.h** file also includes the file **tc_data_defs.h** where the datatypes are defined.

The definition of some of these data types vary depending on what platform and compiler is used. It is important to define these and for the definitions to be correctly set.

Common C-Procedure Definitions

The commonly used definitions in the C-interface are listed in the table. Note that:

- TC_INT and TC_FLOAT are used when only the value of the variables is necessary to pass.
- TC_INT* and TC_FLOAT* are used when the variables are updated and values are

returned within these.

- When a TC_STRING is updated, the allocated size of the string must be passed into the interface in a variable declared as TC_STRING_LENGTH.

Routine	*Definitions*
TC_INT	An integer of platform dependent length passed by value.
TC_INT*	Address of an integer of platform dependent length.
TC_FLOAT	A 64-bit real passed by value.
TC_FLOAT*	Address of a 64-bit real.
TC_STRING	Address of a character string.
TC_STRING_LENGTH	An integer of platform dependent length passed by value defining the length of the string.

Basic Concepts

A thermodynamic system is made up of *components* and *phases*. A number of *state variables* define the properties and the relationships.

Components and Phases

A **component** is a system-wide entity; sometimes it is specifically called a *system component*. A component has a unique name and some thermodynamic properties are associated with it, for example, its amount and activity or chemical potential. At equilibrium the activity or chemical potential of the components are the same in the whole system.

A **phase** is a system-wide entity, which has a composition expressed in the amounts of components, enthalpy content, a volume, and many other properties. The phase has *constituents* that may be different from the components. The **constituents** have a stoichiometry that can be expressed in terms of the components and possibly a charge. *Condensed phases* may have an internal structure like sub-lattices or clusters, and these clusters may be modeled as constituents.

Naming Components, Phases, and Constituents

There are different naming conventions for components, phases, and constituents. The name of a component, phase, or constituent can be maximum of 24 characters and must start with a letter (A-Z or a-z) and contain only letters, digits, and these special characters:

- underscore (_)
- full stop (.)
- parentheses (and)
- plus (+)
- minus (-)
- slash (/)

Component Naming Conventions

The TQ-Interface maintains a list of *components*. These are numbered sequentially from `1` up to the number of components.

A component has a name which can be identical to a chemical formula or any string of letters such as `h2o`, `c2h2cl_cis`, or `au3cu_cvm1`.

Several subroutines are available to get information about the components and to manipulate them, for example:

- TQGCOM returns the total number of components and all component names
- TQGSCI returns the index of one component name
- TQSCOM enables you to re-define the components.

The *component index* is used in most subroutines for defining conditions, etc.

Components can be suspended by TQCSSC, thus leaving gaps in the component list because suspending one component does not change the sequential numbering. The logical function TQGSSC can be used to check if a specific component is suspended or not.

Phases Naming Conventions

The TQ-Interface maintains a list of *phases*. These are numbered sequentially from `1` up to the number of phases in the system.

A phase has many properties and most importantly a list of constituents (see Phase Constituents Naming Conventions). Subroutines are available to get information about the phases, for example:

- TQGNP for the total number of phases
- TQGPN for the name of a phase
- TQGPI for the name of its index
- TQGNPC for the number of phase constituents

Phases can be suspended or set dormant by TQCSP, thus leaving gaps in the list because suspending one phase does not change the sequential numbering. The logical function TQGSP can be used to check if a specific phase is suspended or not.

Phase Constituents Naming Conventions

The TQ-Interface maintains a list of the constituents of each phase (the *phase constituents*). These are numbered sequentially from `1` up to the number of constituents in the phase. The number of constituents can be different in each phase. If a phase has sub-lattices, the numbering goes from the first constituent in the first sub-lattice over all sub-lattices to the last constituent in the last sub-lattice.

Subroutines are available to get information about the constituents, for example:

- TQGNPC for the number of constituents of a phase
- TQGPCN (or its index TQGPCI) for the name of a phase constituent
- TQGPCS for the stoichiometry of a constituent expressed in terms of the components

About Adaptive Interpolation Schemes

A general dynamic interpolation scheme is implemented in the TQ-library. At a slight cost of accuracy, this scheme allows you to rapidly obtain equilibrium values for state variables and functions for many different values of a predefined set of conditions.

Multiple sets of conditions and requested variable values can be defined in order to obtain different values for different situations. These are stored internally as different branches.

The accuracy of the scheme can be adjusted by setting the number of steps in the composition/temperature/pressure space where the interpolation is performed.

For a given set of conditions (a *branch*), the scheme builds up an interpolation matrix within the bounds of the conditions that have been previously defined. As long as the subsequent condition values are kept within these limits, the returned values are calculated from the interpolation matrix. If the condition values are outside these limits then the scheme automatically extends the interpolation matrix. With this procedure the scheme extends the interpolation matrix so that it can return values from a growing range of conditions in composition, temperature and pressure.

For each set of condition values within a branch a unique identifying number is calculated. This number is used to find the correct position in the interpolation matrix using a *hash table*.

If the memory requirements to extend the interpolation exceeds the available memory, the nodes in the matrix that are less frequently used are removed to free up some memory.

For a general reference about the interpolation scheme, see H. Larsson, L. Höglund, A scheme for more efficient usage of CALPHAD data in simulations. Calphad 50, 1–5 (2015).

Initialization Subroutines

Purpose	*Subroutine*
Set the Gibbs Energy System (GES) version to 5 or 6	TQSET_GES_VERSION
Initialize TQ-Interface with user-specified database and temporary directories	TQINI3
Initialize TQ-Interface	TQINI
Set input/output option	TQSIO
Get input/output option	TQGIO
Read thermodynamic data file	TQRFIL
Set unit for a system quantity	TQSSU
Get unit for a system quantity	TQGSU
Check if the system is the same	TQSAME
Retrieve information about the TQ-library	TQGVER

Units for TQSSU and TQGSU

Quantity	*Unit*	*Comment*
Temperature	K, C, F	K=Kelvin (default); C=Celsius, calculated as K-273.15; F=Fahrenheit
Volume	M3	Cubic meter (default)
	L	Liter. Calculated as 0.001 M^3
	IN3	Cubic inch.
	FT3	Cubic feet
	USG	US gallon
Energy	J	Joule (default)
	Cal	Calories. Calculated as J/4.184
	BTU	British thermal units.
Pressure	Pa	Pascal (default)
	Psi	Pounds/sq. inch
	Bar	Bar. Calculated as 0.00001*Pa
	Atm	Atmosphere. Calculated as Pa/101325
	Torr	Torricelli. Calculated as 758*Pa/101325
Mass	kg, g, lb	kg=Kilograms (default); g=Grams; lb=Pounds

Legal Input/Output Options for TQSIO and TQGIO

Option	*Meaning*	*Default value*
INPUT	Input unit	0
OUTPUT	Output unit	0
ERROR	Error output	0
LIST	List output	0

TQINI3

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQINI3(DATABASE_PATH, TEMP_PATH, NWSG, NWSE, IWSG, IWSE)**	
C-interface	**tq_ini3(TC_STRING database_path, TC_STRING temp_path, TC_INT nwsg, TC_INT nwse, TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Initialize TQ-Interface with user-specified database and temporary directories. If a GES file is used (i.e. no databases are opened) the directories can be empty strings.	
Purpose:	The application program initializes the Thermo-Calc package for thermodynamic calculations. This or TQINI must be called before using any other subroutines in the TQ-Interface.	
Arguments		
Name	**Type**	**Value set on call or returned**
database_path	Character*256	Path to the directory holding the data directory, which in turn contains the databases. See the examples collection for a default value for this parameter.
temp_path	Character*256	Path to the directory for temporary and log file output. This directory has to be writable by the user who runs the application. See the examples collection for a default value for this parameter.
NWSG	Integer	Set to size of the workspace IWSG.
NWSE	Integer	Set to size of the workspace IWSE.
IWSG	Integer array	Memory area for storage of data inside the package.
IWSE	Integer array	Memory area for storage of data inside the package.

TQINI

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQINI(NWSG, NWSE, IWSG, IWSE)**	
C-interface	**tq_ini(TC_INT nwsg, TC_INT nwse,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Initialize TQ Interface.	
Purpose:	With this subroutine the application program initializes the Thermo-Calc package for thermodynamic calculations. This or TQINI3 must be called before using any other subroutines in the TQ-Interface.	
Arguments		
Name	**Type**	**Value set on call or returned**
NWSG	Integer	Set to size of the workspace IWSG.
NWSE	Integer	Set to size of the workspace IWSE.
IWSG	Integer array	Memory area for storage of data inside the package.
IWSE	Integer array	Memory area for storage of data inside the package.

TQSIO

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSIO(OPTION, IVAL)**	
C-interface	**tq_sio(TC_STRING option,TC_INT ival);**	
Full name:	Set Input/Output Option.	
Purpose:	With this subroutine the application program can re-direct input and output from the Thermo-Calc package.	
Comments:	OPTION is a character identifying the Input/Output option. The current internal value is set to the value in IVAL. If the value is illegal the error condition is set.	
Arguments		
Name	**Type**	**Value set on call or returned**
OPTION	Character*8	Set to a value given in Legal Input/Output Options for TQSIO and TQGIO
IVAL	Integer	Set to an internal value.

TQGIO

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGIO(OPTION, IVAL)**	
C-interface	**tq_gio(TC_STRING option,TC_INT* ival);**	
Full name:	Get Input/output Unit.	
Purpose:	Obtain a value of Input/Output option.	
Comments:	OPTION is a character identifying the Input/Output option. IVAL is an integer where its current internal value is returned.	
Arguments		
Name	**Type**	**Value set on call or returned**
OPTION	Character*8	Set to a value given in Legal Input/Output Options for TQSIO and TQGIO.
IVAL	Integer	Return the current internal value.

TQRFIL

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQRFIL(FILE, IWSG, IWSE)**	
C-interface	**tq_rfil(TC_STRING file,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Read File.	
Purpose:	Read a thermodynamic data file in the Thermo-Calc format.	
Comments:	The default set of components is supplied by the thermodynamic input file. The thermodynamic data file should contain at least the following information. • System: name of the elements, molecular mass for elements, list of phases • Phase: list of constituents, type of solution model (if not fixed composition), thermodynamic model parameters • Constituents: name, chemical formula (stoichiometric matrix), molecular mass, thermodynamic properties All this data are not necessarily stored separately, for example the molecular weight for a constituent can be calculated from the masses of the elements. The TQ-Interface is not intended to read from a database or a database file and thus selections of data from a database must be made in Thermo-Calc and then stored in a GES file by using the save command in the Gibbs-Energy-System module inside Thermo-Calc. When the GES file is read into the workspace by this subroutine it is possible to manipulate data by changing components and status for components or phases.	
Arguments		
Name	**Type**	**Value set on call or returned**
FILE	Character*60	Legal file name
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSSU

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSSU(QUANT, UNIT, IWSG, IWSE)**	
C-interface	**tq_ssu(TC_STRING quant,TC_STRING unit,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set System Unit.	
Purpose:	Set the unit for a quantity (like mass, volume, etc.).	
Comments:	Default units are SI unless changes are made by this subroutine. The legal quantities and units are listed in Units for TQSSU and TQGSU.	
Arguments		
Name	**Type**	**Value set on call or returned**
QUANT	Character*60	Set to a legal quantity
UNIT	Character*60	Set to a legal unit
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGSU

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGSU(QUANT, UNIT, IWSG, IWSE)**	
C-interface	**tq_gsu(TC_STRING quant,TC_STRING unit,TC_STRING_LENGTH strlen_unit,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get System Unit.	
Purpose:	To find what units the TQ-Interface is currently using for a system quantity.	
Comments:	The legal quantities and units are listed in Units for TQSSU and TQGSU.	
Arguments		
Name	**Type**	**Value set on call or returned**
QUANT	Character*60	Set to a legal quantit.
UNIT	Character*60	Return the current unit.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSAME

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSAME(ICODE, IWSG, IWSE)**	
C-interface	**tq_same(TC_INT* icode,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Same System.	
Purpose:	The application program can check if the thermochemical system has been changed, i.e., not just the conditions but the components or the phases. This is useful if several independent systems operate on the same equilibrium description.	
Comments:	ICODE is an integer with positive value identifying current system. If ICODE is not the same next time TQSAME is called, the system has been changed.This routine may have to be used if the set of components or the set of phases has been changed. The value of ICODE is changed if there are changes of the components, phases, etc., but not with changes in the conditions, or values of thermodynamic model parameters etc.	
Arguments		
Name	**Type**	**Value set on call or returned**
ICODE	Integer	Returns an internal code
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGVER

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGVER(VERS, LNKDAT, OSNAME, BUILD, CMPLER)**	
C-interface	**void tq_gver(TC_STRING version,TC_STRING_LENGTH strlen_version,TC_STRING lnkdat,TC_STRING_LENGTH strlen_lnkdat,TC_STRING osname,TC_STRING_LENGTH strlen_osname,TC_STRING build,TC_STRING_LENGTH strlen_build,TC_STRING cmpler,TC_STRING_LENGTH strlen_cmpler);**	
Full name:	Get version.	
Purpose:	The application program gets information about the TQ-library.	
Arguments		
Name	**Type**	**Value set on call or returned**
VERS	Character*32	Returns the version of TQ-library.
LNKDAT	Character*32	Returns the date and time the TQ-library was built.
OSNAME	Character*32	Returns the name of operating system the TQ-library was built for.
BUILD	Character*32	Returns the software revision version of the TQ-library.
CMPLER	Character*72	Returns the name and version of the compiler with which the TQ-library was built.

TQSET_GES_VERSION

GES6 is a re-write and new implementation of the Gibbs Energy System module of Thermo-Calc and it is the default engine in Thermo-Calc. As of 2026b, TQ-Interface has access to it but GES5 is the default. GES5 continues to be available and works in the background of the program where necessary. The main purpose of GES6 is to support faster development and access to new features, which are then often only available in GES6.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSET_GES_VERSION(VERSION)**	
C-interface	**tqset_ges_version(TC_INT version);**	
Full name:	Set GES version.	
Purpose:	Set the GES (Gibbs energy system) version.	
Comments:	Version can be either 5 (the default) or 6. Using this command with any other number than 5 or 6 will do nothing and keep the currently selected GES version. GES6 has additional physical quantities (e.g. bulk modulus, shear modulus, Young's modulus, etc.) available. Accessing these quantities requires the use of this subroutine to switch GES versions.	
Arguments		
Name	**Type**	**Value set on call or returned**
VERSION	Integer	Set GES version to selected.

System Data Manipulation Subroutines

Purpose	*Subroutine*
Identify components, phases and constituents	
Get number of system components	TQGNC
Set system components	TQSCOM
Get system components	TQGCOM
Get system component index	TQGSCI
Get number of phases	TQGNP
Get phase name	TQGPN
Get phase index	TQGPI
Get phase constituent name	TQGPCN
Get phase constituent index	TQGPCI
Get component chemical formula	TQGCCF
Get phase constituent stoichiometry	TQGPCS
Get number of phase constituents	TQGNPC
Change the status of components, phases, and component reference states	
Change status of system component	TQCSSC
Get status of system component	TQGSSC*
Change status of phase	TQCSP
Get status of phase	TQGSP*
Set reference state	TQSETR
Add a composition set to a phase	TQPACS

Purpose	*Subroutine*
	* Logical function
Contributions to the Gibbs energy of a phase	
Set Gibbs energy addition	TQSGA
Get Gibbs energy addition	TQGGA

Legal Component Status

Status	*Meaning*
ENTERED	The component is included in the system for an equilibrium calculation.
SUSPENDED	The component is excluded from the system and, as a result, some phases may become suspended if their constituents contain this component.
SPECIAL	The specified component(s) are not included in summations for mole or mass fractions. It only works for component(s).

Legal Phase Status

Status	*Meaning*
ENTERED	The phase is included in an equilibrium calculation. It may be stable or unstable.
DORMANT	The phase is included in an equilibrium calculation but not allowed to become stable. The phase should be stable if the calculation shows that its driving force is positive (or activity is larger than unity)
FIXED	The phase is included in an equilibrium calculation and it must be stable.
SUSPENDED	The phase is ignored in an equilibrium calculation.

TQGNC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGNC (NCOM, IWSG, IWSE)**	
C-interface	**tq_gnc(TC_INT* ncom, TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Get Number of Components.	
Purpose:	With this subroutine the application program can get numbers of components.	
Arguments		
Name	**Type**	**Value set on call or returned**
NCOM	Integer	Return the number of components.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSCOM

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSCOM(NCOM, NAMES, STOI, IWSG, IWSE)**	
C-interface	**tq_scom(TC_INT num,tc_components_strings* components,TC_FLOAT* stoi,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set System Component.	
Purpose:	A new set of system components can be defined. The new number of components must be the same as previously. The number of system components can be changed by suspending a component by TQCSSC.	

Comments:	• The set of components must be linearly independent.
	• The names of the new system components are given in NAMES.
	• STOI is a matrix with dimension STOI (1:NCOM,1:NCOM) which gives the stoichiometry of the new components expressed in the old ones.
	• The default set for components is taken from in the input thermodynamic data file.
	• Legal values for the array elements in NAMES are constituent names.
	• The components are numbered as 1 NCOM in the order they are supplied in this call. The conversion from component name to index is also done by TQGSCI.
	
	Example
	
	For example, to transform from the components A, B, C to `A2B`, `B4CC2` use the following values of STOI:
	
	`A2B 2.0 1.0 0.0`
	
	`B4C 0.0 4.0 1.0`
	
	`C2 0.0 0.0 2.0`	

Arguments		
Name	**Type**	**Value set on call or returned**
NCOM	Integer	Set to the number of components.
NAMES	Character*24 array	Set to component names.
STOI	Double precision matrix	Stoichiometry matrix in old

Fortran	**TQSCOM(NCOM, NAMES, STOI, IWSG, IWSE)**	
C-interface	**tq_scom(TC_INT num,tc_components_strings* components,TC_FLOAT* stoi,TC_INT* iwsg,TC_INT* iwse);**	
		components.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGCOM

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGCOM(NCOM, NAMES, IWSG, IWSE)**	
C-interface	**tq_gcom(TC_INT* num,tc_components_strings* components,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get System Component.	
Purpose:	Get components of a system	
Comments:	The number of components are returned in NCOM and their names are returned in NAMES. They are returned in an internal sequential order of the TQ-Interface. In other subroutines one must in some cases use the index of a component rather than the name. TQGSCI	
Arguments		
Name	**Type**	**Value set on call or returned**
NCOM	Integer	Return the current number of components.
NAMES	Character*24 array	Return the current names of components.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGSCI

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGSCI(INDEXC, NAME, IWSG, IWSE)**	
C-interface	**tq_gsci(TC_INT* index,TC_STRING component,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get System Component Index.	
Purpose:	Get index of a system component.	
Comments:	This is a way to translate from a name to an index. In order to translate from a component index to a name, use TQGCOM. The application program may call TQGCOM only once and maintain itself a list of component names stored by indices.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXC	Integer	Return the index of the component.
NAMES	Character*24	Set to a component name.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGNP

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGNP (NPH, IWSG, IWSE)**	
C-interface	**tq_gnp(TC_INT* nph,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Number of Phases.	
Purpose:	The application gets the numbers of phases.	
Comments:	The phases may have any status. They are numbered sequentially from 1 to NPH. Phases with miscibility gap and thus having more than one composition set are counted separately.	
Arguments		
Name	**Type**	**Value set on call or returned**
NPH	Integer	Return the number of phases.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGPN

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGPN (INDEXP, NAME, IWSG, IWSE)**	
C-interface	**tq_gpn(TC_INT index,TC_STRING phase,TC_STRING_LENGTH strlen_ phase,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Phase Name.	
Purpose:	With this subroutine the application program can convert a phase index to the name of the phase.	
Comments:	The conversion from phase name to phase index is done by TQGPI. Note that phases with miscibility gaps must appear with each possible composition set as a separate phase. These are named as BCC#1, BCC#2 etc.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to the index of a phase.
NAME	Character*24	Return the name of the phase.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGPI

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGPI (INDEXP, NAME, IWSG, IWSE)**	
C-interface	**tq_gpi(TC_INT* index,TC_STRING phase,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Phase Index.	
Purpose:	With this subroutine the application program can get the index of a named phase.	
Comments:	The conversion from phase index to phase name is done by TQGPN.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Return the index of a phase.
NAME	Character*24	Set to a phase name.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGPCN

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGPCN(INDEXP, INDEXC, NAME, IWSG, IWSE)**	
C-interface	**tq_gpcn(TC_INT indexp,TC_INT indexc,TC_STRING name,TC_STRING_LENGTH strlen_name,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Phase Constituent Name.	
Purpose:	With this subroutine the application program can get the name of an indexed constituent.	
Comments:	If the same species appear in more than one sublattice site of a phase, they are named as A#2, A#3, etc., which means A on the second sublattice and A on the third sublattice, etc. The opposite conversion is done by TQGPCI.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
INDEXC	Integer	Set to the constituent index.
NAME	Character*24	Return the constituent name.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGPCI

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGPCI(INDEXP, INDEXC, NAME, IWSG, IWSE)**	
C-interface	**tq_gpci(TC_INT indexp,TC_INT* indexc,TC_STRING name,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Phase Constituent Index.	
Purpose:	With this subroutine the application program can get the index of a constituent if its name is known.	
Comments:	The opposite conversion is done by TQGPCN.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
INDEXC	Integer	Return the constituent index.
NAME	Character*24	Set to the constituent name.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGCCF

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGCCF(INDEXC, NEL, ELNAM, STOI, MMASS, IWSG, IWSE)**	
C-interface	**tq_gccf(TC_INT indexc,TC_INT* nel,tc_elements_strings* elname,TC_FLOAT* stoi,TC_FLOAT* mmass,TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Get Component Chemical Formula.	
Purpose:	Get the stoichiometry array for a system component in terms of element.	
Comments:	Obtain the real elements in a component. All other subroutines just deal with a name that does not have to be related to the actual chemical formula. This is also the only subroutine that can provide the symbols of the actual elements in the system. The dimension of ELNAM and STOI is NEL (number of elements in the component).	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXC	Integer	Set to system a component index.
NEL	Integer	Number of elements in chemical formula.
ELNAM	Character*2 array	Element symbols.
STOI	Double precision array	Stoichiometry array.
MMASS	Double precision	Total mass.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGPCS

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGPCS (INDEXP, INDEXC, STOI, MMASS, IWSG, IWSE)**	
C-interface	**tq_gpcs(TC_INT indexp,TC_INT indexc,TC_FLOAT* stoi,TC_FLOAT* mmass,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Phase Constituent Stoichiometry.	
Purpose:	With this subroutine the application program can obtain the stoichiometry of a constituent expressed in the system components and also the molecular mass.	
Comments:	This does not give the chemical formula in terms of elements for the constituent. The dimension of STOI is NCOM (number of components) get by calling TQGCOM.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
INDEXC	Integer	Set to the constituent index.
STOI	Double precision array	Return the stoichiometry array.
MMASS	Double precision	Return the mass.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGNPC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGNPC(INDEXP, NPCON, IWSG, IWSE)**	
C-interface	**tq_gnpc(TC_INT indexp,TC_INT* npcon,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Number of Phase Constituent.	
Purpose:	With this subroutine the number of constituents in a phase can be obtained.	
Comments:	To have also the names, fractions etc. of the constituents, use TQGPD.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
NPCON	Integer	Return the number of the phase constituents.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQCSSC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQCSSC (INDEXC, STATUS, IWSG, IWSE)**	
C-interface	**tq_cssc(TC_INT index,TC_STRING status,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Change Status of System Component	
Purpose:	With this subroutine the application program can change status for a system component.	
Comments:	The legal values for STATUS are ENTERED, SUSPENDED and SPECIAL Legal Component Status By suspending a system component some phases may also become suspended if they contain this component. For example, in the system Fe-O-S if O is suspended all phases that must dissolve oxygen is automatically suspended. The fraction of oxygen is set to zero in phases that can dissolve oxygen but can also exist without oxygen.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXC	Integer	Set to a component index.
STATUS	Character*12	Set to the new status
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGSSC

This is a logical function.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**STATUS=TQGSSC (INDEXC, IWSG, IWSE)**	
C-interface	**status=tq_gssc(TC_INT index,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Status of System Component.	
Purpose:	This function returns TRUE if the system component is ENTERED or FALSE if it is SUSPENDED.	
Comments:	The legal values for STATUS are given in Legal Component Status.If the C-interface is used the value returned is of type: TC_BOOL.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXC	Integer	Set to a component index.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQCSP

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQCSP (INDEXP, STATUS, VAL, IWSG, IWSE)**	
C-interface	**tq_csp(TC_INT index,TC_STRING status,TC_FLOAT amount,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Change Status of Phase.	
Purpose:	Change status for a phase.	
Comments:	The legal values for STATUS are given in Legal Phase Status. For ENTERED phase, VAL is provided as a start value. It is normally set to zero if the phase is not likely to be stable and one if expected to be stable. Setting a phase SUSPENDED or DORMANT is a way to calculate a metastable equilibrium if the phase would be stable. With the DORMANT status one can know if it would be stable or not. For these two statuses, VAL is irrelevant and may be simply put to zero. For FIXED phase the exact amount of the phase must be given. Note that the amount is in number of mole formula units. Setting a phase FIXED decreases the degrees of freedom in the system by 1. To restore the lost degree of freedom the phase should be reset ENTERED. Set a FIXED phase to zero amount is the best way to get the phase stability limits like liquidus or solidus.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
STATUS	Character*12	Set to the status code
VAL	Double precision	Set to phase amount in number of mole formula units.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGSP

This is a logical function.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**STATUS=TQGSP (INDEXP, STATUS, VAL, IWSG, IWSE)**	
C-interface	**status=tq_gsp(TC_INT index,TC_STRING status,TC_STRING_LENGTH strlen_status,TC_FLOAT* amount,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Status of Phase.	
Purpose:	This function is TRUE if the phase is ENTERED or FIXED. If the phase is SUSPENDED or DORMANT it is FALSE. The status is also returned in STATUS. The application program can test the status of a phase by calling this function.	
Comments:	The legal values for STATUS are listed in Legal Phase Status. If the C-interface is used the value returned is of type: TC_BOOL.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
STATUS	Character*12	Return the current status code.
VAL	Double precision	Return the phase amount as mole formula units.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSETR

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSETR (INDEXC, INDEXP, TEMP, PRES, IWSG, IWSE)**	
C-interface	**tq_setr(TC_INT indexc,TC_INT indexp,TC_FLOAT temp,TC_FLOAT press,TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Set Reference State.	
Purpose:	Reset the reference state of a system component.	
Comments:	By default the reference state for a component is determined by the thermodynamic data file. With this subroutine an application may select a different reference state if the one in the data file does not suit a calculation purpose. If the current temperature or pressure should be used for the calculation, the value given should not be larger than zero.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXC	Integer	Set to a component index.
INDEXP	Integer	Set to a phase index.
TEMP	Double precision	Set to a temperature value.
PRES	Double precision	Set to a pressure value.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQPACS

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQPACS (INDEXP, IWSG, IWSE)**	
C-interface	**tq_pacs(TC_INT indexp,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Add composition set to phase.	
Purpose:	Add another composition set to a phase.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSGA

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSGA (INDEXP, VALUE, IWSG, IWSE)**	
C-interface	**tq_gga(TC_INT indexp,TC_FLOAT value,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Gibbs energy addition.	
Purpose:	Add an amount of extra contribution to the Gibbs energy of a phase	
Comments:	The extra contribution may be due to elastic strain energy, surface energy, etc.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
VALUE	Double precision	Set to the value of extra contribution (J/(mol formula unit)
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGGA

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGGA (INDEXP, VALUE, IWSG, IWSE)**	
C-interface	**tq_gga(TC_INT indexp,TC_FLOAT* value,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Gibbs energy addition.	
Purpose:	The contribution added to the Gibbs energy of a phase can be retrieved.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
VALUE	Double precision	Return the value of extra contribution (J/(mol formula unit).
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Condition, Stream and Segment Subroutines

A *stream* is considered as a non-reactive medium for transferring matter to a reaction zone. It has constant temperature and pressure, and contains one or more phases of a certain composition, i.e., for each stream, temperature, pressure, and input amounts of phase constituents must be defined. Different sets of equilibrium *conditions* can be defined for the same system in different *segments*.

Purpose	*Subroutine*
Set condition	TQSETC
Remove condition	TQREMC
Save current conditions	TQSCURC
Remove all conditions	TQREMAC
Restore saved conditions	TQRESTC
Create stream	TQCSTM
Set stream constituent amount	TQSSC
Set stream invariant state variable	TQSSIC
Delete stream	TQDSTM
Create new equilibrium segment	TQNSEG
Select equilibrium segment	TQSSEG

Possible State Variables to Set Conditions in TQSETC

STAVAR	*INDEXP*	*INDEXC*	*Meaning*	*Comments*
T			Temperature	of the whole system
P			Pressure	of the whole system
MU	note[1]	Yes	Chemical potential	of a system component
MUC	Yes	Yes	Chemical potential	of a phase constituent
AC	note[1]	Yes	Activity	of a system component
ACC	Yes	Yes	Activity	of a phase constituent
V			Volume	of the whole system
G			Gibbs energy	of the whole system
H			Enthalpy	of the whole system
S			Entropy	of the whole system
N			Moles	of all system components
N		Yes	Moles	of a system component
NP	note[2]		Moles	of a phase
M			Total mass	of all system components
M		Yes	Mass	of a system component
BP	note[2]		Mass	of a phase

STAVAR	*INDEXP*	*INDEXC*	*Meaning*	*Comments*
IN	Yes	Yes	Input amount	in moles of phase constituents
IM	Yes	Yes	Input amount	in mass units of phase constituents
X		Yes	Mole fraction	of a system component
W		Yes	Mass (Weight) fraction	of a system component
X%		Yes	Mole percent	of a system component
W%		Yes	Mass (Weight) fraction	of a system component

1. Giving a phase index means to define the reference state. If no phase index is given the previous reference state is used. The default reference state is SER (Standard Element Reference) if the thermodynamic data file is created from a SGTE (Scientific Group Thermodata Europe) database. It is necessary that the phase can exist with the constituent as its single constituent. It is an error to set FCC as reference state for carbon if carbon dissolves interstitially in FCC.

2. Not recommended to be used for setting conditions. To calculate stability limit one should use TQCSP with FIXED status and amount of the phase set to zero.

TQSETC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSETC(STAVAR, INDEXP, INDEXC, VAL, NUMCON, IWSG, IWSE)**	
C-interface	**tq_setc(TC_STRING condition,TC_INT indexp,TC_INT indexc,TC_FLOAT val,TC_INT* numcon,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Condition.	
Purpose:	To set conditions for an equilibrium calculation.	
Comments:	In STAVAR the mnemonic of the state variable must be given, see Possible State Variables to Set Conditions in TQSETC. In some cases just the mnemonic is needed, like for temperature or pressure, but in many cases a phase index or a component index must be used to specify the condition. If both a phase index and a constituent index is supplied the condition is set for the specified constituent in the specified phase. The application program must set exactly the same number of conditions as degrees of freedom in the defined system. The degrees of freedom are equal to the number of system components plus two (usually temperature and pressure). Setting a phase FIXED using TQCSP decrease the degrees of freedom in the system by 1. Resetting the phase ENTERED using TQCSP restores one degree of freedom. Possible combinations of STAVAR and indices are listed in Possible State Variables to Set Conditions in TQSETC. Here it is shown that the same value of STAVAR may be used with or without an index. In the case there should not be an index, the value of INDEXP or INDEXC must be negative. Some combination of conditions may be thermodynamically impossible. The TQ-Interface provides relevant help for such cases.	
Arguments		
Name	**Type**	**Value set on call or returned**
STAVAR	Character*8	Set as a state variable
INDEXP	Integer	Set as a phase index (if needed).
INDEXC	Integer	Set as a component or constituent index (if needed).
VAL	Double precision	Set to the value.
NUMCON	Integer	Returned as an identification of the

Fortran	**TQSETC(STAVAR, INDEXP, INDEXC, VAL, NUMCON, IWSG, IWSE)**	
C-interface	**tq_setc(TC_STRING condition,TC_INT indexp,TC_INT indexc,TC_FLOAT val,TC_INT* numcon,TC_INT* iwsg,TC_INT* iwse);**	
		condition.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Examples of TQSETC

Set the temperature to 800 Celsius

```
CALL TQSSU('Temperature','C',IWSG,IWSE)
CALL TQSETC('T',-1,-1,800.0D0,NCOND,IWSG,IWSE)
```

```
Set the incoming amount of a liquid phase constituent named Al2O3 to 1.5 moles
CALL TQGPI(INDEXP,'LIQUID',IWSG,IWSE)
CALL TQGPCI(INDEXP,INDEXC,'AL2O3',IWSG,IWSE)
CALL TQSETC('IN',INDEXP,INDEXC,1.5D0,NCOND,IWSG,IWSE)
```

Set the mass percent of the system component Cr to 13%.

```
CALL TQGSCI(INDEX,'cr',IWSG,IWSE)
CALL TQSETC('W%',-1,INDEX,13.0D0,NCOND,IWSG,IWSE)
```

Set the total amount of system to 1.0 mole components

```
CALL TQSETC('N',-1,-1,1.0D0,NCOND,IWSG,IWSE)
```

Set the mole fraction of H2O in GAS to 5 mol percent

```
CALL TQGPI(INDEXP,'GAS',IWSG,IWSE)
CALL TQGPCI(INDEXP,INDEXC,'H2O1',IWSG,IWSE)
CALL TQSETC('X',INDEXP,INDEXC,0.05D0,NCOND,IWSG,IWSE)
```

TQREMC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQREMC(NUMCON, IWSG, IWSE)**	
C-interface	**tq_remc(TC_INT numcon,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Remove Condition.	
Purpose:	Remove the condition numbered NUMCON.	
Comments:	TQSETC and TQCSTM return an index for each condition set. This value must be supplied in this call. In order to change a condition to something else, not just a new value, one must first remove the condition. If one just wants to change the value of a condition one may call TQSETC again instead.	
Arguments		
Name	**Type**	**Value set on call or returned**
NUMCON	Integer	Set to a condition number.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSCURC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSCURC(IWSG, IWSE)**	
C-interface	**tq_scurc(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Save Current Conditions.	
Purpose:	Save all conditions in case they need to be restored.	
Comments:	The saved conditions can be restored if necessary by using TQRESTC.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQREMAC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQREMAC(IWSG, IWSE)**	
C-interface	**tq_remac(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Remove All Conditions.	
Purpose:	TQREMAC provides the easiest way to remove all conditions. After calling TQREMAC, one can set completely new or restore previously saved conditions.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQRESTC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQRESTC(IWSG, IWSE)**	
C-interface	**tq_restc(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Restore Condition.	
Purpose:	Restore saved conditions.	
Comments:	Before calling TQRESTC, remove all present conditions.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQCSTM

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQCSTM(IDENT, TEMP, PRESS, IWSG, IWSE)**	
C-interface	**tq_cstm(TC_STRING stream,TC_FLOAT temp,TC_FLOAT press,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Create Stream	
Purpose:	To set the system conditions by stream input. Stream calculations are useful when calculating differences between an initial state and a final state. The streams define the initial state of the system components by specifying reactants of different phases at given temperatures and pressures.	
Comments:	A stream is a non-reacting media for transferring matter to a reaction zone. A stream may contain several phases at the same given temperature and pressure. Phases with different temperatures and pressures should be grouped into different streams. Several streams can be transferred to a reaction zone. The input constituents of each phase do not react in a stream.	
Arguments		
Name	**Type**	**Value set on call or returned**
IDENT	Character*24	Set as identifier of the stream.
TEMP	Double precision	Input temperature of stream.
PRESS	Double precision	Input pressure of stream.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSSC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSSC(IDENT, INDEXP, INDEXC, VALUE, NUMIN, IWSG, IWSE)**	
C-interface	**tq_ssc(TC_STRING stream,TC_INT iph,TC_INT icmp,TC_FLOAT value,TC_INT icond,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Stream Constituent Amount.	
Purpose:	Set the amount of phase constituent in a stream.	
Comments:	The last one takes effect if the amount of the same phase constituent have been set several times, i.e., the amount cannot be set additively.	
Arguments		
Name	**Type**	**Value set on call or returned**
IDENT	Character*24	Set as identifier of the stream.
INDEXP	Integer	Set as a phase index
INDEXC	Integer	Set as a constituent index.
VALUE	Double precision	Set to an amount of the constituent INDEXC in the stream.
NUMIN	Integer	Returned as identification of the input constituent in the stream.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSSIC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSSIC(STAVAR, VALUE, IWSG, IWSE)**	
C-interface	**tq_ssic(TC_STRING stavar,TC_FLOAT value,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Stream Invariant State Variable.	
Purpose:	To specify the invariant state variable for calculating the reaction of all streams.	
Comments:	The state variables that could be used are G, H, S, and V with a suffix D, which means difference between initial and final states of the reaction.	
Arguments		
Name	**Type**	**Value set on call or returned**
STAVAR	Character*8	Set as the mnemonic of a state variable.
VALUE	Double precision	Set to change in value of STAVAR.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Examples of TQSSIC

Calculation of adiabatic temperature for knallgas.

```
DIMENSION TPA(2)
C...set input temperature and pressure
TEMP=298.15D0
PRES=1.0D5
C...create the stream
CALL TQCSTM('knallgas',TEMP,PRES,IWSG,IWSE)
C...set amount of H2 and O2 in the stream
CALL TQGPCI(1,INDEXC,'H2',IWSG,IWSE)
```

```
CALL TQSSC('knallgas',1,INDEXC,2.0D0,NUMIN,IWSG,IWSE)
CALL TQGPCI(1,INDEXC,'O2',IWSG,IWSE)
CALL TQSSC('knallgas',1,INDEXC,1.0D0,NUMIN,IWSG,IWSE)
C...set the global temperature and pressure for the reaction
CALL TQSETC('T',-1,-1,500.0D+0,NUMC,IWSG,IWSE)
CALL TQSETC('P',-1,-1,PRES,NUMC,IWSG,IWSE)
C...get the enthalpy of reaction
CALL TQCE(' ',-1,-1,0.0D+0,IWSG,IWSE)
CALL TQGETV1('HD',-1,-1,ENT,IWSG,IWSE)
WRITE(*,*)'Calculated enthalpy of reaction are '
&, ENT, ' at 500 K. '
C...set that the enthalpy shall be constant in the calculation
CALL TQSSIC('HD',0.0D0,IWSG,IWSE)
C...calculate
CALL TQCE('T',-1,-1,1.0D+0,IWSG,IWSE)
C...get temperature
CALL TQGETV1('T',-1,-1,TEMP,IWSG,IWSE)
WRITE(*,*)'Calculated temperature ',TEMP
```

TQDSTM

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQDSTM(IDENT, IWSG, IWSE)**	
C-interface	**tq_dstm(TC_STRING stream, TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Delete Stream.	
Purpose:	Delete all or one stream.	
Comments:	Use an empty string as IDENT removes all the streams entered.	
Arguments		
Name	**Type**	**Value set on call or returned**
IDENT	Character*24	Set as identifier of the stream.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQNSEG

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQNSEG(ID, IWSG, IWSE)**	
C-interface	**tq_nseg(TC_STRING id, TC_INT* iwsg,TC_INT* iwse);**	
Full name:	New Equilibrium Segment.	
Purpose:	With this subroutine the application program can create a new equilibrium description with the same thermodynamic data. This subroutine is useful when simulating several equilibria representing local conditions, for example, in the reactor simulator.	
Comments:	TQNSEG does not read any thermodynamic file. This must have already been done with TQRFIL. Note that when several segments are used, an equilibrium should be computed when a segment is selected before any data is retrieved.	
Arguments		
Name	**Type**	**Value set on call or returned**
ID	Character*24	Set as identifier of the equilibrium segment.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSSEG

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSSEG(ID, IWSG, IWSE)**	
C-interface	**tq_sseg(TC_STRING id, TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Select Equilibrium.	
Purpose:	When the application program has created several equilibrium segments using TQNSEG, this subroutine makes it possible to select a current equilibria which the subroutine calls refer to.	
Comments:	When several segments are used, and before any data is retrieved, an equilibrium should be computed when a segment is selected.	
Arguments		
Name	**Type**	**Value set on call or returned**
ID	Character*24	Set to an equilibrium identification.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Calculations and Results Subroutines

Purpose	*Subroutine*
Calculate equilibrium	TQCE
Calculate global equilibrium	TQCEG
Get equilibrium property values (TQGET) and Get one value (TQGET1)	TQGETV and TQGET1
Get chemical potential value. It is a double precision function.	TQGMU
Get molar Gibbs energy value. It is a double precision function.	TQGGM
Get phase data	TQGPD
Get driving force and local equilibrium compositions for ortho- or para-equilibrium phase transformation	TQGDF2
Get interfacial energy between a matrix phase and a precipitate phase	TQGSE

State Variables Available for TQGETV and TQGET1

There are several state and other variables available for TQGETV and TQGET1.

State Variables for TQGETV and TQGET1

STAVAR	*INDEXP*	*INDEXC*	*Meaning*	*Comments*
T			Temperature	of the whole system
P			Pressure	of the whole system
MU	(yes)	Yes	Chemical potential	of a system component
MUC	Yes	yes	Chemical potential	of a constituent in a gas phase
AC	(yes)	Yes	Activity	of a system component
ACC	Yes	Yes	Activity	of a constituent in a gas phase
QF	Yes		Phase stability function	Negative when phase composition is inside a spinodal, otherwise positive. Can be used to find out if an equilibrium is within the miscibility gap for a solution phase. Cannot be used as a condition.
V			Volume	of the whole system
V	Yes		Volume	of a phase
G^1			Gibbs energy	of the whole system
G^1	Yes		Gibbs energy	of a phase
H^1			Enthalpy	of the whole system
H^1	Yes		Enthalpy	of a phase
S^1			Entropy	of the whole system

STAVAR	*INDEXP*	*INDEXC*	*Meaning*	*Comments*
S^1	Yes		Entropy	of a phase
CP			Heat capacity	of the system
CP	Yes		Heat capacity	of a phase
DG	Yes		Driving force	of a phase
N			Moles	of all system components
N		Yes	Moles	of a system component
NP	Yes		Moles	of a system phase
M			Total mass	of all system components
M		Yes	Mass	of a system component
BP	Yes		Mass	of a system phase
IN	Yes	Yes	Input amount	in moles of phase constituents
IM	Yes	Yes	Input amount	in mass units of phase constituents
X		Yes	Mole fraction	of a component in the whole system
X	Yes	Yes	Mole fraction	of a component in a phase
W		Yes	Mass (Weight) fraction	of a component in the whole system
W	Yes	Yes	Mass (Weight) fraction	of a component in a phase
X%		Yes	Mole percent	of a component in the whole system
X%	Yes	Yes	Mole percent	of a component in a phase
W%		Yes	Mass (Weight) fraction	of a component in the whole system
W%	Yes	Yes	Mass (Weight) fraction	of a component in a phase

STAVAR	*INDEXP*	*INDEXC*	*Meaning*	*Comments*
Y	Yes	Yes	Constituent fraction	of a phase constituent
BULKMOD[2]	Yes		Bulk modulus	of a phase
SHEARMOD[2]	Yes		Shear modulus	of a phase
YOUNGMOD[2]	Yes		Young's modulus	of a phase
Cij[2,3]	Yes		Elastic constant	of a phase
DVIS	Yes		Dynamic viscosity	of a liquid phase
KVIS	Yes		Kinematic viscosity	of a liquid phase
ELCD			Electric conductivity	of the system
ELCD	Yes		Electric conductivity	of a phase
ELRS			Electric resistivity	of the system
ELRS	Yes		Electric resistivity	of a phase
THCD			Thermal conductivity	of a system
THCD	Yes		Thermal conductivity	of a phase
THRS			Thermal resistivity	of the system
THRS	Yes		Thermal resistivity	of a phase
THDF			Thermal diffusivity	of the system
THDF	Yes		Thermal diffusivity	of a phase

STAVAR	*INDEXP*	*INDEXC*	*Meaning*	*Comments*
SURF[2]	Yes		Surface tension	of a liquid phase

1. You can add a normalizing suffix like M (per mole), W (per mass) or V (per volume) on G, H, S, etc. R can also be added as a suffix on G, H, S to get a value that is calculated with respect to the reference state specified by calling TQSETR.
2. Only available in GES6.
3. Valid names are C11, C12, C13, C33, and C44,

Additional Variables for TQGETV and TQGET1

STAVAR	*Meaning*	*Unit*
M(phase,J)	Mobility coefficient where J=diffusing species	$m^2 mol\ J^{-1}\ s^{-1}$
LOGM(phase,J)	10log of the mobility coefficient	log10 ($m^2 mol\ J^{-1} s^{-1}$)
DT(phase,J)	Tracer diffusion coefficient where J=diffusing species	m^2/s
LOGDT(phase,J)	10log of the tracer diffusion coefficient	log10 ($m^2 s^{-1}$)
DC(phase,J,K,N)	Chemical diffusion coefficient where K=gradient species, and N=reference species	m^2/s
LOGDC(phase,J,K,N)	10log of the chemical diffusion coefficient	log10 ($m^2 s^{-1}$)
DI(phase,J,K,N)	Intrinsic diffusion coefficient	m^2/s
LOGDI(phase,J,K,N)	10log of the intrinsic diffusion coefficient	m^2/s

TQCE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQCE(TARGET, INDEXP, INDEXC, VALUE, IWSG, IWSE)**	
C-interface	**tq_ce(TC_STRING var,TC_INT indexp,TC_INT indexc,TC_FLOAT value,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Calculate Equilibrium.	
Purpose:	Calculate the equilibrium with current settings of conditions or streams.	
Comments:	Some software needs a TARGET specified for certain types of calculations. A TARGET is a state variable as specified in TQSETC. When working with Thermo-Calc, it is only useful in stream reaction calculations, where an initial guess of the target variable may be of some help. Otherwise, TARGET is normally set as an empty string and the values of INDEXP, INDEXC, and VALUE are irrelevant.	
Arguments		
Name	**Type**	**Value set on call or returned**
TARGET	Character*8	Set to a state variable, if necessary.
INDEXP	Integer	Set to a phase index, if necessary.
INDEXC	Integer	Set to a component index, if necessary.
VALUE	Double precision	Set to an estimate of the target variable.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Example of TQCE

Calculate enthalpy for an equilibrium gas mixture SO3, SO2 and O2. Input SO3 2%, O2 10% and 88% SO2.

```
CALL TQGPI('GAS',INDEXP,IWSG,IWSE)
C...set temperature, pressure and total amount of moles
CALL TQSETC('T',-1,-1,800.0D0,NCOND,IWSG,IWSE)
```

```
CALL TQSETC('P',-1,-1,1.0D5,NCOND,IWSG,IWSE)
CALL TQSETC('N',-1,-1,1.0D0,NCOND,IWSG,IWSE)
C...set mole fraction of SO3 and O2
CALL TQGPI(INDEXP,'GAS',IWSG,IWSE)
CALL TQGPCI(INDEXP,INDEXC,'SO2',IWSG,IWSE)
CALL TQSETC('IN',INDEXP,INDEXC,8.8D-1,NCOND,IWSG,IWSE)
CALL TQGPCI(INDEXP,INDEXC,'O2',IWSG,IWSE)
CALL TQSETC('IN',INDEXP,INDEXC,1.0D-1,NCOND,IWSG,IWSE)
CALL TQGPCI(INDEXP,INDEXC,'SO3',IWSG,IWSE)
CALL TQSETC('IN',INDEXP,INDEXC,2.0D-2,NCOND,IWSG,IWSE)
CALL TQCE(' ',0,0,0.0D+0,IWSG,IWSE)
CALL TQGETV1('H',-1,-1,ENT,IWSG,IWSE)
```

In this way an application program can calculate the incoming enthalpy into the system. If there is more than one incoming flow it can calculate the enthalpies for each flow and sum them up.

TQCEG

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQCEG(IWSG, IWSE)**	
C-interface	**tq_ceg(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Calculate Equilibrium Global.	
Purpose:	Calculate Equilibrium using Global Minimization Algorithm.	
Comments:	The use of global minimization algorithm is meant to avoid metastable or unstable equilibrium and to obtain truly stable equilibrium. This is mainly due to its ability to find automatically miscibility gap and create accordingly new composition sets. As a consequence, the number of phases may increase after calling TQCEG. The newly added phases (new composition sets of old phases) are always put in the end of the phase list. In this way, the indexes of old phases remain the same as before See Example 13. The global minimization technique starts with discretizing the composition space and calculating Gibbs energy values at each grid point for each phase at a given temperature. This usually leads to a significant increase of computation time. Therefore, it is not recommended to use TQCEG in time-critical application programs. In the cases where phases involved are well known, for example, identifying the local equilibrium at a phase interface, it is absolutely not necessary to use TQCEG. If TQCEG is needed, irrelevant phases should better be rejected in the beginning when fetching thermodynamic data from a database.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGETV and TQGET1

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGETV(STAVAR, INDEXP, INDEXC, NUMBER, VALAR, IWSG, IWSE)** **TQGET1(STAVAR, INDEXP, INDEXC, VAL, IWSG, IWSE)**
C-interface	**tq_getv(TC_STRING stavar,TC_INT indexp,TC_INT indexc,TC_INT number,TC_FLOAT* valar,TC_INT* iwsg,TC_INT* iwse);** **tq_get1(TC_STRING stavar,TC_INT indexp,TC_INT indexc,TC_FLOAT* val,TC_INT* iwsg,TC_INT* iwse);**
Full name:	Get Values. With TQGETV an array of values can be returned; with TQGET1 a single value only.
Purpose:	These subroutines return the value of any variable in the system after an equilibrium calculation, for example, thermodynamic properties for phases and constituents, temperature, pressure and volume of the system, and amount of the system, a phase or a constituent.
Comments:	If an equilibrium is not established, the error code is set on return. Go to State Variables Available for TQGETV and TQGET1 for obtaining values. Valid INDEXC or INDEXP has a positive value. Setting INDEXC or INDEXP to -1 means it is not relevant. Using 0 for INDEXC or INDEXP in TQGETV means all components or all phases, respectively.

Arguments

Name	Type	Value set on call or returned
STAVAR	Character*32	Set to mnemonic of state variable
INDEXP	Integer	Set to a phase index
INDEXC	Integer	Set to a component or constituent index
NUMBER	Integer	Set to the number of values in VALAR.
VALAR	Double precision array	Return the values

Fortran	**TQGETV(STAVAR, INDEXP, INDEXC, NUMBER, VALAR, IWSG, IWSE)** **TQGET1(STAVAR, INDEXP, INDEXC, VAL, IWSG, IWSE)**	
C-interface	**tq_getv(TC_STRING stavar,TC_INT indexp,TC_INT indexc,TC_INT number,TC_FLOAT* valar,TC_INT* iwsg,TC_INT* iwse);** **tq_get1(TC_STRING stavar,TC_INT indexp,TC_INT indexc,TC_FLOAT* val,TC_INT* iwsg,TC_INT* iwse);**	
VAL	Double precision	Return the value
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Examples of TQGETV and TQGET1

Get temperature of the system

```
CALL TQGET1('T',-1,-1,VAL,IWSG,IWSE)
```

Get overall mole fraction of system component Cr

```
CALL TQGSCI(INDEXC,'CR',IWSG,IWSE)
CALL TQGET1('X',-1,INDEXC,VAL,IWSG,IWSE)
```

Get overall mole fractions of all components

```
CALL TQGETV('x',-1,0,NCOM,VALAR,IWSG,IWSE)
```

Get activity of system component SiC

```
CALL TQGSCI(INDEXC,'sic',IWSG,IWSE)
CALL TQGET1('AC',-1,INDEXC,VAL,IWSG,IWSE)
```

Get activity of gas phase constituent SiC (gas is phase 1)

```
CALL TQGPCI(1,INDEXC,'sic',IWSG,IWSE)
CALL TQGET1('AC',1,INDEXC,VAL,IWSG,IWSE)
```

Get total mass of system

```
CALL TQGET1('M',-1,-1,VAL,IWSG,IWSE)
CALL TQGET1('M',0,0,VAL,IWSG,IWSE)
```

Get total mass of liquid phase

```
CALL TQGPI(INDEXP,'LIQUID',IWSG,IWSE)
```

or

```
CALL TQGET1('BP',INDEXP,-1,VAL,IWSG,IWSE)
```

Get mass of all constituents of liquid phase

```
CALL TQGPI(INDEXP,'LIQUID',IWSG,IWSE)
CALL TQGETV('IM',INDEXP,0,NVAL,VALAR,IWSG,IWSE)
```

Get mass of SIC in liquid phase

```
CALL TQGPI(INDEXP,'LIQUID',IWSG,IWSE)
CALL TQGPCI(INDEXP,INDEXC,'sic',IWSG,IWSE)
CALL TQGET1('IM',INDEXP,INDEXC,VAL,IWSG,IWSE)
```

Get volume of GAS phase

```
CALL TQGET1('V',1,-1,VAL,IWSG,IWSE)
```

Get constituent mole fraction of H2O in GAS

```
CALL TQGPCI(1,INDEXC,'h2o',IWSG,IWSE)
CALL TQGET1('y',1,INDEXC,VAL,IWSG,IWSE)
```

Get partial pressure of H2O in GAS (equal to the total pressure times the constituent mole fraction)

```
CALL TQGPCI(1,INDEXC,'h2o',IWSG,IWSE)
CALL TQGET1('y',1,INDEXC,VAL,IWSG,IWSE)
CALL TQGET1('p',-1,-1,PVAL,IWSG,IWSE)
PH2O = PVAL*VAL
```

Get chemical potentials of all constituents in slag

```
CALL TQGPI(INDEXP,'slag',IWSG,IWSE)
CALL TQGETV('MUC',INDEXP,0,NCON,VALAR,IWSG,IWSE)
```

Get the derivative X(LIQUID,CR).X(FE). Where the indices describe the property before the "dot".

```
CALL TQGPI(INDEXP,'LIQUID',IWSG,IWSE)
CALL TQGSCI(INDEXC,'CR',IWSG,IWSE)
CALL TQGET1('X.X(FE)',INDEXP,INDEXC,VAL,IWSG,IWSE)
```

TQGMU

This is a double precision function.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGMU (INDEXC, IWSG, IWSE)**	
C-interface	**tq_gmu(TC_INT indexc, TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Get Chemical Potential.	
Purpose:	This function returns the chemical potential of a component in a faster way.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXC	Integer	Set to a component index
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGGM

This is a double precision function.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGGM (INDEXP, IWSG, IWSE)**	
C-interface	**tq_ggm(TC_INT indexp, TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Get Molar Gibbs Energy.	
Purpose:	This function returns the molar Gibbs energy of a phase more quickly.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGPD

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGPD (INDEXP, NSUB, NSCON, SITES, YFRAC, EXTRA, IWSG, IWSE)**	
C-interface	**tq_gpd(TC_INT indexp,TC_INT* nsub,TC_INT* nscon,TC_FLOAT* sites,TC_FLOAT* yfrac,TC_FLOAT* extra,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Phase Data.	
Purpose:	The application program can get data for the constituents of a phase.	
Comments:	With this subroutine the application program can determine the structure of the phase and the fraction of the constituents and other things. Note that YFRAC is constituent fraction, not mole fractions.A substitutional phase has NSUB equal to 1, which is identical to no sublattice. That is true for the gas phase too. The maximum number of sublattices are 10. The constituents of a phase are numbered sequentially from 1 for the first constituent on the first sublattice, to NPCON (See TQGNPC) for the last constituent on the last sublattice. NSCON (L) is the number of constituents on sublattice L. The sum of NSCON over all sublattices is equal to NPCON. Note that constituents that are DORMANT and SUSPENDED still are counted in NPCON and NSCON. They also have a fraction in YFRAC (which must be zero of course). EXTRA may contain extra information about the phase, total mass for example. These are yet to be defined.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index
NSUB	Integer	Return the number of sublattices.
NSCON	Integer array	Return the number of constituents on each sublattice.
SITES	Double precision array	Return the number of sites on each sublattice.
YFRAC	Double precision array	Return the fractions of the constituents.
EXTRA	Double precision array	Return some special values (see Comments)

Fortran	**TQGPD (INDEXP, NSUB, NSCON, SITES, YFRAC, EXTRA, IWSG, IWSE)**	
C-interface	**tq_gpd(TC_INT indexp,TC_INT* nsub,TC_INT* nscon,TC_FLOAT* sites,TC_FLOAT* yfrac,TC_FLOAT* extra,TC_INT* iwsg,TC_INT* iwse);**	
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Examples of TQGPD

To list the constituent names and fractions by sublattices. It is assumed that there are max 10 sublattices and max 500 constituents on all sublattices altogether.

```
DIMENSION NSCON(10),SITES(10),YFRAC(500),EXTRA(5)

TQGDF2

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGDF2 (MODE, IMATR, IPREC, NIE, IIE, XMATR, TEMP, DF, XPREC, XEM, XEP, MUI, IWSG, IWSE)**	
C-interface	**tq_gdf2(TC_INT mode,TC_INT imatr,TC_INT iprec,TC_INT nie,TC_INT *iie,TC_FLOAT* xmatr,TC_FLOAT temp,TC_FLOAT* df,TC_FLOAT* xprec,TC_FLOAT* xem,TC_FLOAT* xep,TC_FLOAT* mui,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get the driving force of nucleation and local equilibrium concentration for a phase transformation under para- or ortho-equilibrium condition.	
Purpose:	Obtain data on both the chemical driving force for the nucleation of a precipitate and the local equilibrium concentration at the matrix/precipitate interface under para- or ortho-equilibrium conditions. See Example 11.	
Comments:	For ortho-equilibrium calculations, XPREC can be inputs or outputs, depending on whether its values are known before the calculation or not. If unknown, the values of XPREC should be set to zero or negative when calling this subroutine and on return one obtains the composition of the precipitate at which the maximum driving force is available. The use of this subroutine for the ortho-equilibrium calculation supersedes that of the obsolete subroutine TQGDF.	
Arguments		
Name	**Type**	**Value set on call or returned**
MODE	Integer	Set type of output and type of composition to use (±1, ±2, and ±3 correspond to mole fraction, weight fraction and U-fraction respectively. However, ±3 can be used only with para-equilibrium calculations. If negative, calculate and output only driving force data. This saves the time for equilibrium calculation when you are not interested in local equilibrium concentrations)
IMATR	Integer	Set index of matrix phase
IPREC	Integer	Set index of precipitate phase
NIE	Integer	Set number of interstitial element(s). Zero implies no para-equilibrium calculation

Fortran	**TQGDF2 (MODE, IMATR, IPREC, NIE, IIE, XMATR, TEMP, DF, XPREC, XEM, XEP, MUI, IWSG, IWSE)**	
C-interface	**tq_gdf2(TC_INT mode,TC_INT imatr,TC_INT iprec,TC_INT nie,TC_INT *iie,TC_FLOAT* xmatr,TC_FLOAT temp,TC_FLOAT* df,TC_FLOAT* xprec,TC_FLOAT* xem,TC_FLOAT* xep,TC_FLOAT* mui,TC_INT* iwsg,TC_INT* iwse);**	
IIE	Integer array	Set index of interstitial element(s), only relevant for para-equilibrium condition
XMATR	Double precision array	Set composition of matrix phase. Composition type depends on MODE
TEMP	Double precision	Set temperature in Kelvin
DF	Double precision	Return driving force in J/mol of atoms if MODE = ±1, ±2 and J/mole of substitional atoms if MODE = ±3
XPREC	Double precision array	Return composition of the precipitate phase at the maximum driving force under para/ ortho-equilibrium condition or set to a known composition of the precipitate in order to get the driving force of phase transformation. Composition type depends on MODE
XEM	Double precision array	Return, if both MODE and DF are positive, local equilibrium composition of matrix phase. Composition type depends on MODE
XEP	Double precision array	Return, if both MODE and DF positive, local equilibrium composition of precipitate phase. Composition type depends on MODE
MUI	Double precision array	Return, if both MODE and DF are positive, chemical potential of interstitial elements. Relevant for only para-equilibrium calculation.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGSE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGSE (IMATR, IPREC, IMC,TEMP, U, VOLM,VOLP, IWSG, IWSE)**
C-interface	**tq_gse (TC_INT imatr,TC_INT iprec,TC_INT imc,TC_FLOAT temp,TC_ FLOAT* u,TC_FLOAT volm,TC_FLOAT volp,TC_INT* iwsg,TC_INT* iwse);**
Full name:	Get interfacial energy between a matrix phase and a precipitate phase.
Purpose:	With this subroutine the application program can estimate the interfacial energy between a matrix phase and a precipitate phase using thermodynamic data from a CALPHAD database. The approximation model is based on Becker's bond energy approach is available as the *Interfacial Energy* model included with the Property Model Calculator and Precipitation Module (TC-PRISMA). For systems with interstitial elements note the following: • The composition array must contain so-called *u-fractions*. Search for "u-fraction variable" in this PDF or press F1 to search the help. • The molar volumes of the matrix and precipitate should be with respect to substitutional elements. This can be achieved by first setting the component status to 'SPECIAL' for the interstitial elements with TQCSSC, and then retrieve the correct molar volume with TQGET1('VM',...). An equilibrium calculation is not required prior to using this function.

Arguments

Name	Type	Value set on call or returned
IMATR	Integer	Set index of matrix phase
IPREC	Integer	Set index of precipitate phase
IMC	Integer	Set index of major component
TEMP	Double precision	Set temperature in Kelvin
U	Double precision array	Set overall alloy composition in u-fraction

Fortran	**TQGSE (IMATR, IPREC, IMC,TEMP, U, VOLM,VOLP, IWSG, IWSE)**	
C-interface	**tq_gse (TC_INT imatr,TC_INT iprec,TC_INT imc,TC_FLOAT temp,TC_ FLOAT* u,TC_FLOAT volm,TC_FLOAT volp,TC_INT* iwsg,TC_INT* iwse);**	
VOLM	Double precision	Set molar volume of matrix phase with respect to substitutional elements
VOLP	Double precision	Set molar volume of precipitate phase with respect to substitutional elements
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace
Return Value		
TQGSE	Double precision	The interfacial energy in J/m^2

Miscellaneous Subroutines

Purpose	*Subroutine*

TQLS

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQLS(IWSG, IWSE)**	
C-interface	**tq_ls(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	List Status.	
Purpose:	Listing status of all components, phases, and species in a system.	
Comments:	If necessary, use this subroutine to check if the status of all components, phases, and species has been correctly set in an application program. It should only be used for debugging purpose.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQLC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQLC(IWSG, IWSE)**	
C-interface	**tq_lc(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	List Conditions.	
Purpose:	Listing conditions set for the current equilibrium calculation.	
Comments:	If necessary, use this subroutine to check if the conditions for an equilibrium calculation in the application program has been correctly set. It should only be used for debugging purpose.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQLE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQLE(IWSG, IWSE)**	
C-interface	**tq_le(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	List Equilibrium.	
Purpose:	Listing results from the most recent equilibrium calculation. The output depends on the package used and the listing displays on the current output unit.	
Comments:	If necessary, use this subroutine to check if an equilibrium calculation is successful. It should only be used for debugging purpose.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQFASV

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQFASV(IWSG, IWSE)**	
C-interface	**tq_fasv(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Force Automatic Start Value.	
Purpose:	To force automatic start-values for all phases in a single equilibrium calculation.	
Comments:	This is not required unless the calculation fails.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQKEEP_CS_NUMBERS

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQKEEP_CS_NUMBERS(IWSE, KEEP)**	
C-interface	**tq_keep_cs_numbers(TC_INT* iwse, TC_BOOL* keep);**	
Full name:	Keep Composition Set Numbers.	
Purpose:	To prevent composition set ID-numbers from switching between consecutive equilibrium calculations.	
Comments:	This subroutine turns on/off the functionality to keep the composition set numbers from the previous equilibrium calculations. By default the setting is off. Once turned on, it affects all subsequent equilibrium calculations until explicitly turned off again.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSE	Integer array	Workspace
KEEP	Logical	TRUE will turn the functionality on, FALSE off

TQSDMC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSDMC(INDEXP, IWSG, IWSE)**	
C-interface	**tq_sdmc(TC_INT indexp,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Default Major Constituents.	
Purpose:	To set the major phase constituents to the default ones defined in the thermodynamic data file.	
Comments:	Major constituents in a phase can be set in the Gibbs (GES) module of Thermo-Calc and then saved into a thermodynamic data file for the use of this interface.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set as a phase index
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSSPC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSSPC(INDEXP, YF, IWSG, IWSE)**	
C-interface	**tq_sspc(TC_INT indexp,TC_FLOAT* yf,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Start Phase Constitution.	
Purpose:	To set start-values for the constitution of an individual phase.	
Comments:	It is not necessary unless the calculation fails, especially when involving a miscibility gap or an ordering phase.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set as a phase index
YF	Double precision array	Set to the site fraction of each constituent.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSSV

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSSV(STAVAR, IP, IC, VALUE, IWSG, IWSE)**	
C-interface	**tq_ssv(TC_STRING stavar,TC_INT ip,TC_INT ic,TC_FLOAT value,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Start Variable.	
Purpose:	To set start-value for a state variable.	
Comments:	It is not necessary unless the calculation fails.	
Arguments		
Name	**Type**	**Value set on call or returned**
STAVAR	Character*8	Set as a state variable listed in Possible State Variables to Set Conditions in TQSETC
IP	Integer	Set as a phase index (if needed).
IC	Integer	Set as a component or constituent index (if needed).
VALUE	Double precision	Set to the value.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQPINI

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQPINI(IWSG, IWSE)**	
C-interface	**tq_pini(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Poly-3 reINItiation.	
Purpose:	Reinitiate the POLY-3 workspace in Thermo-Calc kernel.	
Comments:	Preparing for a fresh calculation.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSNL

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSNL(MAXIT, ACC, YMIN, ADG, IWSG, IWSE)**	
C-interface	**tq_snl(TC_INT maxit,TC_FLOAT acc,TC_FLOAT ymin,TC_STRING adg,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Numerical Limits	
Purpose:	To set the Numerical Limits to be used inside POLY-3.	
Comments:	It is not necessary unless the calculation fails.	
Arguments		
Name	**Type**	**Value set on call or returned**
MAXIT	Double precision	Set maximum number of iterations when calculating equilibrium. Default value is 500.
ACC	Double precision	Set required relative accuracy when calculating equilibrium. Default value is 1E-6.
YMIN	Double precision	Set smallest fraction to assign to unstable constituents. Default value is 1E-30.
ADG	Character*1	Approximate driving force for metastable phases. Y is the default. Enter N to change the default as required and based on the options described below. This setting involves the convergence of metastable phases and affects their driving forces. It can also have an effect on when an equilibrium is considered successful. The default is to allow an equilibrium with metastable phases that have not converged, as long as the stable phases have converged. This is efficient but often causes approximate values of the driving forces for the metastable phases. If you change the default, it enforces metastable phases to converge. This gives accurate driving forces for metastable phases as well as stable phases. It can however take a slightly longer time, and if metastable phases do not converge it causes the equilibrium calculation to fail.
IWSG	Integer array	Workspace

Fortran	**TQSNL(MAXIT, ACC, YMIN, ADG, IWSG, IWSE)**	
C-interface	**tq_snl(TC_INT maxit,TC_FLOAT acc,TC_FLOAT ymin,TC_STRING adg,TC_INT* iwsg,TC_INT* iwse);**	
IWSE	Integer array	Workspace

TQSMNG

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSMNG(NGP, IWSG, IWSE)**	
C-interface	**tq_smng(TC_INT ngp,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Maximum Number of Grid points for each phase.	
Purpose:	To change the maximum number of grid points that can be used for each phase.	
Comments:	The global minimization technique starts with discretizing the composition space and calculating Gibbs energy values at each grid point for each phase. To balance its efficiency and robustness, an appropriate density of grid points should be chosen. The default value of NGP is 2000. In practice, the number of grid points generated during a normal calculation is much less than this value. However, under certain circumstances, one does need to increase the density of grid point for some phases in order to find a true stable equilibrium.	
Arguments		
Name	**Type**	**Value set on call or returned**
NGP	Integer	Number of grid points
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSECO

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSECO(IPDH, ICSS, IWSG, IWSE)**	
C-interface	**tq_seco(TC_INT ipdh,TC_INT icss,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Equilibrium Calculation Option.	
Purpose:	To choose equilibrium calculation options.	
Comments:	TQ starts with IPDH=1 and ICSS=1 by default.	
Arguments		
Name	**Type**	**Value set on call or returned**
IPDH	Integer	1 = Force positive definite Hessian0 = Do not force positive definite Hessian
ICSS	Integer	1 = Control stepsize during minimization 0 = Do not control stepsize during minimization
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

ST1ERR

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**ST1ERR(IERR, SUBR, MESS)**	
C-interface	**tq_st1err(TC_INT ierr,TC_STRING subr,TC_STRING mess);**	
Full name:	Set Error Code and Give Message.	
Purpose:	This is called when an error that cannot be handled by the current program unit occurs. The error message is printed on the error unit but also saved internally in the error handling package. The program unit should return to the calling program.	
Comments:	The error-handling routines are those defined by SGTE for use in the thermodynamic model package. Note that the error-handling is constructed in such a way that when a subroutine detects an error it cannot handle, it should first call an ST* subroutine to set an appropriate error code and then return to the calling subroutine. In that subroutine the error code should be tested, and possibly that subroutine can correct the error and proceed, otherwise it should return to its calling subroutine and so on, until either the error is corrected or the top level of the program is reached.In this way it is possible to design a program where minor problems at a low level do not cause program to terminate. Instead, the error is passed up to a higher level where it can be corrected or ignored. The normal subroutines to use are ST2ERR to set the error code and SG2ERR to check it. The other subroutines are less used. The TQ subroutines normally do not clear the error code when called. An error set in an earlier subroutine but not tested and detected after that call may cause strange error messages later on. This should be used only for fatal or almost fatal errors.	
Arguments		
Name	**Type**	**Value set on call or returned**
IERR	Integer	Set to an error code.
SUBR	Character*6	Set to the current subroutine name.
MESS	Character*72	Set to the error message to be printed

ST2ERR

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**ST2ERR(IERR, SUBR, MESS)**	
C-interface	**tq_st2err(TC_INT ierr,TC_STRING subr,TC_STRING mess);**	
Full name:	Set Error Code.	
Purpose:	Called when an error occurs that cannot be handled by the current program unit. The program unit should return to the calling program.	
Comments:	Identical to ST1ERR except that it is silent, i.e., no error message is printed. This should be the normal subroutine to call when detecting errors that should be handled by a higher level of the program.	
Arguments		
Name	**Type**	**Value set on call or returned**
IERR	Integer	Set to an error code.
SUBR	Character*6	Set to the current subroutine name.
MESS	Character*72	Set to the error message to be printed

SG1ERR or TQG1ERR

This is a logical function.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**ERROR=SG1ERR(IERR) or ERROR=TQG1ERR(IERR)**	
C-interface	**error=tq_sg1err(TC_INT* ierr);**	
Full name:	Get Error Code and Give Message.	
Purpose:	This is a logical function which could be called after calling a TQ subroutine that can detect an error when the error message should be displayed. If there is an error the function value is .TRUE and the appropriate error code is in IERR. This subroutine also prints the error message on the error unit.	
Comments:	Use when the error is almost fatal. Note that it is possible that the error message is already printed by ST1ERR. Use SG2ERR in most cases. If no error the function value is .FALSE and IERR is zero. If the C-interface is used the value returned is of type: TC_BOOL.	
Arguments		
Name	**Type**	**Value set on call or returned**
IERR	Integer	Set to the error code

SG2ERR or TQG2ERR

This is a logical function.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**ERROR=SG2ERR(IERR) or ERROR=TQG2ERR(IERR)**	
C-interface	**error=tq_sg2err(TC_INT* ierr);**	
Full name:	Get Error Code.	
Purpose:	This is a logical function which should be called after calling any TQ subroutine that can detect an error. If there is an error the function value is .TRUE and the appropriate error code is in IERR. This subroutine does not print the error message.	

Comments:	Use for the normal error checking. Note that it is possible that the error message has already been printed by ST1ERR. The program may be able to handle the error to pass it on upwards. If no error the function value is .FALSE and IERR is zero. If the C-interface is used the value returned is of type: TC_BOOL.
	
	Example
	`LOGICAL SG2ERR`
	`...`
	`CALL TQCE(' ',IWSG,IWSE)`
	`IF(SG2ERR(IERR)) GOTO 900`
	`...`
	`900 RETURN`	

Arguments		
Name	**Type**	**Value set on call or returned**
IERR	Integer	Set to the error code

SG3ERR or TQG3ERR

This is a logical function.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**ERROR=SG3ERR(IERR, SUBR, MESS) or ERROR=TQG3ERR(IERR, SUBR, MESS)**	
C-interface	**error=tq_sg3err(TC_INT* ierr,TC_STRING subr,TC_STRING_LENGTH strlen_subr,TC_STRING mess,TC_STRING_LENGTH strlen_mess);**	
Full name:	Get Error Code and Message.	
Purpose:	This is a logical function which could be called after calling any TQ subroutine that can detect an error. If there is an error the function value is .TRUE and the appropriate error code is in IERR, the subroutine that detected the error in SUBR and the message in MESS. No printing on the error unit. This is useful if the calling program wants to print the message itself in an appropriate context.	
Comments:	This should be used when the error testing subroutine wants to handle the printing of the error message itself. It is possible that the error message has already been printed by ST1ERR. If the C-interface is used the value returned is of type: TC_ BOOL.	
Arguments		
Name	**Type**	**Value set on call or returned**
IERR	Integer	Return the error code.
SUBR	Character*6	Return the name of the subroutine detecting an error.
MESS	Character*72	Return the error message

RESERR or TQRSERR

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**RESERR or TQRSERR**
C-interface	**tq_reserr();**
Full name:	Reset Error Code and Message.
Purpose:	This subroutine resets the error code. A subsequent call to the SG* functions gives no error.
Comments:	This should be used when the error has been cleared so that execution can continue. Unless the error code is cleared by this subroutine the SG* functions continue to report the same error.
Arguments	None

TQSP3F

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSP3F(FILE, IWSG, IWSE)**	
C-interface	**tq_sp3f(TC_STRING filename,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Save the workspaces on a POLY-3 file.	
Purpose:	This subroutine save the current workspaces of a POLY-3 file that can be read into the Thermo-Calc program to see what conditions are set.	
Arguments		
Name	**Type**	**Value set on call or returned**
FILE	Character*72	Set to file name to which workspaces should be saved.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Extra Subroutines–Phase Properties

Purpose	*Subroutine*
Get Gibbs energy of a phase, Method A, B, and C*	TQGMA, TQGMB and TQGMC
Get 1st partial derivative of Gibbs energy w.r.t. site fractions.*	TQGMDY
Get mobility of a species in a phase.	TQGMOB
Set temperature and pressure for TQGMC, TQGMDY, and TQGMOB.	TQSTP
Set site fractions for TQGMB, TQGMC, TQGMDY, and TQGMOB.	TQSYF
Get index of a system species.	TQGSSPI
Check if Mobility data is available Method A and B	TQCMOBA and TQCMOBB†
Get 1st and 2nd partial derivative of Gibbs energy w.r.t. site fractions.*	TQDGYY
Get constitutional properties of a phase.*	TQGPHP
Convert mole fraction to site fraction for phases with no internal degree of freedom.*	TQX2Y
Convert 1st partial derivative of Gibbs energy w.r.t. site fractions to that w.r.t. mole fractions.*	TQGMDX
*in SI unit for one mole of formula unit.	† Logical function.

TQGMA, TQGMB and TQGMC

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGMA(INDEXP, TP, YF, VAL, IWSG, IWSE)** **TQGMB(INDEXP, TP, VAL, IWSG, IWSE)** **TQGMC(INDEXP, VAL, IWSG, IWSE)**	
C-interface	**tq_gma(TC_INT indexp,TC_FLOAT* tp,TC_FLOAT* yf,TC_FLOAT* val,TC_INT* iwsg,TC_INT* iwse);tq_gmb(TC_INT indexp,TC_FLOAT* tp,TC_FLOAT* val,TC_INT* iwsg,TC_INT* iwse);** **tq_gmc(TC_INT indexp,TC_FLOAT* val,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Gibbs Energy – Method A, B, and C.	
Purpose:	Getting Gibbs energy of a phase if temperature, pressure, and site fractions are given as arguments or by other subroutines shown.	
Comments:	The returned value is in J/mole of formula unit. Remember this subroutine requires no action of setting condition and calculating equilibrium. It is for getting the Gibbs energy of a single phase with given temperature, pressure and atomic arrangements no matter if the phase is stable, metastable, or unstable in competition with other phases. The application program should take care of the phase stability or phase equilibrium if it is of interest.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
TP	Double precision array	Set to temperature and pressure values.
YF	Double precision array	Set to site fraction values in the index order of phase constituent.
VAL	Double precision	Return Gibbs energy value.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGMDY

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGMDY(INDEXP, VARR, IWSG, IWSE)**	
C-interface	**tq_gmdy(TC_INT indexp,TC_FLOAT* varr,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Gibbs Energy and its partial Derivative w.r.t. y-fraction.	
Purpose:	Getting Gibbs energy and its 1st partial derivatives with respect to site fractions for a phase if temperature, pressure, and site fractions have been given by other subroutines shown.	
Comments:	The returned value is in J/mole of formula unit. Remember this subroutine requires no action of setting condition and calculating equilibrium. It is for getting the Gibbs energy and its 1st partial derivative w.r.t site fractions for a single phase with given temperature, pressure and atomic arrangements no matter if the phase is stable, metastable, or unstable in competition with other phases. The application program should take care of the phase stability or phase equilibrium if it is of interest. This subroutine is demonstrated in Example 9.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
VARR	Double precision array	Return values of Gibbs energy and its 1st partial derivatives w.r.t. site fractions in the index order of phase constituents.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGMOB

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGMOB(INDEXP, ISP, VAL, IWSG, IWSE)**	
C-interface	**tq_gmob(TC_INT indexp,TC_INT isp,TC_FLOAT* val,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Mobility	
Purpose:	Getting mobility of a species in a phase with the temperature, pressure, and site fractions given by other subroutines shown.	
Comments:	Remember this subroutine requires no action of setting condition and calculating equilibrium. It is for getting the atomic or species mobility in a single phase with given temperature, pressure and atomic arrangements no matter if the phase is stable, metastable, or unstable in competition with other phases. The application program should take care of the phase stability or phase equilibrium if it is of interest. The use of this subroutine is demonstrated in Example 9.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
ISP	Integer	Set to a system species index
VAL	Double precision	Return species or atomic mobility value.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSTP

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSTP(TP, IWSG, IWSE)**	
C-interface	**tq_stp(TC_FLOAT* tp,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Temperature and Pressure	
Purpose:	Setting temperature and pressure.	
Comments:	This subroutine is used before calling TQGMC, TQGMDY, TQDGYY, and TQGMOB. See Example 9.	
Arguments		
Name	**Type**	**Value set on call or returned**
TP	Double precision array	Set temperature and pressure.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSYF

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSYF(INDEXP, YF, IWSG, IWSE)**	
C-interface	**tq_syf(TC_INT indexp,TC_FLOAT* yf,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Set Site Fractions	
Purpose:	Setting site fractions for a phase.	
Comments:	This subroutine is used before calling TQGMB, TQGMC, TQGMDY, TQDGYY, and TQGMOB. See Example 9.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
YF	Double precision array	Set to site fraction values in the index order of the phase constituents.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGSSPI

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGSSPI(SPN, ISP, IWSG, IWSE)**	
C-interface	**tq_gsspi(TC_STRING name,TC_INT* index,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get System Species Index	
Purpose:	Getting index of a system species with given name.	
Comments:	Useful if you want to use TQGMOB. See Example 9.	
Arguments		
Name	**Type**	**Value set on call or returned**
SPN	Character*24	Set to a system species name.
ISP	Integer	Return index value of the system species
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQCMOBA and TQCMOBB

These are logical functions.

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**STATUS=TQCMOBA(INDEXP, ISP, IWSG, IWSE)** **STATUS=TQCMOBB(INDEXP, IWSG, IWSE)**	
C-interface	**status=tq_cmoba(TC_INT indexp,TC_INT* iwsg,TC_INT* iwse);** **status=tq_cmobb(TC_INT indexp,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Check if Mobility data available – Method A and B	
Purpose:	Check if mobility data have been appended into thermodynamic data file.	
Comments:	If the C-interface is used the value returned is of type: TC_BOOL.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index
ISP	Integer	Set to a system species index
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQDGYY

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQDGYY(INDEXP, VARR1, VARR2, IWSG, IWSE)**	
C-interface	**tq_dgyy(TC_INT indexp,TC_FLOAT* varr1,TC_FLOAT* varr2,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Gibbs Energy and its 1st and 2nd Partial Derivative w.r.t. site-fractions.	
Purpose:	Getting Gibbs energy and its 1st and 2nd partial derivatives with respect to site fractions for a phase if temperature, pressure, and site fractions have been given by other subroutines shown below in this Section.	
Comments:	The returned value is in J/mole of formula unit. Remember this subroutine requires no action of setting condition and calculating equilibrium. It is for getting the Gibbs energy and its 1st and 2nd partial derivatives w.r.t site fractions for a single phase with given temperature, pressure and atomic arrangements no matter if the phase is stable, metastable, or unstable in competition with other phases. The application program should take care of the phase stability or phase equilibrium if it is of interest.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
VARR1	Double precision array	Return values of Gibbs energy and its 1st partial derivatives w.r.t. site fractions in the index order of phase constituents.
VARR2	Double precision array	Return values of 2nd partial derivatives of Gibbs energy w.r.t. site fractions in the index order of IR: IR=J+I*(I-1)/2, I>=J; IR=I+J*(J-1)/2, I<J, where I and J are row and column indexes of phase constituents, respectively.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGPHP

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGPHP(INDEXP, NE, NCNV, NC, IWORK, WORK, IWSG, IWSE)**	
C-interface	**tq_gphp(TC_INT indexp,TC_INT* ne,TC_INT* ncnv,TC_INT* nc,TC_INT* iwork,TC_FLOAT* work,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get phase constitution properties.	
Purpose:	Getting phase constitution properties such as number of components, number of constituents, number of constituents without counting vacancies, etc.	
Comments:	This subroutine is designed to speed up conversions of quantities involving mole fractions and site fractions in dynamic calculations where such operations are needed at each local time and space grid point. For each phase involved, one call of this subroutine is enough for subsequent conversions concerning this phases. See Example 10.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index.
NE	Integer	Return number of components
NCNV	Integer	Return number of constituents without counting vacancies
NC	Integer	Return number of constituents
IWORK	Integer array	Return values needed in X to Y conversion, array size >= 4*NCNV
WORK	Double precision array	Return values needed in X to Y conversion, array size >= (NE+1)*NCNV
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQX2Y

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQX2Y(INDEXP, NE, NCNV, NC, IWORK, WORK, XF, YF, IWSG, IWSE)**	
C-interface	**tq_x2y(TC_INT indexp,TC_INT ne,TC_INT ncnv,TC_INT nc,TC_INT* iwork,TC_FLOAT* work,TC_FLOAT* xf,TC_FLOAT* yf,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Y-fraction given X-fraction.	
Purpose:	Converting mole fractions to site fractions in a phase without internal degree of freedom.	
Comments:	This subroutine uses the phase constitution properties obtained by TQGPHP as input. See Example 10.	
Arguments		
Name	**Type**	**Value set on call or returned**
INDEXP	Integer	Set to a phase index
NE	Integer	Set to number of components
NCNV	Integer	Set to number of constituents without counting vacancies
NC	Integer	Set to number of constituents
IWORK	Integer array	Set to values needed in X to Y conversion
WORK	Double precision array	Set to values needed in X to Y conversion
XF	Double precision array	Set to mole fractions
YF	Double precision array	Return site fractions
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGMDX

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGMDX(IP, NE, NCNV, NC, IWORK, WORK, YF, VARR, GM, DGDX, XF, IWSG, IWSE)**	
C-interface	**tq_gmdx(TC_INT indexp,TC_INT ne,TC_INT ncnv,TC_INT nc,TC_INT* iwork, TC_FLOAT* work,TC_FLOAT* yf,TC_FLOAT* varr,TC_FLOAT* gm,TC_FLOAT* dgdx,TC_FLOAT* xf,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Gibbs energy and its partial derivative w.r.t. X-fraction.	
Purpose:	Converting Gibbs energy and its 1st partial derivatives with respect to site fractions (VARR obtained by calling TQGMDY) to that w.r.t mole fractions for a phase.	
Comments:	Uses the phase constitution properties obtained by TQGPHP as input. Note VARR obtained by calling TQGMDY is in unit of J/mole of formula unit. GM and DGDX in the present subroutine is in unit of J/mole of atoms. For the use of this subroutine together with TQGPHP and TQX2Y, see Example 10.	
Arguments		
Name	**Type**	**Value set on call or returned**
IP	Integer	Set to a phase index.
NE	Integer	Set to number of components
NCNV	Integer	Set to number of constituents without counting vacancies
NC	Integer	Set to number of constituents
IWORK	Integer array	Set to values needed in X to Y conversion
WORK	Double precision array	Set to values needed in X to Y conversion
YF	Double precision array	Set to site fractions
VARR	Double precision array	Set to Gibbs energy and its first derivative with respect to site fractions

Fortran	**TQGMDX(IP, NE, NCNV, NC, IWORK, WORK, YF, VARR, GM, DGDX, XF, IWSG, IWSE)**	
C-interface	**tq_gmdx(TC_INT indexp,TC_INT ne,TC_INT ncnv,TC_INT nc,TC_INT* iwork, TC_FLOAT* work,TC_FLOAT* yf,TC_FLOAT* varr,TC_FLOAT* gm,TC_FLOAT* dgdx,TC_FLOAT* xf,TC_INT* iwsg,TC_INT* iwse);**	
GM	Double precision	Return Gibbs energy
DGDX	Double precision array	Return Gibbs energy and its first derivative with respect to mole fractions
XF	Double precision array	Return mole fractions
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Database Subroutines

See Example 12

Purpose	*Subroutine*
Get lists of database names	TQGDBN
Open or switch to a database	TQOPDB
List database elements	TQLIDE
Append a database	TQAPDB
Select an element	TQDEFEL
Reject a selected element	TQREJEL
Reject a phase or all phases	TQREJPH
Restore a phase	TQRESPH
List phases related to the selected element(s)	TQLISPH
List retained phases for the selected element(s)	TQLISSF
Get data from the selected database	TQGDAT
Reject defined system and reinitiate workspace	TQREJSY

TQGDBN

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGDBN(DB_ARR, N, IWSG, IWSE)**	
C-interface	**tq_gdbn(tc_databases_strings* databases,TC_INT* n,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Database Names and Number.	
Purpose:	Get the names and total number of thermodynamic and kinetic databases listed in the database initiation file of Thermo-Calc: `tc_initd.tdb`.	
Comments:	IERR = 1001 is Failed to find the initiation file.	
Arguments		
Name	**Type**	**Value set on call or returned**
DB_ARR	Character*24 array	Return database names.
N	Integer	Return total number of databases available.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQOPDB

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQOPDB(TDB, IWSG, IWSE)**	
C-interface	**tq_opdb(TC_STRING database,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Open Database.	
Purpose:	Open a thermodynamic or kinetic database.	
Comments:	IERR = 1001 Failed to find the initiation file. IERR = 1002 Database or its license not available.	
Arguments		
Name	**Type**	**Value set on call or returned**
TDB	Character*256	Set to the name of a database.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQLIDE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQLIDE(EL_ARR, N, IWSG, IWSE)**	
C-interface	**tq_lide(tc_elements_strings* elements,TC_INT* num,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	List Database Elements.	
Purpose:	List all elements available in the chosen database.	
Arguments		
Name	**Type**	**Value set on call or returned**
EL_ARR	Character*2 array	Return the names of all elements.
N	Integer	Return the total number of elements.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQAPDB

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQAPDB(TDB, IWSG, IWSE)**	
C-interface	**tq_apdb(TC_STRING database,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Append Database.	
Purpose:	Append a thermodynamic or kinetic database.	
Comments:	IERR = 1002 Database or its license not available.	
Arguments		
Name	**Type**	**Value set on call or returned**
TDB	Character*256	Set to the name of a database.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQDEFEL

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQDEFEL(ELNAM, IWSG, IWSE)**	
C-interface	**tq_defel(TC_STRING element,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Define Element.	
Purpose:	Define a system element.	
Comments:	IERR = 1011 Element not included in the chosen database. IERR = 1012 Element already defined.	
Arguments		
Name	**Type**	**Value set on call or returned**
ELNAM	Character*2	Set to the name of an element.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQREJEL

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQREJEL(ELNAM, IWSG, IWSE)**	
C-interface	**tq_rejel(TC_STRING element,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Reject Element.	
Purpose:	Reject a defined system element.	
Comments:	IERR = 1013 Element not included in the chosen database. IERR = 1014 Element already rejected.	
Arguments		
Name	**Type**	**Value set on call or returned**
ELNAM	Character*2	Set to the name of an element.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQREJPH

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQREJPH(PHNAM, IWSG, IWSE)**	
C-interface	**tq_rejph(TC_STRING phase,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Reject Phase.	
Purpose:	Reject a system phase.	
Comments:	IERR = 1017 Phase not included in the chosen database.IERR = 1018 Phase already rejected.	
Arguments		
Name	**Type**	**Value set on call or returned**
PHNAM	Character*24	Set to a phase name If * is used then all phases are rejected
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQRESPH

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQRESPH(PHNAM, IWSG, IWSE)**	
C-interface	**tq_resph(TC_STRING phase,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Restore Phase.	
Purpose:	Restore a rejected system phase.	
Comments:	IERR = 1015 Phase not included in the chosen database. IERR = 1016 Phase already restored.	
Arguments		
Name	**Type**	**Value set on call or returned**
PHNAM	Character*24	Set to a phase name If * is used then all phases are rejected
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQLISPH

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQLISPH(PH_ARR, N, IWSG, IWSE)**	
C-interface	**tq_lisph(tc_phases_strings* phases,TC_INT* num,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	List System Phase.	
Purpose:	List all phases (both rejected and restored) available for the defined system.	
Arguments		
Name	**Type**	**Value set on call or returned**
PH_ARR	Character*24 array	Return phase names.
N	Integer	Return the total number of phases
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQLISSF

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQLISSF(PH_ARR, N, IWSG, IWSE)**	
C-interface	**tq_lissf(tc_phases_strings* phases,TC_INT* num,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	List Selected System Phase.	
Purpose:	List phases not rejected for the defined system.	
Arguments		
Name	**Type**	**Value set on call or returned**
PH_ARR	Character*24 array	Return phase names.
N	Integer	Return the total number of phases
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQGDAT

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQGDAT(IWSG, IWSE)**	
C-interface	**tq_gdat(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Get Data.	
Purpose:	Get data for the defined system from the chosen database.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQREJSY

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQREJSY(IWSG, IWSE)**	
C-interface	**tq_rejsy(TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Reject system.	
Purpose:	Reject the defined system and reinitiate the workspace in order to do a completely new calculation for a different system selected from the same or a different database.	
Comments:	In any application programs, either TQINI or TQINI3 should be called only once. If there is a need to do a completely new calculation on a totally different system without exiting the application program, one should call TQREJS instead before going to (open a new database and) define a new system, get data, and make calculations.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Adaptive Interpolation Schemes

About Adaptive Interpolation Schemes

In order to perform a simulation using the scheme, the TQ-library must be initialized in the normal way using the routine TQINI and thermodynamic information must be loaded, usually with the TQRFIL routine.

The scheme is then initialized using the TQIPS_INIT_TOP routine and each branch in the calculation is initialized using the TQIPS_INIT_BRANCH routine. For each set of interpolated values which are to be defined and obtained from a certain branch of the scheme, the TQIPS_INIT_FUNCTION routine is called. The values for all functions defined in the branch are then returned using the TQIPS_GET_VALUE routine.

Purpose	*Subroutine*
Initiate the interpolation scheme	TQIPS_INIT_TOP
Initiate a branch in the interpolation scheme	TQIPS_INIT_BRANCH
Define a function or state variable to be interpolated	TQIPS_INIT_FUNCTION
Retrieve the interpolated value	TQIPS_GET_VALUE
Write the data of the interpolation scheme to file.	TQIPS_WRITE_IPS_DATA_TO_FILE
Read interpolation scheme data from file.	TQIPS_READ_IPS_DATA_FROM_FILE
Get statistics on the usage of the interpolation scheme.	TQIPS_GET_MEMORY_USAGE

TQIPS_INIT_TOP

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQIPS_INIT_TOP(IERR, IWSG, IWSE)**	
C-interface	**tq_ips_init_top(TC_INT* err,TC_INT* iwsg,TC_INT* iwse)**	
Full name:	Initiate the top structure of the adaptive interpolation scheme.	
Purpose:	Initiates the top structure of the interpolation scheme which may contain several branches with different conditions, phases and values to be interpolated.	
Comments:	IERR is returned with 0 if no error occurs.	
Arguments		
Name	**Type**	**Value set on call or returned**
IERR	Integer	Returns the error code.
IWSG	Integer array	Workspace.
IWSE	Integer array	Workspace.

TQIPS_INIT_BRANCH

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQIPS_INIT_BRANCH(TISCOND, TISCNST, PISCOND, PISCNST, IDEPEL, IDISCRT, NSTEP, IPHSTA, T, TMIN, TMAX, P, PMIN, PMAX, RMEMFR, PHAMNT,XMIN, XMAX, IBRANCH, IERR IWSG, IWSE**	
C-interface	**tq_ips_init_branch(TC_BOOL t_is_condition, TC_BOOL t_is_constant, TC_BOOL p_is_condition, TC_BOOL p_is_constant, TC_BOOL* independent_elements,TC_INT dicretization_type, TC_INT nr_of_steps, TC_INT* state_of_phases, TC_FLOAT t, TC_FLOAT tmin, TC_FLOAT tmax,TC_FLOAT p,TC_FLOAT pmin, TC_FLOAT pmax, TC_FLOAT memory_fraction, TC_FLOAT* amount_of_phases, TC_FLOAT* xmin, TC_FLOAT* xmax, TC_INT* branch_nr, TC_INT* err, TC_INT* iwsg, TC_INT* iwse)**	
Full name:	Initiate a branch of the adaptive interpolation scheme.	
Purpose:	Initiates a branch of the interpolation scheme with a set of conditions, phases and values to be interpolated.	
Comments:	The size of the arrays IDEPEL, XMIN and XMAX are defined as the number of all components supplied by TQGNC must be provided in the same order as supplied by TQGCOM.Composition conditions are set as the normalized number of moles for each component (N(c) =value).The size of the arrays IPHSTA and PHAMNT are defined as the number of all phases supplied by TQGNP must be provided in the same order as supplied by TQGPN.The allocation of memory to each branch is performed at the first time values are retrieved using TQIPS_GET_VALUE, therefore some considerations must be made when using several branches in order to allocate the same amount of memory to each branch.	
Arguments		
Name	**Type**	**Value set on call or returned**
TISCOND	Logical	Set to TRUE if temperature is a condition in this branch.
TISCNST	Logical	Set to TRUE if temperature is constant in this branch.
PISCOND	Logical	Set to TRUE if pressure is a condition in this branch.
PISCNST	Logical	Set to TRUE if pressure is constant in this branch.
IDEPEL	Logical array	Set to TRUE for each element for which

Fortran	**TQIPS_INIT_BRANCH(TISCOND, TISCNST, PISCOND, PISCNST, IDEPEL, IDISCRT, NSTEP, IPHSTA, T, TMIN, TMAX, P, PMIN, PMAX, RMEMFR, PHAMNT,XMIN, XMAX, IBRANCH, IERR IWSG, IWSE**	
C-interface	**tq_ips_init_branch(TC_BOOL t_is_condition, TC_BOOL t_is_constant, TC_BOOL p_is_condition, TC_BOOL p_is_constant, TC_BOOL* independent_elements,TC_INT dicretization_type, TC_INT nr_of_steps, TC_INT* state_of_phases, TC_FLOAT t, TC_FLOAT tmin, TC_FLOAT tmax,TC_FLOAT p,TC_FLOAT pmin, TC_FLOAT pmax, TC_FLOAT memory_fraction, TC_FLOAT* amount_of_phases, TC_FLOAT* xmin, TC_FLOAT* xmax, TC_INT* branch_nr, TC_INT* err, TC_INT* iwsg, TC_INT* iwse)**	
		conditions are present.
IDISCRT	Integer	Indicates the type of discretization where: 1=linear2=logarithmic
NSTEP	Integer	Set to the logarithm (10 base) number of steps to be used to interpolate in the temperature / pressure / composition space.
IPHSTA	Integer array	Set to the status for the phases in this branch, where: 1=ENTERED, 2=SUSPENDED, 3=DORMANT, 4=FIXED
T	Double precision	Set to temperature if temperature is a condition, otherwise used as starting value.
TMIN	Double precision	Set to lower limit of temperature range.
TMAX	Double precision	Set to upper limit of temperature range.
P	Double precision	Set to pressure if pressure is a condition, otherwise used as starting value.
PMIN	Double precision	Set to lower limit of pressure range.
PMAX	Double Precision	Set to upper limit of pressure range.
RMEMFR	Double precision	Set to the fraction of the amount of free physical memory to be allocated to the interpolation scheme for this branch (value < 1.0). If a value larger than 1.0 if set, it is interpreted as the number of

Fortran	**TQIPS_INIT_BRANCH(TISCOND, TISCNST, PISCOND, PISCNST, IDEPEL, IDISCRT, NSTEP, IPHSTA, T, TMIN, TMAX, P, PMIN, PMAX, RMEMFR, PHAMNT,XMIN, XMAX, IBRANCH, IERR IWSG, IWSE**	
C-interface	**tq_ips_init_branch(TC_BOOL t_is_condition, TC_BOOL t_is_constant, TC_BOOL p_is_condition, TC_BOOL p_is_constant, TC_BOOL* independent_elements,TC_INT dicretization_type, TC_INT nr_of_steps, TC_INT* state_of_phases, TC_FLOAT t, TC_FLOAT tmin, TC_FLOAT tmax,TC_FLOAT p,TC_FLOAT pmin, TC_FLOAT pmax, TC_FLOAT memory_fraction, TC_FLOAT* amount_of_phases, TC_FLOAT* xmin, TC_FLOAT* xmax, TC_INT* branch_nr, TC_INT* err, TC_INT* iwsg, TC_INT* iwse)**	
		megabytes allocated to the branch.
PHAMNT	Double precision array	Set to the amount of the phase if defined as a fixed phase with IPHSTA.
XMIN	Double precision array	Set to the lower limit of the composition range of each component.
XMAX	Double precision array	Set to the upper limit of the composition range of each component.
IBRANCH	Integer	Set to branch number for which the variable in STRING is to be interpolated.
IERR	Integer	Returns error code.
IWSG	Integer array	Workspace.
IWSE	Integer array	Workspace

TQIPS_INIT_FUNCTION

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQIPS_INIT_FUNCTION(STRING, IBRANCH, IERR, IWSG, IWSE)**	
C-interface	**tq_ips_init_function(TC_STRING function_string, TC_INT branch_nr, TC_INT* err, TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Initiates a function for a specific branch whose value(s) are to be retrieved from the adaptive interpolation scheme.	
Purpose:	Initiates a function or state variable for a specific branch whose value(s) are to be retrieved from the adaptive interpolation scheme.	
Arguments		
Name	**Type**	**Value set on call or returned**
STRING	Character*128	Set to the name of the function or state variable to be interpolated, wildcards (*) may be used in place of element and/or phase names.
IBRANCH	Integer	Set to branch number for which the variable in STRING is to be interpolated.
IERR	Integer	Returns the error code.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQIPS_GET_VALUE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQIPS_GET_VALUE(IBRANCH, NOSCHEME, ARR, RESULT, IERR, ISHORT, IWSG, IWSE)**	
C-interface	**tq_ips_get_value(TC_INT branch_nr, TC_INT noscheme, TC_FLOAT* variable_values, TC_FLOAT* function_values, TC_INT* err, TC_INT* shortcut, TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Retrieve interpolated value(s) from the adaptive interpolation scheme.	
Purpose:	Retrieves all the values defined by all TQIPS_INIT_FUNCTION defined for branch IBRANCH in sequential order.	
Arguments		
Name	**Type**	**Value set on call or returned**
IBRANCH	Integer	Set to branch number.
NOSCHEME	Integer	Set to 1 if the interpolation scheme is to be disabled.
ARR	Double precision array	Array set to the mole-fractions of all the components followed by the temperature and the pressure, if a component is dependent the value may be arbitrary. The same applies if the temperature or pressure is constant.
RESULT	Double precision array	Returns the interpolated values in the same order as they were defined in TQS_INIT_FUNCTION.
IERR	Integer	Returns the error code.
ISHORT	Integer	Set to the last returned value or zero, `0`. Returns a shortcut to data pertaining to the grid point in virtual composition/temperature/pressure space for the values in ARR
IWSG	Integer array	Workspace.
IWSE	Integer array	Workspace.

TQIPS_WRITE_IPS_DATA_TO_FILE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQIPS_WRITE_IPS_DATA_TO_FILE(FILENAME,IERR,IWSG,IWSE)**	
C-interface	**tq_ips_write_ips_data_to_file(TC_STRING filename, TC_INT* ierr, TC_INT* iwsg, TC_INT* iwse)**	
Full name:	Write the data of the interpolation scheme to file.	
Purpose:	To save all the data of the interpolation scheme in order to read them at a later time with routine tqips_read_ips_data_from_file.	
Arguments		
Name	**Type**	**Value set on call or returned**
FILENAME	Character*256	The name of the file to be saved
IERR	Integer	Returns the error code
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQIPS_READ_IPS_DATA_FROM_FILE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQIPS_READ_IPS_DATA_FROM_FILE(FILENAME, MEMORY_FRACTION, IERR, IWSG, IWSE)**	
C-interface	**tq_ips_read_ips_data_from_file(TC_STRING filename, TC_FLOAT* memory_fraction, TC_INT* ierr, TC_INT* iwsg, TC_INT* iwse)**	
Full name:	Read interpolation scheme data from file.	
Purpose:	To read from file interpolation scheme data that has been saved previously with routine tqips_write_ips_data_to_file.	
Comments:	If memory_fraction has a value smaller than zero the amount of allocated memory will be determined by the value read from file. If memory_fraction is larger than zero it will be interpreted in the same way as argument RMEMFR of routine tqips_init_branch.	
Arguments		
Name	**Type**	**Value set on call or returned**
FILENAM	Character*256	The name of the file to be read
MEMORY_FRACTION	double precision	See comment
IERR	Integer	Returns the error code
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQIPS_GET_MEMORY_USAGE

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQIPS_GET_MEMORY_USAGE(IBRANCH, FRACTION, ISLOTS, IUSEDSLOTS, ICALLS, IEQCALCS, IERR, IWSG, IWSE)**	
C-interface	**tq_ips_get_memory_usage(TC_INT branch_nr, TC_FLOAT* fraction,TC_INT* total_number_of_data_slots, TC_INT* number_of_used_data_slots, TC_INT* total_number_of_calls, TC_INT* total_number_of_equil_calcs, TC_INT* ierr,TC_INT* iwsg,TC_INT* iwse)**	
Full name:	Get statistics on the usage of the interpolation scheme.	
Purpose:	To get some statistics on the performance of the interpolation scheme.	
Arguments		
Name	**Type**	**Value set on call or returned**
IBRANCH	Integer	If IBRANCH>0 it is the branch number for which the data should be returned. If IBRANCH=0 then data is returned summed over all branches.
FRACTION	double precision	This is simply equal to IUSEDSLOTS/ISLOTS
ISLOTS	Integer	The total number of data slots allocated
IUSEDSLOTS	Integer	The number of used data slots
ICALLS	Integer	The number of calls to tqips_get_value
IEQCALCS	Integer	The number of equilibrium calculations performed by Thermo-Calc on behalf of the interpolation scheme
IERR	Integer	error code
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Composition Set Reordering Routines

Purpose	*Subroutine*
Initialize IWSR workspace for reordering of CS in TQ.	TQROINIT
Set ideal composition in this phase	TQSETRX
Reorder CS in current EQ	TQORDER
List content of IWSR set by user.	TQLROX

TQROINIT

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQROINIT(NWSR, IWSR, IWSG, IWSE)**	
C-interface	**tq_roinit(TC_INT nwsr, TC_INT* iwsr,TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Initialize IWSR workspace for reordering of CS in TQ.	
Purpose:	With this subroutine the application program initializes the Thermo-Calc package for use of the reordering subroutines. It must be called before using any of the subroutines TQSETRX, TQORDER, TQLROX.	
Comments:	NWSR=1000 should be enough for several composition sets	
Arguments		
Name	**Type**	**Value set on call or returned**
NWSR	Integer	On call set to size of the workspace IWSR.
IWSR	Integer array	Memory area for storage of data inside the package.
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQSETRX

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQSETRX(PHASE, X, IWSR, IWSG, IWSE)**	
C-interface	**tq_setrx(TC_STRING phase, TC_FLOAT* x, TC_INT* iwsr, TC_INT* iwsg, TC_INT* iwse);**	
Full name:	Set ideal composition in this phase	
Purpose:	Store composition of phase in IWSR for future use.	
Comments:	The order in the X array is the order of the components in the system	
Arguments		
Name	**Type**	**Value set on call or returned**
Phase	Character*24	Phase name (e.g. 'fcc#2')
X	Double precision array	On call set to the ideal composition in this composition set in this phase.
IWSR	Integer array	Workspace
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQORDER

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQORDER(IWSR, IWSG, IWSE)**	
C-interface	**tq_order(TC_INT* iwsr, TC_INT* iwsg,TC_INT* iwse);**	
Full name:	Reorder CS in current EQ	
Purpose:	The ideal composition set by the user is used to reorder the CS in respective phase to minimize the distance compared to present eq.	
Comments:	Calling routines more than once in a row should affect nothing. Routines minimize the distance between the set ideal composition and the composition found in the present equilibria, and reorder the CS in the equilibria to achieve the minima. This does not affect the properties of the equilibria.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSR	Integer array	Workspace
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

TQLROX

Use the guidelines in Naming Conventions for Routines to understand how to read the table.

Fortran	**TQLROX(IWSR, IWSG, IWSE)**	
C-interface	**tq_lrox(TC_INT* iwsr,TC_INT* iwsg,TC_INT* iwse);**	
Full name:	List content of IWSR set by user.	
Purpose:	List the ideal composition set in the output unit using TQSETRX in IWSR. It is for debugging.	
Arguments		
Name	**Type**	**Value set on call or returned**
IWSR	Integer array	Workspace
IWSG	Integer array	Workspace
IWSE	Integer array	Workspace

Compiler Settings

Programming Languages

In the compiler flag paths, *<libraryversion>* is the current name of the library that changes between software releases. Look through your operating system's file structure to determine the current name.

Topics to Explore >

Compiling FORTRAN Code **3739**

Windows: Visual Studio 2019, Intel one API 2025.X *3739*

Linux: GNU compiler version 9.4 ..... *3739*

Linux: Intel one API 2025.X *3740*

Compiling C Code **3741**

Windows: Visual Studio 2019 ..... *3741*

Linux: GNU compiler version 9.4 ..... *3741*

Compiling FORTRAN Code

There is different OS support for Windows and Linux as shown below.

Windows: Visual Studio 2019, Intel one API 2025.X

64-bit Configuration

Compiler flags:

```
/integer-size:64
/real-size:64
/double-size:64
/iface:default
```

Example:

```
ifx /integer-size:64 /real-size:64 /double-size:64 /iface:default /c
tqex01.F
ifx/exe:tqex01.exe tqex01.obj libtq-win-x64-<libraryversion>.lib
```

If you are using an older compiler (e.g. ifort) than the one supported, you might need to use underscore (_) instead of hyphen (-) when specifying these compiler switches: `/integer-size /real-size /double-size` would then be `/integer_size /real_size /double_size`.

Linux: GNU compiler version 9.4

64-bit Configuration

Compiler flags:

```
-fdefault-real-8
-fdefault-double-8
-fdefault-integer-8
```

Example:

```
gfortran –c -fdefault-real-8 -fdefault-double-8 fdefault-integer-8 tqex01.F
gfortran –o tqex01 tqex01.o libtq-linux-x86_64-gfortran-<libraryversion>.so
```

Linux: Intel one API 2025.X

64-bit Configuration

Compiler flags:

```
-real-size 64
-double-size 64
-integer-size 64
```

Example:

```
ifx –c real-size 64 -double-size 64 integer-size 64 tqex01.F
ifx –o tqex01 tqex01.o libtq-linux-x86_64-ifx-<libraryversion>.so
```

Compiling C Code

When compiling the C-code it is necessary to include the files **tqroot.h** and **tc_data_defs.h**, therefore the path to where these files are located must be specified.

Windows: Visual Studio 2019

C programs linked with TQ in Windows, must use release libraries (/MT or /MD) due to clashes in the memory allocation routines causing the global minimization procedure to fail if debug libraries are used.

64-bit Configuration

Compiler flags:

```
/DWIN32
/DWIN64
/I..\tq\C\include
```

Example:

```
cl /c /DWIN32 /DWIN64 /I..\tq\C\include tqex01.c
link /OUT:tqex01.exe tqex01.obj libtq-win-x64-<libraryversion>.lib
```

Linux: GNU compiler version 9.4

64-bit Configuration

Compiler flags:

```
-I../tq/C/include
```

Example:

```
gcc -c -I../tq/C/include tqex01.c
gcc -o tqex01 tqex01.o libtq-linux-x86_64-gfortran-<libraryversion>.so
```
